SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX

ALL FLIGHTS

VOLUME A

FINAL, PCN-1

PREFACE

THIS DOCUMENT, VOLUME A, FINAL, PCN-1, DATED NOVEMBER 21, 2002, IS THE GENERIC VERSION OF THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES AND IS INTENDED TO BE USED IN CONJUNCTION WITH THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX (NSTS-18308) WHICH CONTAINS THE FLIGHT SPECIFIC RULES. INCLUDED IN THIS PUBLICATION ARE FLIGHT RULE CHANGES APPROVED IN FLIGHT RULES CONTROL BOARD (FRCB) MEETINGS 140, 141, 142, AND 143 HELD ON JUNE 27, AUGUST 29, SEPTEMBER 26, AND OCTOBER 24, 2002, RESPECTIVELY.

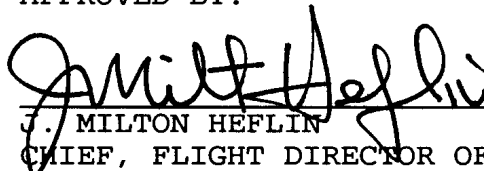

THIS DOCUMENT USES A NEW RULE NUMBER SYSTEM DESIGNED TO FACILITATE NEW DATABASES FOR MAINTAINING CONFIGURATION MANAGEMENT OF JOINT SHUTTLE-ISS ANNEXES, SPACE SHUTTLE OPERATIONAL FLIGHT RULES, VOLUME A; ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME B; JOINT SHUTTLE/ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME C; AND SOYUZ/PROGRESS/ISS JOINT FLIGHT RULES, VOLUME D.

IT IS REQUESTED THAT ANY ORGANIZATION HAVING COMMENTS, QUESTIONS, OR SUGGESTIONS CONCERNING THESE FLIGHT RULES CONTACT DA8/W. PRESTON DILL, FLIGHT DIRECTOR OFFICE, BUILDING 4 NORTH, ROOM 3039, PHONE 281-483-5418.

ALL FLIGHT RULES ARE AVAILABLE ON THE INTERNET. THE URL IS: **HTTP://MOD.JSC.NASA.GOV/DA8**. NO ID OR PASSWORD WILL BE REQUIRED TO ACCESS ANY OF THE RULES PROVIDED THE USER IS ACCESSING FROM A TRUSTED SITE (ALL NASA CENTERS, CONTRACTORS, AND INTERNATIONAL PARTNERS). IF UNABLE TO ACCESS, USERS NEED TO SEND AN E-MAIL NOTE TO DA8/M. L. GRIFFITH (MARY.L.GRIFFITH1@JSC.NASA.GOV) WITH THEIR FULL NAME, COMPANY, IP ADDRESS, AND A JUSTIFICATION STATEMENT FOR ACCESS.

THIS IS A CONTROLLED DOCUMENT AND ANY CHANGES ARE SUBJECT TO THE CHANGE CONTROL PROCEDURES DELINEATED IN APPENDIX B. THIS DOCUMENT IS NOT TO BE REPRODUCED WITHOUT THE WRITTEN APPROVAL OF THE CHIEF, FLIGHT DIRECTOR OFFICE, DA8, LYNDON B. JOHNSON SPACE CENTER, HOUSTON, TEXAS.

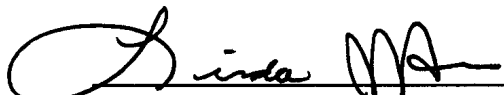

APPROVED BY:

J. MILTON HEFLIN
CHIEF, FLIGHT DIRECTOR OFFICE

JON C. HARPOLD
DIRECTOR, MISSION OPERATIONS

RONALD D. DITTEMORE
MANAGER, SPACE SHUTTLE PROGRAM

Verify that this is the correct version before use.

SPACE SHUTTLE OPERATIONAL FLIGHT RULES

ALL FLIGHTS

VOLUME A

FINAL, DATED JUNE 20, 2002
 PCN-1, DATED NOVEMBER 21, 2002

THIS PCN-1 INCORPORATES CHANGES TO THE FOLLOWING RULES BY THE APPLICABLE CHANGE REQUESTS (CR'S).

SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX

ALL FLIGHTS

VOLUME A

FINAL, PCN-1

PREFACE

THIS DOCUMENT, VOLUME A, FINAL, PCN-1, DATED NOVEMBER 21, 2002, IS THE GENERIC VERSION OF THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES AND IS INTENDED TO BE USED IN CONJUNCTION WITH THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX (NSTS-18308) WHICH CONTAINS THE FLIGHT SPECIFIC RULES. INCLUDED IN THIS PUBLICATION ARE FLIGHT RULE CHANGES APPROVED IN FLIGHT RULES CONTROL BOARD (FRCB) MEETINGS 140, 141, 142, AND 143 HELD ON JUNE 27, AUGUST 29, SEPTEMBER 26, AND OCTOBER 24, 2002, RESPECTIVELY.

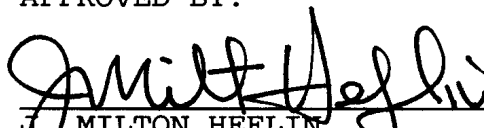

THIS DOCUMENT USES A NEW RULE NUMBER SYSTEM DESIGNED TO FACILITATE NEW DATABASES FOR MAINTAINING CONFIGURATION MANAGEMENT OF JOINT SHUTTLE-ISS ANNEXES, SPACE SHUTTLE OPERATIONAL FLIGHT RULES, VOLUME A; ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME B; JOINT SHUTTLE/ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME C; AND SOYUZ/PROGRESS/ISS JOINT FLIGHT RULES, VOLUME D. AN EXPLANATION OF THE NEW NUMBERING SYSTEM IS SHOWN ON PAGE VII.

IT IS REQUESTED THAT ANY ORGANIZATION HAVING COMMENTS, QUESTIONS, OR SUGGESTIONS CONCERNING THESE FLIGHT RULES CONTACT DA8/W. PRESTON DILL, FLIGHT DIRECTOR OFFICE, BUILDING 4 NORTH, ROOM 3039, PHONE 281-483-5418.

ALL FLIGHT RULES ARE AVAILABLE ON THE INTERNET. THE URL IS: **HTTP://MOD.JSC.NASA.GOV/DA8**. NO ID OR PASSWORD WILL BE REQUIRED TO ACCESS ANY OF THE RULES PROVIDED THE USER IS ACCESSING FROM A TRUSTED SITE (ALL NASA CENTERS, CONTRACTORS, AND INTERNATIONAL PARTNERS). IF UNABLE TO ACCESS, USERS NEED TO SEND AN E-MAIL NOTE TO DA8/M. L. GRIFFITH (MARY.L.GRIFFITH1@JSC.NASA.GOV) WITH THEIR FULL NAME, COMPANY, IP ADDRESS, AND A JUSTIFICATION STATEMENT FOR ACCESS.

THIS IS A CONTROLLED DOCUMENT AND ANY CHANGES ARE SUBJECT TO THE CHANGE CONTROL PROCEDURES DELINEATED IN APPENDIX B. THIS DOCUMENT IS NOT TO BE REPRODUCED WITHOUT THE WRITTEN APPROVAL OF THE CHIEF, FLIGHT DIRECTOR OFFICE, DA8, LYNDON B. JOHNSON SPACE CENTER, HOUSTON, TEXAS.

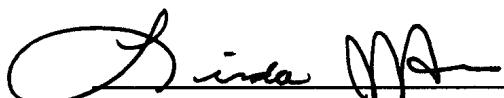

APPROVED BY:

J. MILTON HEFLIN
CHIEF, FLIGHT DIRECTOR OFFICE

JON C. HARPOLD
DIRECTOR, MISSION OPERATIONS

RONALD D. DITTEMORE
MANAGER, SPACE SHUTTLE PROGRAM

Verify that this is the correct version before use.

A2-2

ABORT LANDING SITE REQUIREMENTS (CONTINUED)

Continuous single engine out intact abort capability to a landing site meeting all requirements must be achieved to commit to launch (ref. Rule {A4-1D}, PERFORMANCE ANALYSES). Since the only two engine intact abort mode available for the first 2 to 3 minutes of any flight is the RTLS site, GO conditions are mandatory at the RTLS landing site.

TAL is required unless RTLS/two engine press overlaps. Even in those cases, TAL is the preferred abort mode for an engine out during the RTLS/TAL overlap period. Launching without TAL capability should never be a design goal but a real-time fallback if weather or equipment outages at the TAL sites are the only constraints to launch.

The ATO single SSME out press boundary represents the earliest time at which an engine failure will result in the achievement of an acceptable MECO underspeed based on one of four cases: AOA steep capability; ATO/minimum Hp with shallow deorbit on flight day 1 capability; ATO/minimum Hp with shallow deorbit on flight day 2 capability, including OPS 2 use of Fwd RCS (ref. Rule {A2-53}, FORWARD RCS USAGE GUIDELINES); or ET impact in an acceptable area (ref. Rule {A4-55B}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS). If the design press boundary is based on AOA steep but no AOA site is available, then intact capability can still be provided as long as no gap exists between last RTLS or TAL and the press boundary based on ATO/minimum Hp for flight day 1/shallow deorbit. If no first day PLS site is available, then continuous single SSME out intact abort capability can still be provided as long as no gap exists between last RTLS or TAL and the press boundary based on AOA steep (press capabilities based on AOA steep and ATO/min Hp/flight day 1 shallow come only a few seconds apart). If neither an AOA or first day PLS site are available, then launch commit may be allowed if there is no gap between last RTLS or TAL and a press boundary based on ATO OMS-1/minimum Hp OMS-2/shallow deorbit on flight day 2. This boundary assumes the use of the Fwd RCS in OPS 2. Analysis has shown that there is no delay in this press boundary with respect to the flight day 1 press boundary when the Fwd RCS is allowed. ©[012402-5112B]

Even if a first day PLS site is not technically available at launch time, equipment outages may be resolved or weather may improve by deorbit decision time.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-2**ABORT LANDING SITE REQUIREMENTS (CONTINUED)**

If a first day PLS landing site is not available, and systems failures requiring early flight termination occur, landing will be supported by RTLS, TAL, and AFO sites. This means that deorbit/landing might be made under ACLS/ELS type conditions: less than normally acceptable weather; lack of nav aids; etc. Systems failures requiring first day PLS are typically multiple failures or structural failures. In some cases, immediate deorbit is required. Should these type failures occur during the on-orbit timeframe, it has always been acceptable to land under ACLS/ELS conditions. In other cases, loss of redundancy in entry critical equipment is cause for a first day PLS. When a first day PLS site is not available, for loss of redundancy that normally calls for first day PLS, the risk of staying on orbit until the next day for improved landing conditions outweighs the risk of loss of critical equipment during the on-orbit wait for 24 hours.

If an abort landing site is required, the sites must fully meet the requirements listed in the flight rules (ref. Rules {A2-1G} and {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS, and {A4-107A}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS) for: landing site weather conditions including visibility, clouds, winds, turbulence, precipitation, runway/lakebed surface conditions, and resources necessary to measure low-level winds and atmospheric data (not PLS); crossrange, rollout margin, brake energy, navigation aids, and lighting (not PLS); touchdown margin (not PLS); and tracking (not AOA or PLS), telemetry, command, and air-ground voice (for PLS equipment outage ETRO must be before deorbit decision time). ©[072795-1772]

Rules {A1-106}, LANDING SITES; {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A3-1}, GROUND AND NETWORK DEFINITIONS; {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX; {A3-201}, TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY; {A4-2}, LANDING SITE CONDITIONS; and {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS, reference this rule. ©[ED]

FLIGHT RULES

A2-3 LAUNCH HOLD

NO MCC COUNTDOWN HOLD WILL BE CALLED AFTER T-31 SECONDS.

After T-31 seconds, launch holds will not be called by the MCC. T-31 seconds is the latest time that an MCC voice call for a launch hold can realistically be acted on in real time. Calling such a hold for MCC-related/non-ground launch sequencer (GLS) recognized problems does not merit the risk of such a launch hold. Backup onboard crew procedures can accomplish most abort functions should the MCC have a problem in the last few seconds before launch. @[061396 4005]

A2-4 LAUNCH DAY CREW TIME CONSTRAINTS

A. THE MAXIMUM TIME THE CREW WILL REMAIN IN THE VEHICLE IS 5 HOURS 15 MINUTES (EXCLUDING SAFING AND EGRESS TIME) (REF. LCC 3.2B), WHICH ALLOWS 2.5 HOURS OF HOLD TIME AFTER THE EARLIEST PLANNED LAUNCH TIME.

It is impractical to keep the crew in the launch-seat posture for an extended period of time. The crew enters the vehicle about 2 hours 45 minutes before launch; thus, a 2.5-hour launch window is preserved.

B. THE SCHEDULED CREW AWAKE TIME ON LAUNCH DAY WILL NOT NORMALLY EXCEED 16 HOURS. PRELAUNCH HOLD TIME AND POSTLAUNCH ORBITER/PAYLOAD CONTINGENCIES REQUIRING THE USE OF BACKUP TIMELINES WILL BE ACCOMMODATED AS LONG AS THEY DO NOT EXTEND THE CREW DAY BEYOND 18 HOURS.

Abnormally long days will result in crew fatigue and increase the potential for procedural errors that could affect safety or compromise mission success. Without a waiver, crew awake time on launch day will not be permission scheduled for greater than 16 hours. Since the crew is awake about 4 hours 55 minutes before launch, this allows for up to 11 hours 5 minutes of on-orbit activities before the start of the sleep period. If there is a launch hold or orbiter/payload contingencies require the use of backup timelines for deploy opportunities or off-nominal operations, these adjustments will be accommodated as long as the maximum crew day of 18 hours is not exceeded.

FLIGHT RULES

A2-5

PORT MODING/RESTRINGING GUIDELINES

- A. PORT MODING OR RESTRINGING MAY BE USED PER RULES {A2-254C}, ENTRY STRING REASSIGNMENT; {A2-63B}.2, ASCENT STRING REASSIGNMENT; {A7-5}, PASS GPC BCE FAILURE MANAGEMENT; AND {A7-105}, MDM PORT MODING, TO REGAIN LOST CAPABILITIES DUE TO GPC FLIGHT-CRITICAL BCE FAILURES. THE RECOVERY TECHNIQUE USED WILL DEPEND UPON THE SPECIFIC FLIGHT PHASE AND FAILURE SCENARIO PRESENT IN THE ORBITER. IN GENERAL, PORT MODING WILL BE ATTEMPTED DURING DYNAMIC PHASES OVER RESTRINGING EXCEPT AS NOTED IN THE REFERENCED RULES. [ED]

For flight-critical BCE failures, recovery of lost capability may be attempted via port moding or restringing. Port moding will recover the bypassed FC MDM, but will result in the loss of the other FC MDM on the affected string. Restringing will result in the entire recovery of string capability, but GPC redundancy may be given up.

Port moding is preferred over restringing because of the ease of implementation (crew SPEC entry), port mode reconfiguration is considered to be less hazardous to the PASS redundant set than restring reconfiguration, and the desire to maintain GPC redundancy.

In general, restringing will only be attempted when the appropriate restring criteria is satisfied. Otherwise, port moding may be done to recover lost capability.

- B. A RESTRING WILL BE PERFORMED TO MAINTAIN CRITICAL CAPABILITY FOR THE FOLLOWING POWERDOWNS:
1. LOSS OF AV BAY COOLING (TO RECOVER TWO STRINGS)
 2. LOSS OF CABIN PRESSURE
 3. LOSS OF FLASH EVAPORATOR SYSTEM
 4. LOSS OF TWO FREON LOOPS
 5. LOSS OF TWO FUEL CELLS
 6. LOSS OF TWO H₂O LOOPS

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)*NO MLS*

Without MLS, visual cues provide the only means to correct navigation dispersions remaining from TACAN/ADTA processing. Flight history has shown that the one-sigma position errors in the onboard state when using HAINS IMU's (no piloting dispersions included) just before processing MLS (at approximately 17K feet) are 188 ft u, 232 ft v, 225 ft w, and 374 ft RSS'd. The one-sigma position errors after one cycle of MLS processing are 38 ft u, 37 ft v, 64 ft w, and 83 ft RSS'd. Reference: The Summary of Navigation Errors through STS-88 (STF NAV-99-48500-008, February 4, 1999). Therefore, the crew can rely on guidance commands to a lower altitude when using MLS before beginning transition to visual cues. @[070899-6872A]

REDUNDANT AND SINGLE STRING MLS

The runway and orbiter must have redundant MLS for a night landing except for a lakebed runway. Single string MLS is acceptable because navigation dispersions are more tolerable on the larger area provided by the lakebed environment. If the single-string MLS fails, visual cues provide the only means to correct navigation dispersions. Flight Design and Dynamics personnel in cooperation with the Astronaut Office conducted an analysis to determine the night ceiling limit of 15K feet on the lakebed. The Shuttle Mission Simulator (SMS) and Shuttle Training Aircraft (STA) flew several sessions of night landings with dispersed initial conditions and good navigation. The experience gained from these analyses indicated that a ceiling level of 15K feet would be acceptable. This ceiling level will provide sufficient time for the crew to visually acquire the landing area, assess the need to correct dispersions, and take the necessary actions. If MLS were available, this is the approximate altitude when processing would begin. @[111094-1622B]

INOPERATIVE MLS COMPONENTS

For purposes of this rule, failure of any of the three MLS ground station measurements (azimuth, elevation, or range) constitutes a total failure of that string. Onboard navigation software will not process MLS data if either azimuth or range is unavailable. Although MLS azimuth and range data will be processed in case of ground elevation equipment failure, onboard altitude errors will not be corrected adequately. @[070899-6872A] @[041097-4927A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-6****LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)**

©[ED]

ACLS / ECAL / ELS

The ACLS, ECAL, or ELS limits require accepting additional risk. Emergency deorbit, SSME limits management, and abort gap closure procedures potentially use these sites. Rules {A2-205E} and {A2-205F}, EMERGENCY DEORBIT, and {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS, outline conditions for use of an ELS for emergency deorbit. Rule {A5-103A}.2, LIMIT SHUTDOWN CONTROL, specifies enabling main engine limits at the earliest single-engine capability to reach a prime TAL or ACLS for some cases following an SSME failure. This action precludes exposure to SSME limits-inhibited operation for any longer than necessary. Landing at an ACLS with zero/zero conditions carries less risk than continuing limits-inhibited SSME operation. Rule {A4-56I}.3, PERFORMANCE BOUNDARIES, specifies the use of an ACLS for abort gap closure. It is reasonable to attempt landing at an ACLS with zero/zero conditions if the attempt carries a reasonable probability of success and the only alternative is a bailout.

ONE APU FAILED (OR ATTEMPT TWO APU'S PROCEDURE)

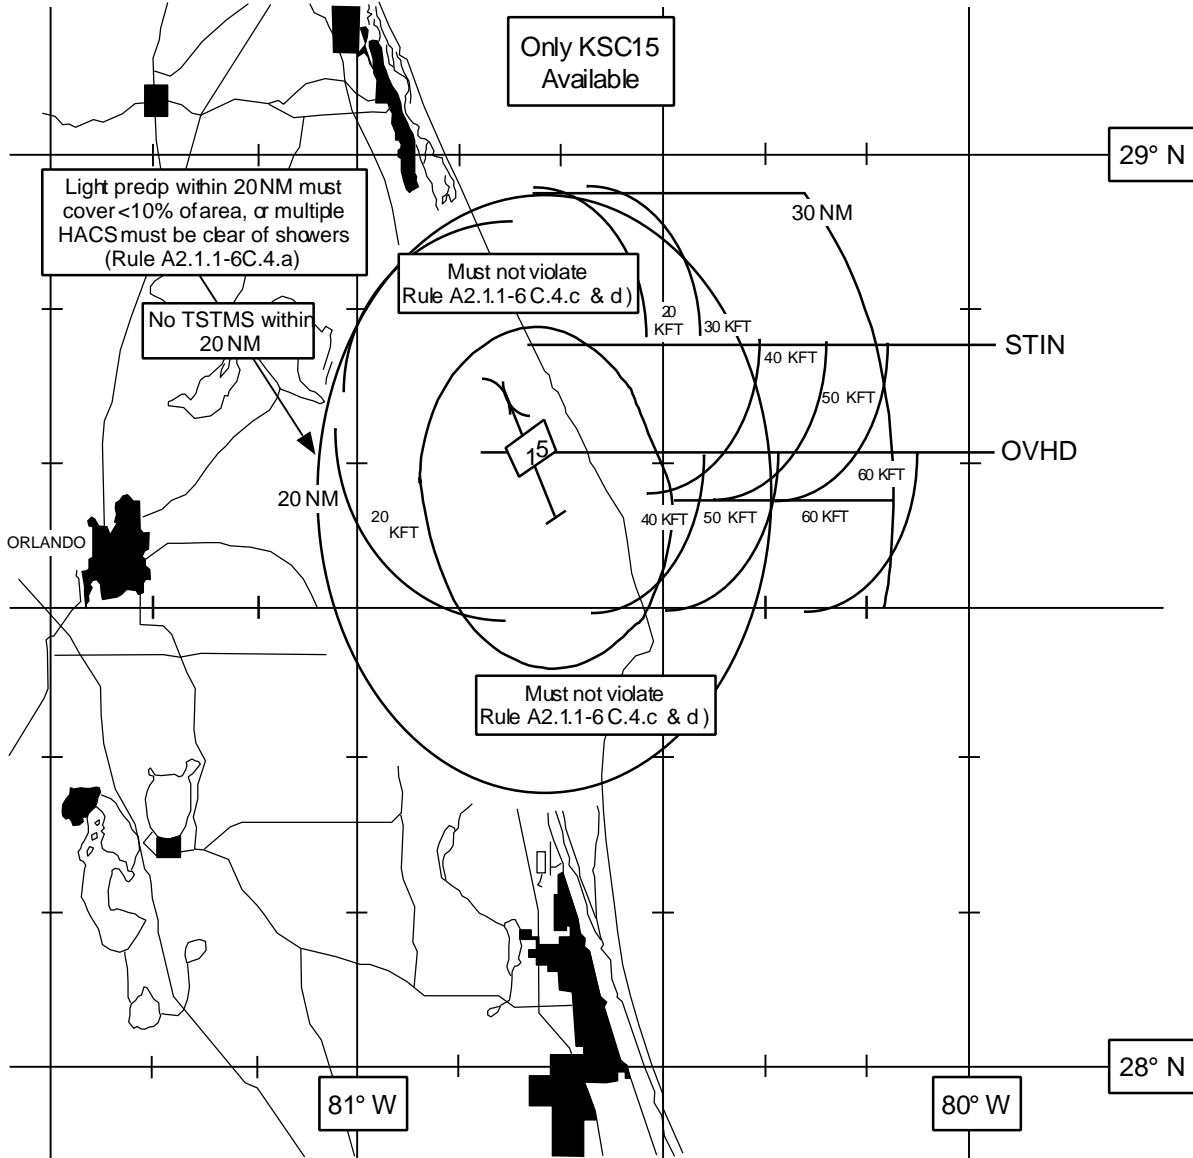

Flight Rules {A2-207}, LANDING SITE SELECTION, and {A10-23}, APU ENTRY START TIME, summarize the conditions and rationale for selecting a landing site with one APU failed and using the ATTEMPT TWO APU's start procedure. With two APU's failed, the loss of hydraulic power causes reduced flight control authority, reduced braking, and loss of nose wheel steering. The APU placards assure safe conditions should the orbiter lose a second APU. ©[111094-1622B]

DAY-OF-LAUNCH ET LOAD DATA

- A. ACTUAL DAY OF LAUNCH (DOL) ET LOAD DATA FROM THE PLOAD PROGRAM WILL BE USED TO RE-COMPUTE ASCENT PERFORMANCE MARGIN, ARD MASS PROPERTIES, AND ARD FPR BASED ON L-1.75 HOUR (OR LATER) DATA. @[050495-1729D] @[081497-6305A]
- B. IF A REVERT HAS OCCURRED, MCC WILL BE NO-GO FOR LAUNCH UNTIL STABLE REPLENISH HAS BEEN RE-ESTABLISHED AND A NEW PLOAD DATA INPUT HAS BEEN RECEIVED AND EVALUATED (APPROXIMATELY 50 MINUTES FOR AN LO₂ REVERT OR APPROXIMATELY 25 MINUTES FOR AN LH₂ REVERT).
- C. IF PLOAD IS UNAVAILABLE, THE ARD WILL BE CONFIGURED TO REFLECT TARGET TDDP LOAD QUANTITIES AND THE ARD FPR WILL BE RE-CALCULATED WITH INCREASED LOAD UNCERTAINTIES TO ACCOUNT FOR ADDITIONAL DISPERSIONS IN THE ACTUAL LOAD. NOTE: THIS IS VALID ONLY FOR A NOMINAL ET LOADING TIMELINE, UNLESS PROPULSION SYSTEMS COMMUNITY CONCURRENCE IS RECEIVED PER PARAGRAPH D, BELOW.
- D. IF BOTH AN LO₂ REVERT HAS OCCURRED AND PLOAD IS UNAVAILABLE, OR IF FOR ANY OTHER REASON LOAD UNCERTAINTY EXISTS WITHOUT PLOAD DATA, MCC WILL BE NO-GO FOR LAUNCH UNTIL THE PROPULSION SYSTEMS COMMUNITY, AS REPORTED BY THE JSC/USA PSIG REPRESENTATIVE IN THE MER, VALIDATES THAT THE MEASURED ULLAGE PRESSURE DOES NOT EXCEED 0.255 PSI ABOVE THE TDDP NOMINAL LOAD ULLAGE PRESSURE OF 0.781 PSIG. @[092602-5668]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-7

DAY-OF-LAUNCH ET LOAD DATA (CONTINUED)

The PLOAD program is executed at L-1.75 hours to estimate LO₂ and LH₂ loads based on ullage pressures and environmental conditions. This data is provided to the flight dynamics team at about L-1.5 hours (subsequent PLOAD run data during extended launch holds will also be incorporated as it becomes available, if necessary). The predicted end-of-replenish quantities are used to calculate DOL ascent performance margin, fuel bias, ARD Main Engine Propellant (MEP) quantity, and vehicle weights. ARD FPR is also recalculated based on the actual load, since the ET load and mixture ratio component of ARD FPR is a function of predicted fuel bias.

If a revert occurs, launch will not be attempted until a valid PLOAD data point can be evaluated (approximately 50 minutes of stable replenish for ullage pressure stabilization and load data transmittal for an LO₂ revert, approximately 25 minutes for LH₂), to assure an adequate ascent performance margin. The minimum time is that which is required before giving a "GO" to pick up the count at T-9 min or T-5 min. These procedures were approved at the PRCB, January 14, 1992. ©[050495-1729D] ©[081497-6305A]

When PLOAD is not available, it is assumed that the load fits within statistical limits of previous load quantities, which historically have been very close to the targeted load specified in the Trajectory Design Data Package (TDDP). In this case, ARD FPR must protect for historical deviations of the reported load from the target load as well as normal PLOAD uncertainties. The historical deviations (reference NSTS 08209, Shuttle Systems Design Criteria; Volume I, Shuttle Performance Assessment Databook; Section 8, Flight Performance Reserve; Table 8.1, System Dispersions for FPR Computation) are root sum squared with the normal PLOAD uncertainties to provide a total load uncertainty that is used to recompute ARD FPR. This increases the ARD FPR by approximately 70 lbs. ©[081497-6305A]

For any case involving loss of PLOAD data, a nominal stable replenish timeline is necessary to ensure that the load has reached TDDP target conditions. In the very unlikely event that both an LO₂ revert has occurred and the PLOAD program is unavailable, or if for any other reason load uncertainty exists, the propulsion systems community, as reported via the Propulsion Systems Integration Group (PSIG) representative in the MER, must be satisfied that the target MPS inventory has been achieved before a "GO" can be given to pick up the count. The MPS inventory is protected if the ullage pressure is less than 1.036 psi. Ullage pressure above this limit indicates an under-load of a magnitude beyond that covered in the FPR. The value of 1.036 psi is derived by adding the ullage pressure used in deriving the inventory (0.781 psi) to a tolerance that is protected by FPR (0.255 psi). ©[081497-6305A] ©[092602-5668]

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS

THE MCC-H FLIGHT DYNAMICS OFFICER (FDO) IS RESPONSIBLE FOR ALL COMPUTATIONS RELATED TO LAUNCH WINDOW. FINAL CALCULATIONS WILL BE MADE AT APPROXIMATELY L-2 HOURS. THESE WILL USE THE LATEST AVAILABLE BALLOON PERFORMANCE ANALYSIS, LATEST AVAILABLE TARGET TRACKING VECTOR, AND THE FINAL PLOAD ANALYSIS OF ET LOADING. THE FDO SHALL INFORM THE MCC-H FLIGHT DIRECTOR OF THE LAUNCH WINDOW TIMES. THE FLIGHT DIRECTOR SHALL BE THE SINGLE POINT OF COMMUNICATION FOR THE LAUNCH WINDOW TIMES TO KSC VIA THE NTD. THE ASSOCIATED LAUNCH TARGETING/AUTO DEL PSI COMMAND LOADS WILL BE GENERATED AND UPLINKED TO THE VEHICLE IN THIS TIMEFRAME. AFTER THIS TIME, UPDATES TO WINDOW TIMES AND/OR A NEW COMMAND UPLINK WILL BE REQUIRED IF THE PANE SWITCH WINDOW TIME CHANGES BY MORE THAN 5 SECONDS (IN EITHER DIRECTION) BASED ON THE L-2.25 HR BALLOON ANALYSIS AT APPROXIMATELY L-30. @[081497-6263B] @[111298-6693]

- A. LAUNCH WINDOW OPEN AND CLOSE TIMES WILL BE COMPUTED TO THE NEAREST SECOND. ON A GIVEN DAY, A RENDEZVOUS LAUNCH WINDOW MAY BE ONLY ONE PLANAR PANE OR THE COMBINATION OF TWO PLANAR PANES. ONLY THE PLANAR PANE WHERE THE PHASE ANGLE IS ACCEPTABLE WILL BE CONSIDERED PART OF THE COMBINED LAUNCH WINDOW. THIS MAY RESULT IN CUTOUTS IN THE LAUNCH WINDOW. CALCULATION OF LAUNCH WINDOW OPEN, CLOSE, AND PANE SWITCH TIMES WILL PROTECT:
1. MPS AND OMS PERFORMANCE MARGIN FOR MISSION SUCCESS AS DEFINED BY THE ANNEX FLIGHT RULE, SHUTTLE TRAJECTORY AND GUIDANCE PARAMETERS, PARAGRAPHS A AND B. THIS IS ZERO PREDICTED MPS USABLE RESIDUALS ABOVE THE FLIGHT PERFORMANCE RESERVE AND THE REQUIRED SIGMA DISPERSION. THE SIGMA DISPERSION IS DEFINED IN THE ANNEX FLIGHT RULE, SHUTTLE TRAJECTORY AND GUIDANCE PARAMETERS. @[062801-4521]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-9

LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS

IN THE PRELAUNCH TIMEFRAME: @[092602-5669A]

- A. FOR THE LOSS OF THE FIRST 100 PERCENT ET LOX LIQUID LEVEL CONTROL SENSOR, NO MCC ACTION IS REQUIRED, REGARDLESS OF WHEN THE FIRST SENSOR FAILS.
- B. LOSS OF A SECOND 100 PERCENT ET LOX LIQUID LEVEL CONTROL SENSOR WILL RESULT IN THE TRANSFER OF ET LOX LOADING CONTROL TO THE 100.15 PERCENT SENSOR.
 1. FOR CONTROL TRANSFER TO 100.15 PERCENT SENSOR PRIOR TO L-25 MINUTES:
 - a. ARD AND LAUNCH WINDOW DATA WILL BE BASED ON A 100.15 PERCENT LOX LOADING ESTIMATE (WITH ADJUSTMENT FOR ADDITIONAL DRAINBACK TIME, AS APPLICABLE).
 - b. IF STABLE REPLENISH USING THE 100.15 PERCENT SENSOR IS REACHED PRIOR TO L-1:20 HOURS, THE LOX LOADING ESTIMATE WILL BE GENERATED USING PLOAD. OTHERWISE, "NO PLOAD" LOADING ESTIMATES WILL BE USED PER RULE {A2-7C}, DAY-OF-LAUNCH ET LOAD DATA, DUE TO MCC OPERATIONAL PROCESSING TIMELINE CONSTRAINTS.
 - c. IF LAUNCH WINDOW UPDATES ARE AVAILABLE PRIOR TO L-39 MINUTES, THE FDO WILL COORDINATE UPDATES TO THE KSC LAUNCH WINDOW DATA. OTHERWISE, THERE WILL BE NO UPDATE TO THE KSC LAUNCH WINDOW TIMES.
 - d. ADDITIONAL DRAINBACK TIME SHALL BE INSERTED INTO THE TIMELINE AFTER THE START OF DRAINBACK AS SPECIFIED BY THE DOLILU OPERATIONS SUPPORT PLAN. FD WILL COORDINATE THE INSERTION OF THE ADDITIONAL DRAINBACK TIME, IF ANY, WITH NTD. @[092602-5669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-9

LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS
(CONTINUED)

2. FOR CONTROL TRANSFER TO 100.15 PERCENT SENSOR AFTER L-25 MINUTES: @[092602-5669A]
 - a. LAUNCH WINDOW DATA AND ARD CALCULATIONS WILL NOT BE UPDATED.
 - b. ADDITIONAL DRAINBACK TIME WILL NOT BE INSERTED INTO THE TIMELINE.
 - c. MCC WILL BE NO-GO FOR LAUNCH UNTIL THE PSIG REPRESENTATIVE IN THE MER VALIDATES THAT THE MEASURED ULLAGE PRESSURE DOES NOT EXCEED 0.255 PSI ABOVE THE TDDP NOMINAL LOAD ULLAGE PRESSURE OF 0.781 PSIG

The ET project has determined that the PLOAD LOX loading estimate based on liquid level control using a 100 percent sensor which subsequently fails will remain valid after a switch to the second 100 percent ET LOX liquid level control sensor. Therefore, switching liquid level control from one 100 percent sensor to the second 100 percent sensor does not invalidate the original PLOAD loading estimate.

The ET project has determined that the PLOAD LOX loading estimate based on liquid level control using either 100 percent sensor is not accurate in the event of a later failure of both 100 percent LOX liquid level control sensors and subsequent fill to the 100.15 percent sensor per LCC ET-10. The ET Project has requested DOSS to rerun PLOAD or revert to 100.15 percent MPS inventory loading estimates. A rerun and QA of PLOAD loading updates, nominal mission performance margin, and launch window impacts requires approximately 40 minutes. KSC Ground Operations is unable to accept launch window updates after L-39 minutes. However, FDO and ARD Support should reflect the best possible estimate of the true LOX loading. Therefore these elements will reconfigure to reflect LOX loading to the 100.15 percent MPS inventory values, if the fail over occurs after the latest time to rerun PLOAD (about L-1:20 hour) and prior to L-25 minutes, regardless of whether or not the KSC launch window is updated.

For any level sensor failure after L-25 minutes, no action is required by the MCC. A late sensor failure (either the first or the second) may result in an underload of approximately 1,100 pounds of LOX, which still meets LCC ET-10 launch requirements. This equates to approximately 15 fps of ascent performance margin. A launch with an underload of this magnitude will result in TAL and ATO abort boundary calls being made approximately 15 fps early and slightly increases the chances of a low level cut-off with a small underspeed. The program accepts this risk due to its low probability of occurrence. @[092602-5669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-9**LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS**
(CONTINUED)

In the event of a failure of both 100 percent sensors and fail-over to a fill to the 100.15 percent sensor failure, no additional drainback time will be added to the countdown. Analysis to clear the ET for flight in this condition is valid only through STS-118. ET LOX tank changes being made subsequent to STS-118 will require additional analysis. @[092602-5669A]

Late fail-over to a LOX tank fill controlled by the 100.15 percent (after failure of both 100 percent level sensors) will require verification that the LOX loading is consistent with MPS inventory loading estimates. The MPS inventory is protected if the ullage pressure is less than 1.036 psi. Ullage pressure above this limit indicates an under-load of a magnitude beyond that covered in the FPR. The value of 1.036 psi is derived by adding the ullage pressure used in deriving the inventory (0.781 psi) to a tolerance that is protected by FPR (0.255 psi). @[092602-5669A]

A2-10 THROUGH A2-50 RULES ARE RESERVED

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES

A2-64

MANUAL THROTTLE CRITERIA

MANUAL THROTTLE CONTROL WILL BE PERFORMED WHEN REQUIRED TO PROTECT SYSTEMS LIMITS, GUIDANCE SOFTWARE PERFORMANCE, OR MISSION CAPABILITY. REFERENCE RULES {A2-61}, Q-BAR/G-CONTROL; {A4-59}, MANUAL THROTTLE SELECTION; {A5-112}, MANUAL THROTTLEDOWN FOR LO2 NPSP PROTECTION AT SHUTDOWN; {A5-152D}.1, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]; AND {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP, FOR SPECIFIC CASES INVOLVING MANUAL THROTTLE. @[090894-1676A] @[041097-4910A] @[ED]

Normally, all SSME throttling action will be commanded by the flight software. However, manual throttling can relieve certain failure conditions, some potentially catastrophic, which are not protected by software; examples include low SSME NPSP, an unstable guidance solution, or any generic failure of the software throttling logic itself. In addition, manual throttle can be used to maximize performance in propellant-critical TAL cases as well as to avoid a TAL or RTLS abort when design underspeed is limited by NPSP. In these scenarios, the use of manual throttle control is preferred to the alternatives. The referenced rules spell out the background and criteria for manual throttle usage in each case.

FLIGHT RULES

A2-65

OMS-1 DELAYED TARGET CRITERIA

THE OMS-1 BURN WILL UTILIZE DELAYED TARGET FOR:

- A. MAIN PROPULSION SYSTEM (MPS) PROPELLANT DISCONNECT VALVE FAILED OPEN.
- B. ANY OMS PROPELLANT FAIL/LEAK OR OMS HE TANK FAIL.
- C. TWO OMS ENGINES FAILED.

NOTE: UNDERSPEED MECO CONDITIONS MAY REQUIRE USE OF ON-TIME (MECO + 2) OMS-1 TARGETS.

Delayed targets are designed for nominal or small underspeed MECO conditions only. Larger underspeeds (mission-dependent) may require on-time targets to remain within orbiter delta V capability.

For OMS propellant or helium tank leaks/failures, significant delta V capability will be lost. Also, loss of two OMS engines implies that all the delta V maneuvers will be accomplished with the RCS 4 +X thrusters. Performing delta V maneuvers with the RCS requires a significant amount of additional propellant to compensate for the reduced engine efficiency of the RCS jets as compared to the OMS engines. For these cases, a delayed ATO OMS-1 burn is performed to minimize delta V requirements for insertion and deorbit and allow time for a thorough assessment of the delta V capability remaining.

FLIGHT RULES**A2-70****DELAYED TRANSATLANTIC LANDING (TAL) ABORT**

IN THE WINDOW BETWEEN TWO-ENGINE TAL PLUS 10 SECONDS AND PRESS-TO-ABORT TO ORBIT (ATO) FOR 51.6 DEGREE INCLINATION MISSIONS, THE SELECTION OF THE TAL ABORT MAY BE DELAYED. THIS DELAY WILL MAXIMIZE EAST COAST ABORT LANDING (ECAL) ABORT COVERAGE WHILE PRESERVING INTACT TAL ABORT MARGIN. THE FOLLOWING GROUND RULES SHALL APPLY TO THE EXECUTION OF A DELAYED TAL ABORT: ©[092602-5667A]

- A. PRIOR TO ABORTING TAL, A MANUAL OMS DUMP WILL BE INITIATED THROUGH A CREW ITEM ENTRY.
- B. THE TAL ABORT SHALL BE SELECTED NO LATER THAN THE 3-SIGMA MAIN PROPULSION SYSTEM (MPS) FLIGHT PERFORMANCE RESERVE (FPR) PERFORMANCE BOUNDARY OR THE SINGLE-ENGINE OPS 3 BOUNDARY (REF. RULE {A4-56G}, PERFORMANCE BOUNDARIES), WHICHEVER COMES FIRST.
- C. DELAYING THE SELECTION OF THE TAL ABORT SHALL NOT APPLY FOR THE FOLLOWING SCENARIOS:
 1. LOSS OF COMMUNICATION
 2. SIGNIFICANT UNCERTAINTY EXISTS IN THE 3-SIGMA MPS FPR PERFORMANCE BOUNDARY.

In accordance with feasibility studies and risk trade assessments brought to the Ascent/Entry Flight Techniques Panel and the Space Shuttle Program Office, delayed TAL shall be implemented on all ISS missions starting with STS-110. The delayed TAL trajectory results in a groundtrack that is closer to the Eastern coast of the United States than if the TAL abort had not been delayed. The benefits of a delayed TAL trajectory include increased ECAL landing opportunities and improved bailout survival/recovery probabilities while maintaining intact TAL performance margins to no less than a 3-sigma confidence level. These benefits come at the expense of delayed single-engine performance boundaries and an extended Space Shuttle Main Engine (SSME) run time that vary as a function of the TAL delay time.

An ITEM 9 OMS propellant dump will be initiated prior to the TAL abort to improve intact TAL performance margins during the TAL delay period. The ECAL trajectory will also benefit from an early ITEM 9 OMS propellant dump because of an overall reduction in orbiter weight that should improve safety margins with respect to External Tank (ET) separation dynamics and overall orbiter load factors.
©[092602-5667A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-70**DELAYED TRANSATLANTIC LANDING (TAL) ABORT
(CONTINUED)**

The TAL abort shall be initiated at the earlier of the 3-sigma MPS FPR performance boundary for the prime TAL site or the single-engine OPS 3 performance boundary. It is expected for early engine-out cases close to the two-engine TAL performance boundary that TAL aborts will be initiated based on the 3-sigma MPS FPR performance boundary. Later engine-out cases and cases that implement an early ITEM 9 OMS propellant dump are likely to initiate TAL aborts based on the single-engine OPS-3 boundary. ©[092602-5667A]

As discussed with the Flight Director Office and the Space Shuttle Program Office, TAL delay will not be implemented during loss of communication situations, since the crew may not be aware of ground-determined performance boundaries used to terminate the TAL delay. More specifically, if there is no comm at the time of the SSME failure, the crew will follow the normal no-comm mode boundaries and abort as required. For all other cases, if comm is subsequently lost, then the crew will abort TAL at the no comm Vi per the MCC Delayed TAL abort call. Also, TAL delay will not be implemented for any scenario that results in a significant uncertainty in the real-time determination of the 3-sigma MPS FPR performance boundary in the ground Abort Region Determination (ARD) processor. In this instance, where significant uncertainty exists, it is conservative to abort TAL prior to the 3-sigma MPS FPR boundary to ensure adequate performance margin in support of the intact TAL trajectory. ©[092602-5667A]

A2-71 THROUGH A2-100 RULES ARE RESERVED

FLIGHT RULES**A2-102****MISSION DURATION REQUIREMENTS (CONTINUED)**

A risk assessment of the IMU, FCS, APU/hydraulic system, and MDM was completed by the AEFTP in 1996 (reference AEFTP #131 and 6/96 AEFTP splinter meeting). This assessment was quantitative for those items which have a sufficient statistical failure database, but relied on engineering judgment for other items. This assessment concluded that the relative risk of remaining on-orbit to NEOM rather than returning MDF for the first failure in these systems is less than the launch risks and orbital debris risks. This risk is acceptable as long as the remaining systems are good and generic problems are exonerated.

The following should be considered when making a flight determination decision: crew and vehicle health, vehicle mass properties, weather, trajectory, and landing site.

Reference Rule {A2-1001}, ORBITER SYSTEMS GO/NO-GO, for the number of failures in each system which result in early mission termination. Reference Rules {A2-207}, LANDING SITE SELECTION; {A10-21A}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS; and {A10-23A}, APU ENTRY START TIME. ©[101796-4561A] ©[ED]

C. FOR A SECOND FAILURE AFFECTING ANY ENTRY-CRITICAL SYSTEM
©[101796-4561A]

1. TERMINATE THE FLIGHT NEXT PLS IF THE AFFECTED SYSTEM HAS LOST ALL FAULT TOLERANCE OR IF THE FAILURE IS CONSIDERED TO BE GENERIC.
2. CONTINUE THE FLIGHT TO MDF IF THE ORBITER IS ONLY SINGLE-FAULT TOLERANT IN ORDER TO ACCOMPLISH DEPLOYMENT OF A PRIMARY PAYLOAD AND TO ENSURE CREW ADAPTATION, BOTH OF WHICH REDUCES THE OVERALL RISK TO THE CREW AND ORBITER.

NOTE: AN MDF WILL LAST APPROXIMATELY 72 HOURS AND LANDING WILL OCCUR AT THE PLS PRIOR TO THE END OF THE FLIGHT DAY 4.

Multiple failures in an entry critical system, even though it remains single-fault tolerant, may be indicative of a generic failure; Exposure to additional failures should be minimized by early termination of the mission.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

D. MDF GENERIC PAYLOAD RULES

1. THE DEORBIT OPPORTUNITY WILL NOT BE DELAYED FOR THE PURPOSE OF ACCOMPLISHING PAYLOAD OBJECTIVES.
2. FIRST PRIORITY WILL BE THE ACCOMPLISHMENT OF THE MINIMUM MISSION-SUCCESS OBJECTIVES OF THE PRIMARY PAYLOAD(S).
3. LOWER PRIORITY MISSION OBJECTIVES WILL BE CONSIDERED IN THE PRIORITY ORDER AS STATED FOR A NOMINAL MISSION.
@[101796-4561A]
4. SIGNIFICANT CONTINGENCY OPERATIONS, E.G., AN UNSCHEDULED EVA OR A CONTINGENCY RENDEZVOUS, WILL BE UNDERTAKEN ONLY IF ALL THE FOLLOWING ARE MET: @[101796-4561A]
 - a. IT IS NEEDED TO ACCOMPLISH A MINIMUM MISSION-SUCCESS OBJECTIVE FOR A PRIMARY PAYLOAD.
 - b. THE OPERATION WOULD NOT RESULT IN AN IMPACT TO THE MINIMUM MISSION SUCCESS OF ANOTHER PRIMARY PAYLOAD.
 - c. RULE {A13-101}, SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS, IS SATISFIED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

E. A NEXT PLS DEORBIT WILL BE EXECUTED AT THE EARLIEST PRACTICAL TIME TO A CONUS LANDING SITE FOR FAILURES WHICH PLACE THE ORBITER SYSTEM AT THE ZERO-FAULT TOLERANT LEVEL OR RESULT IN A CONDITION WHERE ONE MORE FAILURE CAUSES A SEVERE ORBITER CONFIGURATION MANAGEMENT CONDITION. CONUS LANDING SITE SELECTION SHALL PROVIDE FOR:

1. LANDING SITE PRIORITY (REF. RULE {A2-207}, LANDING SITE SELECTION)
 - a. PLS
 - b. SLS
 - c. ANY CONUS SITE
2. EOM LANDING CONSTRAINTS (CROSSRANGE, LIGHTING, WEATHER, AND BACKUP OPPORTUNITIES)
3. CREW SCHEDULE CONSTRAINTS
4. A NOMINAL DEORBIT PREPARATION TIMELINE IF POSSIBLE; OTHERWISE, A MINIMUM OF 3.5 HOURS DEORBIT PREPARATION
@[101796-4561A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

F. IF A FAILURE OCCURS THAT WOULD NORMALLY CAUSE AN MDF BUT THE TIME OF FAILURE IS PAST 72 HOURS FLIGHT DURATION, A LANDING WILL BE ACCOMPLISHED AT THE NEXT PLS OPPORTUNITY THAT PROVIDES ADEQUATE TIME FOR THE NORMAL EOM TIMELINE FOR VEHICLE STOWAGE AND ENTRY PREPARATION. @[101796-4561A]

Since a failure that would cause declaration of an MDF is a reason to shorten a normal flight, further operations of a payload/experiment are not sufficient reason to continue. The flight would be terminated at the next PLS that affords time to accomplish adequate stowage for entry and also allow the crew to have a sufficient sleep period.

G. FOR SOME FAILURE SITUATIONS AND/OR VIOLATION OF GO/NO-GO CRITERIA FOR FLIGHT CONTINUATION, IT IS SAFER TO REMAIN IN ORBIT INSTEAD OF ENTERING AT THE NEXT LANDING OPPORTUNITY. THAT IS, IF THE ADDITIONAL TIME CAN BE USED TO:

1. BETTER UNDERSTAND THE FAILURE AND ITS IMPLICATION ON ENTRY
2. VERIFY SYSTEMS CONFIGURATION PROCEDURES AND PERFORMANCE PRIOR TO ENTRY
3. PROVIDE ADEQUATE TIME FOR CREW REST THE NIGHT BEFORE ENTRY
4. PROVIDE THE OPPORTUNITY TO ACCOMPLISH ACTIVITIES THAT COULD ENHANCE ORBITER ENTRY/LANDING CONDITIONS @[101796-4561A]

Rules {A2-202}, EXTENSION DAY GUIDELINES; {A7-1001}, DPS GO/NO-GO MATRIX; and {A8-4B}, FAULT TOLERANT PHILOSOPHY reference this rule. @[ED]

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS (CONTINUED)

B. PAYLOAD OPERATIONS

ONCE THE DECISION HAS BEEN MADE FOR EARLY FLIGHT TERMINATION, PAYLOAD OPERATIONS MAY CONTINUE UNTIL DEORBIT MINUS 6 HOURS PROVIDED THAT THE OPERATIONS WOULD NOT JEOPARDIZE DEORBIT CAPABILITY. PAYLOAD OR SPACE SHUTTLE ARTICLES WHICH MUST BE MECHANICALLY SECURED FOR SAFE ENTRY/LANDING WILL BE SECURED PRIOR TO PRESLEEP ON DEORBIT MINUS 2 DAYS. IF STOW REDUNDANCY CAN BE DEMONSTRATED, OPERATIONS WILL BE ALLOWED TO CONTINUE UNTIL THE MORNING OF DEORBIT MINUS 1 DAY.

If a payload activity has no failure mode that could delay PLBD closing, there is no risk associated with allowing it to operate until deorbit minus 6 hours. If, however, the payload or space shuttle article must be mechanically or operationally secured prior to PLBD closure, then this operation should begin early enough to conduct an EVA (if required) without extending beyond the selected deorbit opportunity. This correlates to securing 2 days prior to deorbit which allows for an EVA on deorbit minus 1 day. If the potential of having to do an EVA has been significantly reduced (i.e., by demonstrating stow redundancy), then operation may continue until the morning of deorbit minus 1 day. Stowing in the morning will allow time for troubleshooting any unforeseen difficulties.

Rule {A9-4}, CAUTION AND WARNING (C&W), references this rule. ©[ED 1

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM)

A. DEFINITIONS:

1. SCHEDULED IN-FLIGHT MAINTENANCE (IFM) IS ACCOMPLISHED ON A PERIODIC (NOT NECESSARILY TIMELINED) BASIS TO KEEP EQUIPMENT OPERATIONAL AND EXTEND ITS LIFE. SCHEDULED IFM TASKS INCLUDE INSPECTION, CLEANING, AND REPLACING FILTERS AND CONSUMABLES. SPECIFICALLY EXCLUDED FROM THIS DEFINITION ARE REPAIR TYPE ACTIVITIES TO CORRECT OR WORK AROUND MALFUNCTIONS.

Examples of this type of maintenance are filter cleaning, LiOH canister replacement, and calibration of equipment.

2. UNSCHEDULED IFM IS UNDERTAKEN AS A RESULT OF ANOMALIES AND SPECIFICALLY INCLUDES TEST, MEASUREMENT, INSPECTION, AND REPAIR TYPE ACTIVITIES TO CORRECT OR WORK AROUND MALFUNCTIONS.

Definitions of categories of maintenance provide common terms for activities which may be constrained by flight rules. For example, scheduled maintenance is planned and approved preflight and usually accomplished without real-time consultation with the MCC-H. Unscheduled maintenance, which is conducted as a result of a hardware malfunction, is usually reviewed real time by the MCC-H whether or not it was preflight approved. This real-time review is conducted to determine orbiter/crew safety impacts.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-132

THERMAL CONDITIONING FOR FLIGHT DAY 1 LANDING (CONTINUED)

For a launch day deorbit, time may not be available to meet all thermal constraints, due to other constraints such as landing opportunity, burn attitudes, IMU alignment and verification, and communications. Within these other constraints, attitudes will be chosen to meet thermal constraints, such as tail-sun for bondlines or biased starboard-sun for OMS Ox Hi Point Bleedline QD and aft-firing RCS thrusters. ©[092195-1787B]

* TABLE NOTES:

ORBIT AND THEN" REFERS TO THE TIME FROM NOMINAL PLBD OPENING ATTITUDE (1:12) UNTIL MANEUVER TO DEORBIT IMU ATTITUDE (OR DEORBIT COMM ATTITUDE FOR REV 3).

TIMES IN PARENTHESES SHOW THE ATTITUDE DURATIONS WHICH WERE ASSUMED AND ANALYZED. THESE TIMES ALSO REFLECT THE DESIRED DURATIONS. IF MORE (LESS) ATTITUDE TIME IS AVAILABLE BETWEEN THE ACTUAL OMS-2 AND DEORBIT COMM ATTITUDES, THE 'ORBIT' ATTITUDE MAY BE LENGTHENED (SHORTENED). IF TWO ATTITUDES ARE SHOWN, I.E., 'ORBIT' AND 'THEN', THE DURATIONS MAY BE ADJUSTED PROPORTIONALLY.

ORB RATE DEFINITION: ORBITER WILL ROTATE ABOUT A SUN POINTING VECTOR OF P=180, Y=40 OR 45 AT ORBIT RATE, KEEPING THE ORBITER BOTTOM TOWARD SPACE DURING ROTATION (I.E., EQUIVALENT TO OMICRON 90 FOR POSITIVE BETA AND OMICRON 270 FOR NEGATIVE BETA AT NOON).

-ZLV AND ORB RATE ATTITUDES REQUIRE GNC OPS 2 SOFTWARE. IF GNC OPS 2 IS NOT AVAILABLE, "THERMALLY SIMILAR" SOLAR INERTIAL ATTITUDES WILL BE SELECTED.

DOCUMENTATION: CCB February 28, 1995, May 16, 1995, SODB Volume V. ©[092195-1787B]

FLIGHT RULES

A2-133

POCC THROUGHPUT COMMAND RATES

THE GENERIC COMMAND SERVER (GCS) WILL BE CONFIGURED TO ALLOW ONLY ONE POCC THROUGHPUT COMMAND PER SECOND TO BE OUTPUT INTO THE ORBITER UPLINK DATA STREAM. @[121197-6398] @[062702-5513]

The Network Signal Processor (NSP) interface with the Flight Software (FSW) Systems Management (SM) command application may require as much as 960 msec to completely process a single uplinked payload throughput command (PTC) without error. The POCC INPUT RATE CONTROL adjusts the rate at which commands will be accepted into the GCS. By setting this control to one command per second, first word/last word (FW/LW) rejects of commands by the SM GPC caused by too rapid payload commanding can be eliminated. Any setting of this control above one command per second, even if the commands are routed to the same vehicle address, will allow the potential for onboard rejects of commands to exist. See Section 6.2.2.5 of the Space Shuttle Computer Program Development Specifications (CPDS) - SS Downlist/Uplink Software Requirements (SS-P-0002-140). @[062702-5513]

Rejection of commands, for whatever reason, requires analysis of the command system to ensure that it remains intact with no failures. By eliminating this source of command rejects, resources can be more efficiently used. Limitation of payloads to one PTC per second should not present a significant impact if command timelines are planned appropriately. @[121197-6398]

FLIGHT RULES

A2-206

DEROTATION SPEED

- A. NOMINAL DEROTATION WILL BE TARGETED FOR 185 KEAS USING BEEP TRIM.
- B. IN THE EVENT OF A BEEP TRIM FAILURE, THE CDR WILL INITIATE MANUAL DEROTATION BY APPROXIMATELY 175 KEAS AND TARGET FOR A 1-2 DEG/SEC RATE.
- C. FOR A LEAKING/FLAT MAIN GEAR TIRE, BEEP TRIM DEROTATION MAY BE DELAYED TO NO SLOWER THAN 165 KEAS TO ACHIEVE A 10 KT DELTA FROM THE ACTUAL DRAG CHUTE DEPLOY VELOCITY. @[041097-4009E]

Nominal derotation is initiated by the crew using beep trim at 185 KEAS on both concrete and lakebed runways and for all vehicles. Based on a nominal 195 KEAS lightweight MLG touchdown, the drag chute is deployed immediately after touchdown. Flight data and testing at Ames (1/96 and 7/96) show that, to ensure disreef prior to NGTD, the chute should be deployed 10 knots prior to derotation. If the drag chute is deployed at 195 knots (post MGTD), the chute will be in the full-open configuration just prior to nose gear touchdown, thus reducing the slapdown loads. Faster touchdowns result in more time spent in the 2-pt attitude hold stance waiting for the velocity to decelerate to the nominal chute deploy/vehicle derotation cues. Although a nominal drag chute deploy and derotation sequence will usually result in a chute disreef prior to NGTD, dispersions in touchdown speed, chute deploy, and derotation velocities may result in chute disreef after NGTD. Derotation may therefore be delayed until 10 knots below the actual chute deploy velocity to ensure maximum load relief for a leaking/flat tire. The 165 KEAS minimum derotation velocity protects nose gear slap down loads, assuming no beep trim failures. (Reference AEFTP Splinter, October 8, 1996.) @[041097-4009E]

Reference Rules {A4-108A}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS, and {A10-142}, TIRE PRESSURE [CIL]. @[050495-1774A]

FLIGHT RULES

A2-207

LANDING SITE SELECTION

NORMAL LANDING SITE SELECTION WILL BE BASED ON THE FOLLOWING PRIORITIES. ALL REQUIREMENTS FOR ACCEPTABLE WEATHER, LIGHTING CONDITIONS, RUNWAY CONDITIONS, AND ENTRY CONSTRAINTS MUST BE SATISFIED FOR A SITE/RUNWAY TO BE USED. @[102402-5804C]

NOTE: REFERENCE THE FLIGHT-SPECIFIC FLIGHT RULE ANNEX FOR ANY EXCEPTIONS TO THE FOLLOWING LANDING SITE PRIORITIES DUE TO SPECIAL CIRCUMSTANCES/REQUIREMENTS.

A. RTLS/TAL PRIORITIES:

RTLS [1]	
INCLINATION < 39°	INCLINATION > 39°
KSC 15	KSC 33
KSC 33	KSC 15

NOTE:

[1] FOR INCLINATIONS OF EXACTLY 39 DEGREES, THERE IS NO DIFFERENCE IN DOWNMODE RANGING BETWEEN KSC 15/33. RUNWAY WILL BE CHOSEN BASED ON WEATHER, SURFACE WINDS, TOUCHDOWN/ROLLOUT MARGINS, ETC. @[020196-1802A]

TAL			
28.5	39	51.6	57
BEN GUERIR (BEN)	BEN GUERIR (BEN)	ZARAGOZA (ZZA)	ZARAGOZA (ZZA)
MORON (MRN)	MORON (MRN)	MORON (MRN)	MORON (MRN)
	ZARAGOZA (ZZA)	BEN GUERIR (BEN)	BEN GUERIR (BEN)

@[020196-1802A] @[102402-5804C]

RUNWAY SELECTION FOR RTLS OR TAL SHOULD BE IN PRIORITY ORDER OF GO RUNWAYS. HOWEVER, IF A RUNWAY APPROACHES FLIGHT RULE LIMITS OR OTHER CONDITIONS MAKE A RUNWAY LESS DESIRABLE (I.E., SUN GLARE, STA EVALUATION, ETC.), THEN CONSIDERATION MAY BE GIVEN TO SELECTING A LOWER PRIORITY RUNWAY. @[020196-1802A] @[102402-5804C]

Runway priorities for RTLS are based solely on energy downmode capability. For inclinations less than 39 degrees, GRTLS range-to-go analysis has shown that a larger range recovery capability exists for an OVHD KSC 15 downmode to STIN KSC 33 than OVHD KSC 33 downmode to STIN KSC 15.

TAL runway priorities were determined based on the site that provides the best single-engine coverage once a TAL abort has been selected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

B. AOA PRIORITIES @[102402-5804C]

NOTE: AOA PRIORITIES ARE MODIFIED BY INCLINATION. AT 28.5 AND 39 DEGREE INCLINATIONS, ALL AOA SITES ARE AVAILABLE FOR SELECTION. AT 57 DEGREES, ONLY NOR IS AVAILABLE, AND AT 51.6 DEGREES, NOR AND KSC ARE AVAILABLE. @[020196-1802A]

1. EDWARDS 22/04
2. KSC
3. NORTHRUP

Since AOA landings are typically heavyweight, the Edwards complex provides more margin in the event of landing/rollout or vehicle energy problems. For high inclination missions, Northrup may be the only AOA landing site available due to the large crossrange required to land at Edwards or KSC. (ref. Rule {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS). @[111094-1622B]

C. EOM PRIORITIES

1. KSC
2. EDWARDS 22/04
3. NORTHRUP

Due to the advantages in vehicle turnaround, the Space Shuttle Program has directed that nominal end of mission (EOM) landings utilize KSC as the first priority landing site.

After KSC, next in the EOM runway selection priority is Edwards, because of the availability of the concrete runway and because of the significant vehicle post landing and turnaround operations capabilities. NOR is generally last priority, because although it provides an excellent orbiter landing site (laser-leveled runways, crossing runways, significant runway lateral and longitudinal margin, all required landing aids and NAVAIDS for day and night, etc.), the ability to support the orbiter systems postlanding and for turnaround/ferry operations is much reduced as compared to KSC or Edwards, resulting in the potential for significant (several weeks) shuttle schedule/manifest impacts. @[102402-5804C]

Reference Rule {A4-109}, DEORBIT PRIORITY FOR EOM WEATHER.

Reference Rule {A2-202}, EXTENSION DAY GUIDELINES, for cases where the PLS is NO-GO.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

D. SYSTEMS FAILURE PRIORITIES [1][3][5][6] @[102402-5804C]

FOR SYSTEMS FAILURES THE LANDING SITE PRIORITY SHALL FOLLOW THE EOM PRIORITIES. CONSIDERATION WILL BE GIVEN TO THE FOLLOWING EXCEPTIONS:

SYSTEM FAILURES [1]	PRIORITY
1 OR 2 APU/HYD SYSTEMS	LANDING SITES WITHIN SINGLE APU WX PLACARDS [2]
2 IMU'S 2 NORM/LAT AA'S 2 RGA'S	EDW 22/04 NORTHROP KSC
2 ADTA'S	LANDING SITE WITH MOST FAVORABLE ATMOSPHERIC CONDITIONS [4]
2 FCS CHANNELS (SAME SURFACE)	NORTHROP EDW 22/04 KSC

@[102402-5804C]

NOTES:

[1] ALL FAILURES OCCUR PRIOR TO DEORBIT BURN.

[2] WX PLACARDS ARE AS FOLLOWS:

- A. CEILING - GREATER THAN OR EQUAL TO 10K FEET
- B. VISIBILITY - GREATER THAN OR EQUAL TO 7 STATUTE MILES
- C. CROSSWIND - LESS THAN OR EQUAL TO 10 KNOTS (PEAK)
- D. NO GREATER THAN LIGHT TURBULENCE
- E. ACCEPTABLE ROLLOUT MARGIN/BRAKE ENERGY ON HALF BRAKES WITHOUT NOSEWHEEL STEERING (DIFFERENTIAL BRAKING)

(REF. RULE {A10-23A}, APU ENTRY START TIME.) LANDING SITE PRIORITY SHALL MINIMIZE CROSSWINDS AND TURBULENCE.

[3] IF THE PRIMARY LANDING SITE IS NO-GO AND IF THE FORECAST CONDITIONS ARE PREDICTED TO IMPROVE, DEORBIT WILL BE DELAYED, IF PRACTICAL.

[4] UNFAVORABLE ATMOSPHERIC CONDITIONS ARE DEFINED AS UPPER LEVEL HAC WINDS IN EXCESS OF 80 KNOTS, HAC DYNAMICS THAT COULD AFFECT THE VEHICLES ENERGY STATE (I.E., ENERGY DUMP MANEUVERS), OR DENSITY ALTITUDE AFFECTS THAT BIAS THE INDICATED AIRSPEED. PRESENCE OF ANY OF THESE CONDITIONS INCREASES THE WORKLOAD ASSOCIATED WITH MANUALLY FLYING THETA LIMITS, COULD RESULT IN ADDITIONAL ENERGY LOSS, AND INCREASES THE POSSIBILITY OF LANDING FASTER OR SLOWER THAN THE TARGETED AIRSPEED. (REF. RULE {A8-111}, AIR DATA SYSTEM MANAGEMENT).

[5] LIGHTED RUNWAY REQUIRED AT NIGHT.

[6] REFERENCE RULE {A2-202}, EXTENSION DAY GUIDELINES, FOR WAVE-OFF CRITERIA. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

The NEOM landing site priority of KSC, EDW 22/04, NOR is driven by Space Shuttle Program directive, based on the cost in time and money for vehicle turn-around. Exceptions to this standard priority order will be reviewed on a case-by-case basis for orbiter systems failures. Factors in selecting the best landing site include, but are not limited to, weather conditions, runway lateral and rollout margins, and touch-down margins for flight control or navigation issues. KSC 15/33 is a 300 ft wide grooved concrete runway with 50 ft loadbearing paved shoulders and has a total length of 17,000 ft including the 1,000 ft underrun and 1,000 ft overrun. The KSC runway is surrounded by a non-loadbearing grassy area and a moat. EDW 22/04 is a 300 ft wide non-grooved concrete runway with 25 ft lakebed material shoulders that are not generally considered loadbearing. EDW 22/04 has a total length of 16,975 ft. The EDW 04 end has a 1,000 ft underrun and an 1,800 ft overrun with the possibility of rollout onto another 9,588 ft of prepared lakebed surface. The EDW 22 end has a 1,800 ft underrun and no overrun. NOR 17/35 and 05/23 are 300 ft wide leveled lakebed runways with 300 ft shoulders of the same hard mantle material. Each runway has a total length of 39,000 ft including a 12,000 ft underrun and 12,000 ft overrun. For all runways, the existence and location of obstructions in the shoulders should be discussed in situations where lateral margins are a factor in landing site selection. ©[102402-5804C]

The following cases have been addressed in the development of this rule (ref AEFTP #187):

1 or 2 APU HYD SYSTEMS: For loss of a single APU/hydraulic system, vehicle hydraulic capability is unimpaired. However, loss of a second APU, results in potential system losses (nosewheel steering, braking capability, control effectiveness at derotation, etc.) requiring more stringent weather placards to assure a safe landing. If two APU/hydraulic systems are lost, it is desirable to provide significant lateral and longitudinal margins while providing a surface that is hard enough to allow better control of derotation rate in order to limit nose gear touchdown loads. Concrete runways provide a lower coefficient of friction than lakebeds, including Northrup. A lower coefficient of friction reduces the pitch down moment and, thus, reduces hydraulic load. With only one APU remaining for flight control, an evaluation of appropriate weather conditions, including upper level and surface winds, is critical in the planned landing site selection criteria. Since the control degradation and systems losses would only be apparent with a single operating APU during approach and landing, derotation, and rollout, it is prudent to pick the best runway within the stated weather placards. The stability of the weather, and minimizing cross-winds and turbulence, are the key consideration if more than one landing site is within placards. ©[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

2 IMU's, 2 NORM/LAT AA's, 2 RGA's: The IMU's, AA's, and RGA's provide feedback to the orbiter flight control loops. Specifically, the IMU's are used to propagate the vehicle navigation state vector and provide attitude and attitude rate information to the flight control system. Lateral AA's provide feedback to the flight control system to improve stability during turn coordination and roll reversals, and are used to provide feedback during use of nose wheel steering (NWS) on the runway. Normal AA's are used to sense normal acceleration (Nz) during TAEM to prevent from overstressing the vehicle's structure by maintaining the pitch angle such that the vehicle stays below the Nz limits. The RGA's are used to stabilize the flight control system by providing high frequency rate information between IMU rate samples. The IMU's, AA's, and RGA's are used by the Aerojet DAP during the EI-5 through landing and rollout timeframe (MM304 and MM305). A critical failure in one of these systems could result in degraded vehicle control and/or significant energy loss during the entry profile. The intent of selecting Edwards 22/04 as the primary landing site is to provide the maximum number of contingency energy downmode options in the event the next LRU fails early in the entry profile and results in significant energy loss. Downmode options in the vicinity of Edwards 22/04 include Palmdale, China Lake, the Edwards lakebed, etc. If Edwards is not available, then Northrup provides the next best energy downmode capability because the Northrup landing site complex has multiple runways available, and it is collocated with several other contingency landing sites (i.e., Holloman, etc). If Edwards and Northrup are unavailable, then a KSC landing should be targeted since the probability of the next worst failure is low and it is the prime landing site with significant ground forces available. ©[102402-5804C]

2 ADTA's: The ADTA's are only used during TAEM, provide altitude data to navigation, and determine the Mach number and angle of attack (Alpha) for use by flight control. This limits the window of exposure for another ADTA problem to only the last portion of entry. Next worst failures could include a loss of all air data measurements (due to dilemma or a probe problem). Landing site selection with two ADTA's failed protects for landing without air data. Flying without air data requires use of manual flying techniques (i.e., theta limits). The level of difficulty associated with maintaining theta limits and survivability is significantly affected by the atmospheric conditions. As such, only the landing site with the most benign atmospheric conditions should be targeted. Unfavorable atmospheric conditions that could result in a loss of control, significant energy loss due to flying outside the HAC, or difficulty in maintaining theta limits include high upper level winds on the HAC (i.e., winds in excess of 80 knots) or other HAC dynamics such as an energy dump pull-up maneuver. Density altitude effects should also be considered when targeting a landing site, because the density altitude could bias the indicated airspeed and result in a landing that is considerably faster or slower than the targeted touchdown airspeed. This is due to the fact that the flight control system assumes a standard atmosphere as the default with no air data and that default may differ significantly from the actual atmospheric conditions of the day at the selected landing site. (Ref. rule {A8-111}, AIR DATA SYSTEM MANAGEMENT.) ©[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

2 FCS CHANNELS: *The FCS channels control the orbiter aerosurfaces during the later portion of entry once sufficient atmospheric density has built up to give those aerosurfaces effective control authority. This limits the window of exposure of a next worse failure (i.e., a 1-on-1 force fight, bad feedback going into flight control, etc.) to the later portion of entry. Such a failure could result in a control transient or persistent vehicle control problems that impact the vehicle's energy state. Most flights require a concrete runway landing (or equivalent runway hardness) due to the large mass moment at nose gear touchdown. Northrup provides the most flexibility of the available primary landing sites due to the availability of several runways of sufficient hardness. If Northrup is unavailable, then Edwards should be targeted because it provides the option to downmode to the large lakebed landing complex in the event that it is not possible to reach the concrete runway. The Edwards lakebed would only be used in a contingency. If Edwards and Northrup are unavailable, then a KSC landing should be targeted since the probability of the next worst failure occurring is low and KSC is the prime landing site with significant ground forces available. The landing site selection philosophy for FCS channels assumes that sufficient aft RCS margin is available to perform the entry with Wrap-DAP active. Use of Wrap-DAP provides yaw jet control authority to fight any drag that may be caused by degraded aerosurface movement above Mach 1 (i.e., performing an entry with no-yaw-jet selected does not limit window of exposure to TAEM because sufficient RCS jet control authority does not exist to fight a bad aerosurface).* ©[102402-5804C]

MLG TIRE PREDICTED TO BE BELOW THE MINIMUM ACCEPTABLE PRESSURE AT

TOUCHDOWN: *If a tire pressure is low, due to temperature or leakage, such that sufficient load-carrying capability of that tire may not exist (ref. rule {A10-142}, TIRE PRESSURE [CIL]), total loss of that tire may occur at derotation, when the highest tire loading is reached. Based on Northrup hardness data, Northrup is acceptable for blown tire cases. However, the coefficient of friction on the strut if both tires on a MLG fail is greater than at a concrete runway, indicating that the vehicle would be harder to control on the Northrup lakebed than at KSC or EDW 22/04. Runway prioritization, consequently, gives preference to concrete runways. Consideration should be given to minimizing crosswind during landing site selection to reduce loads on the remaining tires. Landing with the crosswind on the side of the vehicle with the flat tire will help reduce loads on the affected landing gear, reducing the risk of blowing the remaining tire. Loads on the NLG tires are low enough that if one tire is failed, the remaining tire is not likely to blow. Loss of one or both NLG tires is not considered a directional control problem, since the vehicle should be controllable with differential braking.*

NWS FAILED (ALL): *With the loss of NWS, differential braking remains as the only method of directional control. Sufficient braking system redundancy exists to accept the risk of landing at KSC or EDW vs. NOR. Consideration should be given to minimizing crosswind during landing site selection.* ©[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

E. PREDEORBIT LANDING SITE EVALUATION @[102402-5804C]

1. AFTER DEORBIT MINUS 2.5 HOURS, IF UNACCEPTABLE WEATHER CONDITIONS EXIST (OBSERVED OR FORECAST) OR ENTRY REQUIREMENTS CANNOT BE SATISFIED (TAEM, A/L, TOUCHDOWN, ROLLOUT, ETC.), THE AFFECTED LANDING SITE MAY BE ELIMINATED AS A PRIMARY OPTION.
2. AFTER DEORBIT MINUS 1.5 HOURS, ONLY A SINGLE LANDING SITE WILL CONTINUE TO BE EVALUATED. OTHER LANDING SITE OPTIONS MAY BE REEVALUATED IN THE EVENT OF A DEORBIT WAVE-OFF.

The above guidelines will allow the evaluation of multiple runways at multiple landing sites for multiple deorbit opportunities without significantly compromising the required evaluation of the actual runway where landing will occur. It is always prudent to eliminate landing site/runway options as they become unlikely to remain within limits. This is especially true after deorbit minus 2.5 hours, the standard time at which deorbit pads will be voiced to the crew. Up until deorbit minus 1.5 hours, sufficient time is available to evaluate multiple landing sites for the nominal deorbit as well as preliminary evaluation of landing sites on the next deorbit. Due to multiple wind sets, landing sites, runways, aimpoints, etc. being evaluated, a total team focus on the primary runway on the last orbit prior to deorbit is necessary.

Rules {A2-102}, MISSION DURATION REQUIREMENTS, and {A2-6}, LANDING SITE WEATHER CRITERIA [HC], reference this rule.

FLIGHT RULES

A2-208

ACES PRESSURE INTEGRITY CHECK @[012402-5089]

DEORBIT WILL NOT BE DELAYED FOR FAILURE OF ANY ADVANCED CREW ESCAPE SUIT (ACES) PRESSURE INTEGRITY CHECK.

ACES pressure integrity is not required for the present bailout scenario. In addition, beyond verifying the proper connections, there is little that the crew could do during flight to locate the source of a leak in an ACES or to repair it. @[012402-5089]

FLIGHT RULES

A2-209

LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY

- A. AN INFLIGHT EMERGENCY WILL BE DECLARED AND AN ATTEMPT WILL BE MADE TO PERFORM AN EMERGENCY LANDING IF A LANDING AT THE TARGETED SITE IS IMPOSSIBLE. @[120894-1744B]

NOTE: THE DETERIORATION OF WEATHER (WINDS, TURBULENCE, CEILING, PRECIPITATION, ETC.) AND/OR LANDING AND ROLLOUT MARGINS, WHICH RESULT IN FLIGHT RULE EXCEEDANCES POST-DEORBIT BURN, ARE NOT CAUSE TO REDESIGNATE FROM THE TARGETED SITE.

- B. LANDING WILL BE ATTEMPTED AT AN EMERGENCY LOCATION THAT MEETS THE FOLLOWING CRITERIA:

1. THE LANDING FIELD IS WITHIN THE ENERGY CAPABILITY OF THE ORBITER AS DEFINED IN RULE {A2-251}, BAILOUT.
2. THE LANDING FIELD FACILITIES SATISFY THE REQUIREMENTS DOCUMENTED IN RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA.

- C. TIME PERMITTING, WITH MULTIPLE SITES OF SIMILAR ENERGY CAPABILITY, SELECTION OF THE EMERGENCY LANDING FIELD WILL BE BASED ON THE FOLLOWING PRIORITY:

1. ANOTHER NASA AUGMENTED LANDING SITE
2. A DOD AIRFIELD WITH COMPATIBLE SHUTTLE UHF COMMUNICATIONS
3. A DOD AIRFIELD WITHOUT COMPATIBLE SHUTTLE UHF COMMUNICATIONS

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-209

LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY (CONTINUED)

4. A COMMERCIAL AIRFIELD WITH COMPATIBLE SHUTTLE UHF COMMUNICATIONS
5. A COMMERCIAL AIRFIELD WITHOUT COMPATIBLE SHUTTLE UHF COMMUNICATIONS

Should orbiter or facility problems be encountered which make landing at the designated NASA landing field impossible, the actions to be taken are identified in order of priority in an attempt to save the crew and orbiter (national resource), while at the same time minimizing public exposure to additional risk. During entry should the need arise, an "inflight emergency" (as declared by all aircraft if in trouble) will be declared, and a landing at an ELS will be attempted if energy is sufficient to reach the landing site (reference Rule {A2-251}, BAILOUT) and the facility meets the minimum requirements (reference Rule {A2-264}, EMERGENCY LANDING FACILITY CRITERIA). ©[120894-1744B]

Weather forecasts for shuttle landings are made by well-trained, experienced meteorologists with the best tools available and within 90 minutes of landing. At the A/E FTP #73, the results of a multimonth study of forecasting accuracy showed that these forecasts were extremely accurate and in the very small percentage of cases where a GO prediction turned into a NO-GO situation, the violations were minor and survivable. It is inconceivable that these forecasts would be in error by a degree that would entail greater risk by continuing to the landing site than would be incurred by diverting to an emergency field with its lack of facilities, navigation aids, trained personnel, and flightcrew familiarity.

Diverting from the targeted site will not be done just for deteriorating weather conditions which will violate weather flight rules or landing and rollout margin reductions. We will accept the nonoptimum conditions rather than divert to another site since it is believed that this option provides less risk to the orbiter and crew as well as the general public. ©[120894-1744B]

Should it be necessary to divert from the primary landing field, another NASA augmented landing field will be selected if available. Otherwise, site selection will be based on facility type (DOD vs commercial) and the availability of compatible shuttle UHF communications. The facility priority has been selected to minimize risk to the general public. ©[120894-1744B]

ENTRY

A2-251

BAILOUT

- A. THE CDR IS RESPONSIBLE FOR BAILOUT ACTION.
- B. THE MCC WILL EVALUATE ALL POSSIBLE ENERGY MANAGEMENT ACTIONS PRIOR TO RECOMMENDING BAILOUT. @[120894-1744B]
- C. THE FOLLOWING DEFINITIONS APPLY TO THE BAILOUT REGIONS DEFINED BELOW:
 - 1. MCC MAX RANGE LINE: THIS LINE IS GENERATED ON LANDING DAY AND BASED ON A STRAIGHT-IN APPROACH TO THE MINIMUM ENTRY POINT HAC, WITH MAXIMUM L/D STRETCH TECHNIQUES AND ACTUAL WINDS AND ATMOSPHERIC CONDITIONS.
 - 2. MCC RTLS MINIMUM ENERGY LINE: THIS LINE IS GENERIC FOR ALL FLIGHTS AND ASSUMES A FORWARD CG, MID-WEIGHT, HEAVYWEIGHT I-LOADS, COLD ATMOSPHERE, AND NO WINDS.
 - 3. MCC BAILOUT LINE: THIS LINE IS GENERIC FOR ALL FLIGHTS AND REPRESENTS A BEST-ON-BEST MAXIMUM CAPABILITY, BASED ON 3 SIGMA FAVORABLE WINDS, MAXIMUM HAC SHRINK, AND MAXIMUM ORBITER L/D.
- D. AN MCC BAILOUT RECOMMENDATION WILL BE MADE BASED ON THE FOLLOWING CRITERIA, USING THE BEST AVAILABLE SITE, RUNWAY, AND STATE VECTOR SOURCE, AND WITHOUT REGARD TO TOUCHDOWN, BRAKE ENERGY AND ROLLOUT MARGIN PLACARDS:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251

BAILOUT (CONTINUED)

1. GREEN: BAILOUT NOT REQUIRED (CALL ONLY REQUIRED IF TRANSITIONING FROM THE "YELLOW" REGION).
 - a. EOM LANDINGS: ORBITER ENERGY/WEIGHT ABOVE THE MAX RANGE LINE.
 - b. ALL OTHER LANDINGS: ORBITER ENERGY/WEIGHT ABOVE THE MCC RTLS MINIMUM ENERGY LINE. @[120894-1744B]
 2. YELLOW: BAILOUT IF DEEMED NECESSARY BY THE CDR; MCC CONTINUES TO MONITOR. @[120894-1744B]
 - a. EOM LANDINGS: ORBITER ENERGY/WEIGHT BELOW THE MAX RANGE LINE AND ABOVE THE MCC BAILOUT LINE.
 - b. ALL OTHER LANDINGS: ORBITER ENERGY/WEIGHT BELOW THE MCC RTLS MINIMUM ENERGY LINE AND ABOVE THE MCC BAILOUT LINE.
 3. RED: MCC RECOMMENDS BAILOUT.

ORBITER ENERGY/WEIGHT BELOW THE MCC BAILOUT LINE.
- E. IF POSSIBLE, BAILOUT WILL BE DECLARED NO LOWER THAN 50K FT ALTITUDE (70K FT FOR ECAL).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251 BAILOUT (CONTINUED)

- F. NORMALLY, ZERO DEGREES OF BANK WILL BE USED FOR BAILOUT GUIDANCE "FREEZE" CONDITIONS. HOWEVER, THE MCC MAY PROVIDE A DESIRED BANK ANGLE (UP TO 10 DEG) IF REQUIRED TO AVOID ORBITER IMPACT IN POPULATED AREAS.
- G. IF BAILOUT IS DECLARED FOR ECAL, A TURN SHALL BE EXECUTED TO A HEADING OF 120 DEG, UNLESS FDO DETERMINES IN REAL TIME A HEADING MORE FAVORABLE FOR SAR OPERATIONS (E.G., PARALLEL THE COAST, ETC.)

Reference Rule {A1-6}, SHUTTLE COMMANDER AUTHORITY, for CDR responsibilities.

The MCC has more accurate evaluation tools with which to determine energy capability and uses radar tracking data (when available) as the prime state vector source. All energy management and recovery procedures will be evaluated prior to any bailout recommendation being issued by the MCC. Three bailout zones, green, yellow, and red, have been identified for MCC bailout recommendation, based on areas delineated on FDO Energy/Weight versus Range-to-go displays.

The bailout green zone is defined as that area above the MCC maximum ranging capability line which is generated for EOM on landing day, based on a straight-in approach to the minimum entry point HAC, with maximum L/D stretch techniques and actual winds and atmospheric conditions. For all other cases, this flight and landing day-specific actual capability line does not exist, and the MCC RTLS minimum energy line will be used. This line is generic for all flights and assumes a forward CG, mid-weight, heavyweight I-loads, cold atmosphere, and no winds. These two lines generally lie very close together. In the green region, bailout is not required. A green zone call is not made unless the vehicle has recovered from the yellow zone below. @[120894-1744B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251 BAILOUT (CONTINUED)

The bailout yellow zone is defined as that area below the MCC maximum ranging capability line, described above (again, when a max range line is not available, the generic MCC RTLS minimum energy line will be used), but above the MCC bailout line. The bailout line is generic for all flights and represents a best-on-best maximum capability, based on 3 sigma favorable winds, maximum HAC shrink, and maximum orbiter L/D. In this region, the a “bailout yellow zone” call will be made. Requests are likely to be made for runway/HAC redesignation, stretch techniques, and relaxation of NZ, surface wind, touchdown point, and rollout margin constraints to increase available runways. Below the maximum ranging capability line, there is less than a 50 percent chance of reaching the field. In this region, the MCC will only advise the crew of the energy situation and continue to monitor their progress in making up the energy shortfall. A final bailout decision is the CDR’s call. @[120894-1744B]

The bailout red zone is defined as that area below the MCC bailout line described above. In this region, there is no chance of reaching the runway threshold and the MCC will recommend bailout. To provide adequate time for bailout operations, bailout will be declared at an altitude no lower than 50K ft, if possible. For ECAL trajectories, 70K ft is used to allow adequate time to execute a maximum turn of 180 deg prior to initiating bailout, thus ensuring bailout over water.

The MCC will recommend a bank angle in order to improve recovery effectiveness or to steer away from populated areas. Analysis has shown that a bank angle of greater than 10 deg can cause the vehicle to turn a full 360 deg of heading with impact occurring in the crew bailout landing area. If bailout is required during an ECAL, a turn to a standard heading of 120 deg will be made to avoid orbiter land impact and to provide search and rescue (SAR) forces with a consistent heading with which to begin rescue operations, unless the FDO can determine a more favorable heading based on knowledge of the positions and potential ranging capability of the SAR forces. @[120894-1744B]

A2-252 GCA CRITERIA

IF THE TRAJECTORY DIVERGES AND APPROACHES ENERGY LIMITS POST-TRACKING, CSS WILL BE SELECTED AND GCA PERFORMED. AUTO GUIDANCE WILL BE RESELECTED WHEN ENERGY AND NAVIGATION ARE WITHIN LIMITS, THE GCA WILL ALSO BE TERMINATED WHEN THE CREW TAKES OVER AFTER VISUAL ACQUISITION OF THE RUNWAY. @[120894-1663]

Generally, the entry trajectory can get into an off-nominal emergency situation by (1) incorporating erroneous navigation data into guidance and flight control, and (2) selecting an incorrect or invalid landing site. Performing GCA provides a possibility of making the runway.

FLIGHT RULES

A2-253

ENERGY MANAGEMENT

IF INSUFFICIENT OR EXCESS ENERGY EXISTS TO ACHIEVE THE TARGETED APPROACH TO THE SELECTED RUNWAY, THE FOLLOWING OPTIONS WILL BE EVALUATED FOR CORRECTION OF THE ENERGY ERROR.

- A. OVERHEAD/STRAIGHT-IN HAC RESELECTION
- B. NOMINAL/MINIMUM ENTRY POINT SELECTION
- C. RUNWAY REDESIGNATION - MAY RESULT IN VIOLATION OF TOUCHDOWN, BRAKING, AND/OR ROLLOUT MARGIN CONSTRAINTS
- D. GROUND CONTROLLED APPROACH (GCA)

Several options are available to correct a bad energy situation. These options include HAC reselection (overhead/straight-in), runway redesignation, final approach entry point downmoding (NEP/MEP), or GCA. No action will be recommended until data shows that the energy error is large enough that the prime selected runway/HAC cannot be achieved or will cause the vehicle to exceed H-dot or g-limits while following auto guidance.

Runway redesignation or HAC reselection are both very powerful methods of changing the required range-to-go (energy requirements). These two methods are preferred since valid guidance commands are available. Runway redesignation may be recommended over HAC reselection, based on the amount of energy correction required. The approach direction relative to the runway layout will define which is the most effective option for correcting the energy error (range error). Redesignation may result in selection of a runway which violates some of the touchdown, rollout, or brake energy constraints. Reaching the runway final approach within an acceptable energy corridor has priority over satisfying the touchdown and rollout constraints. All efforts will be made to redesignate to runways which satisfy the touchdown and rollout criteria.

Downmoding the final approach entry point (NEP to MEP) does provide valid guidance commands; however, the MEP selection greatly reduces the amount of time available for trajectory corrections on final approach. (NEP intercepts final approach at approximately 12K feet; MEP is at approximately 6K feet.) Once each of the above options has been evaluated and excessive energy error persists, a GCA will be required. The GCA may include HAC or runway reselection and will require action outside of the current guidance capability in order to correct the range error.

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT

- A. PRIOR TO MM 304, RESTRINGING WILL BE PERFORMED TO REGAIN FULL CAPABILITY FOLLOWING A GPC FAILURE.

The timeframe between post-deorbit burn and the transition to MM 304 is generally quiet from a computer point of view and crew workload. As such, the risk of restringing is considered to be low. Consequently, restringing will be performed to regain full capability for the dynamic phases of entry (MM 304/305).

- B. RESTRING GPC/STRING COMBINATIONS WILL BE SELECTED WHICH MOVE THE LEAST NUMBER OF STRINGS WHILE SATISFYING CRITICAL CAPABILITY OR ONE-FAULT TOLERANT REQUIREMENTS AS IDENTIFIED IN PARAGRAPH C.

The greater the number of strings moved during a restring attempt, the more complicated the restring process. With this in mind, "good" strings should not be taken from "good" GPC's unless there is no other method of satisfying the identified requirements in orbiter systems.

- C. DURING ENTRY/GRTLS (MM 304, 305, 602, AND 603), RESTRINGING WILL BE PERFORMED AS FOLLOWS (TIME PERMITTING) TO REGAIN THE FOLLOWING CRITICAL SYSTEMS CAPABILITY:

Certain systems capabilities are required to be maintained for safety considerations where the BFS cannot provide additional systems capability.

1. NOSE WHEEL STEERING (FOR RTLS/TAL/AOA (KSC) OR ANY SITE WITH KNOWN DIRECTION CONTROL PROBLEMS).

NWS is required to maintain lateral control during rollout at landing sites where the lateral runway environment is limited. BFS engage at touchdown to recover NWS is an option. However, it was determined to attempt restring during entry to regain NWS and accept risk of BFS engage as a result of the restring instead of nominally engaging the BFS for this case at NGTD. Reference Rule {A10-141A}, NOSE WHEEL STEERING (NWS), for NWS directional control requirements.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT (CONTINUED)

2. ASA COMMAND (MAINTAIN TWO ELEVON, RUDDER, AND SPEEDBRAKE; MAINTAIN ONE BODY FLAP).

Two elevon, rudder, and speedbrake FCS command channels (each of which have four command channels) are required since flying with only one FCS channel on an actuator is an uncertified flight control mode. Only one of three body flap command channels is required to maintain acceptable drive capability. Control may be available long enough to allow restring procedures to be completed to regain the required FCS channels rather than defaulting over to the BFS.

3. VENT DOORS:

- a. FORWARD/AFT VENT DOORS IF REQUIRED TO REGAIN THE CAPABILITY TO OPEN AT LEAST ONE SIDE OF THE FWD AND AFT COMPARTMENTS FOR SUFFICIENT VENTING.

Data presented at the Ascent/Entry Flight Techniques Panel (A/E FTP) #43 (August 1988) showed that adequate venting margins could be maintained if at least one side of the forward and aft compartments is opened by 70,000 feet altitude. Failures resulting in loss of open capability on both sides of the forward or aft compartments would result in structural failure and loss of crew/vehicle. Therefore, a critical bus reassignment prior to or at TAEM to regain the open capability on at least one side should be performed, when applicable.

- b. MIDBODY VENT DOORS: @[051194-1586A]

(1) FOR LOSS OF MORE THAN TWO MIDBODY VENT DOORS

OR

(2) FOR LOSS OF OPPOSING MIDBODY VENT DOORS

JSC Engineering presented a venting analysis of the modified vent door configuration (vents 4 and 7 deleted) at the A/E FTP #87 (February 1992). The data showed that positive structural margins exist for a nominal entry trajectory, even after two midbody vent doors have failed closed. This analysis was performed only for scenarios that could result from two electrical/avionics failures. Because opposite vent door failures (i.e., left/right 5) require more than two failures, they were not specifically analyzed, but to assure adequate venting, a restring should be performed. JSC Engineering also presented data which suggested that opposite forward and aft compartment vent doors are redundant to each other in providing adequate venting for a nominal entry. @[051194-1586A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT (CONTINUED)

The A/E FTP #87 members concluded that a critical bus reassignment should only be performed after loss of more than two midbody vents has occurred for either vehicle configuration. Restringing for these cases provides the most prudent venting management plan, trading the effects of a potentially dispersed entry trajectory with the potential risks of a dynamic restrung of flight-critical buses.

4. MPS LH₂ MANIFOLD ENTRY PRESSURIZATION (FOR RTLS/TAL).
@[022802-5221]

There is insufficient time on RTLS and TAL entries to dump all hydrogen from the Main Propulsion System (MPS) LH₂ manifold. The pressurization of the LH₂ manifold with helium prevents air from being ingested into the manifold during entry. The loss of this helium pressurization will result in the creation of an explosive mixture in the LH₂ manifold as air is ingested and mixes with the hydrogen residuals. Although difficult to quantify, the hazard to the flight crew from an explosive mixture in the MPS LH₂ manifold represents an unnecessary risk. At the A/E FTP #168 (October 27, 2000), it was decided that the recovery technique for the loss of LH₂ manifold pressurization could be a switch throw, temporary port mode (to latch the LH₂ manifold pressurization commands), or restrung. In general, a switch throw will be attempted before a port mode, which will be attempted before a restrung; however, the recovery technique used will depend upon the specific flight phase and failure scenario present in the orbiter. @[022802-5221]

- D. RESTRINGING WILL NOT BE PERFORMED WITHOUT PRIOR MCC COORDINATION.

The MCC is prime for determining when restringing is required as a result of multiple failures and the resulting GPC/string assignments required to satisfy critical capability and systems fault tolerance as identified in the preceding rules. The MCC is prime for determining the acceptability of restringing based upon the failure signature and conditions and for determining an acceptable data bus reassignment configuration. As a minimum, voice description of the failure and identification of the proposed bus reassignment must be coordinated with the MCC prior to performing any restrung.

- E. FOR A SINGLE GPC FAILURE, RESTRINGING WILL NOT BE PERFORMED AFTER EI MINUS 5 MINUTES.

EI minus 5 minutes was selected as the last time for which restringing would be performed as a result of a single GPC failure in order to allow recovery time prior to EI to regain PASS capability should the restrung be unsuccessful.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT (CONTINUED)

F. RESTRINGING WILL NOT BE PERFORMED AFTER HAC INTERCEPT.

Crew workload increases after HAC acquisition as concentration is directed towards the immediate landing tasks. Restringing will not be performed during this timeframe so as not to divert crew attention away from the critical landing phase tasks. Although no fault tolerance exists, the exposure to the next failure is minimized since the time between HAC intercept and touchdown is relatively short.

G. RESTRINGING WILL BE PERFORMED TO REGAIN CRITICAL CAPABILITY INDEPENDENT OF THE BFS STATUS. FOR CASES WHERE RESTRINGING IS ACCEPTABLE TO REGAIN FAULT TOLERANCE (REF. PARAGRAPH A), AN ENGAGEABLE BFS MUST BE AVAILABLE.

The BFS is normally required when restringing is performed as a precaution against the low probability occurrence that the restring action may result in loss of the PASS set. However, when the vehicle has sustained failures such that less than critical capability remains (a capability which must be maintained or a loss of crew/vehicle will result), restringing will be performed to regain the needed capability independent of the BFS status in order to maintain the flying status of the orbiter.

If the BFS is not available and less than critical capability remains, restring is allowed to recover the PASS capability to control the orbiter. If the BFS is available and conditions are such that either a BFS engage or a dynamic restring will recover the critical capability, restring will be attempted if time permits completion of the restring while still maintaining the BFS engage option.

Rules {A2-5}, PORT MODING/RESTRINGING GUIDELINE; {A5-209}, ENTRY MPS HELIUM PURGING FOR CRITICAL VEHICLE POWER/COOLING; {A7-6}, DATA PATH FAILURE; {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA; {A7-105}, MDM PORT MODING; {A7-52}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES; and {A10-25}, APU HIGH SPEED SELECTION/SHIFT reference this rule. ©[022802-5221] ©[ED]

FLIGHT RULES

A2-255

CREW TAKEOVER

CREW TAKEOVER (DOWNMODING FROM AUTO TO CSS) PRIOR TO NOMINAL TAKEOVER ALTITUDE WILL BE PERFORMED FOR THE FOLLOWING REASONS ONLY (REF. RULE {A4-208}, ENTRY TAKEOVER RULES):

- A. TO AVOID LOSS OF CONTROL OF THE VEHICLE.
- B. TO PRESERVE THE TRAJECTORY WITHIN THE TARGETED RUNWAY LANDING CAPABILITY.

Whenever the crew must override the guidance limitations to maintain adequate energy capability for reaching the prime selected runway, the CSS mode must be selected. Whether under GCA control or manually flying with visual assistance, the crew must select CSS and bypass the onboard guidance commands.

- C. DELTA STATE UPDATES:
 - 1. ANY POSITION AND VELOCITY DELTA STATE.
 - 2. A POSITION-ONLY DELTA STATE BETWEEN M5 AND TAEM (M2.5 FOR EOM/AOA, M3.2 FOR RTLS).

CSS mode is required for all position/velocity delta states to avoid severe attitude transients once the onboard NAV is updated. For OPS 3 position-only delta states between M5 and TAEM, CSS must be selected to avoid strong attitude transients. MM 304 entry guidance will very aggressively attempt to remove energy errors by TAEM interface (M2.5). Above M5, the guidance has more time to correct energy errors. Therefore, position delta states above M5 should not cause severe transients. After the energy has converged close to nominal, the crew can reselect auto. GRTLS guidance is not as aggressive as OPS 3 guidance in removal of energy errors by TAEM interface (M3.2). ©[052401-4524A]

- D. GPS NAVIGATION UPDATES WHEN PERFORMED AS AN ALTERNATIVE TO DELTA STATE UPDATES.

Once GPS state vector accuracy has been confirmed with ground filter solutions, a GPS update is preferred over the delta state update process to correct onboard navigation errors that exceed flight rule limits. Metering logic, which limits the updates to the user parameter reset state, may be overridden prior to the GPS force procedure to expedite the time required to update the user parameter reset state. If metering is overridden, CSS mode is required for all GPS to NAV force operations to avoid severe attitude transients once the user parameter reset state is updated. ©[052401-4524A]

FLIGHT RULES

A2-256 **EARLY POWERDOWN**

EARLY POWERDOWNS ARE DEFINED AS REMOVAL OF POWER FROM THE ORBITER ELECTRICAL BUSES PRIOR TO EOM POWERDOWN. EARLY POWERDOWN WILL BE ACCOMPLISHED FOR ELS LANDINGS, FAILURE OF THE COOLING CART, ANY ORBITER MALFUNCTIONS THAT CONSTITUTE A SAFETY HAZARD (E.G., FUEL LEAK), OR THE THREAT OF SIGNIFICANT ORBITER EQUIPMENT DAMAGE. IN ALL CASES, THIS WILL BE WITHOUT REGARD TO THE INTEGRITY OF ANY RETURNED PAYLOAD.

A2-257 **DEORBIT BURN TERMINATION**

THE DEORBIT BURN WILL BE TERMINATED (PRIOR TO EXCEEDING A SAFE PERIGEE AS PROVIDED ON THE DEORBIT/ENTRY/LANDING (DEL) PAD FOR THE FOLLOWING FAILURES:

- A. OMS PROPELLANT TANK (ABOVE SINGLE TANK COMPLETION HP ON DEL PAD).
- B. PASS REDUNDANT SET FAIL OR RS SPLIT FOR WHICH RECOVERY HAS NOT BEEN ATTEMPTED.
- C. IMU DILEMMA.
- D. TWO MAIN BUSES.
- E. TWO OMS ENGINES (IF RCS DOWNMODE CAPABILITY DOES NOT EXIST).

The deorbit burn will be terminated for systems failures which preclude controllability or the ability to perform a safe entry. Loss of fault-tolerance will not be cause for terminating the deorbit burn.

For failure of both OMS engines, propellant may not be available to complete the deorbit burn with the RCS +X jets to the original targets. The deorbit burn must be terminated and retargeted to shallower targets. This retargeting will require a 24-hour deorbit delay.

A2-258 **BFS ENGAGE**

BFS WILL BE ENGAGED IN ENTRY FOR THE FOLLOWING:

- A. LOSS OF REDUNDANT SET.
- B. LOSS OF CONTROL.

Reference Rule {A7-1}, PASS DPS FAILURE. ©[071494-1636]

FLIGHT RULES

A2-259

CHASE AIRCRAFT OPERATIONS

- A. T-38 CHASE AIRCRAFT WILL BE UTILIZED ON AN "AS REQUIRED" BASIS.

T-38 chase aircraft can be used to provide photo documentation of orbiter condition and damage prior to touchdown and rollout, visual inspection for fluids, flames, gear door damage, etc., backup for altitude and airspeed, visual call to orbiter crew in case of wind screen obscurations, and downlink TV to NASA/PAO.

- B. T-38 CHASE RENDEZVOUS WILL BE DISCONTINUED IF:
1. VISUAL/RADAR CONTACT NOT ESTABLISHED WITHIN 1 MINUTE OF ORBITER RENDEZVOUS POINT AT 40K FEET MSL
 2. VISUAL CONTACT NOT ESTABLISHED WHEN WITHIN 4 NM AS REPORTED BY RADAR CONTROLLER DIRECTING THE INTERCEPT
 3. CHASE RENDEZVOUS NOT COMPLETE BY PREFLARE
 4. VISUAL CONTACT LOST AFTER RENDEZVOUS

The T-38 chase aircraft will break off from the rendezvous attempt when it is considered unsafe to continue. Attempting a join-up without visual contact could result in vehicle collision or create a situation that would cause the orbiter to maneuver to avoid impact. Chase aircraft procedures are found in Aircraft Operating Procedures, Volume 1, T-38A Aircraft.

- C. CHASE AIRCRAFT WILL MAINTAIN A MINIMUM LATERAL SEPARATION OF 200 FEET FROM THE ORBITER DURING THE AUTOLAND PORTION OF THE LANDING APPROACH.

The orbiter autoland flight path characteristics are unpredictable and may be abrupt. A 200-foot T-38 chase aircraft separation will allow the chase pilot adequate time to safely avoid unexpected orbiter maneuvers.

FLIGHT RULES

A2-260

ENTRY LOAD MINIMIZATION

IF IT IS REQUIRED TO MINIMIZE ENTRY LOADS, THE FOLLOWING STEPS WILL BE CONSIDERED:

- A. DELETE ENTRY TEST MANEUVERS.
- B. SELECT RUNWAY AND HAC TO MINIMIZE TAILWIND COMPONENT AT HAC INTERCEPT.
- C. SELECT AN SLS IF SIGNIFICANT WINDS AND/OR TURBULENCE CANNOT BE AVOIDED AT THE PLS.

Reference Rule {A10-203B}, PLBD CRITICAL LATCHES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

a. AERO PTI DTO NO-GO:

The AERO PTI and Xwind DTO's will not be performed when navigation or flight control systems are fail critical. Maintaining single-fault tolerance for AUTO flight control, and allowing an acceptable crew workload are required for performing the DTO's. In addition to be GO for the Xwind DTO, single-fault tolerance is required for the CDR's displays and controls.

(1) APU/HYD

2 APU - If two APU/HYD systems are lost, the remaining system must supply all necessary loading to perform entry. PRL will limit the available hydraulic power in an optimum management scheme in order to prevent overloading the single remaining system. Data has shown that entry PTI's place a short duration high load on a hydraulic system. For this reason, aero PTI'S should not be performed in order to minimize stress on the single APU/HYD system.

(2) DISPLAYS

(a) ADI

AERO PTI DTO:

The ADI is required to monitor vehicle attitude and rates for crew takeover.

(b) CDR HUD

XWIND DTO:

The CDR relies on the HUD for critical landing data and cues. Flying is more difficult without this instrument, and landing in high crosswinds increases the level of difficulty. The CDR's HUD is not required if PAPI's and ball bar are available, since these landing aids provide guidance for the approach and glide slope.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(3) *CONTROLLERS*

(a) *RHC*

L RHC-ONE CHNL FAILED L RHC FAILED

XWIND DTO:

The left RHC is either zero-fault tolerant or failed. It is very desirable for the CDR to manually control the vehicle during approach and landing. For this reason, the PLT will not execute the DTO. If the PLT must fly (left RHC failed), then it is prudent to redesignate, if possible, to a runway with more nominal conditions.

TWO RHC CHNL'S FAILED EACH SIDE

AERO PTI DTO, XWIND DTO:

The next failure could cause vehicle control problems since the output from the remaining two channels is summed. The additional maneuvers associated with the DTO's increase the possibility of having vehicle control problems with the next failure. For these failures, at least one of the flight controller power switches should be turned OFF, and both when not being used (ref. Rule {A8-105}, CONTROLLERS).

(b) *RPTA*

TWO RPTA CHNL's FAILED ONE SIDE

XWIND DTO:

The RPTA channels are zero-fault tolerant and the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(4) GNC

(a) AA's

TWO LATERAL AA's FAILED

AERO PTI DTO:

The AA lateral feedback is used for turn coordination to reduce the effects of IMU errors. It is also used in the roll/yaw channel to help form the lateral (Ny) command. The next failure could cause bad vehicle control.

XWIND DTO:

The lateral AA feedback is zero-fault tolerant and the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

(b) TWO NORMAL AA's FAILED

AERO PTI DTO, AUTO MODE:

The NORM AA feedback is used by guidance to form the Nz command for flight control in MM 305. After two failures the system is zero-fault tolerant in AUTO. The crew is required to fly CSS in pitch in MM 305 (ref. Rule {A8-5}, ACCELEROMETER ASSEMBLIES (AA) FAULT TOLERANCE), and aero PTI's are automatically inhibited while in CSS.

(c) RGA's

AERO PTI DTO, XWIND DTO:

The system is zero-fault tolerant for feeding bad vehicle rate data to the flight control system. It is not prudent to perform the DTO's since the added maneuvers increase the risk for control problems with the next failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(d) IMU's

AERO PTI DTO, XWIND DTO:

After the second IMU failure or when one of the remaining two IMU's has a BITE, the system is fail critical. In either case, the next failure can cause navigation and flight control to use bad IMU data. The additional maneuvers associated with the DTO's increase the probability of vehicle control problems with the next failure.

(e) ADTA's

TWO ADTA's FAILED

XWIND DTO:

The system is zero-fault tolerant because the next failure requires the crew to fly theta limits. Manual flying is more difficult with no air data, and the higher crosswinds increase the piloting task.

ADTA NOT INCORPORATED

AERO PTI DTO, AUTO MODE:

If AD is not incorporated into G&C below M=2.5, aero PTI's are automatically inhibited. If below M=2.0 and AD is not incorporated into G&C, the crew is required to fly CSS in the pitch axis to control theta limits. Manual speedbrake is required below 5k feet (ref. Rule {A8-111}, GNC AIR DATA SYSTEMS MANAGEMENT [CIL]). Note that the XWIND DTO is NO-GO if it is known that AD will not be incorporated and it is still possible to redesignate.

(f) FCS CHNL's

AERO PTI DTO, XWIND DTO:

The system is zero-fault tolerant for being in an uncertified flight control mode. The additional maneuvers associated with the DTO's incur more risk with the next failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(g) *RIGHT DDU**XWIND DTO:*

The right DDU provides power for NWS. With two power supplies failed the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

(h) *LOSS OF WOW/WONG**XWIND DTO:*

The crosswinds further complicate the piloting task for loss of WOW or WONG. Both WOW and WONG are required in order to enable NWS, activate AUTO load relief, and enter the rollout DAP mode at nose gear TD. A known loss of WOW or WONG requires the crew to manually set the WOW and WONG discrettes by pushing the SRB or ET Sep pushbutton after nose gear TD. Potential delays in enabling NWS and increased piloting task cause the DTO to be NO-GO.

As a result of OI-21 WOW modifications, the only two-failure scenarios of concern involve the loss of both WONG discrettes (MDM, BUS, or the discrettes themselves).

(5) *AFT RCS*

(a) *Once a leak is detected, the PTI's will be inhibited. This action prevents the PTI's from occurring while performing leak troubleshooting. The leak procedures isolate a leg of RCS jets at a time thus minimizing the amount of jets available for attitude control. Inhibiting the PTI's ensures that any off-nominal perturbations that could possibly occur during PTI execution will be prevented. If a nonisolatable leak is present or the NO-GO criteria is violated due to isolation of the leak (minimum RCS quantity, loss of jets), no further PTI's will be performed.*

(b) *Due to the loss of fail-safe redundancy for orbiter control, the PTI's will not be performed.*

(c) *RCS quantity checks are performed at different points during entry. The minimum quantity includes 3-sigma entry usage at the check and PTI usage to the next check. PTI's will be inhibited to protect 3-sigma entry redlines. ©[041196-1782A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(6) FWD RCS

- (a) *Loss of two FWD RCS yaw jets on the same side would result in unbalanced jet firings during PTI's. The entry command SOP software will prevent the PTI's from occurring as long as RCS RM has deselected the jets. If the FRCs yaw jets have become unavailable prior to entry, the PTI's will not be enabled* @[090894-1562].
- (b) *FWD RCS quantity checks are performed at different points during entry. The minimum quantity includes PTI usage to the next check and ensures positive propellant flow from the FWD RCS.*

Tank residual required to prevent screen breakdown

677 lb	<i>(FWD RCS tanks not designed for entry use)</i>
+ 84 lb	<i>Gauge error</i>
761 lb	<i>Total tank</i>
-307 lb	<i>Hardware trapped</i>
454 lb	<i>Minimum usable FWD RCS</i>
+PTI lb	<i>PTI usage</i>
XXX lb	<i>Total quantity check</i>

- (c) *Once a leak is detected, the PTI's will be inhibited. This action ensures that the PTI's will not occur during leak isolation. Leak troubleshooting consists of securing the entire system. If the leak is nonisolatable or the minimum FWD RCS quantity is violated or minimum jets violated, the PTI's will remain inhibited.*
- (d) *For the loss of RCS RM, the jets will be deselected and not utilized for the PTI's. Per Rule {A6-156}, RCS RM LOSS MANAGEMENT, jets with loss of RM will only be selected if required for attitude hold or to maintain fail-safe redundancy. Because of the risk of firing jets without RM and the low priority of FWD RCS PTI's, the jets will not be reselected to perform PTI's.*
- (e) *FWD RCS gaging is required to monitor the propellant quantity to ensure that minimum FWD RCS quantity will not be violated.*
- (f) *The FWD RCS bulk propellant temperature must be 70 deg F or greater at deorbit TIG. This is required to prevent ZOT's from occurring during PTI's. This is an MCC call since the crew has no insight into the parameter during OPS-3.* @[090894-1562]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

- (7) TRIM/RATES/CG @[041196-1782A]

TRIM

- (a) AILERON TRIM > ± 2.0 DEGREES @[041196-1782A]

AERO PTI DTO:

The aileron trim saturation limit is 3.0 degrees. When the trim reaches 2.0 degrees, the PTI's should be inhibited to avoid possible control problems or high RCS usage. Based on SES analysis and previous flight data, 2.0 degrees is a comfortable margin for control, while not being too restrictive. @[041196-1872A]

- (b) ELEVON TRIM > 3.0 DEGREES (FROM EXPECTED)

AERO PTI DTO:

The elevon schedule has a 1-degree deadband. Performing PTI's with large elevon trim could increase the level of difficulty in trimming the vehicle. Three degrees off schedule is a sufficiently large elevon trim limit to permit aero maneuvers in any reasonable flight condition, yet provides adequate safety margins for control.

XWIND DTO:

This elevon trim condition indicates that the vehicle is in an off-nominal configuration which may lead to additional problems. It is prudent then to NO-GO the XWIND DTO and avoid complicating the situation during A/L and rollout.

- (c) VEHICLE RATES (PTI)

AERO PTI DTO:

These limits are in the software and will automatically inhibit (terminate) any PTI in progress. The additional maneuvers associated with the PTI's could make it more difficult for the FCS to damp the rates and regain good control.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(d) CG

AERO PTI DTO:

With the X or Y CG out of the nominal CG box, continuous firing of ARCS jets may be required to maintain attitude control. To ensure maximum control authority in an uncertified configuration, as well as to save propellant, PTI's will not be performed.
©[041196-1782A]

(8) DOWNMODE

FCS PROBLEM

AERO PTI DTO, AUTO MODE, XWIND DTO:

If the vehicle is experiencing problems with the FCS, due to multiple systems failures and/or unpredicted effects of the environment, then all flight control DTO's are NO-GO, and the crew should fly CSS, if required. The risks associated with performing the DTO's are too great while vehicle control is off-nominal.

(9) PLB

PLBD LATCHES - It is acceptable to perform an entry with any one latch gang (bulkhead or centerline) failed open. Entry loads should be minimized (per Rule {A10-203B}, PLBD CRITICAL LATCHES, and SODB 3.4.2.3). Aero PTI's will not be performed in order to ensure a nominal entry.

(10) DATA

According to the sponsor of the aero PTI DTO, the crew cannot evaluate the results from onboard indications. Either real-time or recorded telemetry is required. This is in agreement with the DTO requirements as documented in NSTS 16725, Flight Test and Supplementary Objectives Document.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

b. XWIND DTO NO-GO

(1) APU/HYD

1 APU and 2 APU

Loss of one APU/HYD system places the orbiter a single failure away from performing entry/rollout on a single system. Orbiter handling qualities have been demonstrated to be degraded when only a single APU/HYD system is operating. If only one APU/HYD system remains, conditions that could adversely affect the already degraded handling qualities should be avoided if possible. Therefore, if one or two APU/HYD systems are lost, the crosswind DTO should be NO-GO.

(2) LANDING/DECEL

(a) TIRE (LEAK)

For a confirmed main gear tire leak, a landing with a crosswind from the side of the affected tire is desirable. If a leak is confirmed in a main or nose gear tire, the load-carrying capability of that tire is reduced.

(b) BRAKE ISOL VLV

Loss of the ability to open one brake isolation valve puts the orbiter one failure away from having only 50 percent braking capability. Full braking capability is required for the crosswind DTO in order to ensure good control of the vehicle in high crosswind conditions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

- (c) <100 PERCENT BRAKES

Full braking capability is required for the crosswind DTO in order to ensure good control of the vehicle in high crosswind conditions.

- (d) NWS

NWS is the primary means of steering the vehicle during rollout. In a strong crosswind, differential braking may not be sufficient to maintain directional control.

- (3) XWIND

- (a) <10 KNOTS PEAK @[041097-4890A]

Winds less than 10 knots are not within the DTO limits and would not produce conditions appropriate for collecting the required DTO data.

- (b) >15 KNOTS PEAK

Crosswinds greater than 15 knots peak violate nominal crosswind limits.

- (c) >10 KNOTS GUST @[041097-4890A]

Crosswinds with gusts greater than 10 knots above the steady-state wind violate nominal limits.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

c. DPS

In general, DPS failures that cause aero PTI DTO, auto mode, and crosswind DTO to be NO-GO are driven by various failures in the GNC, MMACS, and/or PROP systems.

GPC 1 (NOT RSTNG), GPC 2 (NOT RSTNG), FF1, FF2 - Crosswind DTO is NO-GO due to loss of a left RHC channel, and for vehicles without improved NWS, loss of GPC NWS.

GPC 3 (NOT RSTNG), FF3 - Crosswind DTO is NO-GO due to loss of a left RHC channel.

2 GPC (RSTNG) - Aero PTI DTO is NO-GO due to the inherent risk of another GPC failure which would cause GNC systems violations for the DTO.

2 GPC (NOT RSTNG), 2 FF - Aero PTI DTO, auto mode (<M2.5), and crosswind DTO are all NO-GO due to multiple GNC LRU failures.

2 FA - Aero PTI DTO and crosswind DTO are NO-GO due to multiple GNC LRU failures. The aero PTI DTO is also NO-GO due to two aft jets being down.

For additional technical information concerning the rationale for aero PTI DTO, auto mode, and crosswind DTO NO-GO requirements, refer to the rationale for the GNC, MMACS, and PROP systems. @[041097-4890A]

FLIGHT RULES

A2-262

LANDING DTO'S

- A. BRAKING OR NOSE WHEEL STEERING DTO TASKS MAY BE PERFORMED ON DAYLIGHT LANDINGS REGARDLESS OF THE WEIGHT/CG OR FLIGHT DURATION. @[111894-1690B]
- B. BRAKING DTO TASKS MAY BE PERFORMED ON NIGHT LANDINGS SO LONG AS THEY INVOLVE ONLY VARIATIONS IN BRAKING PROFILE OR DECELERATION LEVEL. NO DTO STEERING TASKS USING DIFFERENTIAL BRAKING WILL BE PERFORMED ON NIGHT LANDINGS. @[111894-1690B]
- C. NO DTO STEERING TASKS USING DIFFERENTIAL BRAKING OR NWS WILL BE PERFORMED ON NIGHT LANDINGS. @[111894-1690B]
- D. CROSSWIND LANDING DTO'S ABOVE 12 KNOTS PEAK WILL NOT BE PERFORMED ON NIGHT LANDINGS OR EXTENDED DURATION ORBITER (EDO) FLIGHTS. @[111894-1690B]

Braking or nose wheel steering testing is acceptable during daylight landings since vehicle weight and CG have minimal effects on the rollout piloting task, and visual cues are available to the crew to assess test inputs/results. Braking tests at night are acceptable if they only involve basic braking functions such as varying the deceleration levels or specific braking profile. Steering task DTO's involving either differential braking or nosewheel steering are not acceptable at night due to the loss of visual cues and runway shadowing effects which put the crew and orbiter at unnecessary additional risk. The crosswind limit for EDO or night flights has been set at 12 knots regardless of where you land. You may land with a crosswind between 8 and 12 knots and still meet the crosswind DTO requirements, but the peak wind will not be allowed to exceed 12 knots and approach the 15-knot normal crosswind DTO limit. @[ED]

- E. THE CROSSWIND DTO MAY RESULT IN EXCEPTIONS TO RULE {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES.

If the crosswind DTO is GO per Rule {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, the drag chute will be deployed after NGTD, as stated in the applicable Flight Rule Annex. @[041097-4890A]

- F. LANDING AND ROLLOUT DTO'S WILL NOT BE PERFORMED ON ABORTS (RTL, TAL, AOA, FD1 PLS) UNLESS THEY ARE DATA GATHERING ONLY, INVOLVE NO CREW ACTIONS, AND POSE NO ADDITIONAL RISK TO THE CREW OR VEHICLE. HOWEVER, DATA FROM ANY ABORT LANDING MAY BE USED TO SATISFY PROGRAM DTO OBJECTIVES. @[100997-6294A]

Programmatic risk is high during an abort. Additional risk or crew distraction should not be incurred for the sake of engineering data that can more safely be obtained on another flight. However, some DTO's are data gathering only and are transparent to the crew; these are allowed. Some DTO's cannot be avoided (e.g., crosswind landings) during aborts and thus will be accomplished anyway. This rule means that off-nominal crew actions (such as delayed drag chute deploy for the crosswind DTO) will not be performed. @[100997-6294A]

FLIGHT RULES

A2-263

STA/WEATHER AIRCRAFT RUNWAY APPROACH OPERATIONS FOR SITES WITH ONLY ONE RUNWAY

A. PRELAUNCH (RTL/TAL)/PREDEORBIT (AOA/EOM)

STA AND/OR WEATHER AIRCRAFT APPROACHES TO PLANNED LANDING SITES WITH ONLY ONE RUNWAY (OPPOSITE END MAY OR MAY NOT BE AVAILABLE) MAY BE PERFORMED AS REQUIRED TO ASSESS NAVAID/VISIBILITY STATUS. ONCE THE FINAL GO FOR LAUNCH OR THE DEORBIT BURN HAS BEEN GIVEN, THESE OPERATIONS WILL BE TERMINATED UNLESS REQUIRED PER PARAGRAPH B.

B. POSTLAUNCH (RTL/TAL)/POSTDEORBIT BURN (AOA/EOM)

POSTLAUNCH OR POSTDEORBIT BURN, STA OR WEATHER AIRCRAFT APPROACHES TO THE SELECTED RUNWAY AT LANDING SITES WITH ONLY ONE RUNWAY (OPPOSITE END MAY OR MAY NOT BE AVAILABLE), WILL ONLY BE DONE IF CONDITIONS MAKE SUCH AN APPROACH NECESSARY. APPROACHES WILL BE MINIMIZED AND WILL BE PERFORMED TO REDUCE THE RISK OF RUNWAY LOSS DUE TO AIRCRAFT PROBLEMS ON APPROACH. TO REQUIRE AN APPROACH POSTLAUNCH OR POSTDEORBIT, A CHANGE OR CONCERN IN ONE OR MORE OF THE FOLLOWING AREAS MUST EXIST:

1. VISIBILITY.
2. NAVAID STATUS/CAPABILITY.

For the case where a landing facility has only one runway (availability of its alternate end does not matter), approaches to landing runways are still performed prelaunch or predeorbit burn to aid in assuring that landing flight rules are met with respect to navaid and visibility status. Such approaches are not considered a threat to landing prior to launch or the deorbit burn.

Once committed to a runway, approaches to that runway or its alternate end, should not be done unless necessary to confirm the ability to land on that runway. There is no reason to continue to shoot approaches to the selected runway if conditions have not changed since the commitment to use the runway. If changes are suspected, however, additional approaches may be performed. If required, they will be done such that risk of losing the runway due to approach aircraft problems will be minimized in order to preserve shuttle landing capability. Techniques to accomplish this include breaking off an approach early or runway flybys vice approaches.

FLIGHT RULES

A2-264

EMERGENCY LANDING FACILITY CRITERIA

THIS RULE DOCUMENTS THE MINIMUM ACCEPTABLE LANDING FACILITY REQUIREMENTS FOR COMMITMENT TO AN EMERGENCY LANDING VERSUS BAILOUT. IT APPLIES FOR ALL LANDINGS. @[120894-1744B]

- A. RUNWAY AT LEAST 7500 FT LONG AND 130 FT WIDE. @[110900-3733C]
- B. RUNWAY COORDINATES RESIDENT IN THE ONBOARD SOFTWARE OR AVAILABLE FOR UPLINK.
- C. OPERATIONAL TACAN OR DME WITHIN 50 NM OF THE SITE, AVAILABLE FOR INCORPORATION INTO THE NAV (MAY REQUIRE UPLINK).
- D. AIRSPACE AND RUNWAY CLEAR.
- E. CONFIRMATION OF FACILITY READINESS FOR ORBITER LANDING VIA MCC OR CREW VOICE CONTACT WITH THE AIRFIELD.
- F. ACCEPTABLE WEATHER FOR ORBITER EMERGENCY LANDING OPERATIONS (REFERENCE RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]).
- G. ACCEPTABLE LIGHTING FOR ORBITER EMERGENCY LANDING OPERATIONS. IF LANDING AT NIGHT WITHOUT XENONS, THE FOLLOWING MINIMUM REQUIREMENTS APPLY:
 - 1. OPERATIONAL RUNWAY EDGE LIGHTS
 - 2. ONE HUD OPERATIONAL

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-264****EMERGENCY LANDING FACILITY CRITERIA (CONTINUED)**

Due to the inherent hazards of an orbiter landing, especially at a non-augmented facility, adequate site readiness must be ensured before a landing will be attempted. The runway to be used must be of sufficient length and width to accommodate a safe orbiter landing. The 130 ft value corresponds to the narrowest approved ELS runways in NSTS-07700, Volume X, Book 3. Although the effects of landing on 130 ft wide runways have not been evaluated directly, examination of data from the 2/00 Ames VMS study on minimum acceptable runway length indicates adequate performance should be expected. This study included crosswinds up to 15 kt on runways between 148 ft to 200 ft wide. The maximum lateral excursions seen in this study were less than that required to stay on a 130 ft wide runway. Rio Gallegos, Argentina, the only Program-approved Emergency Site < 148 ft wide, is considered acceptable given the significant gain in emergency deorbit capability it provides. However, until a minimum runway width study is performed, any new runways less than 148 ft being considered for SSP use should be evaluated on a case-by-case basis. The 7500 ft length is based on studies performed in the 2/00 NASA Ames VMS session that showed acceptable performance can be obtained if additional TD energy is removed from the system. ©[1109-3733C]

Prior to OI-30, a manual speedbrake technique can be used to stop the orbiter on a 7500 ft runway and assumes the following: short field speedbrake logic is selected; Auto speedbrake is used down to 3000 ft; the speedbrake is manually set to the Auto speedbrake retract command plus 20 percent at 3000 ft; limiting the maximum speedbrake setting to 75 percent; no speedbrake adjustment made at 500 ft; touchdown at 195 KEAS; at maingear touchdown deploy the chute, derotate, and set the speedbrake to 100 percent; use maximum braking at nosegear touchdown. OI-30 software changes will eliminate the need for the manual speedbrake procedure. Rule {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION, will define when the manual technique is to be employed. Minimum runway length for Space Shuttle purposes, as defined in Vol X, Book 3, considers usable underruns and overruns for runway length. Usable runway length is measured from the threshold (actual or displaced) to the end of the usable overrun. If no overrun is available, usable runway length is measured to the end of the usable runway. Refer to AEFTP #165 minutes for further details. The runway must be resident in the onboard software or available for uplink to allow guidance and navigation aids to be used. ©[110900-3733C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-264****EMERGENCY LANDING FACILITY CRITERIA (CONTINUED)**

An operational TACAN or DME is required to provide sufficient onboard navigation accuracy. The coordinates must be resident in the onboard software or available for uplink to allow incorporation into the navigation state. Fifty miles distance from the TACAN to the field is based on Monte Carlo analysis of various TAL scenarios. Redundancy in the TACAN or its power supply is desirable but not required.
 ©[120894-1744B]

The airspace and the chosen runway must be clear. MCC or crew voice contact with the airfield is required to ensure that the facility is prepared for the landing. In order to reduce the risk to the orbiter, crew, and the general public/civilian population, it is necessary that an intended landing site be notified of an attempted landing as soon as possible. This will allow the airspace and runways to be cleared as well as emergency equipment prepared. Notification may be via state department prearranged channels, NASA agreed to communication channels, or via communication directly with the orbiter crew.
 ©[120894-1744B]

Acceptable weather for orbiter landing operations is required. These criteria are documented in rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC].

Restrictions are placed on night landings due to a significant loss of visual cues. As a minimum, runway edge lights and a HUD must be operational to assist in visually acquiring the runway and the outer glide slope (if MLS is not available) and to provide a visual reference during braking and rollout (regardless of MLS status).

Rules {A2-205}, EMERGENCY DEORBIT, and {A2-209}, LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY, reference this rule. ©[120894-1744B] ©[ED]

FLIGHT RULES

A2-265

SINGLE STRING GPS OPERATIONS @[072398-6586A] @[040899-6847]

- A. THE GPS A/I/F FLAGS WILL REMAIN IN INHIBIT FOR ANY CERTIFIED FLIGHT MODE (NOMINAL ASCENT, ATO, AOA, TAL, RTL, ORBIT, AND NOMINAL ENTRY). GPS USE IN THE PASS AND/OR BFS IN OTHER THAN THE INHIBIT MODE MAY BE CONSIDERED FOR CONTINGENCY CASES WHERE ITS USE COULD PREVENT A CREW BAILOUT AND LOSS OF THE ORBITER. @[072398-6586A] @[040899-6847]

The PASS and BFS have been certified for flight only if the GPS to NAV and GPS to G&C auto/inhibit/force flags remain in the inhibit position. Testing has been performed to confirm the PASS and BFS continue to function with incorporation of GPS; however, full certification testing has not been completed. Performance testing of GPS data incorporated into the onboard navigation has not been completed. Potential contingency scenarios in which GPS may be used could include, but are not limited to, a contingency landing to a site with no ground TACAN or DME and no radar tracking support; a contingency landing to a site with no ground MLS and a low cloud ceiling and visibility; multiple onboard problems resulting in an unacceptable navigation state requiring a command or manual delta state update; multiple IMU problems resulting in a runaway navigation state which is not manageable with delta state updates. In OPS 1 and Major Mode (MM) 601, GPS is only available for incorporation in the BFS. Contingency use of GPS in OPS 1 and MM 601 in the BFS would require CSS in the PASS to fly out the BFS ADI digital errors, unless the commander deemed it necessary to engage in order to fly the vehicle. If possible, contingency use of GPS should be delayed until OPS 3 or MM 602/603. GPS state vector accuracies can be degraded during powered flight due to external tank blockage of GPS satellite signals. BFS navigation updates with GPS during powered flight would only be required to correct extreme errors which could result in unsafe MECO conditions. Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma), since the estimated position error increases rapidly with higher FOM values. The GPS DTO objectives expected to be performed on single string GPS missions may call for the GPS A/I/F function to be in a position other than inhibit. If so, the flight specific flight rules annex will document the exception to this rule and specify the conditions under which the DTO objectives will be performed. @[040899-6847] @[052401-4525]

- B. EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC FLIGHT RULES ANNEX. @[072398-6586A]

FLIGHT RULES

A2-266

SUBSONIC PILOT FLIGHT CONTROL

AT THE DISCRETION OF THE COMMANDER (CDR), THE PILOT (PLT) MAY FLY CONTROL STICK STEERING (CSS) FOR A SINGLE PERIOD (APPROXIMATELY 20 SECONDS) BELOW MACH 1.00 WITH THE FOLLOWING CONSTRAINTS:

@[082202-5636] @[ED 111302]

- A. THE CDR WILL FLY THE ORBITER FROM 15 SECONDS PRIOR TO HAC INTERCEPT THROUGH THE INITIAL ROLL ONTO THE HAC.
- B. THE CDR WILL FLY FROM AN ALTITUDE AGL OF 20,000 FT THROUGH LANDING AND ROLLOUT.
- C. WHEN CSS IS ENGAGED, ONBOARD GUIDANCE COMMANDS WILL BE FOLLOWED.
- D. THE CDR WILL FLY (NO TRANSFER OF CONTROL) FOR THE FOLLOWING CASES:
 1. IF THE MCC RECOMMENDS "DELAYED CSS PREFERRED" PER RULE {A4-156}, HAC SELECTION CRITERIA.
 2. SYSTEMS OR NAVIGATION PROBLEMS THAT REQUIRE CSS, PER RULES {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO NO-GO, AND {A4-208}, ENTRY TAKEOVER RULES.
 3. VEHICLE ENERGY PROBLEMS REQUIRING A GROUND CONTROLLED APPROACH (GCA).
 4. ANY ABORT LANDING.
 5. BFS ENGAGED. @[082202-5636]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-266

SUBSONIC PILOT FLIGHT CONTROL (CONTINUED)

6. ANY GUIDANCE, NAVIGATION, OR FLIGHT CONTROL SYSTEM(S) FAILURE (E.G., CDR HUD) THAT INCREASES THE PROBABILITY OF A TRAJECTORY TRANSIENT RESULTING FROM THE TRANSFER OF CONTROL (MCC CALL). LOSS OF A SINGLE STRING OF REDUNDANCY IN ANY SYSTEM (E.G., ONE AA, ONE FCS CHANNEL, ONE RHC CHANNEL, ETC.) WITH NO OTHER FAILURES IS NOT CAUSE FOR PRECLUDING TRANSFER OF CONTROL. ©[082202-5636]
7. IF THE MCC RECOMMENDS NO-GO FOR PLT FLYING BASED ON HAC DYNAMICS (E.G., HIGH TAIL WINDS AT HAC INTERCEPT).
- E. THE PLT IS THE BACKUP TO THE CDR FOR ANY FLIGHT PHASES REQUIRING CSS CONTROL. IF REQUIRED FOR VEHICLE SAFETY, THE CDR MAY TRANSFER CONTROL TO THE PLT AT ANY TIME.

Allowing the PLT to fly for a short period of time during entry enhances training and better prepares the pilot for future orbiter flying tasks. Regular in-flight exercise of transfer of vehicle control between the CDR and PLT during nominal approaches will better prepare crews for potential off nominal situations where an efficient transfer of control would be required to ensure vehicle and crew safety. The intent of this rule is to allow the PLT to fly for approximately 20 seconds during a single period, either prior to HAC intercept or once established on the HAC. During a normal entry, there is sufficient time below Mach 1.00 to allow the PLT to control the orbiter and still allow the CDR sufficient time to complete the more critical maneuvers, such as the initial roll onto the HAC and lining up on final. For periods prior to HAC intercept, control must be transferred back to the CDR no later than 15 seconds prior to HAC intercept to allow the CDR sufficient time to prepare for the time-critical maneuver to roll onto the HAC. The 15-second limit was chosen based on flight experience (STS-102, 100, 108, 109, and 110) and to make the best use of the onboard cues, primarily the HAC predictor (the HAC predictor begins flashing 20 seconds prior to HAC intercept and begins moving 10 seconds prior to HAC intercept). For periods after HAC intercept, or for straight-in approaches, control must be transferred back to the CDR prior to 20,000 feet altitude above ground level (AGL). For an overhead HAC approach this equates to approximately the 90-degrees to go point on the HAC. When CSS is engaged, onboard guidance will be followed, and no inputs will be made other than those required to fly to the glideslope and course centerline, or otherwise ensure a safe landing. ©[082202-5636] ©[ED 111302]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-266****SUBSONIC PILOT FLIGHT CONTROL (CONTINUED)**

There are some cases in which it is not prudent to allow the PLT to have this training time, however. If the 6 degrees of freedom entry simulation as explained in Rule {A4-156}, HAC SELECTION CRITERIA, indicates that delaying CSS until a HAC turn angle of 180 degrees is preferred, the CDR should fly from CSS initiation through rollout. For these HAC cases, energy stops diverging at the 180-degree point and begins to slowly recover. Handing control of the vehicle between the CDR and PLT in this timeframe is not prudent, since the vehicle energy is already lower than typical and the time to correct any energy problems is diminished. Likewise a vehicle problem as outlined in Rules {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO NO-GO or {A4-208}, ENTRY TAKEOVER RULES, requires significant concentration on the flying task, and a handover of control is inappropriate. Systems failures that would invoke this rule are two AA failures, no or single air data, no yaw jet flight control mode, or a navigation system anomaly that affects the vehicle energy state (GCA). In the event of an abort, flight control handovers between CDR and PLT should be avoided due to the increased risk inherently associated with the abort, and to eliminate the possibility of introducing any handover dispersions to an already challenging abort landing. The transfer of control is assumed to have an insignificant impact on the vehicle trajectory and energy state, although arguably that impact is non-zero. That is, in most cases it is nearly impossible to transfer vehicle control without introducing some very small transient, which for the nominal case is acceptable. However, the transfer of control is not warranted for any guidance, navigation, or flight control system(s) problem(s) that could cause a transfer of control to result in more than an insignificant impact on the trajectory. Additionally, for certain HAC dynamics (e.g., high tail winds at HAC intercept), the flying task requires more setup time prior to HAC intercept, and more time-critical inputs before, during, and after HAC intercept. In these cases, vehicle energy state can be less forgiving for delayed piloting response (at HAC intercept, and for the first 180 deg of HAC) and transfer of vehicle control is not warranted. ©[082202-5636]

Flight crews are trained preflight to transfer control positively and verbally in a CRM environment. Any time that a situation occurs that detracts from the CDR's ability to fly the vehicle, it is acceptable for the CDR to hand control of the vehicle over to the PLT, regardless of the constraints imposed by this rule, if required to ensure a safe landing. LEGEND	
X	= PERFORM CONTINGENCY ACTION
[]	= NOTE
()	= QUANTITY

NOTES:

- [1] CERTAIN RAPID ENTRY CONDITIONS COULD REQUIRE ENTRY PRIOR TO MCC AND LANDING SITE NOTIFICATION.
- [2] COMM/DATA LINES TO SUPPORT LISTED REQUIREMENTS ALSO MANDATORY.
- [3] 24 OF 64 DTE CHANNELS MANDATORY.
- [4] ASSUMES THREE UNRECOVERABLE GPC'S.
- [5] ACCEPT HIGHEST ABORT MODE AVAILABLE.
- [6] REFERENCE RULE {A5-108}, MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP. @[ED]
- [7] SECOND STAGE ONLY (REF. RULES {A4-260}), RANGE SAFETY LIMIT AVOIDANCE ACTIONS.
- [8] REFERENCE RULE {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES). @[ED]
- [9] TAL/AOA IS ACCEPTED TO PROTECT THE CONTINGENCY CG BOX. IF TAL/AOA DUMP MGMT WILL NOT RECOVER CG, CONTINUE UPHILL.
- [10] TO ALLOW TESTING JETS PRIOR TO ENTRY.
- [11] IF PRIOR TO OMS-1, PERFORM DELAYED ATO. FOR DIRECT INSERTION CUTOFF OMS-2 AT MINIMUM HP. FOR DELAYED ATO, THE RAISE ORBIT MANEUVER WILL NOMINALLY BE PLANNED FOR TTA = 2 (TIME TO APOGEE).
- [12] AFTER OMS-1. CUTOFF OMS-2 AT MINIMUM HP.
- [13] WHERE LEAK IN BOTH SIDES SAME PROPELLANT. IF LEAK RATE SUPPORTS (PROPELLANT ONLY) (IF RCS MUST SUPPORT TO A Q-BAR = 20).
- [14] AFTER DEORBIT TIG, TERMINATING BURN FOR THIS FAILURE REQUIRES DEORBIT 24 HOURS LATER.
- [15] SHALLOW ENTRY IF REQUIRED.
- [16] IF LEAK, PERFORM PERIGEE ADJUSTMENT AT PLANNED DEORBIT TIG IF LEAK RESULTS IN PROJECTED VIOLATION OF POD THERMAL CONSTRAINTS.
- [17] THIS HP ALLOWS DEORBIT OPPORTUNITY 24 HOURS LATER WITH WORST CASE ATT PROFILE (PTC).
- [18] DEORBIT DELAY ONLY REQUIRED IF RCS DOWNMODE CAPABILITY DOES NOT EXIST.
- [19] IF BOTH LEAKS IN SAME SIDE OR BOTH SIDES LEAKING BUT DIFFERENT PROPELLANT, PERFORM NOM.
- [20] IF UNABLE TO OBTAIN VIABLE GNC 3 OPERATION, ENTER ON BFS.
- [21] FAILURE PRECLUDES SINGLE FAULT TOLERANCE. DELAY TO VERIFY RM DECLARED FAILURES OR TO RESOLVE A DILEMMA CASE (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION; AND RULE {A8-8}, ENTRY SYSTEMS RM DILEMMA).
- [22] A ONE-ORBIT WAVE-OFF MAY OR MAY NOT ALLOW SUFFICIENT TIME TO REGAIN SINGLE-FAULT TOLERANCE. IN MANY CASES, DELAYING UP TO ONE DAY WILL BE NECESSARY IN ORDER TO ALLOW SYSTEM COMPENSATION/RECONFIGURATION (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION).
- [23] POST-MECO OMS-1/OMS-2, SHALLOW ENTRY IF REQUIRED.
- [24] IF NECESSARY TO RECONFIGURE TO REDUCED POWER LEVEL.
- [25] AFTER OMS-1, CHECKOUT OMS-2 WHEN MINIMUM HP. NEXT PLS DEORBIT WITH MIXED CROSSFEED IF REQUIRED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-301

CONTINGENCY ACTION SUMMARY (CONTINUED)

- [52] IF BOTH LOOPS FAILED IN BYPASS OR MEDIUM FLOW.
- [53] AFTER DEORBIT TIG, TERMINATE BURN FOR FAILURE IF HP > SAFE HP. REQUIRES DEORBIT 24 HOURS LATER.
- [54] RATES > 5 DEG/SEC IN PITCH OR YAW. REFERENCE RULE {A8-54}, FIRST STAGE LOSS OF CONTROL DEFINITION. @[ED]
- [55] AT LEAST ONE CHANNEL REQUIRED EACH SIDE. REFERENCE RULE {A8-1001}, GNC GO/NO-GO CRITERIA.
- [56] IF ONE ORBIT DELAY NOT AVAILABLE, DELAY 1 DAY. FOR PROPELLANT LEAKS, IT MAY BE NECESSARY TO DELAY LONGER THAN ONE ORBIT IN ORDER TO ALLOW POD THERMAL ENVIRONMENT TO SUPPORT ENTRY.
- [57] IF TIG BETWEEN 45 AND 15 MINUTES AND ONE REV LATE DEORBIT IS AVAILABLE, REOPEN PLB DOORS AND WAVE OFF ONE REV. IF RADS ARE COLDSOAKED AND ONE REV LATE DEORBIT NOT AVAILABLE, UTILIZE THE COLDSOAK TO CONTINUE WITH PLANNED TIG. IF RADS ARE NOT COLDSOAKED AND ONE REV LATE IS NOT AVAILABLE, REOPEN PLB DOORS AND WAVE OFF 1 DAY. @[020196-1810A]
- [58] IF TOXIC COMBUSTION PRODUCTS CANNOT BE SATISFACTORILY REMOVED FROM THE CABIN ATMOSPHERE, THE CREW WILL REMAIN ON QDM/LES UNTIL ORBITER EGRESS. EOM IS BASED UPON AVAILABLE N₂ CONSUMABLES FOR MAINTAINING THE O₂ CONCENTRATION WITHIN ACCEPTABLE LIMITS. REF. RULE {A13-152C}, CABIN ATMOSPHERE CONTAMINATION AND {A17-254}, CABIN O₂ CONCENTRATION. @[070201-4726A]
ON ASCENT, FIRST DAY PLS WILL ONLY BE NECESSARY IF THE CABIN ATMOSPHERE CANNOT BE CLEANED UP. IF THE EXTENT OF THE DAMAGE TO EQUIPMENT AND WIRE BUNDLES IS UNKNOWN, EVEN IF THE ATMOSPHERE HAS BEEN CLEANED UP, A NEXT DAY PLS WILL BE PERFORMED TO MINIMIZE THE RISK OF THE OCCURRENCE OF AN ADDITIONAL FIRE OR ARC TRACKING. @[072795-1779] @[070201-4726A]
- [59] PROPELLANT LEAK ONLY.
- [60] ELS WILL PROBABLY BE REQUIRED IF THE NEXT PLS OR SLS IS GREATER THAN 8 HOURS. AS LONG AS CABIN ENVIRONMENT IS ACCEPTABLE, A PLS WILL BE TARGETED. @[020196-1810A]
- [61] CAUSES LOSS OF ONE MOTOR IN EACH OF TWO SEPARATE PLBD LATCH GANGS (REF. RULE {A10-209B}, PLBD RULE REFERENCE MATRIX). DC AND AC SUB-BUSES THAT CAUSE THIS FAILURE ARE:
MNA MPC1, MMC1, MMC3
MNB MPC2, MMC2, MMC4
MNC MPC3, MMC2, MMC4
AC1 MMC1, MMC3
AC2 MMC2, MMC4
AC3 MMC2, MMC4
- [62] ENTER FIRST DAY PLS UNLESS DELTA V IMPROVEMENT POSSIBLE.
- [63] PERFORM PERIGEE ADJUST BURN SEPARATION.
- [64] ORBIT 2 DEORBIT REQUIRED. (REF. RULE {A11-52}, LOSS OF BOTH VOICE AND COMMAND.)
- [65] RESULTS IN LOSS OF TWO FCS CHANNELS.
- [66] EXCEPT COMBINATION OF MDM'S FF4 AND ANY OTHER FF MDM. OTHERWISE, THE FAILURE OF ANY COMBINATION OF MDM'S FF1, FF2, OR FF3 WILL RESULT IN THE LOSS OF TWO IMU'S. MDM IFM MAY BE PERMITTED TO MEET IMU REQUIREMENT. REFERENCE RULE {A7-109}, IN-FLIGHT MAINTENANCE (IFM). @[090894-1684]
- [67] RESERVED
- [68] REFERENCE RULE {A9-158B}, AC POWER TRANSFER CABLE.
- [69] IF REQUIRED TO MAINTAIN TWO-FC ENTRY CAPABILITY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-301****CONTINGENCY ACTION SUMMARY (CONTINUED)**

- [70] FIRST DAY PLS FOR CONFIRMED, UNRECOVERABLE LOSS OF TWO AFT RCS PITCH JETS, SAME AXIS, SAME POD (N/A YAW JETS).
- [71] LOSS OF CNTL CA1 LOSES BFS ENGAGE CAPABILITY FOR GPC 3 AND 5. A DELAY WILL BE INVOKED TO SWITCH BFS MACHINES. REFERENCE RULE {A7-53B}, ON-ORBIT BFS MANAGEMENT GUIDELINES.
- [72] LOSS OF COMPLETE PRIMARY SYSTEM MAY HAVE RESULTED FROM FREEZING OF THE FC H2O RELIEF PANEL. THIS COULD ALSO CAUSE LOSS OF OVERBOARD RELIEF AND LEAVE ONLY THE ALTERNATE SYSTEM FOR FC H₂O REMOVAL. REFERENCE RULE {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA.
- [73] RESERVED
- [74] ENTER NEXT PLS IF A SINGLE ELECTRICAL FAILURE (AC BUS) COULD CAUSE THE LOSS OF AIR COOLING TO TWO AVIONICS BAYS.
- [75] DELAY TO VERIFY POWER, MDM, AND BITE RELATED FAILURES, AND TO ASSESS THE RISKS OF FLYING THETA LIMITS VS. INCORPORATING THE LAST ADTA (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION, AND RULE {A8-111B}), GNC AIR DATA SYSTEM MANAGEMENT [CIL]).
- [76] DELAY TO TARGET FOR REQUIRED RUNWAY (REF. RULE {A2-207}, LANDING SITE SELECTION).
- [77] A LANDING WILL BE REQUIRED WITHIN 4 HOURS OF THE FAILURE.
- [78] PLS REQUIRED IF AUTO/MANUAL PPO2 CONTROL CANNOT MAINTAIN AEROMED MINIMUM (REF. RULE {A13-53A}.1, MINIMUM PPO2 CONSTRAINTS) AND LESS THAN 30 PERCENT O₂ AT TOUCHDOWN. ELS REQUIRED IF 40 PERCENT O₂ IS EXPECTED TO BE EXCEEDED PRIOR TO NEXT PLS TOUCHDOWN.
- [79] ENTER NEXT PLS IF TIRE PRESSURE WILL BE £ 275 PSI MAIN, 260 PSI NOSE AT NEXT PLS LANDING OPPORTUNITY PLUS 2 DAYS.
- [80] RESERVED
- [81] RESERVED @[102402-5804C]
- [82] REFERENCE RULE {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.
- [83] FOR LOSS OF TWO MMU'S DURING ASCENT, CONSIDERATION WILL BE GIVEN TO PERFORMING THOSE MISSION OBJECTIVES THAT DO NOT REQUIRE MASS MEMORY RESIDENT FUNCTIONS (I.E., GNC 2, SM, SM ROLL-IN DISPLAYS, OR TELEMETRY/DECOM FORMAT LOADS).
- [84] REFERENCE RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS. IF FD 1 LANDING SITE IS GO, LAND FD 1. IF FD 1 LANDING SITE IS NO-GO, IF POSSIBLE, DELAY DEORBIT TO FD 2. @[121593-1590]
- [85] IF HIGH-SPEED C-BAND RADAR NOT SCHEDULED FOR ENTRY, DELAY AS REQUIRED TO SCHEDULE (REF. RULE {A3-1}, GROUND AND NETWORK DEFINITIONS), UNLESS GPS IS AVAILABLE AND FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). IF MLS FAILURE, DELAY ONLY IF MLS REQUIRED PER RULE {A3-202}, MLS. @[041196-1914] @[ED] @[092602-5640]
- [86] A TOTAL COMBINATION OF 2 TACAN/GPS LRU'S MUST BE LOST FOR THIS RULE TO APPLY GIVEN THAT THE REMAINING 2 LRU'S PROVIDE AT LEAST FAIL-SAFE CAPABILITY WITHOUT REGARD FOR TRACKING AVAILABILITY. @[092602-5640]

A2-302 THROUGH A2-310 RULES ARE RESERVED

FLIGHT RULES

SPACEHAB OPERATIONS MANAGEMENT

A2-311

SPACEHAB SAFETY DEFINITION AND MANAGEMENT

A. DEFINITIONS: @[102793 -1552]

1. **RAPID SAFING** - SECURING OF ANY PAYLOAD ELEMENT IN A TIME-CRITICAL MANNER AS DEFINED BY THE SPACE SHUTTLE PROGRAM FOR ABORTS AND CONTINGENCY RETURN OF THE ORBITER. @[111501-4981E]
2. **UNSAFE** - ONLY TWO INHIBITS CAN BE VERIFIED TO A CATASTROPHIC HAZARD.
3. **HAZARDOUS** - ONLY ONE INHIBIT CAN BE VERIFIED TO A CATASTROPHIC HAZARD.
4. **SAFE** - SHALL BE DEFINED AS ANY ONE OF THE FOLLOWING:
 - a. AT LEAST THREE INHIBITS REMAIN TO A CATASTROPHIC HAZARD, TWO OF WHICH MUST BE MONITORABLE.
 - b. RESTRAINT/SECURING OF ANY PAYLOAD ELEMENT CAPABLE OF PENETRATING A MODULE AS A RESULT OF ORBITER INDUCED ENTRY/LANDING LOADS.

Reference: NSTS 18798A, MA2-96-190, "CONTINGENCY RETURN AND RAPID SAFING," memo dated January 9, 1997. @[111501-4981E]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-311

SPACEHAB SAFETY DEFINITION AND MANAGEMENT
(CONTINUED)

B. GENERALIZED RESPONSES TO UNSAFE/HAZARDOUS CONDITIONS:

1. **RAPID SAFING** - FOR SPACEHAB, CONTINGENCY DEACTIVATION/EGRESS PROCEDURES ARE USED FOR OFF NOMINAL/EMERGENCY SITUATIONS REQUIRING AN EXPEDITED RESPONSE TO SECURE THE MODULE FOR A SAFE ENTRY AS DEFINED IN RULE {A2-329}, SPACEHAB DEACTIVATION/ENTRY PREP. @102793-1552 @111501-4981E @ED]
2. **UNSAFE** - NO IMMEDIATE ACTION IS REQUIRED. IF POSSIBLE, RESTORATION OF THE SAFE CONDITION WILL NORMALLY BE ATTEMPTED, BUT SUCH ACTION WILL NOT BE ALLOWED TO JEOPARDIZE MISSION SUCCESS.
3. **HAZARDOUS** - QUICK RESPONSE IS MANDATORY: TAKE POSITIVE ACTION TO RESTORE THE SYSTEM TO NO WORSE THAN AN UNSAFE CONDITION. IF UNSUCCESSFUL, TERMINATE THE EXPERIMENT AS SOON AS POSSIBLE (ASAP). @111501-4981E]

FLIGHT RULES

A2-312

REAL-TIME SAFETY COORDINATION

- A. ANY SPACEHAB PAYLOAD FAILURE WHICH POSES AN IMMEDIATE THREAT TO ORBITER SYSTEMS OR CREW HEALTH (FOR EXAMPLE: BROKEN GLASS, TOXIC SPILLS, SMOKE/FIRE, ANIMAL WASTE, AND FREE WATER) WILL BE COORDINATED BY THE CREW DIRECTLY WITH HOUSTON FLIGHT THROUGH EECOM AND SURGEON, WITH ASSISTANCE FROM HOUSTON PAYLOADS/ACO. HOUSTON PAYLOADS/ACO WILL IMMEDIATELY NOTIFY THE PAYLOAD OPERATIONS CONTROL CENTER (POCC) AND WILL PROVIDE ANY ADDITIONAL COORDINATION WITH OTHER MCC FCT DISCIPLINES, IF NECESSARY. [060800-7124] [111501-4981E]

This approach allows the MCC FCT to prioritize, coordinate, and address the immediate health threat to the crew. All payload-specific questions will be relayed to the POCC. It is understood that the crew will work the appropriate onboard contingency procedures to reduce the immediate threat without talking to the ground first. Crew indication of an electrical short is fire/smoke (covered in paragraph A), popped circuit breaker (covered in paragraph B), or maintained increase in current (covered in paragraph B). For coordination of electrical problems/shorts, reference Rule {A9-355}, FUSE/CIRCUIT BREAKER MANAGEMENT. [111501-4981E] [ED]

- B. ANY PAYLOAD FAILURES, WHICH ORIGINATE FROM PAYLOAD HARDWARE AND DO NOT POSE AN IMMEDIATE THREAT TO ORBITER SYSTEMS OR CREW HEALTH AS DEFINED IN PARAGRAPH A, WILL BE COORDINATED BY THE CREW DIRECTLY WITH THE POCC. THE POCC WILL IMMEDIATELY NOTIFY HOUSTON PAYLOADS/ACO OF ANY SITUATION AFFECTING SAFETY (I.E., LOSS OF CONTAINMENT LEVEL, LOSS OF REDUNDANCY, POTENTIAL SHORT WITHIN PAYLOAD HARDWARE, ETC.). IF THE SITUATION IS NOT WITHIN THE SCOPE OF THE PERMISSION-DEFINED FLIGHT RULES AND PROCEDURES, NO ACTION (OTHER THAN REMOVAL OF THE HAZARD POTENTIAL) WILL BE TAKEN WITHOUT FULL AND PRIOR COORDINATION WITH THE MCC FCT. [111501-4981E]

Safety related payload failures which can be addressed directly between the crew and POCC are those which originate in payload equipment and which do not affect the atmosphere leading to an immediate threat to orbiter systems or crew health. These payload-originated failures must be specifically addressed in permission-defined flight rules and procedures. Although the MCC Flight Director is ultimately responsible for the safety of the orbiter/Spacehab and crew, it is recognized that the POCC has the expertise on and sufficient data/insight into the payload hardware. As soon as the POCC is cognizant of a payload safety situation; however, the MCC must be notified for further assessment of orbiter/Spacehab and crew impacts. The only action(s) which may be taken that is (are) not in the scope of the permission defined flight rules or procedures and without prior coordination with the MCC is (are) to eliminate the hazard cause(s) (i.e., remove power, etc.). For coordination of electrical problems/shorts, reference Rule {A9-355}, FUSE/CIRCUIT BREAKER MANAGEMENT. [060800-7124] [111501-4981E] [ED]

FLIGHT RULES

A2-313

GROUND COMMANDING

- A. ALL PAYLOAD COMMANDING WILL BE COORDINATED WITH HOUSTON FLIGHT THROUGH HOUSTON PAYLOADS/ACO. NOMINALLY, POCC COMMANDING WILL BE THROUGHPUT COMMANDS. TWO-STAGE COMMANDING, CONTINGENCY COMMANDING, AND KU-BAND 128 COMMAND LINK (RDM ONLY) WILL REQUIRE COORDINATION WITH INCO. @[060800-7125] @[111501-4981E]

HOUSTON FLIGHT is responsible for all commanding to the shuttle vehicle, and all commanding must be done with the cognizance of HOUSTON FLIGHT. The specific coordination tasks and configuration authority is usually delegated on Spacehab missions to the Instrumentation And Communications Officer, call sign HOUSTON INCO, HOUSTON PAYLOADS/ACO, and their support personnel. Payload commanding will be identified premission with POCC command windows reflected in the command timeline. Nominally, the Payload Operations Control Center (POCC) will only be enabled during these premission-defined windows. If off-nominal conditions arise real time which necessitate sending commands outside the premission-defined windows, coordination between the POCC and HOUSTON PAYLOADS/ACO will be required to discuss these changes to the Command Timeline during the Tracking and Data Relay Satellite (TDRS) pre-pass briefing and/or just prior to the command sequence. As a minimum, the need to use a premission scheduled command window will be identified to HOUSTON PAYLOADS/ACO during the TDRS pre-pass briefing.

The Ku-band 128-command link, in addition to PSP commanding, is used for Spacehab RDM experiment and experiment data system commanding. @[111501-4981E]

- B. IF COMMAND VOLUMES ARE SUCH THAT COMMAND COORDINATION IS A SIGNIFICANT DETRIMENT TO MISSION SUCCESS, CONSIDERATION WILL BE GIVEN TO SIMULTANEOUS (SIMO) POCC COMMANDING THROUGHOUT EACH TDRS PASS UNDER THE FOLLOWING CONDITIONS. SIMO COMMANDING MUST BE APPROVED BY HOUSTON FLIGHT.
1. THE COMMANDING PARTY IS RESPONSIBLE FOR DETECTING AND RETRANSMITTING ANY LOST COMMANDS.
 2. ALL POCC HAZARDOUS COMMANDING WILL BE COORDINATED WITH HOUSTON PAYLOADS/ACO PRIOR TO COMMAND INITIATION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-313

GROUND COMMANDING (CONTINUED)

3. LARGE COMMAND BLOCKS WILL BE COORDINATED.

SIMO commanding includes two or more POCC's enabled for commanding. The addition of the payload throughput buffer in the systems management (SM) GPC allows for continuous commanding by both the MCC and the POCC's; therefore, MCC and POCC commanding is not considered SIMO commanding. ©[060800-7125]

SIMO commanding is possible, with the risk of the ground system rejecting commands that have insufficient spacing. The ground system is set to allow a maximum of one command per second. If this rate is exceeded, then the ground system will reject the additional commands. This method of commanding is less desirable than a more structured method where ground system rejects are procedurally avoided. If the overhead of the coordination is judged to be a significant impact to payload operations and the overhead of retransmitting the commands is judged to be less, consideration will be given to SIMO commanding. Due to safety considerations, hazardous commands must always be coordinated. Since large blocks of commands require more command system time, more care must be used to avoid ground system rejects and loss of these types of commands; therefore, large command blocks will still require coordination. ©[060800-7125]

- C. IF TWO-STAGE POCC COMMANDING IS REQUIRED, POCC COMMANDING AND MCC COMMANDING TO THE SAME GENERAL PURPOSE COMPUTER (GPC) TWO-STAGE BUFFER WILL BE MANAGED SO THAT ONLY ONE IS COMMANDING AT A TIME. ©[111501-4981E]

A POCC may require two-stage commanding for critical commanding or troubleshooting command problems. To avoid two-stage buffer contention, POCC and MCC commanding will be coordinated. ©[060800-7125]

- D. FOR FAILURE OF THE SPACEHAB FAN IN USE OR FAILURE OF A WATER COOLING LOOP PUMP DURING ASCENT/ENTRY, CONTINGENCY COMMANDS WILL BE SENT TO SWAP FANS OR PUMPS ASAP POST MAIN ENGINE CUT OFF (MECO) OR DURING ENTRY PER RULES {A17-706}, SPACEHAB FAN CONFIGURATIONS OR {A18-553}, SPACEHAB SUBSYSTEM PUMP OPERATIONS.

Air circulation is required to maintain module airflow over the Spacehab fire/smoke detectors. Without switching fans following the loss of the fan in use, all fire/smoke detection capability is lost. The Spacehab water-cooling loop is required for achieving thermal control of the module environment. Without switching pumps following a pump failure, all module cooling is lost. Without smoke detection or adequate cooling, the module would need to be powered down. Powering the module down has the potential for a significant mission success impact. No on-board command capability exists in OPS 1 or OPS 3 (SM GPC not available), so reconfiguration during ascent/entry must be performed via ground commands. The water line heaters must be turned ON, to prevent freezing of the PLHX, if the PLBD's are open. ©[111501-4981E]

FLIGHT RULES

A2-314

SPACEHAB MINIMUM DURATION FLIGHT CRITERIA

FOR AN ORBITER FREON LOOP TO SPACEHAB WATER LOOP LEAK, THE SPACEHAB MODULE WILL BE PREPARED FOR ENTRY, EGRESSED, ISOLATED, AND A MINIMUM DURATION FLIGHT (MDF) WILL BE INSTITUTED. ©[111501-4981E]

Entry prep and egress of the Spacehab module are performed to configure the module for entry and to avoid the possibility of the crew being exposed to toxic Freon. Although the water loop is compatible with Freon 21, a relatively high pressure in the water loop (caused by Freon leaking into the water loop) increases the chances of the water loop developing a leak into the module and exposing the crew to Freon.

An MDF is called for a heat exchanger leak between dissimilar fluids because the possibility exists that a generic problem, such as corrosion, exists in the heat exchanger. This problem could eventually result in a total loss of the heat exchanger and orbiter due to the subsequent loss of two Freon loops. The risk of losing the heat exchanger does not warrant a next primary landing site (PLS) but does warrant an MDF. ©[111501-4981E]

A2-315

POWERING OFF AND REPOWERING SPACEHAB EQUIPMENT

A. SPACEHAB EQUIPMENT/COMPONENTS WILL BE POWERED OFF IF THEY HAVE FAILED AND HAVE ON/OFF CAPABILITY. REFERENCE FAILURE DEFINITIONS IN SECTION 9, SPACEHAB SUPPORT AND SPACEHAB ELECTRICAL POWER SUBSYSTEM (EPS) MANAGEMENT. ©[111501-4981E]

Failed equipment will be powered off to prevent possible intermittent operation and/or shorting. Powering off failed equipment also saves power. Equipment powered by the Emergency Bus cannot be powered off unless both the PL AUX and PL AFT B busses are powered off.

B. SPACEHAB EQUIPMENT NOT CONCERNED WITH SAFETY MAY BE OPERATED OUTSIDE THE QUALIFICATION LIMITS BASED ON CUSTOMER CALL.

Operation to the qualification limits may result in unpredictable operation and/or violation of lifetime limits. The Spacehab customer has chosen to allow for equipment operations (ops) outside of qualification limits based on preflight test experience.

C. REPOWERING SPACEHAB EQUIPMENT AFTER FAILURE OR AFTER EXCEEDING QUALIFICATION TEST LIMITS WILL BE ON MCC CALL ONLY.

The MCC has the ability to evaluate data on the equipment. Consideration must be given to possible damage to orbiter systems or further damage to the affected equipment if repowered. MCC may give consideration to an inflight maintenance (IFM) procedure, trend data, etc., after careful review.

FLIGHT RULES

A2-316

ORBITER-TO-SPACEHAB HATCH CONFIGURATION

- A. FOR THOSE OPERATIONS REQUIRING THE ORBITER INNER HATCH OR THE SPACEHAB HATCH TO BE CLOSED AND LATCHED, ALL CREWMEMBERS ARE REQUIRED TO REMAIN ON THE ORBITER SIDE OF THE CLOSED AND LATCHED HATCH. ©[111501-4981E]

There is no air exchange between the orbiter and the Spacehab module with the hatch(es) closed. In addition, conditions could occur, such as an airlock leak or hatch malfunction, which could trap a crewmember in the Spacehab module.

- B. THE SPACEHAB HATCH WILL REMAIN OPEN FOR NOMINAL OPERATIONS, UNLESS REQUIRED TO BE CLOSED FOR EXTRAVEHICULAR ACTIVITY (EVA) OPERATIONS OR DOCKING OPERATIONS.

Reference: Rule {A2-317}, EVA CONSTRAINTS.

- C. THE MODULE WILL BE CONFIGURED FOR A SAFE ENTRY AS REQUIRED BY PAYLOAD SAFETY PRIOR TO CLOSING THE HATCH.

The module is configured for safe entry (i.e., all penetration hazards restrained/stowed) in the event the module cannot be re-entered. ©[111501-4981E]

FLIGHT RULES

A2-317

EVA CONSTRAINTS

- A. PREBREATHING AT 10.2 PSI CAN BE DONE WITH THE SPACEHAB MODULE AT 14.7 PSI AND THE SPACEHAB HATCH CLOSED OR WITH THE SPACEHAB AT 10.2 PSI. THE STRATEGY WILL BE DETERMINED ON A MISSION SPECIFIC BASIS AND DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

The minimum design operating pressure for Spacehab components is 10 psia. Freon flow to the payload heat exchanger will be reduced in order to keep the orbiter cabin within temperature limits. This is accomplished by moving one of the orbiter's Freon flow proportioning valves (FPV's) from the nominal on-orbit payload heat exchanger position to the interchanger position. This will reduce the cooling capability in the Spacehab water loop.

Spacehab may be able to operate at the reduced pressure (and cooling level) of 10.2 psi if these conditions are compatible with experiment science and hardware requirements and if overall module thermal loads allow. The benefit of open hatch operations at 10.2 psi is increased crew access time to the module during prebreathe.

Assessment of 10.2 psi prebreathe strategy will be conducted on a flight specific basis. ©[111501-4981E]

- B. SPACEHAB LEAK DURING EVA ©[111501-4981E]

SCHEDULED/UNSCHEDULED EVA

1. IF A SPACEHAB CABIN LEAK OCCURS DURING AIRLOCK/TUNNEL ADAPTER DEPRESS WHICH IS NOT UNDERSTOOD OR WHICH IS PREDICTED TO REDUCE CABIN PRESSURE BELOW 10.2 POUNDS PER SQUARE INCH ABSOLUTE (PSIA) BEFORE NOMINAL EVA COMPLETION TIME, THE EVA/AIRLOCK DEPRESS WILL BE TERMINATED.
2. IF A SPACEHAB CABIN LEAK OCCURS DURING EVA, THE EVA WILL BE TERMINATED AND THE AIRLOCK/TUNNEL ADAPTER REPRESSURIZED BEFORE THE SPACEHAB IS PREDICTED TO REACH 10.2 PSIA.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-317 EVA CONSTRAINTS (CONTINUED)

CONTINGENCY EVA

3. IF THE EVA IS AN ORBITER CONTINGENCY EVA, IT WILL CONTINUE AND THE SPACEHAB WILL BE UNPOWERED EXCEPT FOR EMERGENCY POWER (AUX A AND AFT B) PRIOR TO REACHING 10 PSIA.

The Spacehab systems are certified to operate above a cabin pressure greater than or equal to 10 psia. For example, a leak rate of 7.3 lb/hr for 4 hours based on 14.7 equivalent will bring the cabin to 10 psia. PL AUX A and AFT MN B provide redundant power to Spacehab sensors. AFT MN B is the only source of power to the Spacehab water line heaters that protect the Spacehab water line from freezing. Additionally, smoke/fire detection sensors are powered by the emergency circuits.

- C. EXPERIMENT IMPACTS TO A 10.2 PSI PREBREATHE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

A2-318 ORBITAL MANEUVERING SYSTEM/REACTION CONTROL SYSTEM (OMS/RCS) CONSTRAINTS

ORBITAL MANEUVERING SYSTEM/REACTION CONTROL SYSTEM (OMS/RCS) CONSTRAINTS ARE EXPERIMENT COMPLEMENT DEPENDENT AND ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

A2-319 CONTAMINATION AND MICROGRAVITY CONSTRAINTS

ANY CONSTRAINTS SPACEHAB HAS ON WATER DUMPS, FES OPS, OMS/RCS LEAKS, ORBITER LEAKS, OR FUEL CELL PURGES WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

FLIGHT RULES

A2-320

COMMAND AND DATA SYSTEM CONSTRAINTS

- A. FOR A NONRECOVERABLE LOSS OF THE DATA MANAGEMENT UNIT (DMU), SPACEHAB ACTIVITIES WILL CONTINUE. HOWEVER, THE WATER LINE HEATERS WILL BE TURNED ON TO PREVENT FREEZING. @[111501-4981E]

Loss of the DMU results in loss of all Payload Data Interleaver (PDI) data to the Orbiter Display System, Payload General Support Computer (PGSC) downlink, and all subsystem control capabilities (except that which is routed through the orbiter multiplexer/demultiplexer (MDM)). All experiment data to the DMU would also be lost. However, safety critical monitoring and control is all routed through the PL MDM and Caution and Warning Electronics Assembly (CWEA). Water line heaters are turned on because a DMU failure results in loss of water pump monitoring capability.

- B. FOR LOSS OF THE MODULE SYSTEMS PGSC CAPABILITY, SPACEHAB OPERATIONS WILL CONTINUE.

The PGSC is used for backup monitoring only. Primary monitoring still exists at the Orbiter Display System, as well as through the Fault Detection and Annunciation (FDA) and CWEA systems. Ground monitoring via the PDI downlink is also still available.

- C. PDI DECOM LOSS IMPACTS WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

FLIGHT RULES

A2-321

SPACEHAB AIR-TO-GROUND (A/G) USAGE

- A. THE STANDARD ORBITER A/G CHANNEL (A/G 1) WILL BE USED FOR ANY DISCUSSIONS RELATED TO SPACEHAB SUBSYSTEMS. THE SSP CAPCOM WILL BE THE GROUND COMMUNICATOR. @[111501-4981E]

Since the module is integrated to the orbiter, it is necessary that any systems issues be discussed on A/G 1, which all Space Shuttle Program (SSP) flight control team members monitor. In addition, this strategy guarantees that emergency/time critical issues are discussed on the prime A/G loop.

- B. EITHER A/G 1 OR A/G 2 WILL BE USED FOR ANY DISCUSSIONS RELATED TO SPACEHAB EXPERIMENTS DEPENDING ON THE AMOUNT OF A/G USAGE. A SPACEHAB CREW INTERFACE COORDINATOR (CIC) WILL BE THE GROUND COMMUNICATOR.

Spacehab is responsible for all experiment procedures and the experiment flight data file. Therefore, the most efficient communication path is directly between the crew and the CIC. The CIC will be in the JSC POCC. The Flight Director will decide which A/G loop is the most appropriate to use. @[111501-4981E]

- C. ANY SAFETY-RELATED ISSUES, INCLUDING THOSE RELATED TO EXPERIMENTS, WILL BE CONDUCTED ON THE PRIME A/G LOOP (A/G 1). @[111501-4981E]

Self-explanatory.

- D. ROUTINE CONVERSATIONS DURING SPACEHAB EXPERIMENTS OPERATIONS BETWEEN THE CIC AND THE CREW ON A/G 1 OR A/G 2 WILL NORMALLY BE INITIATED BY CREW REQUEST. THE FOLLOWING RESTRAINTS SHALL APPLY TO CIC PROTOCOL AND A/G 1 OR A/G 2 USAGE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-321 SPACEHAB AIR-TO-GROUND (A/G) USAGE (CONTINUED)

1. THE VOICE PROTOCOL SHALL BE THE SAME AS THAT USED BY THE JSC CAPCOM.
2. THE SPACEHAB OPERATIONS DIRECTOR (SHOD) IS RESPONSIBLE FOR APPROVING ALL CALLS INITIATED FROM THE GROUND TO THE CREW.
3. DIRECT EXPERIMENTER CALLS TO THE CREW ON A/G 1 OR A/G 2 SHALL BE UPON CREW REQUEST ONLY.
4. THE CALL SIGN FOR THE SPACEHAB POCC SHALL BE "SPACEHAB POCC."
5. OCA S-BAND (MFX) OPERATIONS WILL TAKE PRECEDENCE OVER ROUTINE SPACEHAB A/G 2 USAGE.
6. EXCEPTIONS TO THIS RULE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

Past flight crew comments on overuse of A/G by payloads point out the need for more rigid control of the traffic and voice protocol. In addition, use of the OCA S-Band (OCA Ku-Band is nominal) adds complexity to the scheduled use of one of the A/G links. With the many users as well as the many experimenters on a Spacehab flight, careful definition of the A/G 1 or A/G 2 usage is required. This rule represents an agreed to baseline with the customer for Spacehab flights. ©[111501-4981E]©[111501-4981E] ©[111501-4976A]©[092701-4872]

A2-322 SPACEHAB CAUTION AND WARNING ANNUNCIATION IN MODULE

LOSS OF ALL CAUTION AND WARNING ANNUNCIATION CAPABILITY IN THE SPACEHAB MODULE IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES PROVIDED: ©[111501-4981E]

- A. ANNUNCIATION CAPABILITY EXISTS IN THE ORBITER AND,
- B. VOICE COMMUNICATION BETWEEN THE ORBITER AND SPACEHAB IS AVAILABLE.

All emergency safety parameters are redundantly monitored by the orbiter GPC and CWEA. In addition, both of these monitoring systems cause annunciating in both Spacehab and the orbiter. Loss of the Spacehab C&W annunciating capability is therefore only loss of redundancy. The orbiter crew would alert the Spacehab crew of any emergencies. ©[111501-4981E]

FLIGHT RULES

A2-323

COMMUNICATIONS CONSTRAINTS

LOSS OF VOICE COMMUNICATION BETWEEN THE ORBITER AND SPACEHAB CREWMEMBERS IS NOT CAUSE TO TERMINATE SPACEHAB OPERATIONS PROVIDED CAUTION AND WARNING ANNUNCIATION CAPABILITY STILL EXISTS IN SPACEHAB. @[111501-4981E]

Loss of voice communication does not present a hazard to the crew if caution and warning alarms are still available from the audio control system (ACS). Spacehab operations would be impacted, but may be continued in the best possible manner. Coordination can be carried out by voice calls down the tunnel or possibly by using the BPSMU or a wireless crew comm unit (WCCU) connected in the airlock.
@[111501-4981E]

A2-324

SPACEHAB IN-FLIGHT MAINTENANCE (IFM) PROCEDURES

A. IN SUPPORT OF ALL FLIGHTS RULE {A2-105}, IN-FLIGHT MAINTENANCE (IFM), ALL SPACEHAB UNSCHEDULED IFM PROCEDURES CONTAINED IN THE SPACEHAB OPERATIONS CHECKLIST (JSC-48089) AND SPACEHAB RDM MALFUNCTION PROCEDURES (JSC-48099) HAVE BEEN PERMISSION COORDINATED AND REQUIRE REAL-TIME MCC APPROVAL ONLY PRIOR TO IMPLEMENTATION, EXCEPT THOSE LISTED IN PARAGRAPH B. EXPERIMENT IFM'S ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

These IFM's have been reviewed preflight and identified as acceptable; however, because of their nature, implementation must be coordinated with the MCC.

B. THE FOLLOWING ARE LISTS OF SPACEHAB SCHEDULED IFM PROCEDURES IN THE SPACEHAB OPERATIONS CHECKLIST (JSC-48089) WHICH DO NOT REQUIRE REAL-TIME APPROVAL OR COORDINATION PRIOR TO IMPLEMENTATION.

1. FAN CLAMP REMOVAL (IFM-1.3)
2. FAN CLAMP REPLACEMENT (IFM-1.4)

C. ALL REAL-TIME DEVELOPED SPACEHAB/EXPERIMENT IFM PROCEDURES WILL BE COORDINATED AND APPROVED BY THE MCC.

Implementation of unplanned IFM's may require activities which, if not properly reviewed and coordinated, could result in an array of unsafe conditions. Therefore, unplanned IFM activity must be coordinated with MCC to ensure the safety of the orbiter, payloads, and crew. If no previous IFM work has been done, a minimum of 24 hours may be expected before an experiment IFM may be approved and uplinked. @[111501-4981E]

FLIGHT RULES

A2-325

IFM PROCEDURES ON EXPERIMENTS WITH TOXIC HAZARDS

NO IFM PROCEDURES WILL BE INITIATED BY THE CREW ON AN EXPERIMENT KNOWN TO REPRESENT A TOXIC HAZARD UNTIL CONCURRENCE FOR THE REPAIR PROCEDURE IS OBTAINED FROM THE MCC FLIGHT DIRECTOR. SPACEHAB EVACUATION AND/OR PROTECTIVE EQUIPMENT MAY BE REQUIRED (SEE RULE {A13-156}, SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE). ALL PAYLOAD EXPERIMENTS/SAMPLES CONTAINING HAZARDOUS MATERIALS ARE DEFINED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

A real-time assessment of the possibility of repairing an experiment and the risk of exposing the crew to a toxic substance during the repair will need to be made. The IFM may require that the cleanup equipment specified in Rule {A13-156}, SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE, be used to minimize risk of crew exposure to toxic substances. ©[111501-4981E]

FLIGHT RULES

A2-326

EQUIPMENT EXCHANGE BETWEEN ORBITER CABIN AND SPACEHAB MODULE

- A. ELECTRICAL EQUIPMENT OR EXPERIMENTS, SELF-POWERED OR FACILITY-POWERED, SHALL NOT BE TRANSFERRED BETWEEN THE ORBITER AND SPACEHAB UNLESS CERTIFIED FOR USE IN BOTH LOCATIONS. APPROVED EQUIPMENT WILL BE IDENTIFIED IN PARAGRAPH B. ©[111501-4981E]

Equipment may only be used in areas where it has been approved from an electromagnetic compatibility standpoint. In addition, power budgeting/planning can only be accomplished effectively if equipment movement strategy is coordinated preflight via this rule.

B. SPACEHAB SUBSYSTEM GENERIC EQUIPMENT

1. WIRELESS CREW COMMUNICATION SYSTEM (WCCS)
2. ORBITER COMM EQUIPMENT
3. VACUUM CLEANER AND ACCESSORIES (CABLE AND ATTACHMENT)
4. ORBITER CAMCORDER AND ACCESSORIES
5. PAYLOAD AND GENERAL SUPPORT COMPUTER (PGSC) AND ACCESSORIES
6. ORBITER CAMERA AND ACCESSORIES
7. ELECTRONIC STILL CAMERA (ESC)

EXCEPTIONS TO THIS RULE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

FLIGHT RULES

A2-327

SPACEHAB MODULE/TUNNEL SLEEP CONSTRAINTS

- A. NO CREWMEMBERS SHALL SLEEP IN THE SPACEHAB-TO-ORBITER TUNNEL.
 ©[111501-4981E]

In the event it was necessary to rapidly evacuate the module, a sleeping crewmember either tethered or in a sleeping bag would pose a hazard. In addition, the tunnel does not offer the same amount of protection for radiation that is provided by the module or orbiter cabin.

- B. CREWMEMBERS MAY SLEEP IN THE SPACEHAB MODULE IF:
1. SPACEHAB SYSTEM DATA IS BEING NOMINALLY TRANSMITTED TO THE ORBITER'S SM GPC AND TELEMETERED TO THE GROUND.
 2. THE CAUTION AND WARNING LINK BETWEEN THE ORBITER AND SPACEHAB IS OPERATIONAL.
 3. AT LEAST ONE SPACEHAB SMOKE SENSOR IS OPERATIONAL.
 4. THE AUDIO LINK BETWEEN THE ORBITER AND SPACEHAB IS OPERATIONAL.
 5. THE ARS FAN AND AT LEAST ONE ARS FAN DELTA PRESSURE SENSOR ARE OPERATIONAL IN ADDITION TO THE FOLLOWING:
 - a. (LDM ONLY) THE AFT MODULE FAN AND ITS ASSOCIATED DELTA PRESSURE SENSOR ARE OPERATIONAL.
 - b. (RDM ONLY) AT LEAST ONE HAB FAN ASSEMBLY (HFA) FAN AND ONE HFA FAN DELTA PRESSURE SENSOR ARE OPERATIONAL.

Nominal safety monitoring is via the SM GPC and the Caution and Warning Electronics Assembly (CWEA). Ground monitoring of safety parameters provides a further safety monitoring capability. The audio link to the Spacehab is desirable for communication in the case of a contingency commencing during sleep. The ARS fan and the ARS fan delta pressure sensor are required to verify that the ARS fan is operating, thus ensuring air exchange with the orbiter. In addition to the ARS fan and ARS fan delta pressure sensor, one HFA fan and one HFA fan delta pressure sensor in the RDM configuration are required for cooling, or the aft module fan and its associated delta pressure sensor in the LDM configuration are required to ensure adequate air flow through the aft module. Any one AC fan (Cabin or ARS) in the SM/LDM or one HFA fan in the RDM is adequate for smoke detection.

Reference: Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS, Boeing memo, 2C-SPACEHAB-01044, A90-SPACEHAB-97088, A90-SPACEHAB-2000192, MDC92W5610, and MDC95W5829.

FLIGHT RULES

A2-328

CREW LIMITATIONS IN THE SPACEHAB MODULE

- A. THE MAXIMUM NUMBER OF CREWMEMBERS PERMITTED IN THE MODULE MAY BE LIMITED BASED ON REAL-TIME EVALUATION OF O_2 AND CO_2 LEVELS, RELATIVE HUMIDITY, AND CABIN TEMPERATURE. ©[111501-4981E]

Spacehab SM/LDM is designed to reject 1400/1000 watts (respectively) of waste heat from surface air-cooled experiments with two crewmembers in the module. Spacehab RDM is designed to reject 2000 watts of waste heat from surface air-cooled experiments with three crewmembers in the module. Boeing/Spacehab analysis shows that each additional crewmember over the design value of two will decrease the available experiment air heat rejection accommodations by 115 watts minimum and 265 watts maximum (SM/LDM only). Each additional crewmember is expected to increase module dew point by about 1 deg F. Moisture is not a limiting factor for the Spacehab RDM since it has moisture removal capability. The RDM with the 53 cfm air exchange rate with the orbiter is designed to accommodate three crewmembers continuously. In the RDM, CO_2 generation may be the limiting factor for crew occupancy above its design limit. Increases in oxygen (O_2) consumption show no immediate concern for nominal operations in all module configurations.

- B. ORBITER CREWMEMBERS MAY ASSIST IN OPERATIONS IN THE SPACEHAB MODULE OR SERVE AS TEST SUBJECTS (SUBJECT TO ALL FLIGHTS RULE {A2-135}, COMMANDER (CDR) AND PILOT (PLT) PARTICIPATING AS TEST SUBJECTS) AS NEGOTIATED PREFLIGHT.

Preflight coordination will guarantee that the workloads of the orbiter crewmembers are acceptable and that All Flights Rule {A2-135} COMMANDER (CDR) AND PILOT (PLT) PARTICIPATING AS TEST SUBJECTS, is not violated. ©[111501-4981E]

FLIGHT RULES

A2-329

SPACEHAB DEACTIVATION/ENTRY PREP @[111501-4981E]

SPACEHAB DEACTIVATION WILL PROCEED BY ONE OF THE FOLLOWING METHODS DEPENDING ON CIRCUMSTANCES: @[111501-4982A]

- A. NOMINAL ENTRY PREP - SECURING OF THE SPACEHAB BY NOMINAL CHECKLIST PROCEDURES. THE NOMINAL ENTRY PREP WILL BE DONE FOR:
1. NOMINAL END-OF-MISSION
 2. ANY FAILURE THAT RESULTS IN A PRIMARY LANDING SITE (PLS) WITH DEORBIT TIME OF IGNITION (TIG) OCCURRING BEYOND 12 HOURS.

Nominal entry prep requires approximately 1-2 hours and is scheduled in the Flight Plan. A PLS TIG greater than 12 hours away will allow the crew to perform the desirable, nominal module entry prep.

The procedure will include equipment stowage, nominal deactivation of experiments, and an orderly reconfiguration to the Spacehab entry configuration.

- B. SPACEHAB 30-MINUTE CONTINGENCY DEACTIVATION - SECURING OF SPACEHAB AND EXPERIMENT HARDWARE IN MINIMUM TIME WITHOUT INCURRING DAMAGE TO SPACEHAB, AND WHEN POSSIBLE, EXPERIMENT EQUIPMENT. SPACEHAB 30-MINUTE CONTINGENCY DEACTIVATION PROCEDURES WILL BE DONE FOR:
1. ANY FAILURE THAT RESULTS IN A PLS WITH DEORBIT TIG OCCURRING BETWEEN 3.5 TO 12 HOURS.
 2. UNRECOVERABLE LOSS OF ALL SPACEHAB AIR CIRCULATION FANS.

Spacehab 30-minute contingency deactivation is intended to perform as much of the normal deactivation of the module as possible. It also provides a balance between deactivating the module in a shorter-than-nominal time and preserving equipment (and science, if possible). The procedure will include critical entry stowage, an abbreviated but orderly Spacehab shutdown, and safing of experiments, if time permits. @[111501-4982A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-329

SPACEHAB DEACTIVATION/ENTRY PREP (CONTINUED)

- C. SPACEHAB EMERGENCY DEACTIVATION - IMMEDIATE STOW OF ANY PENETRATORS, EGRESS, AND CLOSURE OF THE HATCH WITHOUT ANY OTHER ACTIVITIES WITHIN THE 3-MINUTE CONSTRAINT. IF CIRCUMSTANCES WARRANT, ALL POWER, EXCEPT PL AFT MN B, WILL BE REMOVED. SPACEHAB EMERGENCY DEACTIVATION PROCEDURES WILL BE DONE FOR: @[111501-4982A]
1. ORBITER PROBLEMS REQUIRING EMERGENCY DEORBIT
 2. AN ORBITER/MODULE LEAK (DEACTIVATION STEPS ONLY NEEDED IF LEAK CANNOT BE ISOLATED). IF THE LEAK IS ISOLATED TO THE SPACEHAB MODULE AFTER EGRESS, THE CREW MAY REOPEN THE SPACEHAB TO PERFORM ADDITIONAL DEACTIVATION/ENTRY PREP, IF CONSUMABLES PERMIT PER RULE {A17-751}, MODULE PRESSURE INTEGRITY.
 3. FOR SPACEHAB MODULE FIRE (DEACTIVATION STEPS ONLY NEEDED IF FIRE SUPPRESSION NOT SUCCESSFUL.)
 4. DISCHARGE OF ALL HALON SYSTEM BOTTLES (EGRESS STEPS ONLY)
 5. SPACEHAB MODULE LEVEL-4 TOXIC SPILL (EGRESS STEPS ONLY)

In emergency situations (i.e., fire, depress, or toxic spill), the crew must be able to safe and isolate the module within 3 minutes. Safe return of the crew is paramount in these cases. Only payload procedures required for safe entry (restraint of penetrators, crew module egress, and hatch closure) are allowed in these time critical situations. No attempt is made to prevent damage to the module or experiments, except stowing any penetrators. Reference NSTS 18798A, MA2-96-190, "CONTINGENCY RETURN AND RAPID SAFING," memo dated January 9, 1997. The Spacehab Emergency Deactivation procedure includes steps for egress and power removal. All main AC and DC power, except PL AFT MN B, which is required to power the Spacehab water line heaters, is removed for an emergency deactivation. In some cases, Spacehab emergency egress steps are integrated into the applicable orbiter procedures (i.e., cabin leak) and Payload powerdowns, when it is appropriate. @[111501-4982A]

FLIGHT RULES

A2-330

EXTENSION DAY GROUND RULES

A. POWER LEVELS @[111501-4981E]

THE SPACEHAB AND ITS EXPERIMENTS WILL BE POWERED DOWN TO THE GREATEST EXTENT POSSIBLE (SURVIVAL POWER CONFIGURATION) AS DEFINED IN RULE {A9-357}, SPACEHAB SURVIVAL POWER CONFIGURATION. @[ED]

The amount of consumables remaining at the nominal end of flight does not allow for operations of experiments without degrading the capability of the orbiter to remain in orbit. For those cases which require that additional power be provided to allow for preservation of experiment samples/data, the consumable must be allocated preflight and thus affect the mission duration.

B. CONSUMABLES

NO SPACEHAB EXPERIMENT ACTIVITIES WHICH REQUIRE ORBITER CONSUMABLES WILL NORMALLY BE PLANNED. FLIGHT-SPECIFIC OPTIONS ARE DEFINED IN THE FLIGHT SPECIFIC ANNEX.

Extension days would generally be required only for weather, orbiter, and/or landing site problems that would benefit from extra time before landing. To prevent further complications, the Spacehab/experiments should be maintained in a safe, deactivated state. This should not impact the Spacehab/experiments since all payload activities should have already been completed by the nominal end of mission. In addition, the crew must be available to perform necessary orbiter activities to ensure a safe return.

C. SPACEHAB CONSTRAINTS ON EXTENSION DAY ATTITUDE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

-ZLV attitude will normally provide a stable thermal environment for the orbiter and Spacehab module during an extension day and is accomplished with a minimum amount of propellant for attitude maintenance. With radiators deployed, the -ZLV attitude will provide sufficient orbiter heat rejection when flying with any beta angle. With radiators stowed, the -ZLV attitude may be acceptable, or a flight-specific attitude can be determined. If a cooler attitude is required, the orbiter can execute passive thermal control (PTC) which gives the advantage of providing a consistent thermal environment for the entire vehicle. @[111501-4981E]

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH AND TUNNEL

THE SPACEHAB HATCHWAY AND TUNNEL SHALL BE FREE AND CLEAR OF OBSTRUCTION TO ENSURE THAT THE CREW IS CAPABLE OF SAFING AND ISOLATING THE MODULE WITHIN 3 MINUTES FOR AN EMERGENCY.

©[111501-4984]

Every effort shall be made to preclude routing cables through the Spacehab hatch and tunnel. In emergency situations (i.e., fire, depress, or toxic spill), the crew must be able to secure penetrators and isolate the module within 3 minutes. The hatch closure itself takes approximately 1 minute, which leaves approximately 2 minutes to safe the module and clear the hatchway. Cables, in addition to anything that may pose interference with hatch closure, are considered "drag-throughs."

IN THE EVENT DRAG-THROUGH ROUTING CANNOT BE PRECLUDED, THE FOLLOWING CRITERIA SHALL APPLY:

- A. THE ABILITY TO SAFE AND ISOLATE THE MODULE WITHIN 3 MINUTES SHALL BE RETAINED.

The 3-minute constraint is paramount for the crew to have the ability to respond to any emergency situation (i.e., fire, depress, or toxic spill) and allow the hatch to be closed regardless of whether or not drag-throughs are present across the hatchway. Tests show it takes approximately 10 seconds to break each quick disconnect (QD) by a single crewmember.

- B. IF THE DRAG-THROUGH IS NOT UNDER THE CONTROL OF A CREWMEMBER, IT SHALL BE RESTRAINED TO AVOID CREW ENTANGLEMENT WHILE TRANSLATING THROUGH THE HATCH AND TUNNEL. IF A QUICK DISCONNECT RELATED TO THE DRAG-THROUGH HAS BEEN POSITIONED IN PROXIMITY TO THE HATCH, THE RESTRAINT SHALL NOT BE LOCATED BETWEEN THE DISCONNECT AND THE HATCH.

A drag-through that is under the control of a crewmember implies short-term use and will be taken back through the hatch as a crewmember exits when circumstances dictate hatch closure. A restraint between the hatch and the quick disconnect complicates the effort to clear the hatchway and close the hatch.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH AND TUNNEL (CONTINUED)

- C. DRAG-THROUGHS SHALL NOT IMPEDE CREW NAVIGATION THROUGH THE HATCHWAY. A TRANSLATION CORRIDOR, SUFFICIENT TO ALLOW A CREWMEMBER TO PASS THROUGH THE HATCH, SHALL BE MAINTAINED.

A 32-inch minimum diameter must be maintained through the Spacehab hatch. ©[111501-4984]

- D. WHERE PRACTICAL, AND WITHIN DESIGN LIMITATIONS AND TIME CONSTRAINTS IMPOSED BY THE HARDWARE AND OPERATIONAL REQUIREMENTS, THE FOLLOWING CONSTRAINTS WILL BE IMPLEMENTED:
©[111501-4984]

1. ALL DRAG-THROUGHS ROUTED THROUGH THE SPACEHAB HATCH SHALL BE CONFIGURED WITHIN A SINGLE 90-DEGREE SECTION OF THE HATCH AS SHOWN BY THE FIGURE BELOW:

Drag-throughs should be routed within the 90-degree section of the Spacehab hatch to aid in the ability of the crew to quickly locate and remove hatch obstructions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH
AND TUNNEL (CONTINUED)

2. DRAG-THROUGHS SHOULD BE ROUTED SUCH THAT A QUICK RELEASE CONNECTOR IS LOCATED WITHIN 2 FEET ON EITHER SIDE OF THE SPACEHAB HATCH. DISCONNECT FEATURES FOR ALL DRAG-THROUGHS ROUTED THROUGH THE HATCH SHOULD BE ON THE SAME SIDE OF THE HATCH.

The quick release connector features, and constraints on having all such connectors lie within 2 feet of the Spacehab hatch and on the same side of the hatch for all drag-throughs, allows quick location and removal (tests show at 10 seconds per quick release connector) of drag-through obstruction(s) to hatch closure. @[111501-4984]

3. DRAG-THROUGHS SHOULD BE LIMITED TO NO GREATER THAN FOUR DURING CREW AWAKE TIME AND, IF LEFT IN PLACE DURING THE CREW SLEEP PERIOD, THE NUMBER OF DRAG-THROUGHS ROUTED THROUGH THE SPACEHAB HATCH AND TUNNEL SHOULD BE REDUCED TO TWO. @[111501-4984]

An operational limit of two drag-throughs across the Spacehab hatch during the crew sleep period has a better chance of accommodating the 3-minute constraint on safing and isolating the module. Limiting the number of drag-throughs to a maximum of four drag-throughs, whether temporary or permanent, will minimize the risk in not being able to meet the 3-minute rapid safing constraint.

4. IF TIME ALLOWS, PRIOR TO DEMATING AN ELECTRICAL CONNECTION EXCEEDING 32 VOLTS UPSTREAM, POWER WILL BE REMOVED.
- E. THE BPSMU IS THE ONLY DRAG-THROUGH APPROVED GENERICALLY FOR USE IN SPACEHAB. ADDITIONAL DRAG-THROUGHS MAY BE APPROVED ON A MISSION SPECIFIC BASIS AND LISTED IN THE FLIGHT SPECIFIC ANNEX.

The BPSMU meets the requirements for drag-throughs in this rule and was the only drag-through identified at the time this rule was written. It can be used nominally for communication between the Spacehab and orbiter or Spacehab and ISS when the Spacehab ACS is not available or operational. @[111501-4984]@[111501-4981E] @[111501-4962A] @[111501-4982A]

FLIGHT RULES

A2-332

LOSS OF SM GPC DURING SPACEHAB ACTIVATION/ENTRY
PREP @[111501-4981E]

- A. LOSS OF THE SYSTEMS MANAGEMENT (SM) GPC PRIOR TO ARS FAN ACTIVATION WILL REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES UNTIL THE SM GPC IS RECOVERED OR THE ARS FAN IS POWERED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS COULD BE OPERATED IN THE SPACEHAB ASCENT CONFIGURATION. @[060800-7116A]

Nominal Spacehab ARS fan activation and subsystem reconfiguration are achieved via the SM GPC. The ARS fan provides the only means for conditioned air exchange with the orbiter. Therefore, Spacehab operations must be postponed until the ARS fan can be activated. When the Spacehab is powered for ascent, the water pump and several experiment utility outlets are powered in addition to the ARS fan or Cabin/HFA fan. In the SM and LDM configurations, the ARS fan is the preferred fan to operate during ascent. In the RDM configuration, one HFA fan is preferred over the ARS fan. Spacehab RDM is always powered for ascent. Reference Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS.

- B. LOSS OF THE SYSTEMS MANAGEMENT (SM) GPC AFTER SPACEHAB ACTIVATION AND BEFORE ENTRY PREP IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES. @[111094-1733]

Spacehab activities may continue because the module remains in a good configuration for operation. Nominal reconfiguration of Spacehab subsystems during entry prep cannot be achieved without the SM GPC. Consideration will be given to leaving Spacehab equipment configured on orbiter power for entry provided orbiter resources are available. @[111501-4981E]

FLIGHT RULES

A2-333

LOSS OF PAYLOAD MDM DURING SPACEHAB ACT/ENTRY PREP

@[111501-4981E]

A. PAYLOAD MDM FAILURE

LOSS OF PAYLOAD (PL) MDM PL1, PRIOR TO ARS FAN ACTIVATION, WILL REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES UNTIL THE MDM IS RECOVERED OR THE ARS FAN IS POWERED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS COULD BE OPERATED IN THE SPACEHAB ASCENT CONFIGURATION. @[060800-7117A]

Spacehab Activation and subsystem reconfiguration are achieved via the Payload MDM 1 (PL1) and otherwise cannot be nominally performed. The ARS fan is important because it provides the only means for conditioned air exchange with the orbiter. Spacehab operations must be postponed until the ARS fan can be activated. Hard failure of PL1 will result in the inability to activate Spacehab. All Flights Rule {A7-109F}, IN-FLIGHT MAINTENANCE (IFM), specifies that a PL MDM will only be swapped to regain PLBD close capability. When the Spacehab is powered for ascent, the water pump and several experiment utility outlets are powered in addition to the ARS fan or Cabin/HFA fan. In the SM and LDM configurations, the ARS fan is the preferred fan to operate during ascent. In the RDM configuration, one HFA fan is preferred over the ARS fan. Spacehab RDM is always powered for ascent. Reference Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS.

B. LOSS OF PAYLOAD MDM PL2 DURING SPACEHAB ACTIVATION WILL NOT REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES. @[111094-1734]

Spacehab activation does not require Payload MDM PL2. @[060800-7117A]

C. LOSS OF EITHER PAYLOAD MDM, PL1 OR PL2, AFTER ACTIVATION AND BEFORE ENTRY PREP IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES.

Caution and warning parameters, which are nominally redundantly monitored by the CWEA directly and via the PL1-GPC-PL2 string, are still monitored by the CWEA if either PL MDM fails. Significant command capability, including that used during the nominal deactivation process (ARS fan, cabin/HFA fan, and water pump reconfiguration for powered entry), is lost if PL1 is lost. However, some operations may still be conducted. Safety-related redundant command capability for fire suppression still exists (Standard Switch Panel and C3A5).

D. IF A CHOICE EXISTS BETWEEN PL1 AND PL2, SPACEHAB PREFERS PL1.

The majority of MDM discrettes are through PL1. The impact of losing PL1 is greater than the impact of losing PL2. @[111501-4981E]

FLIGHT RULES

A2-334

LOSS OF SM MAJOR FUNCTION

TEMPORARY LOSS OF SM MAJOR FUNCTION AFTER SPACEHAB ACTIVATION AND BEFORE SPACEHAB ENTRY PREP IS NOT A CONSTRAINT TO CONTINUING SPACEHAB OPERATIONS IF: ©[111501-4981E]

- A. THE SPACEHAB-TO-CWEA INTERFACE IS OPERATING NOMINALLY.
- B. THE FOLLOWING SAFETY SENSORS ROUTED TO THE CWEA ARE OPERATIONAL:
 - 1. FIRE/SMOKE DETECTOR A OR B
 - 2. ARS FAN DELTA P - SENSOR 2
 - 3. (RDM ONLY) HFA FAN DELTA P - SENSOR 2

If the SM interface is down, one of two redundant methods of monitoring safety-critical parameters is lost. Module operations may continue if the CWEA is still monitoring safety parameters and the sensors feeding the CWEA (at least one fire/smoke and the ARS fan) are nominal. Note that monitoring of Spacehab parameters is still available on the ground and via the PGSC in the module. Redundancy for partial pressure of oxygen (PPO₂) and total cabin pressure is provided by the orbiter sensors via hardware caution and warning.

Loss of SM also eliminates a significant amount of command capability; however, redundant methods are still available for fire suppression. ©[111501-4981E]

FLIGHT RULES

A2-335

LOSS OF ORBITER MASTER TIMING UNIT (MTU)/PAYLOAD TIMING BUFFER

- A. LOSS OF THE MTU DURING SPACEHAB ACTIVATION OR DEACTIVATION IS NOT A CONSTRAINT TO CONTINUING SPACEHAB ACTIVITIES; HOWEVER, NOMINAL ACTIVATION/DEACTIVATION CANNOT BE PERFORMED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS CAN OPERATE IN THE SPACEHAB ASCENT/ENTRY CONFIGURATION. @[111501-4981E]

Loss of the MTU results in loss of a clock signal to the Payload Signal Processor (PSP), which causes loss of commanding to Spacehab. PSP commanding is required to perform a nominal Spacehab activation and deactivation. Operations may still be conducted in the ascent/entry configuration. If Spacehab is unpowered during ascent, operations may still be conducted using SSP and MDM commanding. @[111501-4981E]

- B. LOSS OF THE MTU AFTER SPACEHAB ACTIVATION AND BEFORE SPACEHAB DEACTIVATION IS NOT A CONSTRAINT TO CONTINUING SPACEHAB ACTIVITIES; HOWEVER, THE FOLLOWING IMPACTS OCCUR: @[111501-4981E]
1. LOSS OF PSP UPLINK COMMANDING IS DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

PSP commanding is lost when the MTU fails. All nominal uplink commanding to Spacehab subsystem equipment and to some experiments is through the PSP.

2. LOSS OF GREENWICH MEAN TIME (GMT) TIMETAG INFORMATION INSERTED BY THE DMU INTO THE PDI DATA STREAM.

The GMT timetag is inserted into the PDI data stream by the DMU for subsystem information. It is not used onboard Spacehab.

3. LOSS OF GMT AND MISSION ELAPSED TIME (MET) TO SPACEHAB EXPERIMENTS IS DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

The MTU is the only source of synchronized GMT and MET to Spacehab and experiments. This could cause degraded experiment results. @[111501-4981E]

ORBITER SYSTEMS GO/NO-GO (CONTINUED)

NOTES:

- [1] MDF FOR LOSS OF COOLING TO TWO GPC's (DUE TO UNACCEPTABLE TEMPERATURE).
- [2] PLS FOR POWERDOWN OF C&W. C&W MAY REMAIN POWERED IF IT WAS NOT THE SOURCE OF A POTENTIAL FIRE INDICATION AND IF THE AVIONICS BAY IS EXPOSED TO THE CABIN FOR USE OF THE CABIN SMOKE DETECTORS. REF RULES {A17-51A}.3, MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION, AND {A17-1001A}, LIFE SUPPORT GO/NO-GO CRITERIA. @[090894-1675] @[ED]
- [3] PLS FOR LOSS OF COOLING TO THE C&W.
- [4] ENTER NEXT PLS IF A SINGLE ELECTRICAL FAILURE (AC BUS) COULD CAUSE THE LOSS OF AIR COOLING TO AVIONICS BAYS.
- [5] ENTER NEXT PLS IF TIRE PRESSURE WILL BE \leq 275 PSIG (290 PSIA) MAINS, 260 PSIG (275 PSIA) NOSE AT NEXT PLS LANDING OPPORTUNITY PLUS 2 DAYS. @[090894-1675]
- [6] THE NUMBER OF ALTERNATE WASTE COLLECTION BAGS, NUMBER OF CREW AND THEIR DEFECATION/ URINATION RATE WILL DETERMINE EOM.
- [7] QUANTITY OF LIOH CANISTERS AND CREW SIZE WILL DETERMINE EOM. A MINIMUM OF 2 DAYS OF UNUSED LIOH MUST BE HELD IN RESERVE TO PASS A PLS OPPORTUNITY. REF. RULE {A17-157}, LIOH REDLINE DETERMINATION. @[092293-15316]
- [8] EDO PALLET TANKS ARE EXEMPT FROM THIS RULE UNLESS THE FAILURES ARE DETERMINED TO BE GENERIC.
- [9] PLS, UNLESS AT LEAST ONE CREWMEMBER REMAINS AWAKE IN ORBITER CABIN TO MONITOR SMOKE CONDITIONS AT ALL TIMES. REF RULE {A17-51B}, MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION.
- [10] ELS OR PLS IS REQUIRED BASED UPON AVAILABLE N₂ FOR O₂ CONTROL SINCE CREW MUST REMAIN ON QDM/LES IF TOXIC COMBUSTION PRODUCTS CANNOT BE SATISFACTORILY REMOVED FROM THE CABIN ATMOSPHERE. REF RULE {A13-152C}, CABIN ATMOSPHERE CONTAMINATION. FOR AV BAY FIRES, THE EXTENT OF THE DAMAGE TO EQUIPMENT AND WIRE BUNDLES IS UNKNOWN; THEREFORE, EVEN IF THE ATMOSPHERE HAS BEEN CLEANED UP, A PLS WILL BE PERFORMED TO MINIMIZE THE RISK OF THE OCCURRENCE OF AN ADDITIONAL FIRE OR ARC TRACKING.
- [11] EOM IS BASED UPON HALON EXPOSURE CRITERIA. REF RULE {A13-152}, CABIN ATMOSPHERE CONTAMINATION. @[090894-1675]
- [12] FOR A LEAKING FREON LOOP THAT WILL SUPPORT NEXT PLS BUT NOT THE FOLLOWING PLS, A PLS WILL BE DECLARED IN ORDER TO ACHIEVE A NOMINAL D/O PREP AND ENTRY. A LOSS OF ONE FREON LOOP ENTRY REQUIRES A POWERDOWN TO 14 KW. @[061396-3104A]
- [13] N/A FOR MEDS CONFIGURED VEHICLES. @[040899-2459B]
- [14] IDP'S ARE REQUIRED FOR PASS AND BFS INTERFACE AND TO DISPLAY THE ADI, AMI, AND AVVI AND HSI. @[040899-2459B] @[031500-7172D]
- [15] LOSS OF EITHER FUNCTION, DPS OR FLIGHT INSTRUMENT, IN ANY THREE SEPARATE IDP'S IS PLS.
- [16] NEXT PLS IS REQUIRED (NOT INCLUDING FIRST DAY PLS), FOR LOSS OF RADIATOR COOLING IN ONE LOOP, IF SUPPLY H₂O QUANTITIES AND MANAGEMENT PLAN WILL NOT SUPPORT THE FOLLOWING PLS WITH THE NEXT WORST FAILURE (LOSS OF THE GOOD FREON LOOP). ASSUMING WATER QUANTITIES WILL SUPPORT THE NEXT WORST FAILURE, THE MISSION MAY BE EXTENDED TO THE SUBSEQUENT PLS OPPORTUNITIES. @[050400-7192] @[092701-4865D]
- ELS WILL BE REQUIRED IF THE NEXT WORSE FAILURE OCCURS BEFORE SUPPLY WATER QUANTITIES CAN SUPPORT NEXT PLS. @[050400-7192] @[092701-4865D]
- [17] FOR FAILURES OF CONTROL BUSES AB1, AB2, BC1, BC2, CA1, OR CA2 SUCH THAT A PUBLISHED IFM WOULD RECOVER PLBD FUNCTIONS LOST WITH THE FAILED BUS, THE IFM MAY BE CONSIDERED A LEVEL OF REDUNDANCY FOR MISSION PLANNING PURPOSES. (REF RULE {A9-57}, REUSABLE FC.) @[011801-3851]
- [18] FAILURE OF CNTLAB1 RESULTS IN LOSS OF OMS X-FEED AND REPRESS CAPABILITY. A G-MEM MAY BE SENT TO REGAIN THE LOST FUNCTION. @[011801-3851]

SECTION 3 - GROUND INSTRUMENTATION REQUIREMENTS

GENERAL

A3-1

GROUND AND NETWORK DEFINITIONS

- A. MCC IS DEFINED AS THE EQUIPMENT AND FUNCTIONALITY PROVIDED BY THE JSC BUILDING 30 COMPLEX AND ASSOCIATED INFRASTRUCTURE AT JSC WHICH PROVIDES POWER, COOLING, AND COMMUNICATIONS TO BUILDING 30. @[062702-5502C]
- B. INTEGRATED NETWORK INCLUDES THE FOLLOWING:
1. THE NASA GROUND TRACKING AND DATA STATIONS AT MILA, DFRC, WLP, PDL, AND INCLUDING JDI.

Even though JDI is part of the Eastern Range operated by the USAF 45th Space Wing at the Jonathan Dickinson Missile Test Annex (JDMTA), for the purposes of this rule it is considered part of the NASA network.

2. THE SPACE NETWORK INCLUDING THE WHITE SANDS COMPLEX (WSC) FACILITY AND FUNCTIONALITY AS WELL AS THE TDRS SATELLITES.
3. GSFC FACILITIES THAT PROVIDE COMMUNICATIONS RELAY AND SCHEDULING: THE MISSION OPS SUPPORT AREA (MOSA), FLIGHT DYNAMICS FACILITY (FDF) AND THE NETWORK CONTROL CENTER (NCC) AND ASSOCIATED INFRASTRUCTURE AT GSFC WHICH PROVIDES POWER, COOLING, AND COMMUNICATIONS TO THOSE FACILITIES.
4. NASA AND USAF RADAR TRACKING SITES AS SHOWN IN THE MATRIX IN RULE {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX. @[ED]
5. COMMERCIAL LINKS CONNECTING JSC, GSFC, WSC, KSC, DFRC, ETC.
6. INTERCONNECTIVITY TO USAF RTS SITES @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-1**GROUND AND NETWORK DEFINITIONS (CONTINUED)**

- C. CRITICAL SHUTTLE FLIGHT PHASES ARE DEFINED AS LAUNCH THROUGH GO FOR ORBIT OPS OR INTACT ABORT LANDING AND GO FOR DEORBIT BURN THROUGH WHEELSTOP. @[062702-5502C]
- D. TRAJECTORY PROCESSING IS DEFINED AS THE CAPABILITY OF THE MCC TO TAKE TRAJECTORY DATA FROM VARIOUS SOURCES (RADAR TRACKING, S-BAND DOPPLER, ONBOARD INERTIAL NAVIGATION, ONBOARD GPS) AND IN REAL TIME COMPUTE CURRENT STATE AND PERFORMANCE CAPABILITY THAT ARE USED TO DETERMINE ABORT MODE CAPABILITY, MANEUVER TARGETS, AND TO MAKE OTHER MISSION CRITICAL DECISIONS. REFERENCE RULE {A3-51}, TRAJECTORY PROCESSING REQUIREMENTS. @[062702-5502C]

A3-2**GROUND AND NETWORK OVERALL PHILOSOPHY**

- A. MANDATORY REQUIREMENTS: AIR TO GROUND VOICE, COMMAND, HDR TELEMETRY, AND TRAJECTORY PROCESSING DURING CRITICAL PHASES OF FLIGHT IS MANDATORY. THE MCC AND INTEGRATED NETWORK EQUIPMENT AND ASSOCIATED SOFTWARE TO PROVIDE THESE MANDATORY FUNCTIONS MUST BE AVAILABLE AND SCHEDULED TO INITIATE A CRITICAL ACTIVITY. @[062702-5502C]

The MCC and network provide the ability to collect, process, and display the information needed to invoke mission rule decision, analyze subsystem performance to prevent failures, and to relieve the flight crew of the need to monitor subsystems in detail. Command provides the means to configure onboard systems for nominal operations as well as for anomaly resolution. Command is required to provide uplink remedies to systems problems which require off-nominal systems configurations that can be most effectively accomplished or in some cases only accomplished from the ground. A/G voice provides the means to communicate between the flight crew and the flight control team for mission activities, abort region definition, anomaly resolutions, and many other activities.

This rule states a general principle which must be understood in the light of what is technically feasible. For example, the mandatory requirement is not meant to imply that there can be no short gaps since site handovers, etc., will lead to momentary outages. Additionally, the next rule gives greater detail to parts of critical periods when longer outages can be allowed. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-2

GROUND AND NETWORK OVERALL PHILOSOPHY (CONTINUED)

B. REDUNDANCY: @[062702-5502C]

1. SCHEDULING: REDUNDANCY IN MANDATORY MCC AND INTEGRATED NETWORK FUNCTIONS SHALL BE SCHEDULED AND PLANNED TO BE AVAILABLE AT THE INITIATION OF A CRITICAL ACTIVITY.

NOTE: REDUNDANCY IS NOT REQUIRED WHEN SCHEDULING FOR THE TDRSS NETWORK.

TDRSS network redundancy is well demonstrated and tying up resources by scheduling redundant services is not required. Loss of TDRSS service has been demonstrated in practice to be very remote and emergency rescheduling using alternate equipment is very rapid. TDRSS network redundancy is based on having multiple satellites in both eastern and western locations, two independent ground stations, multiple communication paths between WSC and MCC, and full redundancy in scheduling and other supporting equipment. The TDRSS network has more users than can be scheduled so it is prudent to not explicitly schedule redundant TDRSS coverage.

2. LOSS OF REDUNDANCY: REDUNDANCY IS NOT REQUIRED TO INITIATE A CRITICAL ACTIVITY. FOLLOWING A FAILURE THAT CAUSES LOSS OF REDUNDANCY, IF FEASIBLE, THE REMAINING SINGLE STRING SHOULD BE DEMONSTRATED TO BE FUNCTIONAL PRIOR TO THE INITIATION OF A CRITICAL ACTIVITY.

It is prudent to support mission critical operations with redundancy. MCC and Network functions are by design very reliable. Operational history has demonstrated that MCC and Network functional reliability is very high. When operating on a single string of equipment that is demonstrated to be functioning, which is not annunciating an alarm or operating in an anomalous manner, there is a very low probability of failure in the short time duration of a shuttle critical phase. Unless there is direct evidence to conclude a failure is imminent on operating equipment, there is no reason to delay a critical scheduled event for failure of a redundant string. Conversely, if analysis of a failed system clearly indicates a threat to the remaining equipment, it is prudent not to initiate a critical activity if possible.

3. RECOVERY OF LOST REDUNDANCY: RECOVERY OF REDUNDANT EQUIPMENT SHOULD NOT BE ATTEMPTED IF THERE IS RISK TO THE PLANNED T=0 OR DEORBIT TIG.

Recovery of redundant equipment or function generally has a non-zero risk of operator error or other reason causing loss of the functioning, mandatory equipment string. At pre-defined times for launch or deorbit, this risk should not be incurred. @[062702-5502C]

FLIGHT RULES**A3-3****GROUND AND NETWORK DETAILED REQUIREMENTS****A. ASCENT**

1. NOMINAL ASCENT: AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING ARE MANDATORY FROM LIFTOFF THROUGH MET 15 MINUTES. FROM MET 15 MINUTES THROUGH GO FOR ORBIT OPS, IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING. ©[062702-5502C]

IN ADDITION TO MANDATORY S-BAND TWO-WAY VOICE, UHF TWO-WAY VOICE IS REQUIRED AS A BACKUP DURING LAUNCH FROM LIFTOFF THROUGH NOMINAL HANDUP TO TDRS AND IS HIGHLY DESIRABLE THROUGH MILA LOS OR UNTIL RTLS LANDING.

Redundant A/G voice is necessary for abort request and abort region calls and to rapidly convey verbal responses to observed subsystem anomalies and rule violations. The availability of both S-band and UHF ensures that SRB plume, station handovers, and most onboard and ground subsystem failures will not result in disruption of A/G voice capability causing critical calls to be missed. Early in ascent, TDRS is not thought to be acceptable due to antenna look angles, structural blockage, etc. Therefore, MILA, PDL, and JDI provide communications link capability.

The latter stages of ascent, after TDRS handup between 7 and 8 minutes MET, are supported by TDRS. The TDRS network has more user requirements than can be accommodated thus requiring priority scheduling. TDRS schedule should include uninterrupted communications through the latest underspeed MECO that occurs no later than MET 13 minutes. An additional 2 minutes to assess the situation and provide maneuver direction to the crew can be accomplished by a well-practiced MCC team. This means that TDRS scheduling should support through MET 15 minutes at a minimum.

To ensure mission success for rendezvous missions and to resolve any anomalies that may have occurred during ascent, it is prudent and highly desirable to have the maximum available communications capability through OMS-2 cutoff. Following that, to ensure timely anomaly resolution and to provide the maximum efficiency and mission success through the complex tasks of early post insertion (OPS 2 transition, opening payload bay doors, initiating radiator cooling, etc.), communications is vital. Go for Orbit Ops normally occurs at about 1 hr 30 min MET.

From the TDRS perspective, command, telemetry, and voice are either both available simultaneously or not; they are not independent. ©[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

2. RTLS, TAL: CONTINUOUS AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING ARE MANDATORY FOR RTLS OR TAL FOLLOWING ABORT DECLARATION THROUGH INTACT ABORT LANDING INCLUDING POST-LANDING. @[062702-5502C]

This requirement for TAL may be met by the use of an emergency SHO for the TDRS network since landing occurs at approximately MET 37 minutes. RTLS requirements may be covered by scheduling MILA alone. The declaration of an RTLS or TAL abort results in procedures that involve additional risk. MCC support is required and will normally be available throughout the RTLS or TAL. This increased insight into systems performance and additional expertise significantly increases the probability of a successful landing with a vehicle that has already had a major systems failure. A/G voice is required to coordinate any recommendations to the crew and to relay to the crew final weather, runway, landing aid, and major systems status.

3. ATO, AOA: FOR THE PERIOD FROM MET 15 MINUTES THROUGH LANDING FOR AOA OR LANDING FOR FIRST DAY PLS OR THROUGH GO FOR ORBIT OPS FOR ATO, IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING.
4. ASCENT TRAJECTORY PROCESSING SUPPORT:
 - a. ASCENT RADAR TRACKING: DUAL TRACKING IS HIGHLY DESIRABLE FROM EITHER ONE S-BAND AND ONE C-BAND, OR TWO C-BANDS FROM LIFT-OFF THROUGH MECO PLUS 1 MINUTE.

Dual source tracking is desired to allow monitoring of the health of onboard navigation during powered flight, to provide delta state uplink capability to correct extreme onboard navigation errors which could result in unsafe or mission-limiting MECO conditions for an ascent to orbit or an RTLS, and to provide an independent ground navigation source for ascent performance boundary calls. To obtain an accurate post-MECO ground filter vector, a minimum of 1 minute of tracking post-MECO is required for processor convergence. An accurate post-MECO ground filter vector may be used to update onboard navigation before OMS-2 if required to significantly decrease delta-V cost due to planar error for ground-up rendezvous flights, or before OMS-1 or OMS-2 if the gain in delta-V capability would prevent ascent capability downmoding. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

Ground tracking through MECO+1 is highly desirable rather than mandatory because flight history and Mean Time Between Failure (MTBF) data show that the probability of either software or hardware failures corrupting onboard navigation during ascent are extremely small. MTBF studies for the HAINS IMU's, GPC's, and MDM's indicate a probability of loss of two IMU's to be on the order of 10^{-10} . Although recovery of corrupted onboard navigation by means of a powered flight delta state is theoretically possible, and would be attempted if required, success at all times during the ascent is not a certainty. With regard to onboard navigation errors which are not large enough to pose a safety concern, but which could affect the mission, the history of post-MECO state vector updates shows that although there are worthwhile paybacks in propellant margin, their absence would not adversely impact propellant budgets. For these reasons, ground tracking requirements through MECO for due east launches were abandoned by the shuttle program as a cost savings measure. Ground tracking through MECO +1 is only available for high inclination launches. ©[062702-5502C]

Upon removal of the Range Safety destruct package from the external tank, the flight crew/MCC assumes responsibility for public safety during second stage. The tracking navigation state precludes limit line violation due to severe onboard navigation problems (state vector update or manual MECO) and prevents loss of External Tank Impact Point prediction due to telemetry loss/data dropouts. At the existing limits of ground tracking, ET IP no longer endangers North American landmasses or islands.

Ground radar tracking is only highly desirable for NASA purposes during the early phases of ascent as shown by the table in Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX. Note that the Eastern Range has a more constraining requirement. If all east coast radars are functioning, for high inclination launches radar tracking can be extended to nominal MECO +1 minute. For low inclination launches, radar tracking is lost prior to 8 minutes MET. It is desirable to have ground radar verification of the MECO state. ©[ED]

- b. RTLS ENTRY RADAR TRACKING: TRACKING IS HIGHLY DESIRABLE FROM EITHER ONE S-BAND AND ONE C-BAND, OR TWO C-BANDS FROM RTLS MECO TO 100K FEET.

The TSU trajectory processor Kalman filter cannot meet ground accuracy requirements with only one source of tracking data; the filter requires at least two sources. The 100k feet altitude constraint was chosen to allow sufficient time to assess the vehicle energy conditions and to update onboard navigation state (after nominal TACAN acquisition) in order to correct a violation of delta state limits. Dual tracking capability also allows time to GCA to within guidance limits prior to TAEM. ©[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

- c. AOA/PLS: DUAL TRACKING CAPABILITY ABOVE 100K FEET IS HIGHLY DESIRABLE BUT IS NOT SCHEDULED FOR AOA AND PLS DEORBIT. @[062702-5502C]

In the event that a delta state is uplinked, it allows proper onboard verification to be performed through 100k feet (tracking not required below 100k feet).

- d. FD1 PLS ONLY: AT LEAST ONE TDRS OR TWO C-BAND RADAR PASSES ARE REQUIRED TO SUPPORT PRE-DEORBIT STATE VECTOR ACCURACY.

For AOA and PLS deorbits, best effort call up of high speed tracking resources is accepted (ref. Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). The time between launch and landing for an AOA deorbit is short enough to consider onboard navigation autonomous, and although best effort tracking call up will be requested, it is not mandatory. There is a high probability of obtaining PLS tracking support from KSC or EDW area radars on a best effort basis if the ranges are given more than 3 hours advance notice. There is little chance of obtaining such support for a NOR PLS deorbit unless the request is made during duty hours. Tracking support is virtually assured at all three CONUS sites, given 24 hours notice (ref. AEFTP #82 minutes). @[ED]

Post MECO tracking is required for flight day 1 deorbit cases in order to ensure the onboard state vector meets deorbit burn accuracy requirements. For high inclination launches (57 deg and 51.6 deg), at least one TDRS is required for orbit 3 cases, because the ground tracks for orbits 1 through 3 do not permit adequate C-Band coverage (ref. Rules {A4-101}, ONBOARD NAVIGATION MAINTENANCE, and {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX - Note [2]). @[ED]

- e. FOR COMMIT TO LAUNCH AND SCHEDULING PURPOSES, EOM DUAL TRACKING CAPABILITY (TWO C-BANDS OR ONE S-BAND AND ONE C-BAND) FROM ABOVE 100K FEET TO THE GROUND IS NOT MANDATORY. IF ANY OF THE CAPABILITIES LISTED IN PARAGRAPH B3 BELOW ARE NOT EXPECTED TO BE AVAILABLE PRIOR TO DEORBIT TIG, SCHEDULING EOM DUAL TRACKING BECOMES MANDATORY. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)

5. REDUNDANCY FOR ASCENT INCLUDING INTACT ABORTS:

@[062702-5502C]

- a. REDUNDANCY IN EQUIPMENT AND NETWORK SCHEDULING FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING SHALL BE PLANNED AND SCHEDULED FOR LAUNCH THROUGH GO FOR ORBIT OPS OR INTACT ABORT LANDING. NOTE: FOR TDRS SCHEDULING REDUNDANCY IS NOT REQUIRED.
- b. CONSIDERATION WILL BE GIVEN TO ATTEMPTING TO REGAIN FAILED REDUNDANT EQUIPMENT IF THE RECOVERY WILL NOT AFFECT THE REMAINING MANDATORY EQUIPMENT AND RECOVERY PROCEDURES ETRO IS PRIOR TO THE NOMINAL PLANNED TIME FOR COMING OUT OF THE T-9 MINUTE HOLD.
- c. RECOVERY EFFORTS FOR FAILED REDUNDANT EQUIPMENT IN THE MCC AND INTEGRATED NETWORK WILL NOT BE PERFORMED BETWEEN T-9 MINUTES AND COUNTING AND MET 15 MINUTES OR LANDING FOR RTLS OR TAL.

B. DEORBIT/ENTRY

1. PRE-DEORBIT: IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING FROM TIG-4 HR TO DEORBIT DECISION. REDUNDANCY IS DESIRABLE BUT NOT REQUIRED.

Preparing the orbiter for entry includes a number of complex and critical steps such as moding flight software to OPS 3, closing the payload bay doors, activating FES cooling. Having MCC connectivity troubleshoot any anomalies that may occur is very useful. Additionally, MCC is prime to provide deorbit maneuver targets and to assess landing site readiness including weather. Deorbit decision time is normally TIG - 23 minutes. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS (CONTINUED)

2. DEORBIT DECISION: GROUND AND INTEGRATED NETWORK EQUIPMENT FUNCTIONALITY AND SCHEDULING MUST PROVIDE AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING FROM THE MCC GO FOR DEORBIT TO POST LANDING. REDUNDANCY FOR MANDATORY FUNCTIONS IS HIGHLY DESIRABLE BUT NOT REQUIRED. @[062702-5502C]

UHF TWO-WAY VOICE IS HIGHLY DESIRABLE DURING ENTRY TO KSC OR DFRC WHEN IN RANGE OF THE GROUND STATION AS A BACKUP TO S-BAND VOICE. S-BAND VOICE IS MANDATORY AS DESCRIBED ABOVE.

Monitoring vehicle systems, energy management, anomaly resolution, and landing site evaluation from touchdown parameters to weather conditions is the primary job of the MCC during shuttle entry.

3. TRAJECTORY PROCESSING SUPPORT FOR ENTRY:

IF ALL OF THE CAPABILITIES LISTED BELOW ARE EXPECTED TO BE AVAILABLE PRIOR TO DEORBIT TIG, C-BAND TRACKING IS NOT MANDATORY. S-BAND TRACKING IS HIGHLY DESIRABLE IN THE ABSENCE OF C-BAND TRACKING. IF DURING THE MISSION ANY OF THE FOLLOWING CAPABILITIES ARE LOST, EOM DUAL TRACKING CAPABILITY BECOMES MANDATORY FOR COMMIT TO DEORBIT:

- a. IMU'S: FULL REDUNDANCY (THREE LRU'S AND ASSOCIATED DPS AND EPS FUNCTIONALITY).
- b. ONBOARD TACAN: AT LEAST TWO-FAULT TOLERANCE IN THE TACAN/GPS SYSTEM AND ASSOCIATED DPS AND EPS FUNCTIONALITY) (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). @[092602-5641]
- c. ONBOARD MLS: FULL REDUNDANCY (THREE LRU'S AND ASSOCIATED DPS AND EPS FUNCTIONALITY) REQUIRED IF MLS IS REQUIRED FOR LANDING (REF. RULE {A3-202}, MLS). @[062702-5502C] @[092602-5641]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)

- d. GROUND TACAN STATIONS: TWO STATIONS AVAILABLE AND CONFIRMED OPERATIONAL WITHIN SPECIFICATIONS (REF. RULE {A8-52B}.2, SENSOR FAILURES), OR ONE STATION AVAILABLE AND CONFIRMED OPERATIONAL WITHIN SPECIFICATIONS (REF. RULE {A8-52B}.2, SENSOR FAILURES) WITH A GPS LRU FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). FAA/USAF SPECIFICATIONS ARE NOT ADEQUATE (REF. NSTS 07700, VOL X, BOOK 3, PARAGRAPH 1.3.1.1.1). ©[062702-5502C] ©[092602-5641]

In order to maximize launch probability by alleviating C-Band tracking data scheduling conflicts with the Eastern Range Operations Control Center (ROCC), the mandatory requirement for scheduling dual source high speed tracking for EOM is eliminated, provided that sufficient redundancy is available (TACAN/GPS and IMU) to correct the navigation state prior to violation of entry guidance limits. If sufficient redundancy is lost during the mission, dual source high-speed tracking becomes mandatory for commit to deorbit. The TSU trajectory processor Kalman filter cannot meet ground accuracy requirements with only one source of tracking data. The filter requires at least two sources. The 100k feet altitude constraint was chosen to allow sufficient time to assess the vehicle energy conditions and to update onboard navigation state (after nominal TACAN acquisition) in order to correct a violation of delta state limits. This requirement also allows time to GCA to within guidance limits prior to TAEM. ©[062702-5502C]

With three functioning IMU's and the associated DPS/EPS equipment, the first failure is fully protected by redundancy management. When two IMU's are available, 95 percent of the cases involving the second failure are properly resolved by the IMU RM which uses the IMU BITE logic.

With three functioning onboard TACAN transceivers and their associated DPS equipment, the first failure is fully protected by redundancy management. When two TACAN's are available, 90 percent of the cases involving the second failure are covered with TACAN self-test. GPS provides additional redundancy to the onboard TACAN transceivers (particularly at the TACAN 1-LRU level) assuming that the conditions in Rule {A8-115}, GPS SYSTEM MANAGEMENT, are satisfied. ©[092602-5641]

With three functioning onboard MLS transceivers and their associated DPS equipment, the first failure is fully protected by redundancy management. When two MLS's are available, a dilemma between the LRU's will remain unresolved unless a BITE had been previously set against one of the LRU's. If the dilemma is unresolved, MLS may not process at all (for range/azimuth dilemmas) or only partially process (for elevation dilemmas). For days when MLS is required, as defined in Rule {A3-202}, MLS, ground tracking is required to resolve dilemmas in order to make the MLS useable. Reference Rule {A8-18A}, LANDING SYSTEMS REQUIREMENTS. ©[062702-5502C] ©[092602-5641]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS (CONTINUED)

To ensure that valid TACAN data are available, both primary and secondary ground stations must be confirmed to be within programmatically required limits (NASA operational requirements of 1 deg and 0.3 mile per Rule {A8-52B}.2, SENSOR FAILURES, rather than FAA/DOD certification (2.5 deg and 0.5 mile per NSTS 07700, Vol X specification)). With the pre-deorbit ground station checks, full single fault tolerance exists. If both the primary and the secondary ground station were to fail after deorbit, the MCC can uplink another TACAN station. ©[062702-5502C] ©[092602-5641]

If GPS is functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT), then the following failures will result in requiring high speed tracking for EOM

- a. *Any failure in either the onboard IMU's or MLS LRU's.*
- b. *Loss of two-fault tolerance in the GPS/TACAN system.*
- c. *No TACAN ground stations available.*

If GPS is NOT functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT), then the following failures will result in requiring high speed tracking for EOM:

- a. *Any failure in either the onboard IMU's, TACAN's, or MLS LRU's.*
- b. *Only 1 TACAN ground station available. ©[092602-5641]*

S-band data is highly desired because it may provide insight in the case of a TACAN bias, although it cannot by itself be used as a source of "ground truth."

In relaxing the tracking data requirement from mandatory to highly desirable, it is understood and acknowledged to be an acceptable risk to rely totally on TACAN and GPS as required to achieve a safe landing. If the normal ceiling limit exists, and TACAN data is not processed by navigation, and no independent valid tracking data are present, the vehicle is unlikely to achieve the runway unless GPS is incorporated. ©[092602-5641]

4. POST LANDING: GROUND EQUIPMENT WILL PROVIDE FOR AIR TO GROUND VOICE, COMMAND, AND TELEMETRY FROM LANDING UNTIL VEHICLE HANDOVER TO GOM. REDUNDANCY IS NOT REQUIRED.
©[062702-5502C]

- F. ENTRY PROFILE PROCESSING - MANDATORY
- G. COMMAND/TRAJECTORY INTERFACE PROCESSING - MANDATORY
- H. TRAJECTORY/TELEMETRY AND TELEMETRY/TRAJECTORY INTERFACE PROCESSING - MANDATORY
- I. HIGH SPEED ENTRY RGO AND TAEM PROCESSING - MANDATORY FOR LAUNCH AND LANDING @[022802-5198]
- J. RENDEZVOUS TARGETING PROCESSING - MANDATORY FOR RENDEZVOUS FLIGHT @[061396-4005A]
- K. LAUNCH WINDOW/LAUNCH TARGETING PROCESSING - MANDATORY UNTIL THE LAUNCH TARGET COMMANDS HAVE BEEN GENERATED. THIS ONLY APPLIES TO GROUND-UP RENDEZVOUS AND INERTIALLY TARGETED FLIGHTS. @[061396-4005A]

All mandatory trajectory processing is required to be operational prior to launch, including support processors as well. Any loss of trajectory processing will be assessed in real time in order to determine applicability of the lost capability to the flight at hand.

- L. DOLILU STRUCTURAL LOADS AND TRAJECTORY ANALYSIS TOOLS - MANDATORY UNTIL THE DOLILU I-LOAD HAS BEEN TRANSFERRED INTO THE MCC COMMAND SYSTEM; THEREAFTER, HIGHLY DESIRABLE (REF. RULE {A4-4}, DOLILU OPERATIONS). @[091098-6622C]

DOLILU and Loads assessments are nominally run concurrently by JSC and USA/Systems Integration. In the event that JSC fails to complete analysis after the MCC I-load transfer, USA/Systems Integration becomes prime for providing the remaining prelaunch assessments. This contingency condition is considered acceptable to proceed based on the joint system checkouts that have occurred (L-3 week, L-2 day, and completed launch day verifications). @[091098-6622C]

- M. DESCENT DESIGN SYSTEM (DDS) - MANDATORY @[061396-4005A] @[022802-5198]

FLIGHT RULES

A3-52

MCC INTERNAL VOICE

LOSS OF INTERNAL VOICE LOOPS FD, A/G 1, OIS 232 AND FLIGHT CONTROL OFFICER (FCO), WOULD NOT CAUSE A LAUNCH HOLD BECAUSE OF SUFFICIENT AVAILABLE WORKAROUNDS:

A. MCC FLIGHT CONTROL TEAM COORDINATION CAPABILITY - ONE OF THREE MANDATORY:

1. FD
2. AFD CONF
3. LOOP CONFERENCING

One common voice loop between all MCC flight control team members is required for expedient communication of system conditions/anomalies.

B. A/G TALK CAPABILITY - TWO OF FOUR MANDATORY:

1. A/G 1
2. A/G 2
3. A/G UHF
4. OTHER LOOP WITH KEYING CAPABILITY

Two MCC voice loops with keying capability are required to provide continuous S-band A/G and UHF A/G (ref. Rule {A3-1A}.1.d, GROUND AND NETWORK DEFINITIONS). ©[ED]

C. COMMUNICATIONS INTERFACE WITH LAUNCH TEST DIRECTORS - ONE OF FOUR MANDATORY:

1. OIS 131
2. OIS 232
3. FD (EXTENDED TO LAUNCH SITE)
4. OTHER LOOP PATCHING TO LAUNCH SITE

One MCC voice loop (extended to launch site long lines) is required to call an MCC-initiated countdown hold.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-52

MCC INTERNAL VOICE (CONTINUED)

D. COMMUNICATIONS INTERFACE WITH FCO - TWO OF FOUR MANDATORY:

@[101096-4550]

1. FCO PVT LINE
2. FD (EXTENDED TO FCO)
3. FCO PRIME
4. OTHER LOOP PATCHING TO FCO LONG LINE

A minimum of two MCC voice loops, extended to the Eastern Range 45th Space Wing, are required for FD and FDO voice communication with the FCO. Removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety during second stage flight, with crew-initiated manual MECO replacing range safety command destruct capability. Redundant FCO/MCC communications is therefore mandatory to provide the interaction and situational awareness necessary to implement this requirement. @[101096-4550]

Rules {A3-151C} and D, MCC/KSC/45 SPW INTERFACE, reference this rule.

E. COMMUNICATIONS CAPABILITY WITH REQUIRED ASCENT ABORT SITES -
1 OF 3 MANDATORY: @[111094-1716A] @[ED]

1. LONGLINE (LFP1)
2. INMARSAT
3. COMMERCIAL TELEPHONE

Prelaunch, the MCC must be able to communicate with the required ascent abort landing sites (ref. Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS). This insures that there has not been a change in weather or nav/landing aid status. It also insures that anomalies can be passed to the ground support team and that the runway and airspace are clear for a safe landing. This can be accomplished by insuring that at least one of the communications capabilities listed above are available. @[111094-1716A]

@[051697-6008A]

FLIGHT RULES

A3-53

MCC POWER

A. BUILDING 30M POWER BUSES @[061396 4006A]

BUS A1, A2, B1, B2 - THREE OF FOUR MANDATORY.

All mandatory MCC equipment can be configured to operate on any three of the four power buses. Equipment which cannot tolerate a 20-second power outage is configured on bus A1 or A2. These buses are supported with online UPS (uninterrupted power supply) (critical A power) during ascent. Equipment which can tolerate a 20-second power outage is configured on bus B1 or B2. These buses are supported with backup offline (20-second startup) diesel generators (critical B power) during ascent. @[061396 4006A]

B. BUILDING 30S POWER BUSES

1. POWER BUSES AX1, AX2 - ONE OF TWO MANDATORY.
(SEE NOTE #1)

NOTE #1: IF ONLY ONE POWER BUS IS AVAILABLE, IT MUST HAVE A NON-INTERRUPTIBLE POWER SUPPLY (EITHER UPS OR A RUNNING DIESEL) FEED.

2. POWER BUSES BX1, BX2 - ONE OF TWO MANDATORY.

3. POWER BUSES CX1, CX2 - ONE OF TWO MANDATORY
(SEE NOTE #2)

NOTE #2: MANDATORY FOR FLIGHTS WITH POCC WORKSTATION REQUIREMENTS ONLY; SEE THE FLIGHT SPECIFIC ANNEX.
@[061396-4006B]

All equipment on the A and B buses can be configured entirely onto either single bus, with each capable of carrying the entire load. The AX1 and AX2 buses are supported with UPS (uninterrupted power supply). The BX1 and BX2 buses are backed up with diesels (20-second startup).

The AX buses provide power for most mandatory technical equipment and emergency lighting in the MCC. The BX buses provide power to IPS system, utility outlets, AX1 and AX2 uninterruptible power supplies, and back-up power feed to the AX buses in case of a UPS failure. The CX buses provide power to the third floor POCC consoles.

MCC POWER (CONTINUED)

C. BUILDING 30S AIR HANDLERS @[061396-4006A]

1. SOFT AIR HANDLERS - ONE OF THREE MANDATORY
2. HARD AIR HANDLERS - ONE OF THREE MANDATORY

The hard air handlers provide cooling to the FCR, SVO, GOSR, CDE and fifth floor areas of building 30S. The soft air handlers provide cooling to all other areas not supplied by hard air handlers. One of each type air handler is required to adequately provide cooling for mission essential hardware and personnel. @[061396 4006A]

45 SPW/GSFC/STDN PRELAUNCH REQUIREMENTS

A3-101

GSFC

A. MESSAGE SWITCHES - ONE OF TWO MANDATORY @[121593-1582]

These computers route mandatory telemetry, command, tracking and configuration data between MCC and tracking stations. Each message switcher can handle the total traffic rate.

B. NETWORK CONTROL CENTER (NCC) COMPUTERS - ONE OF TWO MANDATORY
@[121593-1582] @[051697-6008A]

For TDRSS to support TAL aborts, acquisition data must be generated and sent to WSGT for TDRS pointing. The NCC computers and associated equipment manage this acquisition message data for forwarding to WSGT.

FLIGHT RULES

MCC EXTERNAL INTERFACE (VOICE DATA) PRELAUNCH REQUIREMENTS

A3-151

MCC/KSC/45 SPW INTERFACE

- A. 7.2-KB LAUNCH/LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE. @[061297-6004]

These circuits provide launch/landing C-band tracking data from 45 SPW/CCC to the MCC. These are redundant circuits providing backup capability; each one capable of carrying the total traffic. @[061297-6004]

- B. 9.6 KB WIND DATA CIRCUIT - ONE OF TWO MANDATORY. @[ED]

NOTE: CHANGES TO HD AFTER STRUCTURAL GO/NO-GO DECISION IS MADE. @[ED]

These circuits support processing of ascent structural loads. There are two redundant circuits providing backup capability; each one capable of carrying the total traffic.

- C. 9.6 KB FCO ABORT SWITCH INTERFACE CIRCUITS - ONE OF TWO MANDATORY @[101096-4551] @[110900-3701]

Removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety during second stage flight. During this timeframe, crew-initiated manual MECO replaces range safety command destruct capability. One of the elements agreed upon to satisfy this requirement is to provide the FCO with the ability to illuminate the orbiter cockpit abort light via pushbutton as an independent method for the FCO to communicate a manual MECO requirement to the crew.

The Launch Commit Criteria states that at least one of two FCO abort light command paths must be available until T-10 seconds. A path consists of one abort switch circuit connected to one of three MCC workstations (FD WFCR-28, FDO WFCR-10, and SVO-9) to enable FCO abort light commanding through the MCC Command System. Ref. Rule {A3-2}, GROUND AND NETWORK OVERALL PHILOSOPHY. The two external FCO abort circuits and the MCC-internal lines to the three workstations go to a patch panel to allow any combination of one abort circuit and one workstation to complete an FCO abort light path. @[110900-3701] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-151

MCC/KSC/45 SPW INTERFACE (CONTINUED)

D. FCO INTERFACES:

1. VOICE INTERFACE - TWO OF FOUR MANDATORY:
 - a. FDO/FCO PRIVATE LINE
 - b. FCO PRIME LOOP
 - c. FD LOOP
 - d. OTHER LOOP PATCHING TO FCO LONG LINE
2. CONTROLLABILITY VERIFICATION - TWO OF FIVE MANDATORY:
 - a. 45 SPW RANGE SAFETY TELEMETRY DISPLAY SYSTEM (RTDS)
 - b. CONTROLLABILITY LIGHT (GNC CONSOLE TO FCO)
 - c. FCO PRIME LOOP
 - d. FDO/FCO PRIVATE LINE
 - e. FD LOOP

During second stage flight, removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety, with crew-initiated manual MECO replacing range safety command destruct capability. Redundant FCO/MCC communications are therefore mandatory to provide the interaction and situational awareness necessary to implement this requirement. ©[101096-4551]

During first stage, range safety mission rules outline flight termination criteria and provide the FCO with the ability to determine shuttle controllability status in the event of complete loss of communication with MCC. For purposes of making the controllability determination, range safety launch commit criteria require at least two pathways by which vehicle control status may be confirmed. The available sources include the items listed under paragraph D.2 of this rule. ©[101096-4551]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-151

MCC/KSC/45 SPW INTERFACE (CONTINUED)

E. KSC TEST DIRECTORS VOICE INTERFACE - ONE OF THREE MANDATORY:

1. OIS 131
2. OIS 232/212
3. FD

NOTE: OIS 232 IS USED PRIOR TO T MINUS 20 MINUTES AND OIS 212 IS USED AFTER T MINUS 20 MINUTES AS THE PRIMARY VOICE COMMAND CHANNEL.

Same rationale as Rule {A3-52}, MCC INTERNAL VOICE.

FLIGHT RULES

A3-152

GSFC/STDN INTERFACE

A. SITE TO GSFC:

1. MIL/PDL ONLY 224-KB CIRCUIT - ONE OF TWO MANDATORY.
@[072398-6565A]

One of two redundant circuits is required to support mandatory telemetry from MIL/PDL. Reference Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX, for mandatory site requirements and Rules {A3-1A}.1.b and {A3-1A}.2, GROUND AND NETWORK DEFINITIONS, for HDR/LDR telemetry requirements. @[ED]

2. MIL 9.6-KB S-BAND HIGH SPEED TRACKING DATA CIRCUIT - HIGHLY DESIRABLE. @[061297-6004] @[072398-6565A]

This circuit supports high speed S-band tracking data from MIL.

3. 224-KB CIRCUITS: @[061396-3198]

DFRF - ONE OF ONE MANDATORY. @[092398-6565A] @[ED]

NOTE: MANDATORY ONLY WHEN THE SITE IS THE ONLY SOURCE FOR LANDING TELEMETRY (REF. RULE {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). @[ED]

One circuit is required from each site which is mandatory for telemetry.

B. GSFC TO SITE:

1. 224-KB/56-KB VOICE/COMMAND CIRCUITS, MIL/PDL ONLY - ONE OF TWO MANDATORY. @[061396-3198] @[072398-6565A]

The prime voice command circuit from GSFC to MIL/PDL is a 224-kb line, with a 56-kb circuit as backup. The circuit is required to provide uplink command and voice.

2. UHF ANALOG A/G VOICE CIRCUITS: @[061396-3198]

MIL - ONE MANDATORY

MIL is the only site which UHF A/G and S-band A/G are both mandatory (ref. Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). The UHF A/G must be sent to GSFC/STDN via analog circuits. @[072398-6565A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-152 **GSFC/STDN INTERFACE (CONTINUED)**

3. DFRF 224-KB COMMAND/VOICE CIRCUIT - ONE OF TWO MANDATORY.
 @[072398-6565A] @[ED]

NOTE: MANDATORY ONLY WHEN DFRF IS THE ONLY SOURCE FOR
 LANDING COMMAND OR S-BAND VOICE (REF. RULE {A3-102},
 INTEGRATED NETWORK FAILURE DECISION MATRIX). @[ED]

This circuit provides the data path for command and S-band voice from GSFC to DFRF.

4. WLPS 224 - KB CIRCUIT @[061396-3198] @[072398-6565A]

WLPS TLM/CMD/VOICE MANDATORY PER RULE {A3-102}, INTEGRATED
NETWORK FAILURE DECISION MATRIX. @[121593-1579] @[ED]

A3-153 **45 SPW/VAFB INTERFACE**

9.6-KB LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE.
@[061297-6004] @[ED]

NOTE: ONLY USED FOR EDW AOA/PLS. @[ED]

This circuit supports high speed tracking data from the west coast for EDW AOA/PLS. @[061297-6004]

A3-154 **45 SPW/WSMR INTERFACE**

2.4-KB LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE.
@[061297-6004] @[ED]

NOTE: ONLY USED FOR NOR AOA/PLS. @[ED]

This circuit supports high speed tracking data from WSMR for NOR AOA or daily prime opportunity.
@[061297-6004].

FLIGHT RULES

A3-155 MCC/GSFC/NGT INTERFACE

WB MDM NETWORK (BROADCAST MODE) - ONE OF TWO MANDATORY.

The MCC/GSFC and MCC/NGT satellite data links (WB MDM networks) provide the data interface for the GSTDN and TDRSS networks, respectively. Mandatory telemetry, command, S-band track, and S-band voice are routed via these links. There are two completely redundant MDM systems to provide backup capability. One of two is required to provide mandatory data.

A3-156 MCC/ASCENT ABORT SITE INTERFACE

COMMUNICATIONS CAPABILITY WITH REQUIRED ASCENT ABORT SITES - ONE OF THREE MANDATORY: @[111094-1716A]

- A. LONGLINE (LFP1)
- B. INMARSAT
- C. COMMERCIAL TELEPHONE

Prelaunch, the MCC must be able to communicate with the required ascent abort landing site, (ref. Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS). This insures that there has not been a change in weather or nav/landing aid status. It also insures that anomalies can be passed to the ground support team and that the runway and airspace are clear for a safe landing. This can be accomplished by insuring that at least one of the communications capabilities listed above are available. @[111094-1716A]

A3-157 THROUGH A3-200 RULES ARE RESERVED

FLIGHT RULES

NAVAIDS REQUIREMENTS

A3-201 TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY

A. REDUNDANCY REQUIREMENTS @[020196-1807B]

1. REDUNDANT TACAN TRANSPONDER CAPABILITY IS MANDATORY FOR LAUNCH COMMIT AT THE FOLLOWING SITES:
 - a. RTLS
 - b. PRIMARY TAL IF REQUIRED
 - c. AOA IF REQUIRED
 - d. FIRST DAY PLS IF REQUIRED (ETRO FOR EQUIPMENT OUTAGE MUST BE PRIOR TO DEORBIT DECISION)

NOTE: REF RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS FOR ABORT SITE LAUNCH COMMIT REQUIREMENTS.

2. REDUNDANT TACAN TRANSPONDER CAPABILITY IS MANDATORY FOR PLS (OTHER THAN FIRST DAY PLS), MDF, AND END OF MISSION DEORBIT COMMIT (REF RULE {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS).
3. THE REDUNDANT TACAN TRANSPONDER REQUIREMENT CAN BE SATISFIED BY ONE GROUND STATION WITH DUAL STRING (DS) TRANSPONDERS, BY TWO STATIONS WITH SINGLE-STRING (SS) TRANSPONDER CAPABILITY, OR BY ONE GROUND STATION WITH SINGLE-STRING (SS) TRANSPONDER CAPABILITY AND A GPS LRU FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). @[020196-1807B] @[092602 5642]

Rules {A2-2}, ABORT LANDING SITE REQUIREMENTS, and {A2-1F}.3, PRELAUNCH GO/NO-GO REQUIREMENTS, reference this rule. @[121593-1590]

Landing site selection will be based on priorities specified in Rule {A2-207}, LANDING SITE SELECTION. @[022201-3857]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A3-201****TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY (CONTINUED)**

GPS provides acceptable redundancy to a TACAN ground station that has only a single-string transponder. In the event that the single-string transponder becomes unavailable, the onboard GPS LRU will provide a means to keep the onboard state vector within the Guidance constraints. This is contingent upon GPS functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT).

©092602-5642]

Landing sites and TACAN's are loaded in the onboard software and can be changed in OPS 1/6/3. Uplink of an acceptable alternate TACAN may be performed to meet redundancy requirements for OPS 6/3 entries. TACAN requirements for EOM and other landing opportunities are not considered in the decision to launch. ©[020196-1807B] ©[022201-3857]

RTLS

TACAN processing is required to protect the guidance-imposed navigation entry constraints for an RTLS. An offline analysis that assumed a launch on time using IMU's and ADTA with nominal performance characteristics and random noise showed that 3-sigma navigation performance violated the entry guidance constraints of downtrack and crosstrack at altitudes of 85k feet and 40k feet, respectively.

TAL (IF REQUIRED) ©[121593-1590]

TACAN is required to protect against navigation dispersions for TAL because neither delta state nor GCA is available without ground tracking. TACAN is the primary source to correct downtrack and crosstrack errors in the navigation state. ©[020196-1807B]

Redundant TACAN transponder capability near the selected TAL site is mandatory for launch to provide adequate navigation. If weather conditions are unacceptable at the primary TAL site, then redundant TACAN transponder capability becomes mandatory near the secondary site.

AOA/FIRST DAY PLS (IF REQUIRED)

Although an AOA landing site is not normally required for launch commit (ref. Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS), the TACAN requirements are shown in the event that an AOA site is required. Redundant TACAN transponder capability is required for the primary AOA landing site only. The navigation state conditions are worse for AOA compared to RTLS or TAL because the vector is 1 hour older and the vehicle requires one or two OMS burns. For a first day PLS, the site may be considered go if equipment outage resulting in less than single-fault tolerance has an ETRO prior to deorbit decision time. ©[121593-1590] ©[020196-1807B]

- B. IN GENERAL, PROGRAM APPROVED TACAN'S (LISTED BELOW FOR END OF MISSION AND INTACT ABORT SITES; NOT IN ORDER OF PRIORITY) THAT MEET THE CRITERIA IN PARAGRAPH C WILL BE USED TO MEET THE REDUNDANCY REQUIREMENTS. CONSIDERATION WILL BE GIVEN TO OTHER TACAN'S THAT MEET THE CRITERIA IN PARAGRAPH C IF THEY PROVIDE A NAVIGATION IMPROVEMENT OVER AN APPROVED TACAN. ©[020196-1807B]

 - ROTA, AOG (DS) @[020196-1807B]
7. ZARAGOZA: @[020196-1807B]
 - ZARAGOZA, ZZA (DS)

Program approved TACAN's refer to those TACAN's listed in NSTS 07700, Volume X, Book 3, controlled by the PRCB, approved by the SASCB for use in the onboard I-loads, or contained in this flight rule. When selecting an alternate TACAN station to meet redundancy requirements, priority will generally be given to program approved TACAN's that meet the criteria in paragraph C. If no program approved TACAN's meet the criteria or other TACAN's that meet the criteria provide a navigation improvement, non-program approved TACAN's may be used to meet the redundancy requirements. Note that in most cases, there will be no program approved alternate TACAN station since both NSTS 07700 and the onboard I-loads only include a primary and secondary TACAN for each site. @[022201-3857]

C. ALTERNATE TACAN'S THAT SATISFY THE FOLLOWING CRITERIA (NOT IN PRIORITY ORDER) MAY BE UPLINKED IN OPS 1/3 TO MEET THE REDUNDANCY REQUIREMENTS IN PART A. @[022201-3857]

NOTE: THESE CRITERIA APPLY TO GROUND STATIONS REQUIRED FOR LAUNCH COMMIT AND COMMIT TO DEORBIT. REFER TO RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA, FOR ELS MINIMUM REQUIREMENTS.

1. NO COCHANNEL INTERFERENCE PREDICTED BELOW 130K FT ALTITUDE.

NOTE: IN SOME CASES, COCHANNEL INTERFERENCE MAY BE ELIMINATED BY POWERING OFF THE INTERFERING STATION(S) FOR THE PERIOD OF SHUTTLE OPERATIONS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-201

**TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN
SELECTION PHILOSOPHY (CONTINUED)**

2. TACAN MUST BE OPERATING PRIOR TO LAUNCH OR DEORBIT COMMIT AS APPLICABLE PER PARAGRAPH A
3. WITHIN 50 NM OF THE RUNWAY.
4. POWER LEVEL ? 1.5K WATTS. @[020196-1807B]
5. NIMA OR FAA TACAN DATABASE COORDINATES MUST BE AVAILABLE AS A MINIMUM. SURVEY DATA IS HIGHLY DESIRABLE, BUT NOT MANDATORY. @[020196-1807B] @[022201-3857]
6. NASA OR FAA CERTIFIED AND ACCURATE WITHIN 0.3 NM AND 1.0 DEGREE (REF RULE {A8-52}, SENSOR FAILURES). CONSIDERATION WILL BE GIVEN TO THE USE OF A TACAN WHICH HAS BEEN EVALUATED VIA GPS EQUIPPED STA BUT WHICH HAS NOT BEEN COMPLETELY CERTIFIED. @[ED]

Alternate TACAN's may be uplinked in OPS 1/3 to satisfy the redundancy requirements for OPS 6/3 entries. The process of selecting an alternate TACAN begins with the TACAN Cochannel Interference Document (NAV-98-4237-032) which includes several potential TACAN stations for space shuttle landing sites. This document contains cochannel interference data which is generated assuming a nominal range-altitude profile, constant power level of 3.5 KW, and an approximation for the shape of the parabolic TACAN signal propagation. This interference data along with the expected groundtrack can be used to approximate the altitude below which a given TACAN station is clear of interference and to determine which TACAN stations must be powered off to reduce or eliminate interference. In addition to the cochannel interference data, the TACAN Cochannel Interference Document lists the type of station (TACAN, VORTAC, VORDME, or DME), data source (survey or NIMA/FAA database), and the distance and direction from the runway.

Once an acceptable TACAN or VORTAC is identified based on runway proximity and cochannel interference, the operating hours and power level are verified to ensure the TACAN will be available during entry. TACAN's used to meet the redundancy requirements must be operational prior to launch commit for RTLS, TAL (if required), and AOA (if required). If first day PLS is required, the TACAN(s) must have an ETRO prior to deorbit decision time. For PLS, MDF, and end of mission, the TACAN(s) used to meet the redundancy requirements must be operating prior to deorbit commit and until touchdown. The TACAN(s) must be available throughout entry to touchdown to ensure continuous TACAN processing.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-201

TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY (CONTINUED)

A maximum distance of 50 nm from the TACAN to the runway is required to ensure TACAN lock-on until MLS acquisition. The groundtrack proximity may also be considered in the alternate TACAN selection process. The minimum power level of 1.5K watts and cochannel interference requirements were chosen to obtain TACAN lock-on by 130K ft, which is the altitude where 3 sigma downtrack error will exceed the guidance constraints if TACAN data is not processed. Interfering TACAN's may be powered off if possible to eliminate predicted interference below 130K ft.

Although survey data is preferred, it is not required, provided data is available from the NIMA/FAA TACAN database. Non-survey coordinates provided by NIMA/FAA are accurate within about 1000 ft. Past TACAN measurement data quality observed during shuttle missions and flight tests may also be considered in the alternate TACAN selection process. ©[020196-1807B] ©[022201-3857]

The FAA or NASA certification requirements are contained in NSTS 07700, Volume X, Book 3. The FAA accuracy requirements are outside those required by space shuttle navigation. Therefore, an FAA controlled TACAN must also meet the 0.3 nm and 1.0 degree accuracy requirements contained in Rule {A8-52}, SENSOR FAILURES. ©[020196-1807B] ©[022201-3857]

D. IF A TACAN GROUND STATION FAILS AFTER LAUNCH OR DEORBIT AND A TACAN THAT MEETS THE CRITERIA IN PARAGRAPH C DOES NOT EXIST, OTHER ALTERNATES (DME'S INCLUDED) MAY BE CONSIDERED FOR UPLINK TO PROVIDE SOME FORM OF BACKUP CAPABILITY.

The criteria in paragraph C is provided to ensure an acceptable TACAN is used to meet the redundancy requirements for commit to launch or commit to deorbit. However, if a TACAN fails after launch or deorbit and a TACAN that meets the criteria in paragraph C does not exist, the best alternate including DME's may be uplinked. Although this alternate may not protect 3 sigma navigation performance, it provides some form of backup capability. ©[020196-1807B]

FLIGHT RULES

A3-202

MLS

REDUNDANT MLS CAPABILITY, INCLUDING AZIMUTH, ELEVATION, AND RANGE DATA, IS REQUIRED FOR THE FOLLOWING: @[070899-6872A]

- A. REDUCED CEILING, VISIBILITY, OR INCREASED RTLS CROSSWIND LIMITS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]) FOR DAYLIGHT, CONCRETE RUNWAY LANDINGS. @[111094-1622B] @[041196-1817B]

Because MLS provides improved navigation and position accuracy with respect to the runway, a reduction in ceiling, visibility or an increase in RTLS crosswind requirements is allowed. However, because of the dependence on MLS during the critical landing phase with reduced ceilings/visibility, combined with the more stringent navigation requirements for concrete runways, single-fault tolerant capability must exist to guarantee MLS availability. Redundant MLS capability can be either the standard primary/backup MLS ground station or two collocated single-string MLS Jr. stations. The relatively less stringent navigation requirements for lakebed runways make it possible to relax the redundancy requirement to zero-fault tolerant. One-sigma onboard navigation position errors improve from approximately 400 feet without MLS to approximately 85 feet after the first MLS measurement, decreasing to just over 50 feet 1-sigma by touchdown. Azimuth and range measurements are required to allow MLS processing, and elevation is required to correct altitude errors. Detailed definitions of ceiling, visibility and RTLS crosswinds are covered in Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. @[111094-1622B] @[041196-1817B]

- B. NIGHT LANDINGS ON ALL CONCRETE RUNWAYS OR NIGHT LANDINGS ON LAKEBED RUNWAYS WITH CEILINGS LESS THAN THOSE SPECIFIED IN RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. @[111094-1622B]

MLS is required due to the loss of visual cues and the related degradation of the crew's ability to visually compensate for navigation dispersions during night landing operations. Because of this requirement, single-fault tolerant capability must exist to guarantee MLS availability (ref. paragraph A rationale) for landings on concrete runways where large lateral dispersions at touchdown are less tolerable than for lakebed runways.

For lakebed landings only, single-string MLS is acceptable if the lowest ceiling is at or above those specified in the Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. The increased ceiling provides additional time for the crew to compensate for navigation dispersions using visual cues. In addition, the larger area provided by the lakebed environment makes navigation dispersions resulting from the possible failure of the single-string MLS more tolerable. @[111094-1622B]

Rules {A2-1F}.3, PRELAUNCH GO/NO-GO REQUIREMENTS; {A2-2}, ABORT LANDING SITE REQUIREMENTS; {A3-203}, LANDING AID REQUIREMENTS; and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule. @[111094-1622B] @[070899-6872A]

FLIGHT RULES

A3-203

LANDING AID REQUIREMENTS

LANDING AIDS (CONCRETE / LAKEBED) @[070899-6881]

	PAPI LIGHTS	AIMPOINT	BALLBAR [1]	XENON LIGHTS	EDGE LIGHTS/ REFLECTORS	ALS	CENTER LINE LIGHTS	RUNWAY REMAINING MARKERS
CDR HUD W/MLS	1 OF 2 HD		HD	RUNWAY LIGHTS AND MARKERS NOT REQUIRED FOR DAYLIGHT LANDINGS				
CDR HUD W/NO MLS	1 OF 2 M		M					
NO CDR HUD	M	HD	M					
NIGHT LANDING	M	N/R	M	M	M	HD	HD	M [2]

@[102402-5786]

[1] BALLBAR IS MANDATORY FOR TAL.

[2] RUNWAY REMAINING MARKERS (RRM'S) ARE MANDATORY FOR NIGHT LANDINGS ON CONCRETE ONLY.

PAPI lights are required at the proper aimpoint position (nominal or close in as recommended) for all lighting and surface conditions. The exceptions are daylight landings where the use of an aimpoint and a HUD will substitute for a PAPI, or when the CDR HUD and MLS are available. PAPI lights allow the pilot to visually acquire the proper outer glide slope with a good degree of accuracy. In daylight, the use of an aimpoint and a HUD (visual glide slope information provided by onboard navigation) will provide the crew with similar cues to the outer glide slope. The combination of the HUD and MLS can also provide the necessary cues for flying the outer glide slope in daylight. In this case, either the PAPI lights or aimpoint are only highly desirable. For purposes of this rule, the MLS capability is required. For specific MLS ground station redundancy and LRU requirements reference Rules {A3-202}, MLS, and {A8-18}, LANDING SYSTEMS REQUIREMENTS. If MLS is not available, then either the PAPI lights or aimpoint are mandatory (PAPI lights preferred). Without MLS, navigation accuracy may not be good enough to provide a reliable crosscheck of the HUD runway overlay for confirming and flying the outer glide slope. PAPI lights are mandatory for night landings or landings without the CDR HUD to help offset the loss of visual cues and references and the degraded ability to compensate for navigation errors. @[070899-6881]

Ball bars are mandatory for TAL sites because of the reduced runway length and width (< 300 feet) as compared to CONUS runways. Without the ball bar, the reduced width of the runway can result in a false visual perception of being too high above the glide slope which can lead to descending through the inner glide slope and landing short of the runway.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-203

LANDING AID REQUIREMENTS (CONTINUED)

For daylight CONUS landings where the visual scene is “as trained to,” a ball bar is only highly desirable when both the CDR HUD and MLS are available. MLS plus the CDR HUD provides sufficient cues to allow an accurate transition to the inner glide slope. For purposes of this rule the MLS capability is required. For specific MLS ground station redundancy and LRU requirements, reference Rules {A3-202}, MLS, and {A8-18}, LANDING SYSTEMS REQUIREMENTS. Without MLS, the navigation accuracy (primarily the HUD velocity vector) may not be good enough to guide the pilot on the H/Hdot profile required to capture (Pre-Flare) and fly the inner glide slope through threshold crossing; therefore, a ball bar is mandatory. Ball bars are mandatory for night landings or landings without the CDR HUD to help offset the loss of visual cues and references and the degraded ability to compensate for navigation errors. ©[070899-6881]

Runway remaining markers (RRM's) are only mandatory for night concrete landings. The length of concrete runways and night conditions necessitate the need for RRM's due to the reduced margin of error in determining runway remaining. These markers give the pilot a visual cue to the rollout distance remaining and the brake profile required to stop on the field.

Runway lighting is required for night landings in order for the pilot to see the runway on approach, touchdown, and rollout. The Xenon lights are considered mandatory, as they provide the primary means for lighting the immediate runway area (approach path, threshold, and touchdown point). Runway edge lights/reflectors are mandatory as they provide the primary visual cue for lateral margin during touchdown and rollout. Approach Lighting System (ALS) lights are not mandatory because the Xenon lights, edge lights/reflectors, and PAPI/ball bar requirements suffice for centerline/threshold lighting and targeting cues. Centerline lights are available as a secondary cue at the KSC SLF and are only highly desirable. ©[102402-5786]

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES**A4-59****MANUAL THROTTLE SELECTION (CONTINUED)**

E. THROTTLE COMMAND NOT DECREASED TO MAINTAIN 3-G ACCELERATION.

The 3-g acceleration-limiting logic is provided to assure that vehicle loads do not exceed design constraints. Therefore, manual throttle will be invoked to protect this limit if the flight software fails to do so. Reference the rationale for Rule {A4-58C}, AUTO GUIDANCE NO-GO, for further background.

F. ANY TIME CSS IS SELECTED.

As a conservative guideline, any time the AUTO guidance is unacceptable for vehicle attitude control, it should not be allowed to control the main engines. If the vehicle attitude is not maintained to satisfy the guidance solution, the guidance may go unconverged and potentially could issue an undesired MECO command. Thus, to avoid an inadvertent shutdown, manual throttle should be selected whenever CSS takeover is initiated.

Rule {A2-64A}, MANUAL THROTTLE CRITERIA, references this rule.

G. THROTTLES WILL BE MANUALLY COMMANDED TO THE MINIMUM POWER LEVEL AT 2 PERCENT PROPELLANT REMAINING IF THE EXPECTED MECO UNDERSPEED EXCEEDS THE VALUE ASSURING EXECUTION OF FLIGHT SOFTWARE MECO PREP THROTTLING:

1. TWO OR THREE ENGINES ON: 500 FPS
2. ONE ENGINE ON: 250 FPS ®[092195-1770A]

Flight software MECO preparation throttling is triggered by K-loaded timing values. When the guidance-computed TGO becomes less than TGO_FCD K-load, the MPS guidance cutoff task begins cyclic execution. This task determines when to command the SSME's to the cutoff power level, and assumes that they will remain at that setting for K-load DT_MIN_K seconds. However, the software also assumes a guided MECO will result and has no way of compensating for an impending early (low-level) cutoff. Therefore, for predicted MECO underspeeds greater than a threshold value, a low-level shutdown may be commanded before the engines reach the desired cutoff throttle setting. In such instances, the throttles will be manually retarded to the minimum power level shortly before MECO to provide the required safe shutdown configuration.

Under most circumstances, the onboard propellant remaining computation is sufficiently accurate to use as a throttledown cue. Ascent/Entry Flight Techniques #62 determined in January 1990 that 2 percent propellant remaining provided a generic value that covered both the pre-MECO dump and no-dump cases. However, the flight software computation is inaccurate when off-nominal mixture ratios are involved, due to the buildup of unusable LOX or LH₂; the software senses the extra mass but does not recognize it as unusable. Likewise, the onboard mass estimation algorithm in first stage assumes all

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-59

MANUAL THROTTLE SELECTION (CONTINUED)

engines are operating at the commanded power level; therefore, an engine locked before the bucket will consume more propellant than the mass tracking function accounts for. This leads to the second stage software believing it has more propellant than is actually available.

Although the resultant mass dispersions are a function of the size and direction of the mixture ratio upset or the depth and length of the bucket, the 2 percent propellant remaining cue still provides sufficient time to throttle down. (Reference Flight Rule {A5-112}, MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN.) ©[ED]

H. FOR LOW LH2 NPSP PER FLIGHT RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP.

Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP, addresses scenarios requiring manual throttles. Manual throttles will be maintained and a manual MECO required for the flow control valve anomaly case. Uphill capability will be evaluated at each throttle setting. Two-engine and single-engine performance boundaries will be made based on minimum power level as time permits. Since this dynamic throttle profile is difficult to model, two-engine and single-engine capability may not be evaluated accurately until the failure actually occurs.

Manual throttles will be selected prior to aborting TAL for a LH2 leak. OI-8D software (STS-38 and subs) automatically throttles the engines down if TAL is selected above an I-loaded inertial velocity. To prevent the software from throttling the engines down when there is an LH2 tank leak, manual throttles are selected prior to selecting TAL. Once TAL is selected, the throttles will be returned to auto where they will stay at 104 percent until 3 g's are reached. Three-g throttling may cause engine failures but this is an accepted risk to avoid vehicle structural damage. Operating the SSME's at 104 percent results in a higher inertial velocity at MECO than if the SSME's had been throttled down to 67 percent. ©[092195-1770A]

I. A TAL UNDERSPEED IS PREDICTED AND CAN BE REDUCED BY FLYING AT A LOWER THROTTLE SETTING. THROTTLES WILL BE RETARDED TO MINIMUM POWER LEVEL WHEN THE PERFORMANCE GAIN IS MAXIMIZED.

The slope of the TAL range-velocity target line results in a point in the powered flight trajectory where MPS propellant margins may be increased by flying at a reduced throttle setting. As the throttle is retarded, the powered flight time is extended which in turn results in a MECO position which is farther downrange than would have occurred at a higher power level. The farther downrange position equates to less distance to the TAL site at MECO, and hence, a lower MECO target velocity. This in turn translates to increased MPS margin since less delta V is required to reach the smaller target velocity. Early in powered flight, gravity losses at the lower throttle are large and offset any R-V target benefit; however, eventually sufficient velocity is achieved such that the inverse is true; i.e., the smaller target velocity offsets the gravity losses, which diminish with time and the square of the current velocity.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-59****MANUAL THROTTLE SELECTION (CONTINUED)**

In real time, the MCC ARD can determine when this boundary condition is reached, and subsequently when the performance gain is maximized. The FDO will then call for throttledown to minimize the R-V underspeed. Improving proximity to the R-V line in this manner reduces the likelihood of requiring low-energy guidance during entry, and is especially critical for out-of-plane sites where high crossrange severely limits underspeed tolerance. ©[120894-1663]

Note that this procedure will not be utilized unless an underspeed is predicted at the current power level.

Rules {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS; and {A5-112}, MANUAL THROTTLE DOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN, reference this rule. ©[ED]

- J. THREE ENGINES RUNNING AND TWO STUCK THROTTLES PRIOR TO TAL OR RTLS ABORT.
1. TAL: SELECT MANUAL THROTTLES, ABORT TAL, SELECT AUTO THROTTLES.
 2. RTLS: SELECT MANUAL THROTTLES, MINIMUM THROTTLES, WAIT 10 SECONDS, ABORT RTLS, SELECT AUTO THROTTLES.

For TAL, it is undesirable to throttle down the good engine due to the guidance transients which may occur and the fact that little time would be gained to perform the abort dump. Therefore, manual throttles will be selected to prevent an automatic throttledown when TAL is declared. This action is not required if TAL is declared early enough that automatic throttling will not occur at abort selection. However, since there is no disadvantage to selecting manual throttles for this short period of time, manual throttles will always be selected for consistency. AUTO throttles will be reselected after TAL is declared.

For three-engine RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of an early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection.

FLIGHT RULES

A4-59 MANUAL THROTTLE SELECTION (CONTINUED)

- K. TO MAINTAIN THROTTLES AT 109 PERCENT POWER LEVEL DURING THE FLYBACK PHASE OF AN RTLS ABORT.

When maximum throttles are enabled (SPEC 51 Item 4), guidance replaces the maximum power level (KMAX) of 104 percent with 109 percent. However, during the flyback phase, the commanded power level (KCMD) is not simply set to KMAX but is adjusted to achieve the desired mass conditions at MECO (assuming CSS or manual throttles did not occur anytime during flyback). For two engines running, the typical throttle command during flyback is about 100 percent and is unaffected by KMAX. Therefore, if 109 percent power level is desired during the flyback phase of an RTLS abort, manual throttles are required.

Reference Rule {A4-53E.1}, USE OF MAXIMUM THROTTLES; and Rule {A5-151D.3}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL].

- L. IF A LOWER SSME POWER LEVEL IS REQUIRED SUBSEQUENT TO ENABLING MAXIMUM THROTTLES.

When maximum throttles are enabled (SPEC 51 Item 4), guidance replaces the maximum power level (KMAX) of 104 percent with 109 percent. If throttle selection is auto and 3-g throttling is not active, the commanded power level (KCMD) is set to the new maximum power level of 109 percent (except during RTLS flyback phase, see paragraph K. above). If a lower power level is required subsequent to enabling maximum throttles, manual throttles must be selected and the lower power level commanded manually. (Note, if throttle selection is auto, the fine count throttle setting will be commanded regardless if maximum throttles have been enabled). A second SPEC 51 Item 4 will not reset the maximum or commanded power level to 104 percent. Therefore, the lower power level must be commanded manually. Once the desired power level is reached, throttles can be returned to auto. However, a subsequent engine failure with auto throttles selected will result in the commanded power level being reset to 109 percent.

Rule {A2-64A}, MANUAL THROTTLE CRITERIA, references this rule.

FLIGHT RULES

A4-60

MANUAL SHUTDOWN CRITERIA

IF THE ONBOARD PREDICTED MET OF MECO IS 2 SECONDS DIFFERENT THAN THE GROUND PREDICTED MET OF MECO AND IF CONFIRMED BY OBSERVED NAVIGATION VELOCITY ERRORS, A MANUAL SHUTDOWN WILL BE INITIATED AT THE GROUND-COMPUTED TIME.

If the ground predicted MET of MECO is 2 seconds different than the onboard predicted MET of MECO, a manual shutdown will be initiated on the ground-computed value to maintain the capability to achieve a nominal mission. A difference in the onboard and ground predicted times indicates an auto MECO will not achieve the target cutoff conditions. An early cutoff may require downmoding because of OMS performance limitations. A late cutoff may cause the desired thrust direction for OMS-1 to be radially downward and/or retrograde. The uncertainty in the ground prediction is estimated to be ± 0.9 second. This value is the RSS of the computational uncertainties of ± 0.6 second for 3-sigma ground navigation accuracy, and ± 0.5 second for onboard response to throttledown commands. Allowing a 1-second pad to ensure detection of a true onboard error and rounding to a whole number, a 2-second tolerance is enforced.

Reference: CA4-79, Ascent Flight Techniques Meeting #35, dated March 27, 1979. Rule {A2-60}, NAVIGATION UPDATE CRITERIA, references this rule.

A4-61

THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP

- A. BASED ON RECOMMENDATION FROM THE BOOSTER SYSTEM ENGINEER, AN ABORT REGION DETERMINATOR (ARD) ADJUSTMENT WILL BE MADE FOR:
1. THRUST LIMITING FLAG SET.
 2. Pc SENSOR SHIFT.
 3. ELECTRONIC LOCKUP.
 4. HYDRAULIC LOCKUP.
 5. HPOT EFFICIENCY LOSS.
 6. LH₂ FLOW METER SENSOR SHIFT.
 7. LPFT DISCHARGE TEMPERATURE SHIFT.
 8. NOZZLE LEAKS.

The ARD FPR is designed to cover only those SSME failures that are not detectable with engine instrumentation, but are sufficient to cause performance degradation. Therefore, it is necessary to model in the ARD those failures with performance impacts that exceed FPR coverage. Reference Rule {A5-110}, SSME PERFORMANCE DISPERSION. ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-61

THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP
(CONTINUED)

B. A PERFORMANCE-LIMITED SSME WILL BE SHUT DOWN EARLY, OR A MAIN ENGINE CONTROLLER CHANNEL TURNED OFF, BASED ON BOOSTER SYSTEMS ENGINEER (BSE) CONFIRMATION OF THE FAILURE AND ARD PERFORMANCE EVALUATION FOR THE FOLLOWING CASES:

1. LOW MIXTURE RATIO:

Preservation of the ATO region by early shutdown of an SSME has priority over a possible abort downmode to an AOA.

IF THE FOLLOWING CRITERIA ARE MET, THE AFFECTED SSME WILL BE SHUT DOWN EARLY TO PROTECT 3-SIGMA ATO CAPABILITY OR THE DESIGN UNDERSPEED, WHICHEVER IS THE MOST CONSTRAINING:

a. THE ACTUAL NOMINAL MARGIN INDICATES LOSS OF ATO CAPABILITY.

The ARD's actual mode nominal margin is a prediction of MECO underspeed on a 2-sigma bad day. This prediction can be used to determine if ATO capability exists. This rule refers to the design underspeed as a criterion for pressing uphill with a performance-limited SSME. In addition, the dispersed-performance protection level (3-sigma) is stated explicitly for uphill capability assessment.

b. THE HYPOTHETICAL AOA MARGIN (REFLECTING THE SICK ENGINE OUT) IS DECREASING.

The ARD's hypothetical mode AOA margin is the indicator of when continued sick engine operation will degrade performance. As long as the margins are increasing, the three-engine configuration is improving MECO conditions. When the margins start trailing off, the sick engine is degrading uphill capability. If the hypothetical nominal margin is greater than the actual nominal value; i.e. it is better to have two healthy engines than two healthy and one sick, the bad engine will be shut down.

c. THE HYPOTHETICAL NOMINAL MARGIN IS GREATER THAN THE ACTUAL NOMINAL MARGIN.

Rationale is the same as for paragraph b above.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-61

THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP (CONTINUED)

2. Pc SENSOR SHIFT (HIGH OR LOW)

FOR A Pc SENSOR SHIFT THE AFFECTED MAIN ENGINE CONTROLLER CHANNEL WILL BE TURNED OFF BY THE CREW TO PROTECT 3-SIGMA ATO CAPABILITY (i.e., AVOID AOA) OR THE DESIGN UNDERSPEED, WHICHEVER IS THE MOST CONSTRAINING. THIS PROCEDURE WILL NOT BE IMPLEMENTED IF IT WILL CAUSE ENGINE SHUTDOWN OR NOT CORRECT THE PERFORMANCE DISPERSION (REF. RULE {A5-110}, SSME PERFORMANCE DISPERSION, FOR CASES THAT CAUSE ENGINE SHUTDOWN). @ED]

Large Pc shift can cause mixture ratio excursions that will result in a LOX or LH₂ depletion prior to ATO capability. Generally, the bad Pc sensor can be isolated and turned off with the other sensor returning the mixture ratio to a nominal value. This rule refers to the design underspeed as a criterion for pressing uphill with a performance-limited SSME. In addition, the dispersed-performance protection level (3-sigma) is stated explicitly for uphill capability assessment.

3. HYDRAULIC OR ELECTRICAL LOCKUP

AN SSME IN HYDRAULIC OR ELECTRICAL LOCKUP WHEN COUPLED WITH LOW VEHICLE PERFORMANCE MAY BE MANUALLY SHUT DOWN TO PREVENT A VIOLATION OF THE ENGINE LO₂ NET POSITIVE SUCTION PRESSURE (NPSP) REQUIREMENTS NEAR MECO. IF THE ARD PREDICTED DELTA V MARGIN AFTER SRB SEPARATION INDICATES LOW PERFORMANCE, THE NONTHROTTLING ENGINE WILL BE SHUT DOWN AT $V_I > 23K$ FPS. @[061297-4892]

For low performance in first stage with one or more engines in hydraulic or electrical lockup, there is potentially insufficient LOX at MECO to support the stuck engine's shutdown from the higher throttle level. This results in a LOX depletion and subsequent uncontained engine damage.

C. FOR A THREE-ENGINE RTLS, AUTO GUIDANCE WILL BE PRESERVED BY SHUTTING DOWN PERFORMANCE-LIMITED SSME WHEN THE PROBLEM IS IDENTIFIED BUT NOT LATER THAN POWERED PITCHDOWN (PPD) MINUS 40 SECONDS TO PROTECT A 3-SIGMA GUIDED MECO (RTLS MARGIN > 0 FPS). CRITERIA FOR ET SEPARATION PROPELLANT CONDITIONS WILL NOT BE CONSIDERED WHEN DETERMINING SSME SHUTDOWN REQUIREMENTS DURING AN RTLS.

Manual throttle, manual guidance, and early manual turnaround during an RTLS is more risky than shutdown of a performance-limited SSME. There is no real-time determination of propellant conditions at ET separation currently available. It is highly desirable to protect a 3-sigma guided MECO. This will be done at the possible expense of executing an RTLS ET separation with a slightly heavier tank.

FLIGHT RULES

A4-62**OMS-1/OMS-2 EXECUTION**

THE OMS-1 AND/OR OMS-2 TARGETS AND TIG WILL BE SELECTED TO ACHIEVE THE HIGHEST PRIORITY MISSION MODE POSSIBLE. ALLOWABLE UNDERSPEEDS FOR EXECUTION OF NOMINAL TARGETS WILL ENSURE ACCOMPLISHMENT OF HIGH PRIORITY MISSION OBJECTIVES. THE AME WILL BE USED TO DETERMINE THE HIGHEST PRIORITY MISSION MODE THAT CAN BE ACHIEVED.

For standard insertion flights, the nominal OMS-1 and OMS-2 targets are designed to be performance optimized. The nominal targets will be executed and the nominal flight profile flown only if there is sufficient fuel available to perform the required on-orbit burns and the deorbit burn. Otherwise, the highest priority mission mode that can be supported by the fuel available will be executed. (Reference Rule {A2-52D}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES.)

For direct insertion flights, a range of underspeeds will result in no OMS-1 being required but the apogee is lower than nominal. For these cases, assuming no OMS leaks have occurred, it is desired to circularize at the resulting pre-OMS-2 apogee altitude with the OMS-2 burn. The details for this case with and without OMS propellant problems are in Flight Rule {A4-103}, OFF-NOMINAL ORBITAL ALTITUDE RECOVERY PRIORITIES, and its rationale.

The AME will be used in real time to determine the highest priority mission mode that can be achieved. Actual post-MECO state vectors and actual OMS quantities are used by the AME. Should the MOC be unavailable, the backup method for determining the correct targets is the crew chart in the Ascent Checklist.

A4-107

PLS/EOM LANDING OPPORTUNITY REQUIREMENTS

A. ALL OF THE FOLLOWING CRITERIA ARE REQUIRED FOR A PLS (OTHER THAN FIRST DAY PLS, REF. RULE {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS) MDF, OR EOM LANDING OPPORTUNITY (NOT IN PRIORITY ORDER):

1. NASA CONUS SITE: KSC, EDW, NOR. FOR NO-COMM PLS PLANNING, EDW IS PREFERRED.

Only the three prime NASA CONUS sites should be considered for PLS or EOM. The daily PLS planning results in a crew message for no-comm execution if total communications are lost; ref. Rule {A11-52}, LOSS OF BOTH VOICE AND COMMAND. In the case of other problems, ground evaluation of the landing site can be made very shortly before deorbit burn. However, for the no-comm case, the crew may be required to execute a deorbit to a site that was picked many hours previously. Since EDW weather is in general much more stable than KSC and additional lateral and longitudinal margins are available in the case of poor navigation (likely for a no-comm entry) or other orbiter systems problems, EDW is the preferred no-comm PLS site when all other considerations are equal. ©[ED]

2. WIND AND WEATHER CONDITIONS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]) ©[120894-1622B]

3. ACCEPTABLE ENTRY ANALYSIS INCLUDING:

NOTE: ENTRY ANALYSIS IS NOT PERFORMED FOR DAILY NO-COMM PLS SELECTION.

- a. APPROACH AND LAND TRANSITION (REF. RULE {A4-156}, HAC SELECTION CRITERIA).
- b. NORMALIZED TOUCHDOWN DISTANCE (REF. RULE {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION). ©[072795-1788A]
- c. MAXIMUM TIRE SPEED, ROLLOUT MARGIN, AND BRAKE ENERGY CONSTRAINTS (REF. RULE {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-107

PLS/EOM LANDING OPPORTUNITY REQUIREMENTS
(CONTINUED)

- d. NZ AND Q-BAR CONSTRAINTS (REF. RULE {A4-207}, ENTRY LIMITS). @[072795-1788A]

Rule {A4-112}, LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA, requires accurate lower level atmospheric data that is used for analysis of the entry trajectory to ensure safety. The main gear tires are certified to 225 knots groundspeed. This constraint may limit the allowable tailwind based on the predicted EAS and density altitude. Violation of brake energy and rollout constraints may result, in dispersed cases, in runway departure or excessive braking requirements that could lead to tire fires. Rule {A2-6A}, LANDING SITE WEATHER CRITERIA [HC], references this rule. Since the no-comm PLS landing would be executed many hours after the site had been selected, entry analysis using environmental observations are not relevant and therefore will not be performed. @[071494-1621A] @[120894-1622B] @[ED]

4. ENTRY CROSSRANGE LESS THAN DISPERSED OR THE THERMAL CROSSRANGE LIMIT, WHICHEVER IS MORE CONSTRAINING.

The dispersed crossrange limit represents the vehicle capability to converge to nominal conditions by TAEM interface (Mach 2.5) assuming 3-sigma combinations of navigation, atmosphere, energy, and winds. All planned and acceptable entries must have a crossrange which is less than the dispersed crossrange limit. Landing sites with crossrange between the dispersed and undispersed limits should not be considered. (Ref. the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS.) @[ED]

The flight specific thermal crossrange limit protects the upper surface thermal constraints for high crossrange entries. During high crossrange entries, the orbiter maintains a roll angle for a long period of time to reduce crossrange prior to the first roll reversal. Heading rates incurred by non-zero roll attitudes will be sensed by the FCS pitch rate gyros as small positive pitch rates. As a result, the FCS will maintain an angle of attack somewhat less than that desired as it attempts to compensate for this pseudo pitch rate. This results in increased heating to the upper surface, which may result in excessive structural temperatures. The actual thermal crossrange limit is flight specific. (Ref. the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS.) @[071494-1621A] @[ED]

5. SUFFICIENT GROUND EQUIPMENT SUPPORT INCLUDING REDUNDANCY MUST BE PROVIDED TO SATISFY A/G VOICE, TELEMETRY, TRACKING, AND COMMAND REQUIREMENTS AND FULL REDUNDANCY TO NAVIGATION AIDS AS SPECIFIED IN SECTION 3. NOTE: TRACKING SUPPORT IS NOT SCHEDULED FOR THE DAILY PLS OPPORTUNITY. IF A PLS IS REQUIRED, TRACKING SUPPORT WILL BE ON A "BEST EFFORT" BASIS.

FLIGHT RULES

A4-110 AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION

- A. AIMPOINT SELECTION - AIMPOINT EVALUATION WILL ASSUME AUTO SPEEDBRAKE AND WILL NOT MODEL ANY MANUAL PROCEDURES DESIGNED TO INCREASE TOUCHDOWN DISTANCE. ©[072795-1788B]
1. IF THE PREDICTED TOUCHDOWN POINT USING THE NOMINAL AIMPOINT IS < 1000 FEET PAST THE RUNWAY THRESHOLD, THEN THE CLOSE-IN AIMPOINT WILL BE SELECTED.
 2. IF THE PREDICTED TOUCHDOWN POINT IS < 1000 FEET PAST THE RUNWAY THRESHOLD FOR BOTH THE NOMINAL AND CLOSE-IN AIMPOINTS, THE RUNWAY IS NO-GO. FOR DAYLIGHT LAKEBED LANDINGS ONLY, IF AFTER APPLYING ALL TECHNIQUES (CLOSE-IN AIMPOINT, ALTERNATE RUNWAY) THE PREDICTED TOUCHDOWN POINT IS STILL < 1000 FEET, CONSIDERATION SHALL BE GIVEN TO RELAXING THE 1000-FOOT CONSTRAINT RATHER THAN DELAYING DEORBIT OR SELECTING AN ALTERNATE LANDING SITE.
 3. FOR RTLS WITH LIGHT RAIN SHOWERS IN THE APPROACH CORRIDOR (RULE {A2-1C}.4, PRELAUNCH GO/NO-GO REQUIREMENTS), IF THE PREDICTED TOUCHDOWN POINT IS < 2000 FEET PAST THE RUNWAY THRESHOLD FOR BOTH NOMINAL AND CLOSE-IN AIMPOINTS, THE RUNWAY IS NO-GO. ©[ED]

NOTE: MANUAL SPEEDBRAKE RETRACTION AT 3000 FEET AGL MAY BE CONSIDERED TO ACHIEVE THE 2000-FOOT MINIMUM TOUCHDOWN ENERGY.
©[020196-1808A]

This rule is designed as a planning guide and represents crew and flight controller inputs developed over many flights. All of these criteria were discussed at Flight Techniques and other meetings.

A TD point 1000 feet from the runway threshold was selected to accommodate variations in actual TD point from prelanding predictions due to off-nominal EAS, landing gear deploy altitude, and deviations from the forecast wind profile. With the increased margins available on a lakebed runway, the risks of landing closer to the threshold are significantly reduced. Therefore, engineering judgment may be used to accept a TD point of less than 1000 feet in order to avoid an otherwise NO-GO situation on a lakebed runway if no increased risk is identified. Factors involved in making this assessment include visibility restrictions, underrun characteristics (hardness, surface conditions, obstructions, etc.), the availability of landing aids, wind persistence predictions, and pilot (e.g., STA) judgment and recommendations. Due to visibility restrictions at night, however, the 1000-foot criterion always applies to night landings on lakebed runways.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

There are two aimpoints used to locate the base of the outer glide slope, one at 7500 feet from the threshold (nominal) and one at 6500 feet from the threshold (close-in). Aimpoint selection is based on an evaluation of the predicted TD point and speedbrake setting using current and forecast winds, density altitude, and orbiter weight. The descent design system (DDS) and the Approach and Landing Plan (ALP) processor are used to compute these parameters. ©[072795-1788B]

Tile damage due to showers encountered during fly back could result in a loss of up to 1000 feet of touchdown distance. Typical touchdown distances carry adequate margin to protect this type of energy loss. A dispersed entry that is flown through a shower on a day that predicted touchdown conditions are at the limits specified in Rule {A4-110}, AIMPOINT EVALUATION VELOCITY, AND SHORT FIELD SELECTION, could result in a vehicle touchdown on the edge of the underrun. The touchdown distance is increased for RTLS to handle the tile damage combined with the other dispersions. ©[020196-1808A] ©[062801-4307C]

4. IF THE PREDICTED SPEEDBRAKE RETRACT CALCULATION INDICATES THAT THE SPEEDBRAKE WILL BE COMMANDED CLOSED (15 PERCENT) AT BOTH 3000 FEET AGL AND 500 FEET AGL USING THE NOMINAL AIMPOINT, THEN THE CLOSE-IN AIMPOINT MAY BE SELECTED TO ACHIEVE A PREDICTED TOUCHDOWN POINT CLOSER TO THE GUIDANCE TARGET (NOMINALLY 2500 FEET) AND POSSIBLY GAIN ADDITIONAL SPEEDBRAKE, PROVIDED THAT ROLLOUT MARGIN AND BRAKE ENERGY CONSTRAINTS (REF. RULE {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS) ARE STILL SATISFIED. ©[072795-1788B] ©[020196-1808A] ©[101096-4210]

Approach and landing guidance was designed to control the orbiter's TD energy state by modulating the speedbrake. Using the speedbrake retract I-loads, guidance will command a speedbrake position that should result in a targeted energy state at TD of 195 knots EAS (205 KEAS heavyweight) at 2500 feet past the runway threshold. At 3000 feet AGL, if guidance predicts that the TD energy state will be less than that targeted, the speedbrake will be commanded fully closed. In this case, selecting the close-in aimpoint will provide an additional 1000 feet of energy margin at TD and may result in carrying a small amount of speedbrake for energy control. The preference for open speedbrake and touchdown as close as possible to the 2500 foot guidance target does not preclude considering either aimpoint for other reasons, such as conditions which result in a different aimpoint recommendation from the STA. Rollout margin and brake energy requirements, as specified in Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS, must still be satisfied after selection of the close-in aimpoint. If selection of the close-in aimpoint results in violation of these criteria, the nominal aimpoint will be used. ©[101096-4210]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-111

RUNWAY ACCEPTABILITY CONDITIONS

A. THE FOLLOWING CONDITIONS WILL NO-GO USE OF ANY EOM OR INTACT ABORT RUNWAY TO WHICH THEY APPLY. CONDITIONS ARE ASSESSED OVER THE ENTIRE SURFACE OF THE RUNWAY. @[111094-1622B] @[062702-5149C]

1. ALL RUNWAYS (GROOVED, UNGROOVED, LAKEBED):

STRUCTURAL FAILURES (BREAKTHROUGH, POTHOLE, FISSURE),
STANDING WATER, SNOW, OR ICE

2. UNGROOVED RUNWAYS:

VISIBLE MOISTURE

3. LAKEBEDS:

WET OR SLUSHY SURFACE MATERIAL

THE FOLLOWING CHART CATEGORIZES THE APPROVED EOM AND INTACT ABORT RUNWAYS:

RUNWAY	SURFACE
KSC	GROOVED
EDW22/04	UNGROOVED
MRN	UNGROOVED
BEN	UNGROOVED
ZZA	GROOVED
NOR	LAKEBED

@[062702-5149C] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-111****RUNWAY ACCEPTABILITY CONDITIONS (CONTINUED)**

- a. *Due to the large load bearing requirements of the orbiter, structural failures are not acceptable on any runway surface. Fissures or cracks, which may lead to or be evidence of structural failures, are not allowable. Potholes are not acceptable owing to the possibility of tire or strut damage caused by impact. Standing water, snow or ice on any runway surface may result in hydroplaning, loss of traction, and loss of brake effectiveness.* ©[062702-5149C]

Grooves on a runway are designed to provide drainage of water from the runway surface. Flooding occurs when the water cannot be shed quickly enough and the grooves fill. Any depth of water above this point is defined as standing water (depth of water above the runway surface, not including groove depth). The Shuttle Landing Facility at KSC is considered grooved although the 3500 feet at each end of the runway are ungrooved and treated with a Skidabrader™ Shotpeening Process. The A/E FTP#176 members concluded that the effects of landing in the ungrooved region and/or rolling across the grooved/ungrooved transition zones on a wet KSC runway (grooves not flooded) were not significant enough to alter the desired landing profile. These conclusions were based on LRC tire track testing, SES evaluations, and the assumption that significant lateral excursions could not occur since the time spent in the ungrooved region at high speeds was of a very short duration and occurred with light main gear loading.

- b. *Visible moisture on an ungrooved concrete runway may also result in a loss of lateral directional control. The orbiter MLG tires can lose up to 75 percent of the dry friction value at high speeds on a wet ungrooved runway. Ref A/E FTP #176.*
- c. *Wet, slushy lakebed surface materials thrown up during landing and roll out can result in orbiter damage. Reference Entry FTP #42 and A/E FTP #176.*
- B. FOR EMERGENCY LANDINGS, THE CONDITIONS IN PARAGRAPH A WILL BE CONSIDERED IN RUNWAY SELECTION IF MORE THAN ONE SITE IS AVAILABLE.

Contingency aborts (e.g., ECAL, emergency deorbit) do not require the same level of dispersion protection as NEOM or Intact Abort landings. In addition, emergency landings typically only have capability to one site, so runway NO-GO criteria are not appropriate. In the event overlapping coverage does exist (e.g., ECAL), runway condition should be considered when selecting the landing site. Emergency landings include, but are not limited to, ACLS, ECAL, and ELS sites. Ref A/E FTP #176. ©[062702-5149C] ©[102402-5804C]

Rules {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A2-2}, ABORT LANDING SITE REQUIREMENTS; {A2-103}, EXTENSION DAY REQUIREMENTS; and {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS, reference this rule. ©[111094-1622B]

UPPER AND LOWER LEVEL MEASURED WIND AND
ATMOSPHERIC DATA @[062801-4423]

A. UPPER LEVEL WINDS

UPPER LEVEL MEASURED WINDS (HAC ACQUISITION TO 10K FEET) ARE USED TO ASSESS HAC SELECTION OPTIONS AND TRANSITION TO APPROACH AND LANDING GUIDANCE.

PREDEORBIT: A SOURCE FOR ACCURATE UPPER LEVEL MEASURED WINDS IS HIGHLY DESIRABLE FOR EOM. IT IS HIGHLY DESIRABLE THAT THE SOURCE ENCOMPASS ALTITUDES FROM HAC ACQUISITION AND BELOW FOR THE HAC SELECTION ASSESSMENT AND IT IS OBTAINED NO MORE THAN 6.5 HOURS FROM TOUCHDOWN.

B. LOW LEVEL WINDS @[111094-1622B]

LOWER LEVEL MEASURED WINDS (0 TO 10K FEET) ARE USED TO ASSESS TOUCHDOWN, ROLL OUT, AND BRAKE ENERGY CONDITIONS IN ORDER TO SUPPORT COMMIT TO LAUNCH OR DEORBIT DECISIONS.

1. PRELAUNCH: A SOURCE FOR ACCURATE LOWER LEVEL MEASURED WINDS IS MANDATORY FOR RTLS, TAL AND AOA(IF REQUIRED) WITH THE FOLLOWING EXCEPTIONS: @[020196-1799A]

IF A SOURCE FOR LOWER LEVEL WINDS IS NOT AVAILABLE AT BEN GUERIR, BEN 36 WITH CLOSE-IN AIMPOINT WILL BE USED UNLESS UNUSUAL WIND CONDITIONS ARE SUSPECTED.

2. PREDEORBIT: A SOURCE FOR ACCURATE LOW LEVEL MEASURED WINDS IS MANDATORY FOR FD1 OR FD2 PLS, NEXT PLS, AND EOM. IT IS HIGHLY DESIRABLE THAT THE SOURCE FOR LOWER LEVEL WINDS IS OBTAINED NO MORE THAN 4.5 HOURS FROM TOUCHDOWN.

NOTE: FOR AOA OR FD1 PLS TO NORTHRUP, STANDARD BALLOON DATA IS NOT AVAILABLE. FOR THESE CASES, THE WIND PROFILERS DATA (IF AVAILABLE) AND FORECAST WINDS WITH THE 62 STANDARD ATMOSPHERE WILL BE USED FOR TOUCHDOWN AND ROLLOUT ANALYSIS. @[020196-1799A]

C. ATMOSPHERIC CONDITIONS @[062801-4423]

A4-202

DEORBIT BURN COMPLETION

THE FOLLOWING TECHNIQUES, IN ORDER OF PRIORITY, WILL BE UTILIZED IN THE EVENT OF DELTA V DEFICIENCY AT OMS CUTOFF FOR THE DEORBIT MANEUVER.

- A. TRIM WITH THE ARCS, NOT TO EXCEED ARCS QUANTITY 1.
- B. TRIM WITH THE FORWARD RCS TO DEPLETION.
- C. PREBANK TO THE REDESIGNATION CONTINGENCY LIMIT FOR THE PRIME LANDING SITE (PROTECTS THERMAL CONSTRAINT OR NO GREATER THAN 135-DEGREE PREBANK).
- D. REDESIGNATE TO THE BACKUP SITE (IF AVAILABLE) WITH PREBANK TO THE REDESIGNATION CONTINGENCY LIMIT (NORTHROP FOR EDWARDS PLS).
- E. TRIM WITH THE AFT RCS, NOT TO EXCEED ARCS QUANTITY 2.
- F. PREBANK AS REQUIRED UP TO 180 DEGREES.

This rule was developed in various working group meetings to define the procedures for completing the deorbit burn after all OMS downmode options have been exercised and ARCS fuel to the ARCS entry redline has been used. The deorbit burn completion cue cards incorporate the techniques, according to the defined priorities.

ARCS propellant is budgeted, including entry DTO's, PTI's, etc., in option A for burn completion. If the targets can be accomplished using the fuel down to ARCS quantity 1, the vehicle integrity and crew safety have not been compromised. This ARCS option is preferred to the FRCS because no large attitude change is required, nor is the execution of the more complicated FRCS burn procedure required.

Option B is trimming with the FRCS. This propellant, if not used for trimming the burn, is either dumped prior to entry or maintained for ballast. Use of the FRCS fuel is preferred over an equivalent prebank. The thermal effects of the prebank are considered more severe than execution of the FRCS trim procedures.

Options C and D incorporate use of the prebank to obtain atmospheric capture while maintaining ARCS quantity 1 fuel. Use of the prebank stresses the TPS. Option C limits the prebank to the redesignation limit while maintaining the capability to land at the prime site. The redesignation limit will not be greater than 135 degrees of prebank, or exceedance of a thermal limit based on 35 mission wing leading edge reuse temperature constraint (TBD degrees F). Current analysis tools use a simplified thermal model which overpredicts wing leading edge temperature by 150 degrees F. For analysis purposes, the wing leading edge thermal limit will be 2950 degrees F. Option D calls for a prebank to the redesignation limit to the backup

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-202****DEORBIT BURN COMPLETION (CONTINUED)**

landing site (if available). Vehicle turnaround may be lengthened due to the lack of postlanding support at the backup landing site. The computations of L OMS Hp, R OMS Hp, PRI Hp, and B/U Hp will assume the delta Hp due to prebank to the redesignation limit, regardless of whether a backup site is available or not.

Option E uses fuel below the ARCS entry redline, down to ARCS quantity 2. This provides enough fuel for attitude control to $Q\text{-bar} = 20$ psf. After $Q\text{-bar} = 20$, aerodynamic control is possible but risky without the yaw jets. NO YAW JET is now a certified entry mode.

The last option calls for using prebank between the redesignation limit up to the maximum of 180 degrees. This is the last resort since the use of maximum prebank and no yaw jet control after $Q\text{-bar} = 20$ psf indicate that the capability to reach the landing site, vehicle stability, TPS integrity, and crew safety are being compromised. Preserving this prebank (from the redesignation limit to 180 degrees) as the very last option also provides some margin in case the FRCS burn does not provide the delta V predicted.

A4-203**ENTRY NAVIGATION UPDATE PHILOSOPHY** @[072601-4530B]

A. GPS WILL BE USED TO CORRECT ONBOARD NAVIGATION ERRORS THAT EXCEED FLIGHT RULE LIMITS (REF RULES {A4-204}, DELTA STATE POSITION UPDATES, AND {A4-205}, DELTA STATE VELOCITY UPDATES) WHEN GPS IS VERIFIED TO BE FUNCTIONING PROPERLY AND THE FOLLOWING CRITERIA ARE SATISFIED: @[062702-5439]

1. GPS VERSUS GROUND FILTER UVW POSITION DIFFERENCES ? 3000 FEET FOR EACH COMPONENT ABOVE 130 KFT ALTITUDE AND ? 1000 FEET FOR EACH COMPONENT BELOW 130 KFT ALTITUDE.
2. GPS COMPUTED VERSUS ACTUAL TACAN RANGE DIFFERENCES ? 0.5 NM FOR TACAN STATIONS OPERATING WITHIN ACCEPTABLE LIMITS (REF RULE {A8-52B}.2, SENSOR FAILURES).

THE GROUND DELTA STATE PROCESSOR WILL BE USED AS A SECOND PRIORITY TO CORRECT ONBOARD NAVIGATION ERRORS. @[062702-5439]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-203

ENTRY NAVIGATION UPDATE PHILOSOPHY (CONTINUED)

A GPS update or a delta state update will be performed to correct onboard state vector errors that exceed flight rule limits. The ground delta state update process assumes the following: the ground Kalman filter solution is valid (reference Rule {A4-51}, KALMAN FILTER SOLUTION), state vector errors are linear with time, velocity errors are constant, ground and onboard runways agree, and the onboard navigation update time will be close to the predicted update time. Navaid inhibits are required for velocity delta state updates and navigation corrections after HAC intercept. After a delta state update is performed, it is possible that the remaining onboard navigation errors would have to be corrected with an additional delta state update. The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. If GPS receiver performance has been good, the decision to perform a GPS update instead of a delta state update is made based on state vector differences between GPS and the ground filter. The criteria for acceptable UVW position differences were discussed at the AEFTP #182 on February 15, 2002 and were established based on: 1) the amount of onboard navigation error correction and associated delta state update accuracy, 2) ground filter errors at initial low elevation tracking angles, 3) onboard Navaid processing and guidance capability after a biased GPS state vector update, and 4) the desire to have a simple two-tier console limit procedure which reflects the increased accuracies at lower altitudes. Once the criteria for GPS versus ground filter position differences have been satisfied, a direct verification that GPS is acceptable for the update has been performed. This is the primary method for GPS state vector confirmation. Ground filter velocity output is very noisy throughout the entry period and is therefore not used in the criteria for evaluating the GPS vector. Significant errors in the GPS velocity components without a corresponding error in the position components or the FOM value would be a rare condition. ©[062702-5439]

Another crosscheck on GPS position accuracy is the difference between GPS computed and actual TACAN range measurements. The MCC has a ground processor that computes equivalent TACAN measurements based on downlisted GPS state vectors. If the TACAN ground station is confirmed to be within acceptable limits (ref. Rule {A8-52B}.2, SENSOR FAILURES), the difference between the GPS computed and actual TACAN range measurements should not be more than 0.5 nm. The 0.5 nm range check accounts for small spec errors in the GPS vector at the FOM = 5 limit (0.1 nm) and for potential spec-level calibration errors in both the TACAN LRU (0.1 nm) and ground station hardware (0.3 nm). Navaid inhibits are not required before a GPS navigation update. Once GPS state vector accuracy has been confirmed with ground filter solutions, a GPS update would provide a more accurate onboard navigation correction in a timelier manner compared to the delta state update process. ©[072601-4530B] ©[062702-5439]

FLIGHT RULES

A4-203

ENTRY NAVIGATION UPDATE PHILOSOPHY (CONTINUED)

- B. GPS OR VELOCITY DELTA STATE UPDATES WILL REQUIRE CSS MODE TO PREVENT EXCESSIVE TRANSIENT MANEUVERS. @[072601-4530B]

If a GPS update is incorporated with metering logic overridden or a total delta state update is incorporated, the velocity corrections put a step function into the flight control system. The transients caused by the step function can cause large maneuvers which could overstress the vehicle or cause loss of control. Going CSS when a GPS (with metering overridden) or velocity delta state update is incorporated allows the crew to manually filter transients.

- C. POSITION DELTA STATE UPDATES OCCURRING NEAR TAEM INTERFACE (M = 5 TO M = 2.5 FOR EOM AND AOA AND M = 5 TO M = 3.2 FOR RTLS) WILL REQUIRE CSS TO PREVENT EXCESSIVE TRANSIENT MANEUVERS.

Entry guidance is targeted towards a specific set of end conditions at TAEM interface. For any given position error, the correction needed to satisfy the interface conditions grows as you approach TAEM. Going CSS for a delta state update close to TAEM interface allows the crew to filter the guidance commands to keep from overstressing the vehicle.

- D. DELTA STATE UPDATES WILL NORMALLY NOT BE PERFORMED AFTER HAC ACQUISITION. HOWEVER, IF VISUAL CONTACT WITH THE RUNWAY CANNOT BE MAINTAINED BY THE CREW, GPS OR DELTA STATE UPDATES WILL BE CONTINUED AS LONG AS THE ONBOARD STATE VECTOR CAN BE IMPROVED.

After HAC intercept, a delta state update will normally not be performed if the crew has visual contact with runway because transients caused by a delta state could prove distracting. Also, the external data sources (TACAN, BARO, MLS) would need to be deselected in order to allow the ground processor to compute the proper corrections. A GPS update may be performed after HAC intercept to allow the crew to fly good guidance commands. @[072601-4530B]

FLIGHT RULES

A4-204

DELTA STATE POSITION UPDATES

A. FOR POSITION COMPONENT EXCEEDANCE, A GPS OR THREE-COMPONENT (POSITION ONLY) UPDATE WILL BE EXECUTED (REF RULE {A4-203}, ENTRY NAVIGATION UPDATE PHILOSOPHY). ©[072601-4531] ©[062702-5440]

The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values.

B. POSITION REQUIREMENTS:

RTLS				EOM			
	DELTA POSITION (FT)				DELTA POSITION (FT)		
	X	Y	Z		X	Y	Z
H > 100K FT...	18K	18K	6K	H > 130K FT...	48K	48K	12K
H < 100K FT...	6K	6K	3K	H < 130K FT...	6K	6K	6K
				H < 90K FT...	6K	6K	3K

This rule contains the criteria for performing a position-only delta state update to correct the onboard navigation for both GRTLS and end of mission. The delta state processor is a ground processor that compares the onboard vector to time-correlated radar tracking data and outputs the deltas in runway Cartesian coordinates. This data is observed on the ground as three components of position and three components of velocity. The position update limits were set in order to meet guidance imposed navigation accuracy requirements (ref. STS 81-0366, appendix A, Navigation Performance Requirements). These accuracy requirements were identified to ensure auto guidance capability to achieve the runway after correcting the onboard navigation state. The guidance requirements are ramp functions of altitude, but in order for a ground operator to observe six error components on a constantly updating digital display and compare them to variable error limits, it was necessary to simplify the update criteria. When the errors observed in the onboard state exceed the limits defined in this rule, a GPS or delta state update is initiated on the ground. For GRTLS, the two tier set of limits was chosen with a breakpoint at 100,000 feet altitude, since it is desired to remove state errors before TAEM initiation. The limits above 100,000 feet altitude are tighter than for EOM, since there is little ranging control exercised in GRTLS until TAEM, which is initiated at M=3.2 or around 92,000 feet altitude. For EOM, the guidance requirements dictate that the errors be under control and decreasing with altitude by around 130,000 feet, the point at which TACAN's are usually incorporated into the onboard navigation state. Therefore, this point was chosen as the breakpoint for the EOM three-tier update criteria.

©[072601-4531]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-204****DELTA STATE POSITION UPDATES (CONTINUED)**

The third tier was added for EOM to allow a further breakdown of allowable altitude error. Instead of a delta-Z limit of 3k feet at an altitude of 130,000 feet, a 6k-foot error is permitted between 130,000 and 90,000 feet, and then the 3k limit applies below 90,000 feet altitude. This additional limit may preclude the likelihood of an unnecessary delta state update to correct a delta-Z error that could be reduced by the use of DRAG processing in the more accurate lower region of the onboard altitude atmospheric model. TACAN processing will not have much effect on the altitude error unless the orbiter passes over the TACAN ground station so that the majority of the range measurement is altitude rather than downtrack and crosstrack.

Rule {A4-151}, IMU ALIGNMENT, and Rule {A4-206}, NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF), reference this rule.

A4-205**DELTA STATE VELOCITY UPDATES**

DUE TO ONBOARD DRAG ALTITUDE UPDATING, THE DELTA STATE VELOCITY COMPONENTS ARE NOT SUFFICIENTLY ACCURATE TO MONITOR THE ONBOARD VELOCITY ERRORS; THEREFORE, THE ONBOARD VELOCITY ERRORS WILL BE EVALUATED USING GPS AND THE RADAR HIGH SPEED FILTER VELOCITY ERRORS. AN ONBOARD VELOCITY UPDATE WILL BE PERFORMED FOR A VELOCITY ERROR > 75 FPS IN ANY COMPONENT. RADAR VELOCITY 3 SIGMA UNCERTAINTIES OF UP TO 60 FPS COULD RESULT IN ONBOARD VELOCITY ERRORS OF UP TO 135 FPS PRIOR TO A GROUND UPDATE. IF A DELTA STATE VELOCITY UPDATE IS REQUIRED, DRAG ALTITUDE UPDATING WILL BE INHIBITED TO ASSURE VALID COMPUTATION OF PROPAGATED VELOCITY ERRORS, AND A SIX-COMPONENT UPDATE (POSITIONS AND VELOCITIES) WILL BE EXECUTED. GPS WILL BE USED TO CORRECT ONBOARD VELOCITY ERRORS IF GPS IS VERIFIED TO BE FUNCTIONING PROPERLY. NAVAID INHIBITS ARE NOT REQUIRED FOR A GPS UPDATE (REF RULE {A4-203}, ENTRY NAVIGATION UPDATE PHILOSOPHY). @[072601-4532] @[062702-5441A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-205

DELTA STATE VELOCITY UPDATES (CONTINUED)

An update of onboard velocity will be performed for velocity errors > 75 fps in any runway component. This number was chosen to meet a flight control system requirement when the FCS is using navigation-derived air data, while at the same time, considering the radar 3-sigma velocity uncertainty of 60 fps. Drag altitude updating of the onboard navigation must be inhibited prior to computing a velocity delta state since it corrupts the computation of velocity errors in the delta state processor. Two sets of state vector errors are available on a ground display in runway coordinates. The output of the high speed radar filter is referred to as local deltas, whereas, the output of the delta state processor is referred to as propagated deltas. The local deltas represent the current state errors. The propagated deltas represent the expected state errors at some time in the future; these deltas are used to generate a delta state update. They are computed assuming that the state errors are linear, that the current velocity errors are constant over some short period of time, and that the update will be applied at the end of that time. Since the velocity errors are computed from changes in position, any external update, such as drag altitude updating, will mask the true state error and cause the velocity delta to be wrong. Therefore, external navigation aids have to be inhibited prior to computing a delta state update involving velocities. Any time a velocity update is required, a position and velocity delta update will be executed, since velocity errors will also cause position errors.

The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. The three-sigma velocity accuracy requirement for GPS is 0.1 meters/sec for the horizontal and vertical components when GPS is operating in the Precise Positioning Service (PPS) mode and satisfying the assumptions for Table 3.4.1-1 of the System Requirements Document for Orbiter GPS Navigation System (SSD94D0096). Postflight analyses have confirmed very good GPS state vector accuracies in the TACAN processing region. Radial, downtrack, and crosstrack position and velocity differences between GPS and the USA Navigation Best Estimated Trajectory (BET) product have been less than 200 feet and 2 fps, respectively the majority of the time. Navaid inhibits are not required before a GPS navigation update. ©[072601-4532]

FLIGHT RULES

A4-209

AERO TEST MANEUVERS

AERO TEST MANEUVERS WILL NOT BE ATTEMPTED IF THE CROSSRANGE AT ENTRY INTERFACE IS GREATER THAN THE DTO CROSSRANGE LIMIT (REF. THE ANNEX FLIGHT RULE, TRAJECTORY AND GUIDANCE PARAMETERS) UNTIL THE FIRST ROLL REVERSAL HAS BEEN COMPLETED AND THE ORBITER ENERGY STATE AND DRAG PROFILE ARE NOMINAL. VALID TELEMETRY IS REQUIRED FOR EVALUATION OF THE ORBITER ENERGY STATE. ®[ED]

For the purposes of this rule, any PTI that inhibits entry guidance is considered an aero test maneuver. Since entry guidance is locked out, there is no attempt to follow the optimal energy profile or to respond to roll reversals. High crossrange at entry interface requires optimum bank angle and energy control to ensure a manageable energy state at TAEM interface. If energy is nominal and the orbiter is on the nominal drag profile, guidance will be able to manage energy properly, even under given dispersions. Valid telemetry is needed to verify that the energy and drag profiles are within limits.

Rule {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, references this rule.

FLIGHT RULES

A4-210

EOM ENTRY DTO/RUNWAY SELECTION PRIORITIES

DTO 805, CROSSWIND LANDING PERFORMANCE, WILL BE EXECUTED AS A DTO OF OPPORTUNITY. DTO 805 WILL NOT BE A CONSIDERATION IN SELECTING LANDING SITES OR RUNWAYS. IF CROSSWINDS ARE OBSERVED TO BE 10 KNOTS OR GREATER AS THE ORBITER APPROACHES THE HAC, DRAG CHUTE DEPLOY WILL BE DELAYED UNTIL POST NOSE GEAR TOUCHDOWN TO ACCOMPLISH DTO 805. ©[022201-3801]

No drag chute, braking, or nose wheel DTO's are scheduled. Drag chute deploy will be per nominal flight rules (ref Rules {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES, and {A10-144}, DRAG CHUTE DEPLOY CONSTRAINTS), unless the crosswind DTO is likely to be performed. In this case, drag chute deploy will be delayed until post nose gear touchdown to allow for pilot handling evaluation of the orbiter without any complications that drag chute dynamics may induce. Nominal touchdown speed is 195 keas with derotation performed using the beep trim switch at 185 keas, or manually (if beep trim fails) at 175 keas. Drag chute nominal deploy is immediately prior to the initiation of derotation. However, the drag chute DTO program has cleared drag chute deploy as early as 15 keas prior to the initiation of derotation. ©[102402-5804C]

All ISS rendezvous flights have a probability of a night landing which would mean that the crosswind limit is 12 knots. Therefore, DTO 805, Crosswind Landing Performance Evaluation, which requires a crosswind of 10 knots or greater at touchdown, is not likely to be achieved. With this small window of environmental conditions, it is not prudent to change landing sites (e.g., from KSC to EDW) to attempt DTO 805. Also, programmatic priorities make it highly desirable to land at KSC to avoid the cost and risk associated with ferry operations. Since a decision to change from KSC to EDW would have to be made approximately 2 to 4 hours before landing, it is unlikely that confidence in wind forecasts would be such that landing at EDW solely to achieve DTO 805 is prudent. ©[022201-3801] ©[102402-5804C]

SECTION 5 - BOOSTER

FAILURE DEFINITIONS

A5-1 **LOSS OF SRB THRUST VECTOR CONTROL (TVC)** @[012402-4987]

SRB TVC IS LOST WHEN THE HYDRAULIC SUPPLY PRESSURES OF BOTH HPU'S ON THE SAME SRB ARE 1000 PSIG OR LESS. @[041196-1874A]

The SRB TVC system has a lock-out style valve which will actuate to the lock position when the hydraulic supply pressure is 1000 to 600 psig. Two hydraulic power units (HPU's) are installed per SRB, and both can supply hydraulic power to the TVC actuators. Actuator source pressure is switched from the primary HPU to the secondary HPU when the hydraulic supply pressure on a single HPU reaches 2050 ±150 psig. This switchover is indicated by an Actuator Primary Pressure OK discrete value of False and it effectively loses one HPU. However, TVC is not lost until neither HPU can deliver hydraulic supply pressure of 1000 psig to the actuators. (Reference System Handbook Drawing 9.14 and USBI documents 10SPC-0055, rev B, section 4.2.2.10, and 10MNL-0045, Rev D). @[012402-4987]

Note: Above 1000 psig, the lock-out valve opens, and TVC is still available. @[041196-1875A]

A5-2 **SPACE SHUTTLE MAIN ENGINE OUT** @[121197-6472A]

PREMATURE ENGINE SHUTDOWN IS CAUSED BY AN ENGINE LIMIT EXCEEDED, DUAL CONTROLLER ELECTRONICS FAILURES, OR A COMBINATION OF A SINGLE CHANNEL LIMIT EXCEEDED AND A CONTROLLER ELECTRONIC FAILURE. THE CUES FOR DETERMINING AN ENGINE SHUTDOWN ARE DEFINED IN PARAGRAPHS A, B, C, AND D OF THIS RULE. THE SHUTDOWN SOFTWARE LIMITS ARE DEFINED IN PARAGRAPH E. THE AVIONIC FAILURE COMBINATIONS ARE DEFINED IN PARAGRAPH F.

ENGINE OUT DETERMINATION WILL BE BASED ON THE FOLLOWING CUES:

- A. ONBOARD (WITH VALID SSME DATA):
1. RED MAIN ENGINE STATUS LIGHT IS ILLUMINATED.
 2. PC < 30 PERCENT (METER)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-2 SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)**

3. SSME FAIL L (C,R)

Two cues are required for calls that may cause an abort. The MPS dedicated display driver sequence in the flight software illuminates the red status light if the SSME is in the shutdown or post-shutdown phase. The SSME operations sequence in the flight software uses power level < 30 percent as the indication that the SSME has shut down. The 30 percent value represents a power level below which the engine cannot operate. The PASS SSME fail message is generated by the GAX when the engine fail flag is set by the SSME OPS sequence. The flag is set when either the engine status word shows shutdown or post shutdown phase, or a data path failure has occurred and the engine safing command flag has been set.

B. MCC (WITH VALID SSME DATA):

AT LEAST TWO OF THE FOLLOWING CUES ARE REQUIRED:

1. SSME FAILURE IDENTIFIER (FID) "013" INDICATING SSME SHUTDOWN FOR REDLINE VIOLATION.
2. SHUTDOWN OR POST-SHUTDOWN PHASE (REFLECTED IN ENGINE STATUS WORD).
3. PC < 900 PSIA.
4. SSME FAIL L (C,R)

Two cues are required for calls that may cause an abort. A FID 013 issued by the SSME controller represents an engine shutdown due to a redline exceedance. The redline that was exceeded is defined by the delimiter part of the FID. Shutdown and post-shutdown phases are set in the engine status word when the SSME controller commands shutdown. Pc of 900 psia corresponds to approximately 30 percent power level. The PASS SSME fail message is generated by the GAX when the engine fail flag is set by the SSME OPS sequence. The flag is set when either the engine status word shows shutdown or post shutdown phase, or a data path failure has occurred and the engine safing command flag has been set. ©[121197-6472A]

C. ONBOARD (WITH SSME DATA PATH FAILURE):

AT LEAST THREE OF THE FOLLOWING ARE REQUIRED:

1. G-LEVEL DECREASE (ON DEDICATED DISPLAY G-METER OR BFS CRT TRAJECTORY DISPLAY G-LINE).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

2. A HELIUM, DP/DT FAULT MESSAGE FOLLOWED BY CONSTANT ENGINE HELIUM TANK PRESSURE (IF NO PREVIOUS FAULT MESSAGE FOR A HELIUM LEAK).
3. MPS H₂ OUT P L (C,R)
4. MPS O₂ OUT T L (C,R)

During second stage when the first, second, and third engines shut down in sequence, the g-level decreases by 33, 50, and 100 percent, respectively. During first stage, the SRB thrust far exceeds the SSME thrust making it difficult to detect an engine shutdown based upon changes in vehicle acceleration. If the engine did not previously have a helium leak, the crew will get a helium DP/DT fault message, followed by constant helium tank pressure on the affected engine. If the tank pressure remains constant, no helium is being used and; therefore, the engine has shut down. In OI-22 and subs, the crew will get fault messages for both the GH₂ outlet pressure and GO₂ outlet temperature dropping below 1050 psia and 125 deg F, respectively. Because both of these parameters are channelized through the same OI MDM and powered from the same OI DSC, the two fault messages could be generated by a single MDM or DSC failure. For this reason, the crew must use three of the four cues when determining an engine out behind a data path failure. ©[020196-1812] ©[121197-6472A]

D. MCC (WITH SSME DATA PATH FAILURE):

AT LEAST TWO OF THE FOLLOWING CUES ARE REQUIRED:

1. A SUDDEN DROP IN ACCELERATION OR THRUST FACTOR AS DETERMINED FROM TELEMETRY DATA. (THRUST FACTOR AVAILABLE IN SECOND STAGE ONLY).
2. ORBITER GH₂ OUTLET PRESSURE < 800 (1050) PSIA OR ORBITER GO₂ OUTLET TEMPERATURE < 260 DEG (300 DEG) F.
3. A HELIUM DP/DT FAULT MESSAGE FOLLOWED BY CONSTANT ENGINE HELIUM TANK PRESSURE (IF NO PREVIOUS FAULT MESSAGE FOR A HELIUM LEAK).
4. A DROP IN SECOND STAGE PERFORMANCE AS DETERMINED BY THE ARD.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

Two cues are required for calls that may cause an abort. For an engine failure in second stage, an abrupt drop in vehicle acceleration will result. The GH_2 outlet pressure and GO_2 outlet temperature are orbiter parameters that can be used to determine the status of an engine. Both the GH_2 and GO_2 limits are set to correspond to an engine power level of approximately 30 percent. This is well below the power level that an engine can operate. Flight data from STS 51-F indicates the GO_2 outlet temperature was < 125 deg F for about 15 seconds post engine shutdown. The GO_2 outlet temperature did rise again post shutdown to a value of approximately 300 deg F. Since both orbiter parameters are channelized through the same OI MDM and powered from the same OI DSC, the two are grouped together as one engine out cue. If an engine did not previously have a helium leak, the crew will get a DP/DT fault message while the engine initiates shutdown purges. Once the helium purges have terminated, the engine will no longer use helium and; therefore, the helium tank pressure will remain constant. Thrust factor (FT FACTOR) is a second stage guidance downlisted parameter from the vehicle and is calculated by dividing the expected thrust by the calculated thrust. If an engine shuts down behind a data path failure, the thrust factor will drop to a value less than 1.0. If an engine fails in first stage, thrust factor is not available, but the second stage performance as determined by the ARD would reflect the loss in performance from the engine shutdown.

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

NOTES:

- [1] MUST EXCEED LIMIT OR FAIL REASONABLENESS FOR 60 MSEC.

A parameter must be over its redline or reasonableness limit for three consecutive 20 msec controller cycles before action is taken by the controller. This requirement prevents action from being taken on a data hit.

- [2] THE HPOTP SECONDARY SEAL PRESSURE REDLINE IS ONLY ACTIVE ON THE PHASE II SSME. THIS REDLINE IS NOT PRESENT ON THE BLOCK I SSME, BLOCK IIA SSME, OR THE BLOCK II SSME. @[032395-1765A] @[121197-6472A]

- [3] SHUTDOWN FOR AN OUT-OF-LIMIT CONDITION INITIATED BY MAIN ENGINE CONTROLLER IF LIMIT ENABLED. LIMIT INHIBIT/ENABLE OPERATIONS DEPENDENT ON THE POSITION OF THE MAIN ENGINE LIMIT SHUTDOWN SWITCH.

This indicates that, if the limit shutdown logic is enabled, then a redline violation will result in an SSME shutdown.

- [4] IF ALL SENSORS FAIL REASONABLENESS, THAT REDLINE IS DELETED. @[092195-1792B]

Redline monitoring is no longer performed because the redline sensors have failed.

- [5] THE HPOTP INTERMEDIATE SEAL PRESSURE LOWER REDLINE IS 170 PSIA ON THE PHASE II SSME AND IS 159 PSIA ON THE BLOCK I SSME, BLOCK IIA SSME, AND THE BLOCK II SSME. @[032395-1765A] @[020196-1812]

- [6] THE REDLINE UPPER LIMIT IS CALCULATED IN REAL TIME BY CONTROLLER SOFTWARE AND IS A FUNCTION OF ENGINE POWER LEVEL. THEREFORE, THE LIMITS AT 67, 100, 104, AND 109 PERCENT POWER LEVELS ARE APPROXIMATELY 2436, 3543, 3677, AND 3846 PSIA FOR A PHASE II SSME, 2447, 3559, 3694, AND 3862 PSIA FOR A BLOCK I SSME, AND 2243, 3254, 3392 (@104.5), AND 3530 PSIA FOR A BLOCK IIA SSME, RESPECTIVELY. THIS REDLINE HAS BEEN DELETED FOR THE BLOCK II SSME. @[111094-1732] @[092195-1792B] @[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

The HPFTP coolant liner pressure varies with actual chamber pressure.

- [7] THIS REDLINE MAY BE REVISED ON A FLIGHT-BY-FLIGHT BASIS TO ENSURE COMPARABLE MARGIN ON CHANNEL A AND CHANNEL B BETWEEN THE PREDICTED NOMINAL VALUE AND THE REDLINE VALUE. IF A CHANNEL A TO B BIAS IS ADDED, THEN THIS BIAS IS CARRIED OVER INTO THE REASONABLENESS CALCULATIONS FOR THE INTERCHANNEL CHECKS. @[092195-1792B]

Some flight SSME HPFTP's may operate at a lower temperature. Engines with these turbopumps may have their channel A redline adjusted downward to provide the same 100 deg R difference between the main stage operating temperature and the redline as present on other HPFTP's. @[111094-1732]

- [8] THE INTRACHANNEL CHECK AND THE CHANNEL AVERAGE MUST BE WITHIN THE SPECIFIED LIMITS IN ORDER TO BE PROCESSED BY THE CONTROLLER'S SHUTDOWN LIMIT LOGIC. THESE REASONABLENESS CHECKS ARE IN ADDITION TO THE NORMAL SENSOR MONITORING PERFORMED FOR IGNITION CONFIRMED AND CONTROL LOOP PROCESSING QUALIFICATION.

The MCC Pc channels will be disqualified for control purposes for an intrachannel difference of greater than 75 psi. The MCC Pc redline logic incorporates two reasonableness criteria to ensure that only valid pressures will be used.

- [9] THE LOGIC FOR THE HPFT AND THE HPOT DISCHARGE TEMPERATURE WAS MODIFIED BY THE IMPLEMENTATION OF THE THERMOCOUPLES. THE THERMOCOUPLE MODIFICATION UTILIZES TWO SENSORS PER CHANNEL FOR A TOTAL OF FOUR SENSORS PER REDLINE. @[092195-1782B] @[092195-1782B]

The sensor processing logic was modified to accommodate the different failure modes for the thermocouple sensors (versus the previous resistive thermal devices-RTD's) and to handle the additional number of sensors. The additional sensors were added to increase reliability against sensor failures resulting in pad aborts, erroneous in-flight shutdown, or the loss of redline protection. @[121197-6472A]

- [10] THE HPFTP COOLANT LINER PRESSURE REDLINE IS ONLY AVAILABLE FOR THE PHASE II, BLOCK I, AND BLOCK IIA ENGINE TYPES. @[121197-6472A]

The Block II SSME uses a Pratt & Whitney HPFTP/AT which does not have a coolant liner.

- [11] A COLD JUNCTION REFERENCE TEMPERATURE (T_{CJ}) IS PROVIDED FOR EACH CONTROLLER CHANNEL TO PROCESS THE HOT GAS THERMOCOUPLE SENSOR DATA. THE T_{CJ} IS USED TO CALIBRATE THE TEMPERATURE MEASUREMENT INPUT. EACH CHANNEL HAS A SINGLE RTD T_{CJ} WHICH IS USED FOR BOTH THE HPOT AND HPFT TEMPERATURE MEASUREMENTS. IF ONE CHANNEL'S T_{CJ} IS DISQUALIFIED, THE OTHER CHANNEL'S T_{CJ} WILL BE USED FOR BOTH CHANNELS. IF BOTH T_{CJ} S ARE DISQUALIFIED, THE LAST QUALIFIED VALUE WILL BE USED FOR SENSOR PROCESSING.

Thermocouple measurements require a cold junction reference temperature to provide accurate readings. The controller and its software was modified to accommodate the addition of these two transducers, which are required for use with the thermocouples.

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

- a. *PARAMETERS - This table covers parameters which the SSME controller qualifies, monitors, and uses to shut down the engine.*
- b. *CONTROLLER SHUTDOWN PROCESSING - All qualified sensors must vote for shutdown for action to proceed. ©[092195-1792B]*
- c. *QUALIFICATION/REASONABLENESS TESTING - Qualification, also known as reasonableness testing, is required to qualify the sensors for application to shutdown logic. The values chosen screen out sensors with identified sensor problems. ©[121197-6472A]*
- d. *SHUTDOWN LIMITS - Redline parameters are monitored to assure that the engine is performing within safe operating conditions. Limits are set to guard against uncontained SSME damage. The limits are based upon test stand data, flight experience, and engineering analysis. The engine redline design criteria was defined by MSFC and approved by Level II.*
- e. *HPFTP COOLANT LINER PRESSURE ©[092195-1792B]*

Phase II, Block I, and Block IIA SSME's - The redline limit was selected to prevent buckling of the coolant liner and subsequent stalling of the HPFTP. This limit was derived from an uncontained failure of SSME 0108 during a ground test. The exhaust turnaround duct buckled, the HPFTP stalled, and the low pressure fuel duct ruptured. Based upon this incident and analysis, the buckling pressure has been determined to be 595 psid with the delta pressure being measured between the coolant liner cavity and the turnaround duct. The redline was set to protect for a delta pressure of 400 psi and has been verified by lab tests. The reasonableness limits of 4500 and 1800 psi were established because they bracket the sensor range.

- f. *HPFT TURBINE DISCHARGE TEMPERATURE ©[092195-1792B]*

The limit was derived from analysis and protects against stress rupture of the HPFT blades due to high temperature operation. This redline was developed following uncontained failures on engines 0204 and 2013 during ground testing. These failures were attributed to turbine blade failure which resulted in HPFTP seizure and low pressure fuel duct rupture. Subsequent analysis determined a 2160 deg R maximum turbine blade root temperature capability for 109 percent power level. This temperature equates to a 2060 deg R turbine exhaust temperature. The 1960 deg R limit provides a 100 deg R margin for the Phase II and Block I SSME's. The 1860 deg R limit provides a 200 deg R margin for the Block IIA and Block II SSME's. This reduction for the Block IIA and Block II SSME's still leaves satisfactory margin from nominal operating conditions to the redline, due to the reduced temperature environment facilitated by the large throat MCC (reference 8/15/97 Ascent/Entry Flight Techniques Panel). The channel A location on some HPFTP's may run cooler, thus necessitating a lower redline value (potentially as low as 1850 deg R for the Phase II and Block I or 1750 deg R for the Block IIA and Block II). ©[111094-1732] ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

The upper reasonableness limit of 2650 deg R guards against open circuits and analog-to-digital (A/D) converter failures. The intrachannel and interchannel reasonableness limits are screens for internal short circuits. An absolute lower limit is not feasible since a short will result in an in-range failure signature. If only one sensor remains, only the open circuit failure mode is detectable.

©[092195-1792B] ©[121197-6472A]

g. **HPOT TURBINE DISCHARGE TEMPERATURE** ©[092195-1792B]

The upper redline limit was derived from analysis to protect the heat exchanger from overheating and rupturing leading to catastrophic failure. The limit of 1760 deg R provides a 100 deg margin (1860 deg R is based on meeting one mission life capability; i.e., until nominal predicted MECO) for the Phase II, and Block I SSME's. The 1660 deg R limit provides a 200 deg R margin for the Block IIA and Block II SSME's. This reduction for the Block IIA and Block II SSME's still leaves satisfactory margin from nominal operating conditions to the redline, due to the reduced temperature environment facilitated by the large throat MCC (reference 8/15/97 Ascent/Entry Flight Techniques Panel). The lower redline limit of 720 deg R provides protection against inadvertent deep throttling of the engine, which causes ice formation in the HPOT turbine, subsequent turbine imbalance, and potential catastrophic HPOTP failure. ©[121197-6472A]

The reasonableness limit of 2650 deg R guards against open circuits and A/D converter failures. The intrachannel and interchannel reasonableness limits are screens for internal short circuits. An absolute lower limit is not feasible since a short will result in an in-range failure signature. If only one sensor remains, only the open circuit failure mode is detectable. ©[121197-6472A]

h. **HPOTP SECONDARY SEAL PRESSURE**

PHASE II SSME - The redline limit was derived from analysis to prevent the LO₂ from the HPOTP pump combining with the hot fuel-rich turbine gas in the seal purge cavity. The redline protects against failures of the HPOTP primary or secondary turbine seals. The limit is set to ensure that the HPOTP intermediate seal cavity pressure is greater than the HPOTP secondary seal cavity pressure by 9 psi during main stage, with a minimum seal purge flow rate and a maximum seal gap. Both reasonableness tests provide protection against avionics failures of the pressure sensor system.

©[032395-1765A] ©[092195-1792B]

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME - Due to significant design changes in the alternate HPOTP seal package on these engines, this transducer and its redline have been eliminated. Rationale for this is the oxidizer and secondary H₂ drain pressure margins are large, and a secondary labyrinthine (lab) seal analysis at more than six times its maximum possible operating clearance showed helium barrier delta pressure is insensitive to lab seal clearance changes. ©[032395-1765A]

©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

i. HPOTP INTERMEDIATE SEAL PRESSURE -

PHASE II SSME - The redline limit was derived from analysis to prevent the LO₂ from the HPOTP pump combining with the hot fuel-rich turbine gas in the purge cavity. This redline guards against excessive seal wear or loss of helium purge by ensuring that the HPOTP intermediate seal cavity pressure is greater than the HPOTP secondary seal cavity pressure by 9 psi during main stage under the worst seal gap condition. Both reasonableness tests provide protection against avionics failures of the pressure sensor system. ©[032395-1765A] ©[092195-1792B] ©[121197-6472A]

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME - The redline limit was derived from analysis to prevent LO₂ from the alternate HPOTP pump combining in the purge cavity with H₂ from the fuel cooled roller and ball bearing package. This redline guards against excessive seal wear or loss of helium purge by ensuring that the HPOTP intermediate seal cavity pressure is greater than the HPOTP O₂ cavity and secondary H₂ cavity pressures by 10 psi during main stage under the worst seal gap condition. Both reasonableness tests provide protection against avionics failures of the pressure sensor system. ©[032395-1765A] ©[092195-1792B] ©[121197-6472A]

- j. *MCC PC SENSOR AVERAGE - The redline was initially added to protect the engine against the type of failure seen on engine 2106, in which a burnthrough of the bellows section of the high pressure oxidizer turbopump turbine section occurred. This failure was caused by an oxidizer preburner failure and resulted in a bypass of hot gas flow from the turbine directly into the hot gas manifold which caused a massive drop in MCC Pc. The original redline limit of 400 psi below the commanded Pc was chosen based upon the amount of damage sustained by the engine 2106 high-pressure oxidizer turbopump at the time the engine was shut down by a facility redline. The MCC Pc redline was updated for STS-89 and subsequent flights to 200 psi below the commanded Pc during steady state operations, while retaining the 400 psi during throttling and when power level is less than or equal to 75 percent RPL. This update was based upon the amount of damage sustained by engine 0524 which experienced a nozzle failure and uncontained shutdown during test 901-933. ©[121197-6472A]*

The intrachannel reasonableness limit (|Bridge 1 - Bridge 2| ? 125 psi) protects against single-bridge failures. Due to hardware and software limitations in the controller for sampling sensor inputs, the delta value must be set large enough to account for differences in the actual MCC Pc if the actual MCC Pc is decreasing rapidly due to a real engine combustion problem. If the value is set too tight, the actual MCC Pc could drop greater than the reasonableness limit between sampling the bridge 1 and bridge 2 sensor measurements. A smaller value could allow one or both MCC Pc channels to be erroneously disqualified. If both channels are disqualified, the MCC Pc redline is disabled at a time it is most needed. The redline qualification limit was increased from 75 psi to 125 psi in response to the catastrophic failure of development SSME 0212 (test 904-44), during which the actual decay rate of the MCC Pc was 105 psi between input samples of the A1/A2 and B1/B2 Pc pairs. The channel average upper reasonableness limit protects against an off-scale high sensor pair or input electronics failure. The lower limit protects against a failed low sensor pair or input electronics failure. ©[121197-6472A]

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

This matrix identifies failures which result in loss of controller redundancy and in premature engine shutdown. Shutdown caused by dual controller failures cannot be prevented even if the limit shutdown monitoring is inhibited. In these cases when the second failure occurs, the engine will immediately shut down via the controller's fail-safe pneumatic shutdown sequence. Shutdowns caused by redline violations can be inhibited manually by the limit shutdown monitoring switch or automatically by the GPC software after an engine out or data path failure.

Rules {A5-5}, SUSPECT ENGINE; {A5-6}, SSME REDLINE SENSOR FAILED; {A5-7}, SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN; {A5-8}, SPACE SHUTTLE MAIN ENGINE TYPES; {A5-110}, SSME PERFORMANCE DISPERSION; and {A5-111}, AC BUS SENSOR ELECTRONICS CONTROL [CIL], reference this rule. ©[121197-6482B] ©[121197-6472A] ©[111298-6785A] ©[ED]

A5-3

STUCK THROTTLE

FAILURE OF A MAIN ENGINE TO THROTTLE COULD BE CAUSED BY COMBINATIONS OF ENGINE AND AVIONICS FAILURES WHICH CAUSE THE ENGINE OPERATING MODE TO CHANGE TO ELECTRICAL OR HYDRAULIC LOCKUP, OR BY ORBITER AND MAIN ENGINE AVIONICS FAILURES CAUSING A COMMAND PATH FAILURE.

A. ELECTRICAL LOCKUP

THE ENGINE PROPELLANT VALVES ARE ACTIVELY CONTROLLED AT THEIR LAST COMMANDED POSITION THAT EXISTED PRIOR TO LOSS OF BOTH SENSOR CHANNELS OF EITHER THE LH₂ FLOWMETER TRANSDUCERS OR MAIN COMBUSTION CHAMBER PRESSURE TRANSDUCER PAIRS.

The SSME valves are controlled to their last commanded values to minimize mixture ratio excursions. Mixture ratio is a function of measured main combustion chamber pressure (Pc) and LH₂ flowrate. The mass flowrate is calculated from measured volumetric flowrate and calculated fuel density (as calculated from LPFT discharge pressure and temperature). Should the LPFT discharge pressure or temperature be disqualified, a "fixed" density value for the LH₂ density will be used. Should both channels of either the measured Pc or volumetric flowrate be disqualified, or a combination of loss of controller redundancy and a loss of the remaining channel's Pc or volumetric flowrate, the engine enters into the "electrical lockup" mode and all valves are maintained at their last commanded position until shutdown is commanded. If the controller implements the shutdown, it will be a hydraulic shutdown. If the crew must manually shut down the engine (ref. Rules {A5-108}, MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP, and {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES), the shutdown will be a hydraulic shutdown. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002. ©[030994-1614A] ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-3 STUCK THROTTLE (CONTINUED)

B. HYDRAULIC LOCKUP

ALL FIVE ENGINE PROPELLANT VALVES ARE HYDRAULICALLY ISOLATED AT THEIR LAST POSITION WHEN BOTH CHANNELS OF SERVOACTUATORS HAVE BEEN DISQUALIFIED FOR ANY COMBINATION OF THE FOLLOWING FAILURES: ISSUANCE OF A SERVOACTUATOR ERROR INDICATION INTERRUPT (SEII), FAILURE OF THE DIGITAL-TO-ANALOG CONVERTER (DAC) TEST, FAILURE OF THE SERVOACTUATOR MODEL, OR LOSS OF CONTROLLER REDUNDANCY. THE SEII LIMIT IS 6 PERCENT FOR CHANNEL A AND 10 PERCENT FOR CHANNEL B.

Hydraulic isolation of the valves minimizes, but does not prevent, valve drift which could result in further deviations from nominal valve positions causing loss of performance and/or possible engine shutdown. One hydraulic system supplies hydraulic actuation to the five engine valves (a different hydraulic system for each engine). Each valve has a redundant servocontrol system. Channel A is normally controlling unless it has been disqualified. Channel A disqualification could be due to loss of channel A power, loss of channel A input or output electronics, failure of the SEII 6 percent test (expressed in terms of percent full range valve travel), failure of the output electronics (OE) DAC test, or failure of the channel A servoactuator model. The SEII test compares the actual valve position to the expected valve position based on an internal servoactuator model. The OE DAC test verifies that each DAC's output voltage level is equal to its last commanded value, and that the command decoder addresses the correct OE DAC by proper decoding of the four LSB's of the OE storage register. The servoactuator model/monitor test verifies proper operation of the hardware and software associated with SEII's. Channel B disqualifications could be due to the same type of failures listed for channel A, except channel B uses an SEII test limit of 10 percent error comparison instead of 6 percent to take into account the switchover transient from channel A to B. Should both channels be disqualified, the SSME enters into "hydraulic lockup." In this mode, the engine might experience loss of performance due to valve drift. If this occurs and a redline limit is exceeded, the engine will be pneumatically shut down. If a redline is not exceeded, then shutdown of the engine will be accomplished by engine pneumatics when a manual or commanded shut down occurs. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-3 STUCK THROTTLE (CONTINUED)

C. COMMAND PATH FAILURE

LOSS OF COMMAND CAPABILITY FROM THE GPC TO AN SSME ON AT LEAST TWO COMMAND CHANNELS. @[030994-1614A]

Without GPC commands, the SSME will not be able to accomplish the following functions: change throttle settings, inhibit/enable shutdown limits, respond to shutdown commands, or perform an LO₂ dump. Shutdown commands could be issued by guidance software, from a low level cutoff, or from a manual shutdown pushbutton. Each controller normally requires two of three valid command paths from the GPC's to control the SSME (start commands require three of three functional command paths). SSME controller software change RCN 4354 implemented in version OI-6 and subs added the capability for the engine to accept a shutdown enable/shutdown command pair on a single channel under special circumstances: an internal timer has expired (currently set at 512.86 seconds from engine start); limits have never been inhibited; the shutdown enable/shutdown command pair come in on the same channel, sequentially (with no other command in-between); and a valid command is not concurrently being received on the other two channels. Shutdown of the SSME without GPC control is accomplished by the removal of ac power to the controller. This action activates the fail-safe engine pneumatic system, shutting the engine down safely. A data path failure will also result from this action, requiring the crew to push the affected engine's shutdown pushbutton to inform guidance of an engine out and to safe the engine by closing the LH₂ and LO₂ prevalues. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002. @[030994-1614A]

A5-4 DATA PATH FAILURE

LOSS OF ALL PRIMARY AND SECONDARY DATA FROM THE SSME CONTROLLER TO GPC'S.

Since TREF, engine status word and average Pc values are present in both the primary and secondary data, the loss of both data types from the controller is required for the GPC to acknowledge a data path failure. This failure is identified by the GPC SSME SOP software. The loss of both data paths will prevent onboard and ground monitoring of all SSME data. (Ref. FSSR for SSME SOP).

FLIGHT RULES

A5-5

SUSPECT ENGINE

A SUSPECT ENGINE IS A RESULT OF ANY OF THE FOLLOWING FAILURE CONDITIONS:

- A. ALL QUALIFIED REDLINE SENSORS ON A PARAMETER SHIFT IN THE SAME DIRECTION, WITH AT LEAST ONE, BUT NOT ALL, QUALIFIED SENSORS VIOLATING THE REDLINE LIMIT(S). @[092195-1795]

If all redline sensors pass their reasonableness limits, at least one, but not all, are violating their redline limit(s) and all non-voting sensors have shifted toward their redline(s), the SSME can continue to operate but will shut down if the remaining qualified sensors exceed their shutdown limits. The fact that all qualified sensors have moved toward their redlines indicates that something is wrong with the engine and that shutdown could occur at any moment. Reference rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for reasonableness/qualification limits and redline limits. @[ED]

- B. ALL QUALIFIED SENSORS EXCEED THE LIMITS FOR A PARTICULAR REDLINE AFTER SHUTDOWN MONITORING IS INHIBITED.

If all qualified sensors exceed limits with the shutdown monitoring inhibited, the SSME is approaching the failure situation which the limits were designed to prevent. The redline will only remain inhibited as long as the vehicle is in an abort region gap. While the limits are inhibited, the engine may fail at any moment with uncontained engine damage and loss of vehicle and crew, since the shutdown limit protection is not available for this case. Reference rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for redline limits. Reference rule {A5-103}, LIMIT SHUTDOWN CONTROL, for re-enabling boundaries. @[092195-1795] @[ED]

- C. NONISOLATABLE MPS HELIUM LEAK

Using the MPS helium leak isolation procedure, the crew can determine if isolating a given leg will stop the leak. If the procedure does not stop the leak, it is nonisolatable and may result in SSME shutdown due to HPOT intermediate seal pressure dropping below the redline. The SSME with a helium leak is considered suspect since its leak rate could increase at any time and thus could cause the engine to shut down earlier than predicted by the MCC. Reference rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[032395-1766]

- D. LOW LH₂ NPSP

If LH₂ NPSP is low enough to require manual throttling or cause a TAL due to an LH₂ tank ullage leak or failed closed GH₂ flow control valves, at least one SSME may be approaching a redline limit shutdown due to high HPFTP turbine discharge temperatures. Reference rules {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-5 SUSPECT ENGINE (CONTINUED)

- E. DRIFTING PERFORMANCE WITH ALL QUALIFIED CHANNELS OF ANY GIVEN REDLINE PARAMETER APPROACHING THEIR REDLINE LIMITS.

An engine in hydraulic lockup is expected to drift. This performance drift should elevate HPOTP turbine discharge temperatures which may eventually exceed the redline causing the engine to shutdown. Nozzle leaks and HPOTP efficiency loss cases may cause redline exceedance and subsequent shutdown due to violation of one of the turbine temperature redlines or the MCC Pc low redline. MCC Pc shifts and FFM shifts may cause a redline exceedance (probably one of the turbine temperatures) and subsequent shutdown. Electric lockups due to large FFM shifts can cause a redline exceedance (due to turbine temperatures or the MCC Pc redline). Reference rule {A5-2}, paragraph E, SPACE SHUTTLE MAIN ENGINE OUT, for redline limits. @ED]

Rules {A4-56}, PERFORMANCE BOUNDARIES; and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES; reference this rule. @[092195-1770A] @[092195-1795]

A5-6 SSME REDLINE SENSOR FAILED

AN SSME REDLINE SENSOR WILL BE DECLARED FAILED PER THE FOLLOWING CRITERIA: @[092195-1794] @[121296-4624]

- A. AN SSME REDLINE SENSOR IS DECLARED FAILED IF IT WAS DISQUALIFIED BY THE SSME CONTROLLER DUE TO VIOLATION OF ITS REDLINE QUALIFICATION LIMIT DURING THE START PREP (PRELAUNCH), START, OR MAINSTAGE PHASE. IN ADDITION, AN MCC PC CHANNEL SHALL BE CONSIDERED FAILED IF IT HAS FAILED ITS CONTROL INTRACHANNEL QUALIFICATION LIMIT. @[111699-7096]

Once an SSME redline sensor has been disqualified, it can no longer be used by the SSME controller software for redline monitoring (reference rule {A5-2}, paragraph E, SPACE SHUTTLE MAIN ENGINE OUT, for qualification limits). Redline pressure sensors that fail during start prep (prelaunch) will generate a major component failure (MCF) and preclude launching. However, because of the quadruple redundancy scheme, a redline temperature sensor can fail during start prep (prelaunch) without generating an MCF and without an LCC violation. For the purpose of limits management, this is considered a failed sensor. (Ref. Rule {A5-103}, LIMIT SHUTDOWN CONTROL). @[111699-7096]

A failure of the MCC Pc control intrachannel qualification monitor (pressure delta between the two bridges exceeds 75 psia) is also indicative of a sensor failure, even though the Pc channel is still used for redline monitoring. The redline intrachannel qualification delta is larger (125 psia) to account for the case of a real engine failure dropping the Pc so quickly that the delta between bridges could exceed the 75 psia in the time it takes the controller to read in the two values. The control intrachannel check is included in the failure criteria because that channel could degrade at any time and violate the redline intrachannel check. @[111699-7096]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-6

SSME REDLINE SENSOR FAILED (CONTINUED)

The SSME controller performs a Pc reference (ref) check as part of the Pc control logic. The Pc ref logic evaluates the health of the Pc channel, as opposed to the individual sensors, by comparing the Pc channel averages to the reference Pc. It checks to see if the Pc channel average is greater than 75 psi from the reference Pc (200 psi when throttling or below 75 percent RPL). In order for sensors to cause this check to fail, both sensors would have to fail simultaneously and in the same direction. It is more likely that there is a channel failure causing the Pc ref limits to be violated, and thus this is not considered a failed sensor. If a channel fails the Pc discriminator logic check, it is considered a channel failure, not a sensor failure.

Rule {A5-7}, SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, references this rule. @[121296-4624] @[ED]

- B. AN HPOTP DISCHARGE PRESSURE SENSOR OR AN HPFTP DISCHARGE PRESSURE SENSOR SHALL BE CONSIDERED A FAILED REDLINE SENSOR IF IT WAS DISQUALIFIED BY THE SSME CONTROLLER DUE TO VIOLATION OF ITS QUALIFICATION LIMIT DURING THE START PREP (PRELAUNCH), START, OR MAINSTAGE PHASE.

NOTE: THE DISCHARGE PRESSURES DO NOT HAVE AN ASSOCIATED REDLINE BUT ARE ELECTRONICALLY THE SAME AS THE REDLINE PRESSURE SENSORS.

The HPOTP and HPFTP discharge pressure sensors are electronically the same as the redline pressure sensors and thus are operationally considered the same as a redline sensor. Qualification limits were added to these parameters when the Pc discriminator logic was introduced post STS-91 (ref. SSME Requirement Change Notices # 6503 & 6524). Once an HPOTP DP or HPFTP DP sensor is disqualified, it is no longer used in the controller's Pc discriminator logic. The first of these two sensors to fail will not generate an MCF and will not cause an LCC violation. Therefore, if this sensor fails in the start prep (prelaunch), start, or mainstage phase, it is considered failed for the purpose of limits management (ref. Rule {A5-103}, LIMIT SHUTDOWN CONTROL). Note: a second discharge pressure sensor failure in start prep (prelaunch) or start will post an MCF and will preclude launching. @[111699-7096]

- C. IF THE FLIGHT CONTROLLERS CAN POSITIVELY IDENTIFY THE SENSOR FAILURE MODE(S) AS BEING THE CAUSE OF AN ENGINE SHUTDOWN, THE AFFECTED SSME REDLINE SENSOR(S) WILL BE DECLARED FAILED.
@[092195-1794] @[111699-7096]

Rule {A5-103}, LIMIT SHUTDOWN CONTROL, references this rule.

FLIGHT RULES**A5-7****SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN
ERRONEOUS SHUTDOWN** [ED]

- A. AN SSME WILL BE DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE OF THE HPFTP COOLANT LINER PRESSURE TRANSDUCERS (PHASE II AND BLOCK I SSME ONLY), ONE OF THE HPOTP SECONDARY SEAL PRESSURES (PHASE II SSME ONLY), OR ONE OF THE HPOTP INTERMEDIATE SEAL PRESSURE TRANSDUCERS, IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING. [121296-4624]

NOTE: AN SSME IS NOT DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE OF THE TWO SSME MCC PC CHANNELS IS DISQUALIFIED.

The HPFTP coolant liner pressure redline (Phase II and Block I SSME only), the secondary seal pressure redline (Phase II SSME only), and the intermediate seal pressure redline each have two pressure transducers per redline (single transducer per controller channel). Therefore, if one or more transducers are disqualified for either a controller failure (input electronics or power supply, reference Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT) or a sensor failure (reference Rule {A5-6}, SSME REDLINE SENSOR FAILED), causing any remaining pressure redline to have a single qualified transducer, the engine will be considered one redline sensor failure away from an erroneous shutdown. This definition is used by Rule {A5-103}, LIMIT SHUTDOWN CONTROL, but only after the criteria outlined there (e.g., at least one redline sensor has failed) has been met. [121296-4624] [ED]

No single main combustion chamber pressure (MCC Pc) transducer failure can cause an engine to shut down on the MCC Pc redline when only one channel remains. Engine shutdown is prevented because of the way the MCC Pc transducers are qualified (redline processing is performed on channel pairs). An MCC Pc channel must have a channel average between 1000 and 3500 psia, and the two transducers on the channel must be within 125 psia of each other, for the channel to be qualified to vote for shutdown, reference Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT. The channel is disqualified for redline processing if either of these conditions is not met. The redline is violated if all qualified channel averages are 400 psia less than reference Pc (defined by the SSME controller for a given SSME power level). If one of the Pc transducers drifts high, with only one channel remaining, the controller channel's two Pc sensors will be disqualified for thrust control processing. This disqualification will occur when the delta between the two channels reaches 75 psia. This will place the SSME in electrical lockup. Additionally, if the sensor continues to drift such that delta between the two sensors is 125 psia, the controller channel's Pc transducers will be disqualified for redline shutdown processing. This disqualification will occur prior to the 400 psia redline being violated. For cases where both transducers are on the remaining channel drift, (thermal isolator problem or lee jet/sense tube problem), the engine will continually rebalance in response to the drifting Pc. If the drift is severe enough, the engine may exceed the 400 psia engine redline. In either case, SSME redline limits should be reenabled as specified in Rule {A5-103}, LIMIT SHUTDOWN CONTROL. [ED]

FLIGHT RULES

A5-7

SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN (CONTINUED)

- B. AN SSME IS DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE HPOT TURBINE DISCHARGE TEMPERATURE (TDT) TRANSDUCER IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING.
- C. AN SSME IS NOT DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE HPFT TURBINE DISCHARGE TEMPERATURE TRANSDUCER IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING.

Once a sensor has been disqualified, it can no longer be used by the SSME controller software for redline monitoring. Reference Rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for information on qualification/reasonableness testing. There are known thermocouple failure modes that can cause a sensor to fail below the lower HPOT turbine discharge temperature redline, but above the qualification limit. Therefore, the HPOT turbine discharge temperature redline will be considered one redline sensor failure away from an erroneous shutdown if only one qualified HPOT turbine discharge temperature sensor is qualified. Because there is no lower HPFT turbine discharge temperature redline limit, an SSME is not declared one redline sensor failure away from an erroneous shutdown if only one qualified HPFT turbine discharge temperature transducer is qualified for shutdown. ©[121296-4624] ©[ED]

A failure causing one turbine discharge temperature to remain qualified, but vote for shutdown on the upper redline, can result in SSME shutdown - if there are three or less qualified transducers at the redline location. This can occur because the redline logic disqualifies the "lower" transducers. Reference Rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for information on qualification/reasonableness testing. The only known thermocouple failure mode, where the thermocouple fails in-qualification-range high while violating the upper redline limit, is a "smart" failure in the SSME controller thermocouple sensor signal conditioning pre-amp circuit. This failure mode has a very low probability of occurrence (reference the special Rocketdyne briefing on this topic to the Shuttle Program Manager on 11/9/95). The entire thermocouple turbine discharge temperature redline processing philosophy of disqualifying the "lower" transducer depends on this low probability. Since the redline processing philosophy does not protect for this case, this flight rule does not protect for this case either. ©[ED]

Rules {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT; {A5-6}, SSME REDLINE SENSOR FAILED; and {A5-103}, LIMIT SHUTDOWN CONTROL, reference this rule. ©[121296-4624] ©[ED]

SPACE SHUTTLE MAIN ENGINE TYPES @[ED]

	HPOTP	MCC	HPFTP
PHASE II	ROCKETDYNE	STANDARD	ROCKETDYNE
BLOCK I/IA	P&W	STANDARD	ROCKETDYNE
BLOCK IIA	P&W	LARGE THROAT	ROCKETDYNE
BLOCK II	P&W	LARGE THROAT	P&W

@[121197-6472A]

THERE ARE MANY HARDWARE DIFFERENCES ASSOCIATED WITH THE VARIOUS SSME TYPES. ONLY THE DIFFERENCES WITH SIGNIFICANT BOOSTER SYSTEMS FLIGHT CONTROLLER OPERATIONAL IMPACTS ARE LISTED HERE.

FROM THE BOOSTER SYSTEMS FLIGHT CONTROLLER'S PERSPECTIVE, THE BLOCK I AND THE BLOCK IA OPERATIONAL CHARACTERISTICS ARE IDENTICAL. FOR THE PURPOSES OF THE FLIGHT RULES, THE NOMENCLATURE 'BLOCK I' WILL BE USED FOR BOTH.

FOR BLOCK I/IIA/II: INCORPORATION OF THE PRATT AND WHITNEY (P&W) ALTERNATE HPOTP IN PLACE OF THE ROCKETDYNE BASELINE HPOTP ELIMINATES THE SECONDARY SEAL REDLINE AND LOWERS THE INTERMEDIATE SEAL REDLINE (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

FOR BLOCK IIA/II: INCORPORATION OF THE LARGE THROAT MCC IN PLACE OF THE STANDARD THROAT MCC REDUCES THE OVERALL OPERATING PRESSURES AND TEMPERATURES AT A GIVEN POWER LEVEL AND LOWERS THE HPOTP AND HPFTP TURBINE DISCHARGE TEMPERATURE REDLINES (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

FOR BLOCK II: INCORPORATION OF THE PRATT AND WHITNEY ALTERNATE HPFTP IN PLACE OF THE ROCKETDYNE BASELINE HPFTP ELIMINATES THE COOLANT LINER REDLINE (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

DETAILS OF THESE CHANGES ARE COVERED IN BOOSTER SYSTEMS' CONSOLE TOOLS AND DOCUMENTATION.

Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT, references this rule. @[121197-6472A]

FLIGHT RULES

A5-9

LH2 ULLAGE LEAK @[ED]

WITH THREE SSME'S RUNNING AT MISSION POWER LEVEL, AN ET LH₂ ULLAGE LEAK IS CHARACTERIZED BY ALL OF THE FOLLOWING: @[040899-6818A] @[102501-4880A]

- A. LH₂ ULLAGE PRESSURE IS STEADILY DECAYING AND:
1. HAS DROPPED BELOW 32.6 (32.2) PSIA PRIOR TO AN MET OF 2 MINUTES 30 SECONDS, OR
 2. HAS DROPPED BELOW 31.0 (30.6) PSIA AFTER AN MET OF 2 MINUTES 30 SECONDS
- B. THE GH₂ 2-INCH DISCONNECT PRESSURE IS GREATER THAN 444 (414) PSIA.

The ET LH₂ ullage pressure is maintained by the three flow control valves (FCV's) in the orbiter GH₂ pressurization system. The set point for the GH₂ FCV signal conditioners is 33.0 psia. A 0.4 psi signal conditioner deadband encompassing the set point results in actual activation values as low as 32.6 psia or as high as 33.4 psia. A significant LH₂ ullage leak or an orbiter GH₂ pressurization system anomaly (reference Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP) will cause the LH₂ ullage pressure to drop below the set point for the GH₂ FCV signal conditioner. The orbiter GH₂ pressurization system will then respond by opening the three GH₂ FCV's in an attempt to increase ullage pressure. The FCV's have been shimmed, such that an open FCV provides 70 percent flow through the valve and 31 percent flow when the valve is commanded closed. These settings are also referred to as the 'high flow' and 'low flow' positions, respectively.

Data provided by Lockheed Martin/Michoud (reference PSIG telecon May 22, 2001) indicates that a GH₂ pressurization system operating at -3 sigma could cause the ullage pressure to decay to a minimum pressure of 31.0 psia (30.6 indicated when a 0.4 psi worst case transducer bias is included). To avoid erroneously declaring an ullage leak when the GH₂ pressurization system is functioning nominally, an ullage leak will not be declared unless the ullage pressure is decaying and has dropped below 32.6 (32.2) psia prior to an MET of 2 minutes 30 seconds or below 31.0 (30.6) psia after an MET of 2 minutes 30 seconds. These ullage pressures (during the specified time periods) are the lowest that could possibly occur for a nominally operating GH₂ pressurization system (reference PSIG telecon May 22, 2001). @[102501-4880A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-9

LH₂ ULLAGE LEAK (CONTINUED)

It is important to establish the difference between an ullage leak and an orbiter GH₂ pressurization system anomaly since the required actions are different (reference Rule {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES). The 2-inch disconnect pressure cue is sufficient to distinguish between an ullage leak and an orbiter GH₂ pressurization system anomaly once the LH₂ ullage pressure has decayed below 32.6 (32.2) psia or 31.0 (30.6) psia (depending on the MET that it occurs) with all three GH₂ FCV's open. If the GH₂ 2-inch disconnect pressure is consistent with the expected value for three open FCV's (high flow position), then the LH₂ ullage pressure problem is determined to be the result of an LH₂ ullage leak. If the GH₂ 2-inch disconnect pressure is below that expected for three open FCV's, then the cause of the low ullage pressure is an orbiter GH₂ pressurization system anomaly. ©[102501-4880A]

A value for the 2-inch disconnect pressure was chosen at the lowest expected value for three flow control valves open and not less than the predicted value for one flow control valve failed closed (low flow position) to avoid erroneously calling an ullage leak. Data provided by BNA/Huntington Beach (reference PSIG telecon May 18, 2001), on all flights since the reshimming of the flow control valves (70 percent/31 percent), showed that the lowest 2-inch disconnect pressure seen to date for three flow control valves open at mission power level was 448 psia (on STS-99, 97, 100, and 106). These pressures were all for Block IIA cluster flights, which have shown to provide the least amount of ullage pressurization gas. Subtracting out a one sigma dispersion (4 psia) and a 3 percent instrumentation error (30 psia) yields a 2-inch disconnect pressure value of 414 psia. Analysis and data obtained from STS-104 (first flight of a single Block II engine) indicates a Block II SSME will provide the same amount of ullage pressurization gas as a Block IIA engine; therefore, the disconnect pressure of 444 (414) psia can be used to determine the presence of an ullage leak for any engine configuration of a Block IIA or Block II type SSME. The disconnect pressure cue is only valid at the mission power level with three SSME's running. ©[102501-4880A]

Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, references this rule. ©[040899-6818A]

A5-10

SIGNIFICANT ENGINE HELIUM SYSTEM LEAK [ED]

TANK PRESSURE DECAY RATE (DP/DT) > 20 PSIA OVER 3 SECONDS, OR AN INDICATED HELIUM USAGE WHICH IS GREATER THAN 0.055 LBM/SEC AFTER AN MET OF 1 MINUTE. [090894-1676A]

NOTE: DECAY RATE CORRESPONDS TO THE BFS DECAY RATE COMPUTATION AND THE INDICATED HELIUM USAGE IS BASED ON MCC MASS FLOW RATE COMPUTATIONS.

Tank pressure decay rate (DP/DT) > 20 psia/3 seconds is twice the nominal value of approximately 10 psia/3 seconds. This value takes into account normal data noise and the 10 psi data granularity and represents the minimum value usable to detect helium leaks on board the vehicle. In addition to the DP/DT computation, the MCC uses a mass flow rate computation (lbm/sec) in order to detect helium leaks. The maximum nominal mainstage usage for the engine HPOTP IMSL purge is 0.047 lbm/sec (ref. SSME-to-Orbiter ICD 13M15000). Usage above 0.047 lbm/sec is indicative of an off-nominal condition in the associated MPS helium system supply.

Small leaks which are above 0.047 lbm/sec and below the crew alarm criteria (approximately 0.087 lbm/sec) will not be isolated prior to an MET of 1 minute. Action to isolate small helium leaks is not taken within the first minute after liftoff because the ground computation requires 20 seconds of data after liftoff for proper initialization and because additional time is required by the MCC for leak evaluation. Also, a leak of this size which is isolated shortly after an MET of 1 minute will probably not violate the single regulator zero-g shutdown requirements. However, continued usage at this rate may significantly reduce the helium available to support engine shutdown at MECO.

Even though helium usage above 0.047 is off nominal, MCC action is only taken for leaks with a usage above 0.055 lbm/sec or greater. This number accounts for noise in the ground computation and protects nominal MECO helium requirements.

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule.
[090894-1676A]

FLIGHT RULES

A5-11 SIGNIFICANT PNEUMATIC SYSTEM HELIUM LEAK [ED]

ANY LEAK IN THE PNEUMATIC TANK SYSTEM OR PNEUMATIC ACCUMULATOR WHICH WILL ANNUNCIATE THE CREW SYSTEMS MANAGEMENT (SM) ALERT (PNEU TK P < 3800.0 PSIA) PRIOR TO MECO -30 SECONDS. [090894-1676A] [021199-6790]

An attempt is made to isolate leaks in the MPS pneumatic helium supply in order to conserve helium for LO₂ prevalve closure at MECO. Furthermore, if the leak is isolated, the pneumatic helium supply will be available to support the operation of a leaking MPS helium engine supply.

Isolation will only be performed if the leak is large enough to annunciate the crew SM Alert prior to MECO -30 seconds. [021199-6790]

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule. [090894-1676A]

A5-12 INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE [ED]

A PNEUMATIC ACCUMULATOR PRESSURE WHICH IS LESS THAN 700 PSIA. [090894-1676A]

Seven hundred psia is the minimum actuation pressure which will ensure proper LO₂ and LH₂ prevalve closure timing at MECO. Pressures of 400 to 500 psia will fully position the valves; however, timing requirements may not be satisfied (ref. SODB, Vol. ii, Section 4.3.1). Four of six test cases of three engine prevalve closures at an initial pressure of 400 psia were within the timing specification of 1.15 seconds maximum closing time. Of the two that violated requirements, one was 0.03 seconds slow and the other was 0.06 seconds slow (reference PSIG telecon charts, 5/19/93).

It is critical that the LO₂ prevalves close within timing constraints at MECO. LO₂ prevalve closure and the injection of helium into the pogo accumulator are used to maintain pressure on the engine high pressure oxidizer turbopump, preventing pump cavitation during the shutdown sequence.

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule. [090894-1676A]

A5-13

MPS DUMPS AND VACUUM INERTING DEFINITIONS @[092701-4867A] @[ED]

A. MPS DUMP

A PRESSURIZED MPS LO₂ AND UNPRESSURIZED LH₂ DUMP PERFORMED IN MM 104 FOR NOMINAL, ATO, AND AOA MISSIONS THAT IS NORMALLY AUTOMATIC AT MECO + 2 MINUTES, BUT CAN BE STARTED OR DELAYED MANUALLY. @[092195-1791]

B. MPS GH₂ INERT @[092195-1791]

A MANUAL INERTING OF GH₂ THROUGH THE PRESS LINE VENT VALVE PERFORMED AFTER THE MPS POWERDOWN AND ISOLATION PROCEDURE FOR NOMINAL, ATO, AND AOA MISSIONS. @[111094-1719]

C. FIRST AUTOMATED VACUUM INERT @[092195-1791]

AN AUTOMATIC INERTING OF THE LH₂ AND LO₂ FEEDLINE SYSTEMS THROUGH THE LH₂ BACKUP DUMP VALVES AND THE LO₂ FILL/DRAIN VALVES RESPECTIVELY. THIS INERT IS PERFORMED AFTER THE MPS DUMP FOR NOMINAL, ATO, AND AOA MISSIONS AT MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) AND CAN ALSO BE PERFORMED MANUALLY.

D. MANUAL VACUUM INERT @[092195-1791]

A MANUAL INERTING OF THE LH₂ OR LO₂ FEEDLINE SYSTEM WHICH IS PERFORMED DUE TO INEFFICIENT AUTOMATED VACUUM INERT(S). THE MANUAL VACUUM INERT IS PERFORMED ANY TIME AFTER MPS DUMP START + 22 MINUTES (APPROXIMATELY MECO + 24 MINUTES) SUCH THAT THE AUTOMATED COMMANDS AND THE CREW'S SWITCH THROWS WILL NOT COINCIDE. THE LO₂ FEEDLINE SYSTEM IS MANUALLY INERTED THROUGH THE LO₂ FILL/DRAIN VALVES. THE LH₂ FEEDLINE SYSTEM IS MANUALLY INERTED THROUGH EITHER THE LH₂ BACKUP DUMP VALVES OR THROUGH THE LH₂ FILL/DRAIN VALVES.

A5-13

MPS PROPELLANT DUMPS AND INERTING DEFINITIONS
(CONTINUED)

E. SECOND AUTOMATED VACUUM INERT

AN INERTING OF THE LH₂ FEEDLINE SYSTEM THROUGH THE LH₂ BACKUP DUMP VALVES PERFORMED AFTER THE FIRST AUTOMATED VACUUM INERT FOR NOMINAL, ATO, AND AOA MISSIONS THAT IS AUTOMATICALLY STARTED AT THE MM 106 TRANSITION, BUT CAN ALSO BE PERFORMED MANUALLY. @[092701-4867A]

F. ENTRY MPS DUMP @[092195-1791] @[092701-4867A]

AN MPS LH₂ AND LO₂ PROPELLANT DUMP/INERTING STARTED AUTOMATICALLY IN MM 303 FOR NOMINAL, ATO, AOA, AND TAL MISSIONS, AND IN MM 602 FOR AN RTLS ABORT.

The non-contingency dumping and inerting of propellants are done to ensure there are no propellants in the manifolds prior to landing. The orbiter center of gravity is affected by dumping the residual MPS propellants. The hazard from venting LH₂ during entry and ingesting it into the aft compartment is removed by dumping the residual LH₂.

SRB SYSTEMS MANAGEMENT

@[021694-ED]

A5-51 **LOSS OF SRB THRUST VECTOR CONTROL (TVC)** @[012402-4987]

FOR THE LOSS OF TVC ON ONE SRB, THE FLIGHT WILL BE CONTINUED UNTIL LOSS OF VEHICLE CONTROL.

The loss of two Hydraulic Power Units (HPU's) on one SRB results in no TVC control on that SRB. This may result in loss of control depending on nozzle position. There is no manual control available; therefore, there is no crew action that can be taken. @[012402-4987]

A5-52 THROUGH A5-100 RULES ARE RESERVED

FLIGHT RULES

SSME SYSTEMS MANAGEMENT

A5-101 ABORT CUE REQUIREMENT

ANY ENGINE CONDITION THAT CAUSES AN ABORT DECISION WILL BE CONFIRMED USING TWO CUES.

Two cues are required so that a single instrumentation failure will not cause an erroneous abort decision.

A5-102 AUTO/MANUAL SHUTDOWN

MANUAL SHUTDOWN OF AN ENGINE WILL NOT BE ATTEMPTED IF AUTOMATIC LIMIT SHUTDOWN CAPABILITY IS ENABLED AND AN ENGINE IS APPROACHING A SHUTDOWN LIMIT. AN EXCEPTION TO THIS RULE IS WHEN EXCESSIVE HELIUM LEAKAGE REQUIRES A MANUAL ENGINE SHUTDOWN AS DISCUSSED IN RULE {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[032395-1766]

The automatic limit shutdown system was designed to prevent a catastrophic failure of an engine. Due to response times and the complexity of the SSME, the ground and crew will not try to interfere with this system.

A5-103 LIMIT SHUTDOWN CONTROL

A. PREMATURE MAIN ENGINE SHUTDOWN @[121296-4625]

THE MAIN ENGINE LIMIT SHUTDOWN CONTROL CAPABILITY WILL BE MANAGED AS FOLLOWS: @[121296-4625] @[111298-6785A]

1. INHIBITED AT ONE ENGINE-OUT

GPC AUTOMATICALLY COMMANDS INHIBIT TO THE REMAINING TWO ENGINES.

The main engine limit shutdown switch is a three-position switch: ENABLE, AUTO, and INHIBIT. At lift-off, the switch is in the AUTO position, and the limit shutdown control logic is enabled on all three engines. After one engine-out occurs, the main engine limit shutdown control capability on the two remaining engines is automatically inhibited. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

2. WITH ONE ENGINE OUT AND BFS NOT ENGAGED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" THEN "AUTO." REENABLING WILL BE BASED UPON THE FOLLOWING CONDITIONS:
 - a. THE CREW WILL MANUALLY REENABLE THE LIMITS AS SOON AS POSSIBLE FOLLOWING THE ENGINE OUT. @[111298-6785A]

The reenabling of the main engine limit shutdown software is required to regain, as soon as possible, the engine redline shutdown protection in the event of a second engine failure. The reenabling of the main engine limit shutdown software will be accomplished by taking the main engine limit shutdown switch to ENABLE then to AUTO. This allows one of the running engines to shut down due to a limit violation while automatically inhibiting the main engine limit shutdown control capability on the one remaining engine. Single-engine flight control capability would then take the vehicle to MECO.

The philosophy of when to reenable the main engine limit shutdown software attempts to balance the risk of an engine failing catastrophically while the limits are inhibited against the risk associated with a two engine-out contingency abort.

A meeting was held with the Shuttle Program Manager on September 10, 1998, to discuss the risks. Insufficient data is available to perform a risk trade since 1) The likelihood of an SSME running safely above a redline limit is unknown, and 2) The likelihood of surviving a contingency abort and the associated ET separation, flight control, thermal, crew bailout, and rescue is also unknown. The two engine-out contingency abort risks were accepted over running an SSME with limits inhibited. The risk of running an SSME with limits inhibited was accepted over the three engine-out contingency abort. Based on this philosophy, the main engine limit shutdown software will remain enabled (or reenabled) for one engine-out cases and inhibited for all two engine-out cases. @[121296-4625]@[111298-6785A]

The September 15 and November 18, 1987, and June 2, 1995, Ascent/Entry Flight Techniques panels reviewed the failure history of the redline sensors and came to the conclusion that the engine redline sensors are reliable and should, in general, be trusted to not cause an inadvertent shutdown.

- b. IF THE MCC DETERMINES ONE OF THE REDLINE SENSORS IS FAILED AND:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

- (1) EITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED UNTIL THE FOLLOWING BOUNDARY IS REACHED AND THEN REENABLED: @[121296-4625] @[111298-6785A]

RTLS - SINGLE ENGINE RTLS BOUNDARY

TAL, AOA, ATO, NOM - SINGLE ENGINE LIMITS BOUNDARY FOR A PRIME TAL SITE OR OTHER AUGMENTED TAL/CONTINGENCY SITE IF WEATHER OR LANDING AIDS PERMIT (REFERENCE RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). IF WEATHER AND/OR LANDING AIDS DO NOT PERMIT, REENABLE AT SINGLE ENGINE PRESS. @[092195-1793]

- (2) NEITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, REENABLE THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE AS SOON AS POSSIBLE.

The MCC is responsible for evaluating sensor failures since the flight crew has no visibility into the sensor health. Software flags issued by the onboard main engine controller sensor reasonableness software or previously observed failure modes would be used by the MCC as criteria to say that a sensor had failed. If, previous to the first engine shutdown, a sensor failure were detected and then the engine shut down based on the remaining redline sensor, that second failure would not be counted as a sensor failure unless the flight controllers could positively identify the sensor failure mode. A subsequent sensor failure on another running engine would have to occur before two sensor failures could be counted. This type of situation occurred on STS 51-F. All sensor failures on STS 51-F were detected by the onboard main engine sensor reasonableness software. This software also informed the flight controllers of the failures via the downlisted failure identifier data words. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-103****LIMIT SHUTDOWN CONTROL (CONTINUED)**

The main engine limit shutdown software will be enabled at an appropriate boundary with one sensor failure on one of the three engines, because one sensor failure does not indicate a trend for a generic failure of the sensors. If either of the remaining two engines is one sensor failure away from an erroneous shutdown, limits will remain inhibited until an abort boundary is reached. The limits will be reenabled when an abort boundary (as defined in Rule {A4-56}, PERFORMANCE BOUNDARIES) is reached such that a single-engine abort can be accomplished to the desired site. On an RTLS, this abort boundary is Single Engine RTLS (which is designated by the "two-out red on the TRAJ display" call). If neither of the remaining engines is one sensor failure away from an erroneous shutdown, limits can be reenabled as soon as possible. This allows the redlines to provide the earliest protection against a real engine hardware failure. @[111298-6785A]

On a TAL, AOA, ATO, or nominal profile, this abort boundary is Single Engine Limits if weather or landing aids permit. Otherwise, the limits will be reenabled at Single Engine Press (ref. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). With one sensor failure and either of the remaining engines one sensor failure away from shutting down erroneously, the risk of an engine shutdown due to another sensor failure is higher than that due to an actual engine failure if the limits were reenabled. Because of this increased risk of an engine shutdown caused by sensor failures, the exposure to bailout is not acceptable unless the next sensor failure will not cause an erroneous shutdown. For these reasons, the limits are inhibited until the single engine limits boundary to minimize the need for a contingency abort and crew bailout. @[121296-4625]

- c. IF THE MCC DETERMINES TWO OR MORE OF THE SAME TYPE (TEMPERATURE OR PRESSURE) ENGINE REDLINE SENSORS HAVE FAILED AND:
- (1) EITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED THROUGH MECO.
 - (2) NEITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, REENABLE THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE AS SOON AS POSSIBLE:

The shutdown sensors on the same redline will be suspected of having a generic problem if more than one sensor fails (two or more sensors failed on the same type of redline). If either remaining engine is one sensor failure away from an erroneous shutdown, limits will remain inhibited through MECO in order to prevent the next sensor failure from shutting down a good engine. The two failures could occur on one or more engines including the failed engine. If neither engine is one sensor failure away from an erroneous shutdown, then limits are reenabled as soon as possible. This allows the earliest possible protection by the redline sensors against a real engine hardware failure. @[121296-4625] @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

3. WITH ONE ENGINE OUT AND BFS ENGAGED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED THROUGH MECO BY THE BFS AUTOMATIC COMMAND. @[121296-4625] @[111298-6785A]

The main engine limit shutdown control will be inhibited on two remaining engines if the BFS is engaged. The BFS does not have single-engine flight control software and therefore cannot control the vehicle with two engines shut down. If the engine shuts down after the BFS is engaged, the BFS will automatically command inhibit to the remaining engines. If the engine shuts down while on the PASS, limits subsequently reenabled, and then BFS engaged, the BFS will again automatically command inhibit to the remaining engines since the BFS reevaluates and responds to engine out status when engaged.

4. WITH TWO ENGINES OUT, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN INHIBITED THROUGH MECO.

Since three engine-out contingency aborts contain "black zones" and are more severe than the two-engine contingency aborts, limits will remain inhibited on the last running engine.

Rules {A2-6}, LANDING SITE WEATHER CRITERIA [HC]; {A2-55}, USE OF LOW-ENERGY GUIDANCE; and {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL, reference this rule. @[120894-1663]

B. STUCK THROTTLE IN THE THRUST BUCKET

IF A STUCK THROTTLE CONDITION OCCURS DURING MAX Q THROTTLING SUCH THAT THE POWER LEVEL IS LESS THAN THE NOMINAL FLIGHT POWER LEVEL, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN ENABLED.

When an engine experiences a stuck throttle in the thrust bucket, performance may be reduced sufficiently that an abort gap may occur between RTLS capability and any downrange abort capability. Uphill capability may also be lost. Main engine limit shutdown software remains enabled to allow for the stuck engine to shut down if it exceeds redline limits. In the case of a hydraulic lock-up, valve drift may occur resulting in potential redline limit exceedance; therefore, the main engine limit shutdown software remains enabled. It has been accepted that the loss of a good engine could result in a 1 and 2/3 RTLS contingency abort.

- C. WITH ONE ENGINE OUT AND ONE OF THE REMAINING ENGINES HAS A NON-ISOLATABLE MPS HELIUM LEAK, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED BASED ON THE FOLLOWING: @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-103****LIMIT SHUTDOWN CONTROL (CONTINUED)**

1. PRIOR TO THE SINGLE ENGINE LIMITS (TAL ABORT) OR SINGLE ENGINE RTLS (RTLS ABORT) BOUNDARY: @[111298-6785A]

WHEN THE PNEUMATIC HELIUM AND/OR FAILED ENGINE'S MPS HELIUM TANK PRESSURE REACHES 1150 PSIA FOLLOWING THE INTERCONNECT TO THE LEAKING SYSTEM'S HELIUM OR WHEN BOTH LEAKING ENGINE'S HELIUM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA

2. OTHERWISE, NO ACTION REQUIRED.

IF THE SINGLE ENGINE LIMITS (TAL ABORT) OR SINGLE ENGINE RTLS (RTLS ABORT) BOUNDARY IS REACHED WITHOUT INTERCONNECTING TO THE NON-LEAKING, RUNNING ENGINE'S HELIUM, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED.

IF HELIUM FROM THE NON-LEAKING, RUNNING ENGINE IS REQUIRED TO SUPPORT THE LEAKING ENGINE'S OPERATION (REF. RULE {A5-152}, PRE MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]), THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN INHIBITED THROUGH MECO. @[090894-1676A] @[121296-4625]

For the case of two engines running (one with a non-isolatable MPS helium leak), the main engine limit shutdown software will be reenabled by the crew per paragraph A.2.a. If the leaking engine cannot support the SE Limits or SE RTLS boundary with an interconnect from pneumatic and/or the failed engine's helium, the leaking engine will be allowed to operate below the HPOTP IMSL redline to avoid a two engine-out contingency abort (per Rules {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], and {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS). To operate below the redline, limits must be inhibited. The MCC will call for the main engine limit shutdown switch to "inhibit" when the pneumatic helium and/or failed engine's helium tank pressure reaches 1150 psia following the interconnect to the leaking system or when the leaking system's regulator pressures are below 715 (679) psia. The 1150 psia tank pressure cue was selected as the operational cue corresponding to the crew's MPS helium tank pressure C&W (not the pneumatic helium tank pressure C&W) while ensuring that the HPOTP IMSL redline limit is not exceeded prior to inhibiting the limits. It also minimizes the amount of time that the remaining engines are exposed to main engine limits being inhibited. The 715 (679) psia regulator pressure cue was selected as a backup cue for large MPS helium leaks to ensure that the HPOTP IMSL redline limit is not exceeded before main engine shutdown limits are inhibited. The main engine limit shutdown software will be reenabled upon reaching the first single engine abort landing site capability, which is either SE Limits or SE RTLS (ref. AEFTP #107, 11/4/93), if an interconnect from a running engine has not been performed. This represents the earliest time after which an attempt can be made to reach a landing site with a good engine out. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-103****LIMIT SHUTDOWN CONTROL (CONTINUED)**

The main engine limit shutdown software will remain inhibited if the non-leaking, running engine's helium has been interconnected to a leaking engine (no three engine-out abort capability). Keeping limits inhibited in this configuration will allow the main engine with the leaking MPS helium supply to continue to operate below the normal HPOTP IMSL redline. Running the engine below the normal redline is an acceptable risk while the vehicle is in an abort gap since the only alternative is an early MECO and the loss of the vehicle and crew. @[121296-4625] @[111298-6785A]

Reference Rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[090894-1676A]

- D. IF FLOW CONTROL VALVE FAILURES OR AN ULLAGE GAS LEAK CAUSE A LOW LH₂ NPSP CONDITION, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" PER FLIGHT RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. @[121296-4625]

Reference Rule and rationale {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP.

- E. IF A DATA PATH FAILURE OCCURS ON AN ENGINE THAT IS CONFIRMED RUNNING, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED PER FLIGHT RULE {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

Reference Rule and rationale {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

- F. IF A GPC SET SPLIT OCCURS AND THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE ON TWO ENGINES IS AUTOMATICALLY INHIBITED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED.

In a set split condition, two GPC's will not see data from one of the engines and will automatically inhibit the main engine limit shutdown software on the other two engines. If limits are reenabled by taking the main engine limit shutdown switch to ENABLE then AUTO, the limits would be automatically inhibited on the next cycle. Therefore, the main engine limit shutdown switch will only be taken to ENABLE. Reference Rule and rationale {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

- G. FOR LOSS OF TVC CONTROL ON AN OPERATING MAIN ENGINE, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED (THREE ENGINES RUNNING) UNTIL TWO-ENGINE TAL CAPABILITY IS ACHIEVED OR, ON AN RTLS, UNTIL AFTER POWERED PITCH-AROUND (PPA) IS COMPLETE.

The risk of running an engine with the main engine limits inhibited is accepted over the risk of loss of control during the RTLS powered pitch around (PPA) as a result of a gimbaling engine failure. If a main engine has lost TVC capability, the failure of a gimbaling engine could result in a loss of control, even if single-engine roll control (SERC) is active. Since an RTLS trajectory is much more demanding than an uphill or TAL case from a control standpoint, avoiding an RTLS abort is highly desirable. Additionally, if the loss of TVC is due to hydraulic system failures, the engines in hydraulic lockup could fail due to valve drift, so a trajectory that provides the earliest possible single-engine capability is desirable. If a three-engine RTLS is performed, the main engine limit shutdown software will be inhibited until after PPA, since a loss of control is very possible if PPA is attempted with one gimbaling and one nongimbaling engine. ©[121296-4625] ©[111298-6785A]

Reference rule {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.

- H. DURING A THREE ENGINE RTLS ABORT, TIME PERMITTING, THE MAIN ENGINE LIMIT SHUTDOWN SWITCH WILL BE TOGGLED TO INHIBIT, ENABLE, AND BACK TO AUTO. THIS ACTION WILL BE DELAYED AS LONG AS POSSIBLE, BUT MUST BE COMPLETED PRIOR TO AN MET OF 8 MINUTES. ©[121296-4625] ©[111298-6785A]

A GPC or manual toggle of the main engine limit shutdown software to inhibit will be required on a three engine RTLS abort due to the incorporation of single command channel shutdown logic in the main engine controller software. The intent of this is to protect the vehicle and crew from exposure to a latent orbiter/main engine command path failure at MECO (catastrophic). This is accomplished by reducing the normal 2 of 3 shutdown command channel agreement criteria to 1 of 3 shutdown command channel acceptance processing. The software, which is invoked after a mission specific timer has expired, will allow acceptance and execution of the following two sequential commands, shutdown-enable followed by a shutdown command on a single command channel. Should a limit's inhibit command be processed and accepted by the controller prior to the execution of the single command channel logic, single command channel processing will no longer be performed. The mission specific timer is calculated by subtracting 5.5 seconds (3 sigma dispersion) from the predicted MECO time referenced to SSME start. That is, the predicted MECO time in MET plus the time from the last SSME start (6.36 seconds) minus 3 sigma dispersion (5.5 seconds). ©[091098-6710A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

Toggling of the main engine limit shutdown switch on a three engine RTLS is performed in order to preclude the possibility of losing all main engines due to a failed-to-sync GPC after the controller timer has expired. Normally, exposure to this condition is either minimized (to approximately 5 seconds) by projected MECO times on the order of 511 seconds on uphill missions and TAL aborts, or eliminated by a main engine out (the GPC's command inhibit on the remaining engines and the single command channel shutdown processing is disabled). However, the time of exposure to a three engine out condition may be significant (120 seconds) on a systems RTLS abort. This exposure results from the extended main engine burntime (MECO at approximately 630 seconds MET) and the absence of an engine-out limits inhibit command. Consequently, the main engine limit shutdown software will be manually toggled to inhibit in order to minimize exposure to a failed-to-sync GPC. This action will be delayed as long as possible in order to retain main engine shutdown capability, and to possibly eliminate an unnecessary action, should a main engine out occur prior to the expiration of the controller timer. The cue of 8 minutes provides margin prior to expiration of the timer. ©[090894-1679A] ©[121296-4625] ©[091098-6710A]

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

WITH A DATA PATH FAILURE AND THE ENGINE CONFIRMED ON BY THE MCC, THE MAIN ENGINE LIMIT SHUTDOWN CONTROL CAPABILITY WILL BE MANAGED IN THE FOLLOWING MANNER: @[121296-4594A]

A data path failure occurs when the GPC's (PASS or BFS) either do not see the main engine time reference word (TREF) updating or when the two main engine identification words (ID words 1 & 2) are not one's complements. If this occurs in the controlling GPC's, the controlling GPC's will automatically inhibit the main engine limit shutdown software on the other two main engines. However, the GPC software will not inhibit the limits on the engine with the data path failure. This response occurs because the GPC's assume the engine has failed behind the data path failure.

A. BFS NOT ENGAGED:

1. THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" THEN "AUTO".

Once the MCC confirms that the engine with the data path failure is running, the crew will remove the inhibits by manually placing the main engine limit shutdown switch to ENABLE, then AUTO. This switch movement causes the main engine limit shutdown software to be reenabled on all running engines.

2. FOR AN ENGINE OUT: @[111298-6785A]
 - a. IF THE ENGINE THAT SHUT DOWN WAS THE ONE THAT HAD THE DATA PATH FAILURE, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN ENABLED.

If the engine that shuts down is the engine with the data path failure, the GPC's will not automatically inhibit the main engine limit shutdown software. The main engine limit shutdown software will remain enabled to allow for a second engine out (ref Rule {A5-103}, LIMIT SHUTDOWN CONTROL).

@[121296-4594A] @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

- b. IF THE ENGINE THAT SHUT DOWN WAS NOT THE ONE WITH THE DATA PATH FAILURE, THE PASS WILL AUTOMATICALLY INHIBIT LIMITS. LIMITS WILL REMAIN INHIBITED UNTIL MECO.
 @[121296-4594A] @[111298-6785A]

If the engine that shuts down did not have the data path failure, the limit shutdown control capability of the two remaining engines will automatically be inhibited by the PASS GPC's. In this case, however, the limits will remain inhibited until MECO. The reason is that, if the limits were reenabled and the remaining engine with the good data path exceeds a redline and shuts down, MECO confirmed conditions would be satisfied by having two engines with main combustion chamber pressure less than 30 percent power level and one engine with a data path failure. MECO command would be sent, resulting in the shutdown of the engine with the data path failure. This early MECO could result in an unacceptable underspeed. @[121296-4594A]

B. BFS ENGAGED:

1. THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE ENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" (UNLESS THE BFS AUTOMATICALLY REENABLED LIMITS UPON BFS ENGAGE). @[111298-6785A]

If the data path failure occurs before BFS engage, when the BFS is engaged, all data path failure flags are reset in the BFS software. The BFS immediately attempts to establish communication with the engines. However, if this is not successful a data path failure is annunciated on that engine. At this point, the BFS software automatically inhibits the main engine limit shutdown software on the other two engines. If the data path failure occurs after BFS engage, the BFS will inhibit limits on the other two engines. Once the MCC confirms the engine with the data path failure is running, the crew will remove the inhibits by manually placing the main engine limit shutdown switch to ENABLE to prevent running the engines for the remainder of the flight with limits inhibited. The BFS main engine limit shutdown switch logic does not work the same way it does in the PASS (in the BFS, ENABLE/AUTO will cause the limits to go back to inhibit).

The BFS will automatically reenable limits if the data path failure is recovered when the BFS is engaged.
 @[121296-4594A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

2. FOR A SUBSEQUENT ENGINE OUT: @[121296-4594A]

THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "INHIBIT" (UNLESS THE BFS AUTOMATICALLY INHIBITED LIMITS AT ENGINE OUT). LIMITS WILL REMAIN INHIBITED UNTIL MECO.

If the BFS has been engaged, a subsequent engine shutdown will require the limits to be inhibited because BFS does not have single engine roll control logic (ref Rule {A5-103}, LIMIT SHUTDOWN CONTROL). BFS will automatically inhibit limits if the engine that shut down did not have a previous data path failure, had a data path failure at shutdown, or had a previous data path failure prior to BFS engage but was recovered upon BFS engage. Limits will have to be manually inhibited by taking the main engine limit shutdown switch to INHIBIT if the engine that shut down had a non-recovered data path failure prior to shutdown.

Rules {A5-102}, AUTO/MANUAL SHUTDOWN, {A5-103}, LIMIT SHUTDOWN CONTROL, and {A5-113}, MANUAL MECO/MECO CONFIRMED, reference this rule. @[121296-4594A]

FLIGHT RULES

A5-105

DATA PATH FAIL/ENGINE-OUT ACTION

IF THE MCC CONFIRMS THAT AN ENGINE WITH A DATA PATH FAILURE HAS SHUT DOWN, THAT ENGINE'S SHUTDOWN pb WILL BE PUSHED TO MODE THE GUIDANCE AND FLIGHT CONTROL LOGIC AND TO CLOSE THE ASSOCIATED PREVALVES.

SHOULD THE SAFING FUNCTION OF THE pb BE INOPERATIVE DUE TO SHUTDOWN pb OR CONTROL BUS PROBLEMS, THE APPROPRIATE MDM PER THE TABLE BELOW WILL BE POWER CYCLED FOR 1 SECOND TO ALLOW THE pb TO OPERATE. THE POWER CYCLED MDM MAY BE REGAINED VIA AN I/O RESET POST SAFING. @[021397-4823]

<u>S/D pb CONTACT</u>	<u>CONTROL BUS</u>	<u>MDM</u>
CTR A	AB1	FF1
CTR B	BC1	FF2 @[111699-7140]
LEFT A	BC2	FF2
LEFT B	CA2	FF3
RT A	CA3	FF3
RT B	BC3	FF4

The GPC guidance software will not know an engine has shut down prematurely if the data path from that engine has also failed. Pushing the corresponding shutdown pb will set the safing command in the GPC for that engine. When the safing command is set, the SSME OPS sequence will close the prevalues and set the engine fail flag for that engine. Closing the prevalues is essential to isolate the failed engine if the engine failure caused damage to the engine propellant supply lines. There is a potential for a fire or propellant loss with the prevalues open. The engine fail flag is used by the ascent guidance software to mode the guidance and targeting functions to correspond to the number of SSME's that are operating. This is required for proper control of the vehicle.

If the two contacts on the shutdown pb disagree, the safing command will not be set. A contact disagreement can be caused by a failure of a contact, the loss of the fuse to a contact, or the loss of the control bus providing power to a contact. Power cycling the MDM associated with that contact will cause the failed contact to be comm faulted; this will allow the safing command to be set when the pb is pushed. For FF 1, 2 or 3, the power cycle must be of approximately 1 second in duration before moding guidance. This is to ensure that the MDM is off long enough to be comm faulted, yet repowered quickly to avoid caging the associated IMU. The comm faulted MDM can be recovered with an I/O reset after the appropriate shutdown pb is pushed and guidance has been moded. @[021397-4823]

FLIGHT RULES

A5-106

MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES

MANUAL SHUTDOWN OF AN AFFECTED ENGINE WILL BE PERFORMED PRIOR TO OR AT MECO FOR THE FOLLOWING COMMAND AND/OR DATA PATH FAILURE CASES:

A. COMMAND PATH FAILURE.

1. NOMINAL/ATO/AOA:

- a. THREE ENGINES ON - SHUT DOWN AT VI = 23K FPS USING THE AC POWER SWITCHES AND SHUTDOWN PB.
- b. TWO ENGINES ON - SHUT DOWN AT VI = 24.5K FPS USING THE AC POWER SWITCHES AND SHUTDOWN PB.
- c. MCC CONFIRMS COMMAND PATH FAILURE BY NO THROTTLING OF AFFECTED ENGINE WHEN THE ENGINES ARE COMMANDED TO THROTTLE.

2. RTLS:

TWO OR THREE ENGINES ON - SHUT DOWN DURING POWERED PITCHDOWN AT ALPHA = -1 USING THE AC POWER SWITCHES AND SHUTDOWN PB. @[032395-1759]

3. TAL:

TWO OR THREE ENGINES ON - SHUT DOWN AT VI = 22.5K FPS USING AC POWER SWITCHES AND SHUTDOWN PB.

In the case of a command path failure, the only way to shut down an engine is with the engine ac power switches. Shutting down with the ac power switches also creates a data path failure. Therefore, the shutdown pushbutton is pushed to tell guidance that an engine is out. The engine is shut down approximately 30 seconds before MECO to prevent depleting LO₂ through an SSME and causing uncontained engine damage. A velocity which equates to MECO minus 30 seconds also gives guidance time to compensate for late engine out and converge to the proper MECO targets. The only exception is an RTLS where the engine is shut down during powered pitchdown at alpha = -1 degrees. On a three- or two-engine abort RTLS, if an engine is shut down at TGO ? 60 seconds, guidance will not mode to the target set corresponding to the remaining number of engines. @[032395-1759A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-106

**MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES
(CONTINUED)**

The cue of alpha = -1 degree (approx MECO-5 sec) was chosen to allow SSME shutdown to begin prior to predicted MECO while the LO₂ is still under G's from the other engine(s). This alleviates LO₂ net positive suction pressure concerns for the high pressure oxidizer turbopump (HPOTP). Alpha = -1 degree also protects for 1-sigma aerodynamic dispersions. Although sizable transients can be expected subsequent to engine shutdown, flight control has been demonstrated to null these transients prior to ET separation (in some cases ET separation inhibits of approximately 1 second will occur, reference AEFTP #87 and #122 minutes). On a three-engine press-to-MECO case, MECO minus 30 seconds occurs at a VI = 23 kfps. On a two-engine press-to-MECO case, MECO minus 30 seconds occurs at a VI = 24.5 kfps. On a TAL abort, MECO minus 30 seconds occurs at a VI = 22.5 kfps. ©[032395-1759A]

B. DATA PATH FAILURE

1. MCC DECISION (PRIME)

NOMINAL/ATO/AOA/TAL/RTLS:

- a. NO ACTION REQUIRED.
- b. MCC CONFIRMS COMMAND PATH OPERATIONAL BY GH₂ OUTLET PRESSURE COMPARISON TO POWER LEVEL COMMAND.

2. ONBOARD DECISION (NO COMMUNICATION).

NOMINAL/ATO/AOA/TAL/RTLS:

CREW ACTION SAME AS FOR COMMAND PATH FAILURE.

For a data path failure, the engine will accept throttling and MECO commands so that no action is required. The crew cannot tell the difference between a data path failure and a command/data path failure. The two failures that caused the data path failure may also have caused a command path failure (i.e., two controller interface adapters (CIA's), or a CIA and a multiplexer interface adapter (MIA) in the EIU). Unless the command capability is verified by the MCC, the crew will assume a command and data path failure and will take the same action as a command path failure. The MCC can verify the command path status by observing that the GH₂ outlet pressure changes with the throttle command. If an engine throttles down when commanded, its command path is operational.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-106 **MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES**
(CONTINUED)

C. COMMAND AND DATA PATH FAILURE.

1. MCC DECISION (PRIME)

NOMINAL/ATO/AOA/TAL/RTLS:

a. ACTION SAME AS COMMAND PATH FAIL

b. MCC CONFIRMS CASE BY NO CHANGE IN GH2 OUTLET PRESSURE ON THE AFFECTED ENGINE WHEN ENGINE COMMANDED TO THROTTLE.

2. ONBOARD DECISION (NO COMMUNICATION)

NOMINAL/ATO/AOA/TAL/RTLS:

CREW ACTION SAME AS FOR COMMAND PATH FAILURE.

The loss of an EIU or the loss of an MIA and a CIA or the loss of two CIA's will cause a data path failure and a command path failure on the same engine.

This is a very serious failure mode because this failure will close the LO₂ prevalues on an operating engine if preventative action is not taken. A water-hammer effect could occur which would rupture the LO₂ feedline and result in uncontained engine damage and loss of vehicle. At MECO, the GPC logic assumes an engine with a data path failure does not have a command path loss (i.e., the GPC assumes the engine accepted and complied with the shutdown command); therefore, the prevalues are commanded closed. To prevent this catastrophic shutdown of the engine at MECO, the engine ac power switches must be used to shut down the engine before MECO is commanded. The ac power switches will shut down the engine; the pushbutton is then pressed to mode guidance.

Rules {A2-59D}, BFS ENGAGE CRITERIA; {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES); {A5-110}, SSME PERFORMANCE DISPERSION; {A5-107}, MANUAL SHUTDOWN FOR SUSPECT COMMAND PATH FAILURES; {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS; and {A7-9}, REDUNDANT SET SPLIT, reference this rule. ©[032395-1766] ©[061296-6147A] ©[ED]

FLIGHT RULES

A5-107

MANUAL SHUTDOWN FOR SUSPECT COMMAND PATH FAILURES

AN ENGINE WITH SUSPECT COMMAND CAPABILITY FOR SHUTDOWN WILL BE MANUALLY SHUT DOWN PRIOR TO MECO USING THE SAME CUES LISTED FOR A COMMAND PATH FAILURE IN FLIGHT RULE {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES.

If a transient failure observed during powered flight results in the temporary loss of a command channel, the respective command channel will be considered suspect since the failure could return at any time. If another avionics failure and a reoccurrence of the previously observed transient failure results in a command path failure (per Rule {A5-3}, STUCK THROTTLE), the command capability of this engine will be considered suspect even if the engine reacts to the 3g throttle back command. Therefore, this engine will be shut down pre-MECO per Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURE. The engines have single command channel shutdown logic that allows the engine to shut down by accepting shutdown commands on only one out of three command channels. Operationally, this logic is only relied upon for late, unexpected failures. ©[111501-4939]

One example of a transient failure is an EIU power-on-reset failure. A power-on-reset failure causes the temporary loss of a single power supply in an EIU. Since the EIU MIA ports 1 and 3 are on the same power source (MIA ports 2 and 4 are on another), this failure will cause the temporary loss of command and data transfer capability on two MIA ports (ground data only shows the status of MIA ports 1 and 4; therefore, MIA ports 3 and 2 are assumed bypassed with ports 1 and 4, respectively). After this failure has occurred, the command transfer capability will be regained automatically while the data transfer capability will be regained via an I/O Reset. The following scenario is an example of the concern that this failure raises: If an engine has a command channel B failure and a power-on-reset failure on MIA ports 1 and 3, the engine will be considered to have suspect command capability even if the engine responds to throttle commands and will be shut down pre-MECO. ©[111501-4939]

FLIGHT RULES**A5-108****MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP**

AN SSME IN HYDRAULIC OR ELECTRICAL LOCKUP MAY HAVE TO BE MANUALLY SHUT DOWN TO PREVENT A VIOLATION OF THE ENGINE LO₂ NPSP REQUIREMENTS NEAR MECO. MANUAL SHUTDOWN WILL BE REQUIRED UNDER THE FOLLOWING CONDITIONS FOR ANY ENGINE LOCKED UP ABOVE THE MINIMUM POWER LEVEL (KMIN). ©[061297-6171] ©[090999-7052A]

A. NOMINAL/ATO: ©[ED]

1. THREE ENGINES ON:

a. ONE STUCK THROTTLE - SHUT DOWN THE AFFECTED ENGINE AT VI = 23K FPS USING THE SHUTDOWN PB.

b. TWO STUCK THROTTLES - (REF. RULE {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES), AND RULE {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES). ©[ED]

2. TWO ENGINES ON - NO ACTION REQUIRED.

B. RTLS AND TAL - NO ACTION REQUIRED.

Manual shutdown of an engine in hydraulic or electrical lockup is only required for a three-engine nominal or ATO mission. The three-engine LO₂ low level cutoff delay timer (as defined by the I-load NOM_LO2_LOW_LVL_TIME_DELAY_L - currently 0.358 seconds) is designed for three engines shutting down from the minimum power level (as defined by the I-load KMIN - currently 67 percent power level). If one engine is stuck above the minimum power level, the LO₂ net positive suction pressure (NPSP) and post shutdown LO₂ mass requirements may be violated. Therefore, an LO₂ depletion cutoff at power levels greater than that accounted for by the low level timers could cause high pressure oxidizer pump overspeed resulting in a potentially catastrophic engine shutdown. Given the potentially catastrophic nature of the shutdown and given that an LO₂ low level cutoff cannot always be predicted (reference the STS-93 unpredicted LO₂ low level cutoff which was caused primarily by an SSME nozzle leak which was smaller than the minimum criteria of Rule {A5-110}, SSME PERFORMANCE DISPERSION, and therefore not modeled in the Abort Region Determinator (ARD)), it was decided to accept the operational impacts of always shutting down a locked up engine when three engines are on as opposed to relying on the ARD to make a real-time performance evaluation (reference Ascent Flight Techniques Panel Meeting #160, August 27, 1999). These impacts include up to 60 feet per second of lost performance and a planar error at MECO of up to 10 feet per second (some planar error is inevitable for these cases even if the stuck engine is not shut down).

FLIGHT RULES

A5-108

MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP (CONTINUED)

Analysis performed without dispersions indicates the LO₂ residual mass requirement is satisfied for an engine stuck at up to 76 percent power level (reference PSIG telecon, August 25, 1999). However, to protect for dispersions in the analytically derived LO₂ mass requirement, to protect for potential uncertainties in the engine power level prediction at shutdown, to maximize the NPSP and LO₂ residual mass provided, and to provide operational simplicity, a manual engine shutdown is performed for any engine stuck greater than the minimum power level. By shutting down the stuck engine prior to MECO, the two remaining engines will throttle to 91 percent power level for fine count. The low level cutoff delay timer for the two-engine on case is zero, thereby maximizing the NPSP and LO₂ residual mass for two engines shutting down from 91 percent. @[061297-6171] @[090999-7052A]

For the two-engine-on case with stuck throttles at any power level, the technical community determined that the NPSP would not be severely violated and the minimum post shutdown LO₂ mass requirements would be satisfied. Therefore, no action was required (reference the 24th PSIG in November 1983 and Ascent Flight Techniques on May 21, 1984). For an RTLS or TAL abort, the LO₂ residuals should be sufficient enough to prevent an LO₂ low level shutdown.

Shutdown of an engine in either a hydraulic or electric lockup will be performed by shutdown pushbutton only. The shutdown pushbutton method for manual shutdown of an engine in either hydraulic or electric lockup minimizes the exposure to the unnecessary risk of a pneumatic shutdown in the case of the electrically locked-up engine and simplifies crew procedures in the case of the hydraulically locked-up engine. @[090999-7052A]

FLIGHT RULES

A5-109

MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES)

A. THREE ENGINES RUNNING:

1. NOMINAL/ATO - MANUALLY SHUT DOWN ONE ENGINE AT V_T ? 23K FPS.
2. TAL - MANUALLY SHUT DOWN ONE ENGINE AT V_T ? 22.5K FPS. ENABLE MANUAL THROTTLES PRIOR TO ABORT SELECTION TO MAINTAIN NOMINAL POWER LEVEL. @[082593-1464C]
3. RTLS - BEFORE SELECTING RTLS, MANUAL THROTTLES WILL BE ENABLED AND MINIMUM THROTTLES SELECTED. AT LEAST 10 SECONDS OF MINIMUM THROTTLE LEVEL IS DESIRED PRIOR TO RTLS SELECTION. AUTO THROTTLES WILL BE RESELECTED ANYTIME PRIOR TO POWERED PITCH-AROUND (PPA). IF BOTH ENGINES WITH STUCK THROTTLES ARE AT MORE THAN 85 PERCENT, MANUALLY SHUT DOWN ONE ENGINE 2 MINUTES PRIOR TO MECO. @[082593-1464C]

SHUTDOWN PRIORITY: (1) COMMAND PATH FAIL, (2) HYDRAULIC LOCKUP, (3) ELECTRICAL LOCKUP

B. TWO ENGINES RUNNING - NO ACTION REQUIRED.

For dual command path failures, reference Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES. For dual hydraulic failures, ref. Rule {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.

If two of three operating engines have stuck throttles, manual shutdown of an engine will be required to prevent violation of the 3.5g acceleration limit. This limit cannot be violated with only two engines operating. Also, this limit cannot be violated on a three-engine RTLS if at least one of the stuck throttles is less than or equal to 85 percent. Above 85 percent, shutting down an engine 2 minutes prior to MECO ensures that it will not be violated. @[110900-7242]

For all RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of an early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection. @[082593-1464C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-109

MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES) (CONTINUED)

For TAL, it is undesirable to throttle down the good engine due to the guidance transients which may occur and the fact that little time would be gained to perform the abort dump. Therefore, manual throttles will be selected to prevent an automatic throttledown when TAL is declared. This action is not required if TAL is declared early enough that automatic throttling will not occur at abort selection. However, since there is no disadvantage to selecting manual throttles for this short period of time, manual throttles will always be selected for consistency. AUTO throttles will be reselected after TAL is declared. ©[082593-1464C]

Shutdown priorities are established to protect against the maximum risk. Command path failure means the engine will not automatically shut down at MECO, which is catastrophic. Hydraulic lockup means shutdown requires the nonredundant pneumatic system. Electric lockup results in a nominal shutdown.

Shutdown will be performed on the command path failed engine using the ac power switches and shutdown pushbutton. Shutdown of an engine in either a hydraulic or electric lockup will be performed by shutdown pushbutton only. The shutdown pushbutton method for manual shutdown of an engine in either hydraulic or electric lockup minimizes the exposure to the unnecessary risk of a pneumatic shutdown in the case of the electrically locked-up engine and simplifies crew procedures in the case of the hydraulically locked-up engine.

Rule {A2-301}, Note 8, CONTINGENCY ACTION SUMMARY, and {A4-59}, MANUAL THROTTLE SELECTION, reference this rule. ©[092195-1770A]

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION @[070899-6819]

- A. SHOULD AN SSME PERFORMANCE DISPERSION ARISE, THE ABORT REGION DETERMINATOR (ARD) PROGRAM IN THE MCC WILL BE ADJUSTED ASAP WITH THE FOLLOWING INFORMATION: @[070899-6819]
1. AFFECTED SSME CAUSING THE PERFORMANCE DISPERSION
 2. TIME OF OCCURRENCE
 3. MODE AND LEVEL OF THE PERFORMANCE DISPERSION CONDITION INCLUDING INSTANTANEOUS PERFORMANCE INFORMATION.

The SSME performance dispersion rule defines the failures and the minimum criteria which must be met prior to updating the ARD with an SSME performance case. The Booster Main Engine Tables quantify each of the performance cases and include the minimum criteria for calling the performance cases. These tables are generated using the SSME Power Balance Model data provided by Rocketdyne in response to a Shuttle Operational Data Book (SODB) Request. The Engine Status Word (ESW), MCC Pc, HPOT/HPFT discharge temperatures, LPFP discharge temperature, OPOV/FPOV position, and/or HPOP/HPFP discharge pressures are the primary cues used for determining performance cases. Updates to the ARD consist of changes in power level (thrust), specific impulse (Isp), and mixture ratio (MR). The ARD uses these SSME performance parameters to predict abort mode capabilities real time. A change in any of these parameters could affect the abort boundaries significantly.

- B. AN SSME PERFORMANCE EVALUATION CAN ONLY BE MADE WHEN THE SSME COMMANDED POWER LEVEL IS KNOWN AND THE SSME IS IN A STEADY-STATE CONDITION. QUANTIFIABLE PERFORMANCE DISPERSIONS ARE AS FOLLOWS:
1. SINGLE MCC PC CHANNEL SHIFT HIGH OR LOW WILL BE CALLED IF THE DELTA BETWEEN MCC PC CHANNEL A AND MCC PC CHANNEL B IS ? 50 PSI:
 - a. FOR PC SHIFT HIGH ACTUAL LOW, THE LOWEST MCC PC CHANNEL WILL BE USED FOR PERFORMANCE EVALUATION.
 - b. FOR PC SHIFT LOW ACTUAL HIGH, THE HIGHEST MCC PC CHANNEL WILL BE USED FOR PERFORMANCE EVALUATION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

- c. FOR A SINGLE MCC PC CHANNEL SHIFT, THE AFFECTED MAIN ENGINE CONTROLLER CHANNEL WILL BE POWER CYCLED FOR 1 SECOND BY THE CREW IF AN ATO CANNOT BE ACHIEVED. THIS PROCEDURE WILL NOT BE IMPLEMENTED IF IT WILL CAUSE AN SSME SHUTDOWN OR NOT CORRECT THE PERFORMANCE DISPERSION AS DEFINED BELOW: @[061297-6147A] @[070899-6819]
- (1) LIMIT EXCEEDED ON ANY REMAINING SHUTDOWN SENSOR(S) ON OTHER CHANNEL SO THAT IT CAUSES ENGINE SHUTDOWN.
 - (2) LOSS OF OTHER CHANNEL'S DCU, INPUT ELECTRONICS, OR OUTPUT ELECTRONICS (CAUSES SSME SHUTDOWN). @[070899-6819]
 - (3) WHEN IN ELECTRICAL LOCKUP OR WHEN CHANNEL POWER CYCLE CAUSES ELECTRICAL LOCKUP. @[061297-6147A]
 - (4) WHEN IN HYDRAULIC LOCKUP OR WHEN CHANNEL POWER CYCLE CAUSES HYDRAULIC LOCKUP. @[061297-6147A]

NOTE: IT IS ACCEPTABLE TO CAUSE A MOMENTARY OR PERMANENT SSME COMMAND PATH FAILURE, BECAUSE THE SSME CAN STILL REBALANCE TO CORRECT FOR THE PERFORMANCE CASE. @[061297-6147A]

The SSME thrust is controlled using the MCC Pc channel average. A single MCC Pc channel erroneously shifting high or low will cause the SSME to shift in the opposite direction in an attempt to rebalance the SSME. That is, for an MCC Pc channel shift high case, the SSME will actually shift low. The good MCC Pc channel will shift in the direction of the actual SSME shift causing a delta between the two MCC Pc channels. The good MCC Pc channel will be used for performance evaluation. A difference of 50 psi between the two MCC Pc channels is the minimum detectable single MCC Pc channel shift, and it equates to an actual MCC Pc error of 25 psi (level 1, MCC Pc Shift Tables).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

A shifted MCC Pc channel can so adversely impact SSME performance that an ATO cannot be achieved. For such a case, the Booster will call for the controller channel with the malfunctioning MCC Pc channel to be power cycled for 1 second. Booster must be ready to identify the channel and switch to be cycled by the crew. The controller channel that has been power cycled will remain available for command and data transfer, but the controller IE (sensor data to the controller) and OE (control to the valve servo-actuators and servo-switches) on that channel will be disqualified. Disqualification of a shifted Pc sensor's IE will restore engine operation to nominal thrust and mixture ratio conditions. This action should not be taken if it will cause engine shutdown or not correct the performance dispersion. Cases that would cause engine shutdown consist of redline shutdown sensor(s) violating redline limits on the remaining channel or loss of the remaining channel's DCU, IE, or OE. Reference {Rule A5-2}, SPACE SHUTTLE MAIN ENGINE OUT, paragraphs E and F. If the SSME is in electrical or hydraulic lockup or when channel power cycle causes electric or hydraulic lockup, disqualifying the faulty sensor (channel) will not correct the dispersion since the engine valves cannot be repositioned. It is acceptable to create a momentary or permanent command path failure because it is not necessary for the controller to have good GPC commands in order for the SSME to rebalance. However, command path failures are unlikely since the SSME command channel is expected to be regained once the controller power is turned back on. If a command path failure does occur, the affected SSME must be shut down prior to MECO based on the cues listed in Flight Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES. @[070899-6819]

2. A DUAL MCC PC CHANNEL SHIFT HIGH OR LOW CASE WILL BE CALLED WHEN THE MCC PC ERROR IS ≥ 37.5 PSI. A MINIMUM MCC PC ERROR OF 37.5 PSI IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL THREE TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPOP DISCHARGE PRESSURE, AND HPFP DISCHARGE PRESSURE) EXCEED THE LEVEL 1.5 CRITERIA PER THE MCC PC SHIFT TABLES. A DELTA BETWEEN THE MCC PC CHANNELS MAY OR MAY NOT BE PRESENT. @[070899-6819]

Actual MCC Pc error can also result from shifts in both the MCC Pc channels (shifting by the same or different amounts) or a shift in one MCC Pc channel with the other channel previously disqualified; this is defined as a dual MCC Pc channel shift. For this case, the actual SSME MCC Pc error will be determined using the HPOT discharge temperature, HPOP discharge pressure, and HPFP discharge pressure. A dual MCC Pc channel shift will be assessed when all three of these telemetry parameter deltas exceed the minimum criteria (SSME MCC Pc error ≥ 37.5 psi) listed in the Booster Main Engine Tables (approved at the A/EFTP No. 152 on September 18, 1998). Both the single and the dual MCC Pc channel shift cases will use the same MCC Pc Shift Tables for the ARD updates, and the level in both cases will be based on the actual MCC Pc error. For a dual MCC Pc shift case, waiting for MCC Pc error of 37.5 psi (level 1.5) protects against erroneously calling the case due to prediction sigmas, and it reliably differentiates this case from other cases that have similar SSME temperature and pressure movements.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

3. LPFT DISCHARGE TEMPERATURE SHIFT CASE WILL BE CALLED WHEN THE LPFT DISCHARGE TEMPERATURE SENSOR SHIFTS LOW? 2 DEG R.

A shift in LPFT discharge temperature sensor will cause an error in the fuel density calculation. This error in fuel density will propagate into an error in the mixture ratio calculation. The SSME controller will then attempt to return the calculated mixture ratio to the nominal value by adjusting the SSME valves causing an off-nominal engine performance dispersion. A performance adjustment to the ARD will only be made for a shift low of the LPFT discharge temperature sensor because the LPFT discharge temperature cannot realistically get colder. The minimum detectable error is 2 deg R to cover instrumentation accuracy, run to run variations, and to ensure sufficient change in the SSME parameters for failure identification.

4. ELECTRICAL LOCKUP WILL BE CALLED WHEN THE ENGINE STATUS WORD (ESW) INDICATES THAT THE SSME IS IN ELECTRICAL LOCKUP.
- a. IF THE MCC PC OR THE LH₂ FLOWMETER SENSORS SHIFT PRIOR TO ELECTRICAL LOCKUP AND IF THE SSME IS LOCKED UP AT THE MISSION POWER LEVEL, AN ARD ADJUSTMENT WILL BE MADE USING THE MCC PC SHIFT TABLES OR LH₂ FLOWMETER SHIFT TABLES. @[070899-6819]
- b. IF THERE IS NO QUANTIFIABLE SHIFT IN THE MCC PC OR THE LH₂ FLOWMETER SENSORS PRIOR TO ELECTRICAL LOCKUP, AN ARD ADJUSTMENT WILL BE MADE USING THE BACKUP ELECTRICAL LOCKUP TABLES. @[070899-6819]

An electrical lockup will be called when the ESW mode indicates that the SSME is in electrical lockup. Electrical lockup is caused by disqualification of both channels of either the MCC Pc or the LH₂ flowmeter sensors (reference Flight Rule {A5-3}, STUCK THROTTLE). If the MCC Pc or LH₂ flowmeter sensor shift caused an SSME to rebalance prior to disqualification, an ARD adjustment will be made using the MCC Pc shift tables or the LH₂ flowmeter shift tables. If there is no quantifiable shift in the SSME performance prior to an electrical lockup, then an ARD adjustment will be made using the backup electrical lockup table.

The fuel flow meter and Pc shift tables are only valid at the mission power level. For electrical lockups that do not occur at the mission power level, the backup electrical lockup tables are used. The backup electrical lockup tables adjust thrust, Isp and MR for LO₂ inlet pressure at the time of the lockup.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

5. AN LH₂ FLOWMETER SHIFT HIGH OR LOW WILL BE CALLED WHEN THE FUEL FLOW ERROR IS ? 450 GPM. A MINIMUM FUEL FLOW ERROR OF 450 GPM IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL FOUR TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPOP DISCHARGE PRESSURE, HPFP DISCHARGE PRESSURE, AND FPOV POSITION) EXCEED THE LEVEL 1 CRITERIA.

The SSME mixture ratio is controlled using the measured volumetric flowrate from the LH₂ flowmeter. A shift in the LH₂ flowmeter will cause the SSME controller to calculate incorrect values for LH₂ mass flowrate, propagating into a mixture ratio error. The controller will then attempt to return the calculated mixture ratio to the nominal value by adjusting the SSME valves. This will cause the real thrust, Isp, and MR to be off-nominal. A flowmeter shift low will cause the controller to increase LH₂ flow, "shift low actual high," causing the real mixture ratio to be low. A LH₂ flowmeter shift high will cause the controller to decrease the LH₂ flow, "shift high actual low," causing the real mixture ratio to be high. The LH₂ flowmeter shift case will be assessed only when all four telemetry parameter deltas (HPOT discharge temperature, HPOP discharge pressure, HPFP discharge pressure, and FPOV position) exceed the level 1 criteria (SSME fuel flow error ? 450 GPM) listed in the Booster Main Engine Tables. The OPOV position cue was replaced by the HPFP discharge pressure cue after the Block I SSME's were introduced into the fleet - due to OPOV position oscillations (reference PSIG Action No. 940112-D01).

6. HYDRAULIC LOCKUP WILL BE DECLARED WHEN THE HYDRAULIC SUPPLY PRESSURE DROPS BELOW 1500 PSIA OR WHEN THE ESW INDICATES HYDRAULIC LOCKUP. THE INSTANTANEOUS AND DRIFT PERFORMANCE WILL BE COMPUTED IN REAL-TIME, AND THE ARD WILL BE ADJUSTED ACCORDINGLY. @[070899-6819]

The SSME propellant valves will not properly actuate with the hydraulic supply pressure below 1500 psia and will begin to drift due to flow torque effects. As the SSME propellant valves drift and as the SSME controller also attempts to adjust the valves to account for vehicle acceleration/inlet pressure effects, the SSME controller will disqualify both servo-actuators and mode the SSME into hydraulic lockup as indicated by the ESW. The SSME controller can also mode the SSME into hydraulic lockup for reasons other than loss of hydraulic supply pressure (reference Flight Rule {A5-3}, STUCK THROTTLE). For either case, the ARD will be updated with an instantaneous thrust, Isp and MR. If the performance is changing with time due to valve drift, the mainstage performance during lockup will be calculated real time via an algorithm in the Booster Operational Support Software. Once the drift performance can be quantified, the drift level and the drift time used in these calculations will be passed to the Trajectory Officer for ARD update. The drift rate is assumed to be linear (based on SSME test stand data). Ground testing of hydraulic lockup has shown that significant valve drift can occur on an engine in hydraulic lockup. Design changes to the SSME valve actuators have been incorporated to minimize valve drift in case of hydraulic lockup. @[070899-6819]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

7. PRE-THRUST LIMITING NOZZLE LEAK WILL BE CALLED AT LEAK RATES \geq 7 LBM/SEC. A MINIMUM LEAK RATE OF 7 LBM/SEC IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL FOUR TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPFT DISCHARGE TEMPERATURE, HPFP DISCHARGE PRESSURE, AND OPOV POSITION) EXCEED THE LEVEL 1 CRITERIA.

Leakage from the nozzle tubes is the most likely source of a fuel leak based upon SSME experience, but Booster will call any fuel leak downstream of the fuel flowmeter a nozzle leak. During a nozzle leak, fuel is lost overboard causing a decrease in thrust, and the SSME will command the OPOV open in an attempt to maintain a constant SSME thrust. As the leak rate gets larger, the OPOV will continue to open causing the actual SSME mixture ratio and thrust to increase. When the maximum OPOV command limit is exceeded, the SSME will enter a mode called thrust limiting where the OPOV will no longer be commanded to open further. If the leak rate continues to increase after thrust limiting, the actual SSME mixture ratio and thrust will start to decrease. Due to the difference in performance parameter trends for pre-thrust limiting and post-thrust limiting nozzle leaks, the Booster Main Engine Tables considers them separate performance cases for the ARD update. ©[070899-6819]

Pre-thrust limiting nozzle leaks will be assessed for an ARD update only when all four telemetry parameter deltas (HPOT discharge temperature, HPFT discharge temperature, HPFP discharge pressure, and OPOV position) exceed the level 1 criteria (fuel leak rate \geq 7 lbm/sec) listed in the Booster Main Engine Tables (approved at the A/EFTP # 152 on September 18, 1998). The minimum criteria protects against erroneously calling the case due to prediction sigmas, and it reliably differentiates this case from other cases that have similar SSME temperature, pressure, and valve movements. In the case of pre-thrust limiting nozzle leaks, the level 1 criteria for OPOV position delta (approximately 3 percent) is large enough to prevent the Block I SSME OPOV position oscillation (approximately 1 percent) from erroneously exceeding the minimum cue during nominal operations. The approximately 1 percent OPOV oscillation is only present on Block I SSME and not on Phase II/Block IIA/Block II SSME's. ©[070899-6819]

8. POST-THRUST LIMITING NOZZLE LEAKS WILL BE CALLED WITH THRUST LIMITING FLAG SET.
9. AN HPOT EFFICIENCY LOSS WILL BE CALLED WITH THRUST LIMITING FLAG SET.

An ARD update will be made for a post-thrust limiting nozzle leak or HPOT efficiency loss case only when the SSME has entered the thrust-limiting mode. Subsequent to thrust limiting, the two cases are differentiated by using the HPOT discharge temperature. The HPOT discharge temperature will rise in both of the thrust limiting cases, but the delta value is much greater in the case of a nozzle leak. In order to differentiate between the two cases, the HPOT discharge temperature delta cue was developed as the breakover value for each of these cases. The HPOT efficiency loss will not result in off-nominal SSME operation prior to thrust limiting; therefore, it is only assessed after thrust limiting is initiated.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110 SSME PERFORMANCE DISPERSION (CONTINUED)

The SSME Project Office acknowledges that there are "Overall Call Uncertainties" associated with each of the off-nominal SSME performance cases. Uncertainties exist in mixture ratio, power level, and Isp values. Subsequent to the quantification of an off-nominal performance case, mixture ratio, power level, and Isp are passed to the Flight Dynamics Officer and are used to update the ARD. The uncertainties associated with each of these parameters, for each of the performance cases, are documented in MSFC letter EE21/095-016 (Review of Booster Real-time Software (BRTS) Algorithm's, D. R. Goslin to B. R. Stone, March 17, 1995). On February 6, 1996, the Integration Control Board (ICB) made the decision not to protect these uncertainties (ICB Item WACMO0167, Booster Console Uncertainty on ARD Performance). Therefore, ARD Flight Propellant Reserve (FPR) will not reflect these uncertainties.
 ©[041196 1877]

Rules {A4-61}, THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP; {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT; {A5-3}, STUCK THROTTLE; and {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES reference this rule. ©[061297-6147A] ©[ED]©[070899-6819]

A5-111 AC BUS SENSOR ELECTRONICS CONTROL [CIL]

THE ORBITER AC BUS SENSOR ELECTRONICS POWER SWITCH WILL BE PLACED TO "OFF" FOR THE FOLLOWING ENGINE FAILURE CASES:

- A. ENGINE OUT (REF. RULE {A9-152}, AC BUS SENSORS SWITCH MANAGEMENT) ©[121296-4624]
- B. LOSS OF SSME CONTROLLER REDUNDANCY (REF. RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT) ©[ED]
- C. ALL QUALIFIED REDLINE SENSORS ON A SINGLE REDLINE, ON A SINGLE CHANNEL, VOTING FOR SHUTDOWN. ©[121296-4624]

There are single point failures in the ac bus sensor electronics that can cause loss of a single phase of an ac bus which powers the SSME controllers. After an engine failure or electrical/avionics failures that leave an engine one failure away from shutdown, the bus overvoltage protection is less important than keeping an engine running. Therefore, the sensor monitoring electronics power is terminated by moving three switches (AC BUS SNSR) on panel R1 to OFF.

FLIGHT RULES

A5-112

MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN

MANUAL THROTTLING TO THE MINIMUM SSME POWER LEVEL WILL BE PERFORMED TO PROTECT MECO LO₂ NPSP REQUIREMENTS WHEN LO₂ LOW-LEVEL CUTOFF IS PREDICTED TO OCCUR BEFORE FINE COUNT THROTTLEDOWN. MANUAL THROTTLING TO THE MINIMUM POWER LEVEL WILL BE PERFORMED WHEN THE ONBOARD PROPELLANT REMAINING COMPUTATION REACHES 2 PERCENT, AND THE MCC FLIGHT DYNAMICS OFFICER (FDO) IS PREDICTING A VELOCITY UNDERSPEED AT MECO WHICH IS GREATER THAN THE FOLLOWING: @[071494-1645] @[121296-4630B]

- A. TWO OR THREE ENGINES ON: 500 FT/SEC
- B. ONE ENGINE ON: 250 FT/SEC

THE CREW WILL PERFORM SSME THROTTLEBACK FOR THE ONE ENGINE-ON CASE EXCEPT FOR CERTAIN CONTINGENCY ABORT CASES (AS DOCUMENTED ON THE CONTINGENCY ABORT CUE CARDS IN THE ASCENT CHECKLIST FLIGHT DATA FILE) OR UNLESS INSTRUCTED TO DO OTHERWISE BY THE MCC. @[071494-1645] @[121296-4630B]

If FDO is predicting a low-level cutoff prior to the guidance software issuing the fine count command (ref. rationale of Rule {A4-59G}, MANUAL THROTTLE SELECTION), the engines will shut down at an unsafe power level. This will cause the LO₂ NPSP to be well below the required value, possibly causing uncontained engine damage at shutdown. For two or three engine-on cases, analysis indicates that the vehicle acceleration near MECO will be sufficient to prevent SSME shutdown prior to fine count as long as the predicted underspeed (based on 2 sigma MPS propellant protection) is no greater than 500 ft/sec. Because of low vehicle acceleration, analysis of the single engine-on case indicates that SSME requirements will not be violated as long as the predicted underspeed (based on 2 sigma MPS propellant protection) at MECO is less than 250 ft/sec. The two/three engine-on case assumes a vehicle mass of 379,000 lbs at MECO minus 10 seconds and the one engine-on case assumes 368,000 lbs (the difference is based on the additional 11,000 lbs MPS propellant needed for the two engine-on case, which will also protect the three engine-on case). Both cases assume that the thrust provided by a single engine at 104 percent is 488,800 lbf. The 500 ft/sec and 250 ft/sec cues are derived from using the $F = M \cdot A$ equation, as well as those used by the fine count throttle logic in the guidance software (reference NASA memorandum DF6-94-08, dated 5/11/94). If the predicted underspeed is greater than allowed for either case, manual throttling will be performed to the minimum power level, thereby reducing the NPSP requirements prior to reaching a low-level cutoff condition. The minimum throttle level was selected because it provides the best LO₂ NPSP shutdown conditions. The throttledown cue of 2 percent propellant remaining was selected to allow sufficient time to perform the manual throttling while minimizing any performance impact.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-112

MANUAL THROTTLEDOWN FOR LO2 NPSP PROTECTION AT SHUTDOWN (CONTINUED)

Analysis (reference Ascent/Entry Flight Techniques Panel #91, 7/17/92) shows that most of the error in the onboard propellant remaining computation occurs on the two-engine-out press-to-MECO abort when no OMS dump is performed. Engine performance problems also contribute to the propellant remaining error. The worst case engine problem is low specific impulse (Isp). Worst-on-worst analysis with two engines out simultaneously at the press-to-MECO boundary and the third engine running with an Isp which is 10 seconds below nominal shows that the 2 percent cue still provides sufficient time to throttle the engine down before low-level cutoff occurs. ©[071494-1645]

After throttledown, the crew will be prepared to perform a manual MECO at the desired MECO velocity should it be reached prior to the low-level cutoff.

The crew will not always throttleback for the one engine-on case. For certain contingency aborts, the software determines and performs fine count throttles (throttleback) as required for MECO. No manual throttles are required in these cases as documented on the contingency abort cue cards in the ascent checklist flight data file. ©[121296-4630B]

Rule {A2-64}, MANUAL THROTTLE CRITERIA, references this rule.

FLIGHT RULES

A5-113

MANUAL MECO/MECO CONFIRMED @[110900-7230A]

A. PERFORMING MANUAL MECO

MANUAL MECO IS PERFORMED BY PRESSING ALL THREE MAIN ENGINE SHUTDOWN PUSHBUTTONS SIMULTANEOUSLY. IF FAILURE(S) CAUSE THE MAIN ENGINE SHUTDOWN PUSHBUTTONS TO NOT COMMAND MECO, THEN THE MANUAL MECO WILL BE PERFORMED VIA THE ALTERNATE METHODS FOR SETTING THE MECO CONFIRMED FLAG OUTLINED IN PARAGRAPH B.

If required, manual MECO is usually performed by pressing the three SSME shutdown pushbuttons simultaneously. The crews are trained to perform manual MECO using all three pushbuttons rather than just the pushbuttons of running engines because pushing all three pushbuttons protects against certain failure scenarios without creating any additional risk. However, under certain conditions, pressing all three pushbuttons will not command MECO. If a failed contact (i.e., due to control bus or bad contact) on any pushbutton cannot be comm-faulted prior to MECO or if both contacts have either failed or are comm-faulted, MECO will not be commanded when all three pushbuttons are pushed. These failures will result in two engines being shut down while the engine associated with the bad pushbutton will continue to run. If such a failure is recognized prior to MECO and manual MECO is required, the crew will be instructed to command MECO by setting the MECO confirmed flag via the appropriate alternate method outlined in paragraph B.

Performing a manual MECO on any trajectory is very time critical, and it must be recognized ahead of time if the three pushbuttons will not work so that alternate methods may be employed at the required moment.

B. SETTING THE MECO CONFIRMED FLAG

THE THREE MAIN ENGINE SHUTDOWN PUSHBUTTONS WILL BE PUSHED POST MECO FOR MULTIPLE COMMAND/DATA PATH FAILURE CASES TO SET THE MECO CONFIRMED FLAG. IF THE MECO CONFIRMED FLAG WILL NOT BE SET WHEN THE SHUTDOWN PUSHBUTTONS ARE PRESSED, IT WILL BE OBTAINED VIA THE FOLLOWING ALTERNATE METHODS:

1. NOMINAL/ATO/TAL: MANUALLY PROCEEDING TO OPS 104
2. RTLS: PERFORMING A FAST SEP FROM THE EXTERNAL TANK
@[110900-7230A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-113

MANUAL MECO/MECO CONFIRMED (CONTINUED)

The SSME operations sequence will set the MECO confirmed flag for chamber pressure less than 30 percent on all three engines or a data path failure on one engine and the chamber pressure less than 30 percent on the other two engines. If two engines experience a data path failure, the software will never pass this check and MECO confirmed flag will not be set. To work around this problem, the crew can push the three shutdown pushbuttons after MECO to set the MECO confirmed flag. Prior to OI-22, all three SSME pushbuttons had to be pressed simultaneously in order to set the MECO confirmed flag in the BFS. In OI-22 and subsequent, the SSME pushbuttons can be pressed individually to set the MECO confirmed flag (CR# 89203A). The MECO confirmed flag must be set to start the ET separation sequence. ©[110900-7230A]

In the event that multiple avionics failures or a failed pushbutton contact has disabled a shutdown pushbutton, alternate methods of setting the MECO confirmed flag must be performed. On nominal ATO and TAL trajectories, the MECO confirmed flag can be set by manually keying in OPS 104 PRO. Since the OPS 104 transition is not legal on an RTLS trajectory, the MECO confirmed flag must be set by performing a fast sep from the external tank. A fast sep is performed by taking the ET SEPARATION switch to MAN and pressing the ET SEPARATION pushbutton. In PASS, fast sep logic is only supported in major modes 102, 601, or in major mode 103 when the Second SSME Fail Confirm flag had been set. BFS only supports fast sep logic in major mode 102. ©[110900-7230A]

The above steps are taken post MECO because setting the MECO confirmed flag at or before MECO causes MECO to be commanded. On uphill and TAL trajectories, setting the MECO confirmed flag to allow the ET separation sequence to proceed is not particularly time critical so the three pushbuttons can be tried first before other methods. However, setting MECO confirmed on an RTLS trajectory is very time critical. In time critical situations, it must be recognized ahead of time if the three pushbuttons will not work so that alternate methods may be employed at the required moment. ©[110900-7230A]

FLIGHT RULES

A5-114 **SSME HYDRAULIC REPRESSURIZATION/POSTLANDING SSME REPOSITIONING**

A. ON-ORBIT/ENTRY-1 DAY REPRESSURIZATION

APPLICATION OF MPS HELIUM TO SSME VALVE ACTUATORS IS NOT REQUIRED DURING HYDRAULIC REPRESSURIZATION AND SSME REPOSITIONING WHEN THE TVC ACTUATORS DRIFT OUT OF POSITION PER FLIGHT RULE {A8-106}, TVC-SSME STOW/ACTUATOR FLUID FILL (REPRESSURIZATION).

B. ENTRY/POSTLANDING REPOSITIONING

MPS HELIUM WILL BE PROVIDED TO THE ENGINES DURING HYDRAULIC REPRESSURIZATION AND SSME REPOSITIONING. THIS ENSURES THAT ENGINE VALVES DO NOT DRIFT OPEN. HOWEVER, LACK OF HELIUM IS NOT A CONSTRAINT AGAINST PERFORMING EITHER PROCEDURE.

Hydraulic pressure is applied to the TVC actuators to prevent SSME movement during on-orbit, entry, and postlanding operations. Maintaining helium pressure on the closed side of the engine valves will keep the valves from opening when hydraulic pressure is applied to the TVC actuators. Keeping the valves closed prevents engine contamination during entry and postlanding. On-orbit SSME contamination is unlikely; therefore, the application of helium for on-orbit TVC drift is not required. This will also reduce MPS helium regulator cycles.

MPS MANAGEMENT: PRELAUNCH THROUGH MECO

A5-151 PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL]

- A. MPS ENGINE SYSTEM HELIUM LEAK ISOLATION WILL BE PERFORMED FOR ANY SIGNIFICANT LEAK (PER RULE {A5-10}, SIGNIFICANT ENGINE HELIUM SYSTEM LEAK) AS LONG AS THE ATTEMPT TO ISOLATE THE LEAK WILL NOT CAUSE THE ENGINE TO SHUT DOWN. @[090894-1676A] @[ED]

If an MPS engine helium system experiences a helium leak the crew will perform a helium leak isolation procedure. However, since certain power bus failures will result in helium leg A isolation valves failing closed (MNA, APC4 or ALC1; MNB, APC5 or ALC2; or MNC, APC6 or ALC3 failure will close the center, left, or right SSME isolation valve, respectively), the crew must be reminded not to attempt leak isolation for these cases. The closing of the leg B isolation valve will stop helium flow to the engine and cause an SSME redline limit shutdown due to low HPOTP intermediate seal (IMSL) purge pressure. The shutdown may cause engine damage since both regulator isolation valves are closed. No helium will be available for SSME IMSL purging during the shutdown sequence.

- B. AN ATTEMPT WILL BE MADE TO ISOLATE ANY SIGNIFICANT PNEUMATIC SYSTEM LEAK (REF. RULE {A5-11}, SIGNIFICANT PNEUMATIC SYSTEM HELIUM LEAK). @[ED]

A significant pneumatic system helium leak could result in insufficient pressure for prevalve actuation at MECO. The LO₂ prevalves are required to close at MECO in order to maintain pressure at the HPOTP pump inlet. This prevents pump cavitation and overspeed which could result in uncontained SSME damage. An attempt is made to isolate the pneumatic helium supply so the remaining helium can be used to pressurize the pneumatic accumulator and support prevalve closure at MECO.

- C. IF AN MPS PNEUMATIC HELIUM SYSTEM LEAK/ISOLATION CAUSES INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE (REF. RULE {A5-12}, INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE), THE SYSTEM WILL BE RECONFIGURED AT MECO-30 SECONDS. @[ED]

Seven hundred psia in the pneumatic accumulator is the minimum non-resupplied pressure which will close all the LO₂ prevalves within timing constraints at MECO. If the pneumatic helium supply has been isolated due to a leak or is used to support the mainstage operation of an engine with a helium leak, the pneumatic accumulator pressure may fall below 700 psia. Should the accumulator pressure fall below 700 psia for any reason, the pneumatic helium isolation valves, the left engine helium crossover valve and, if necessary, the engine interconnect valves, will be reconfigured to repressurize it. This will be accomplished at MECO minus 30 seconds and ensures that 700 psia is available in the pneumatic accumulator until the start of prevalve closure at MECO.

Note: Taking the interconnect out-open to open on an engine when the pneumatic tank is depleted will not cause a large enough flow transient to cause the engine to shut down (documented by RI Downey internal letter number 287-100-93-259, dated 11/09/93). @[090894-1676A]

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]

- A. TO SUSTAIN THE OPERATION OF AN ENGINE WITH AN MPS HELIUM LEAK, FOR SINGLE REGULATOR OPERATION, OR FOR EXTENDED BURN TIME, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AT THE FOLLOWING CUES: ©[090894-1676A] ©[050400-7195A]

If a helium leak develops and the decay rate is such that the engine will not meet zero-g shutdown requirements or will cause an early shutdown, the helium system of an engine and/or the pneumatic helium system will be interconnected to that engine's system. This action may allow the engine to meet the zero-g shutdown requirements and will maintain engine operation as long as possible. Similar action is taken if the leak has been isolated and the system will not meet shutdown requirements.

A tank pressure of 920 psia (900 psia required + 20 psia instrumentation error) is the minimum value, including instrumentation error, which will support the normal operating range of the helium system regulators. The difference between the actual requirement, 920 psia, and the C&W value, 1150 psia, results from a change in the estimated instrumentation error of the helium tank pressure transducers as a result of vehicle specific calibration curves. With calibration curve coefficients unique to each helium tank pressure transducer, the accuracy of each reading is 0.15 percent. An accuracy of 0.15 percent over the 5000 psia transducer range equates to an error of 7.5 psia. To account for any potential degradation in accuracy (e.g., transducer replacements where the new transducer is less accurate or calibration equipment changes), one PCM count (10 psia) was added to the 7.5 psia error. This new instrumentation error of 17.5 psia was then rounded to the nearest PCM count resulting in 20 psia instrumentation error used by the MCC and incorporated into crew procedures. The interconnect cues shown in the subsequent paragraphs are used as a guideline to ensure sufficient helium to sustain SSME operation with a helium leak. It is important to note that the interconnect must be performed above the minimum tank pressure required to support the shutdown mode. That is, the interconnect must be performed at a higher tank pressure for a pneumatic shutdown than for a pre-MECO redline shutdown due to helium depletion because the pneumatic shutdown requires more helium. The tank pressure of 920 is quoted as the "no later than" cue in order to provide the absolute minimum tank pressure above which the interconnect must be performed. Since there is not one tank pressure interconnect to satisfy all cases (leak types, shutdown mode, leak size, etc.), the C&W cue of 1150 is sufficient for the crew to use in no-comm cases. The change in calculated instrumentation error did not warrant a change to the onboard software or hardware caution and warning. ©[050495-1767B] ©[100997-6298] ©[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

Since the helium tank and regulator pressure requirements were derived using vehicle specific calibration curves, it must be noted that the onboard readings will vary between the BFS GNC SYS SUMM 1 display and the OMS/MPS MEDS display / MCDS MPS meter. The BFS GNC SYS SUMM 1 data is based on vehicle specific calibration curve coefficients; whereas due to system limitations, the OMS/MPS MEDS display and the MCDS MPS meter data are based on generic calibration curve coefficients. When the MCC calls for an interconnect or SSME shutdown based on a helium tank or regulator pressure, it is understood that the crew will use the data available on the BFS GNC SYS SUMM 1 display. This understanding was accepted by CB, DT, and DA8 (reference AEFTP #152, September 18, 1998). @[110900-7239]

Dropping helium system regulator outlet pressure is also used to detect potential SSME HPOTP intermediate seal (IMSL) purge pressure violations. If both helium regulators have been in steady state operation between 715 psia and 785 psia outlet pressure, a sudden decrease in outlet pressure may be indicative of a system failure. Action is taken as soon as both regulator outlet pressures fall below 715 (679) psia in an attempt to prevent the engine from shutting down. Six hundred and seventy nine psia was derived from the minimum normal regulator outlet pressure, 715 psia, minus 36 psia instrumentation error prior to OI-26B. For OI-26B and subsequent flights, the instrumentation error was reduced to 5 psia. However, the Caution and Warning limit remains at 679 psia because the change to 5 psia would result in a Caution and Warning value very close to the nominal control band of the regulator (regulator is psig, instrumentation is psia) and was not considered worth the effort in updating Caution and Warning. With regard to helium system leaks, a regulator outlet pressure below 715 psia does not indicate that the regulator is malfunctioning. Low outlet pressures are indicative of helium system leaks which result in high helium mass flow rates or supply tank depletion resulting in low inlet pressures to the system regulators. Taking action at 679 psia not only prevents premature helium system interconnecting, but also gives some assurance that another helium system can be interconnected to the leaking supply before the engine interface pressure reaches the expected shutdown value of 518 psia for the Phase II SSME, or 576 psia for the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME (reference SODB data requests R1-1507 and R1-1640, respectively) even with the reduction in instrumentation error with OI-26B. @[050495-1767B] @[020196-1812] @[121197-6472A] @[050400-7195A] @[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

1. FOR A NON-ISOLATABLE UPPER SYSTEM LEAK: @[050400-7195A]
 - a. WITH THREE ENGINES ON, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS LATE AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B]
@[110900-7239]

When a non-isolatable upper system leak occurs, it is best to perform helium interconnects as close to the minimum shutdown requirement as possible. If the interconnect is performed too early and the system leak is a tank leak, helium in the leaking tank will no longer be used to support engine operation and will therefore be wasted.

- b. WITH LESS THAN THREE ENGINES ON, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL BUT ABOVE THE CUES GIVEN IN PARAGRAPH A.1.a.

When a non-isolatable upper system leak occurs after an engine has shut down, helium interconnects can be performed as soon as practical. An upper system leak could be either a leak in the engine's helium tank or an upper system leak above the helium regulators. If the leak is an upper system leak, then interconnecting as soon as practical does not waste any helium. If the leak is in the tank, interconnecting as soon as practical will result in the helium from the leaking tank being wasted. However, a good interconnect from a previously shutdown engine will provide a nominal feed rate to the engine with the tank leak and will allow it to support a zero-g shutdown. Interconnecting early not only allows the reconfiguration to take place while the crew is in a low g environment, but also allows for an earlier assessment of the shut down requirements of the leaking engine. @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

2. FOR A NON-ISOLATABLE LOWER SYSTEM LEAK, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B] @[050400-7195A] @[110900-7239]

For non-isolatable lower system leaks, helium interconnects can be performed immediately after leak identification, but must be performed above the minimum tank pressure needed to support engine shutdown. A leak below the regulator will have the same mass flow rate after the interconnect that it had prior to the interconnect. Interconnecting early allows the reconfiguration to take place while the crew is in a low g environment.

3. FOR A NON ISOLATABLE LEAK THAT REQUIRES INTERCONNECTING THE HELIUM SYSTEM OF A NON-LEAKING RUNNING ENGINE, THE INTERCONNECT WILL BE PERFORMED WHEN THE TANK PRESSURES ON ALL PREVIOUSLY INTERCONNECTED SYSTEMS REACH 500 PSIA OR THE AFFECTED SSME HPOTP IMSL PRESSURE REACHES 70 PSIA.

If the leaking engine supply, the previously shut down engine supply, and the pneumatic supply are insufficient to obtain single engine abort capability to a landing site, interconnecting is also allowed, within certain limits, from the remaining engine which has a good MPS helium supply in an attempt to regain landing site abort capability per paragraph B.2.a. Because an attempt is being made to avoid a contingency abort due to insufficient MPS helium, the interconnect from a non leaking running SSME helium supply to an engine with a leaking helium supply will be performed as late as is reasonably possible. The interconnect will be performed once the leaking system reaches 500 psia (500 psia is a generic tank pressure which, with SSME limits inhibited, should ensure that crossover margin is maintained in the SSME HPOT IMSL package) or an HPOTP IMSL pressure of 70 psia (70 psia provides 10 psia interconnect margin against the Block I/IIA/II SSME limit of 60 psia in rule {A5-153C}.2.a, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS). An interconnect cue of 500 psia in the tank or 70 psia in the IMSL package should also prevent the SSME HPOT IMSL pressure from decaying below 60 psia while the SSME is operating. @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

4. FOR SINGLE REGULATOR OPERATION OF THE MPS HELIUM SYSTEM, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM TANK PRESSURE REQUIRED TO SUPPORT THE SINGLE REGULATOR SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920) OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B] @[050400-7195A] @[110900-7239]

If a helium system is operating on a single regulator, due to an isolated leak or any other system failure, the resulting mass flow rate of helium through the system is nominal. Therefore, helium system interconnects may be accomplished as soon as convenient. When operating on a single regulator, all shut down modes must protect for single regulator operation. A single regulator providing helium flow to an engine must flow the equivalent helium of two operating regulators. Higher pressures must be maintained at the regulator inlet in order to ensure that shutdown pressure and mass flow rate requirements are satisfied.

5. FOR AN ENGINE REQUIRING EXTENDED ENGINE BURN TIME, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER THE HELIUM CURVES FOR A NON-ISOLATABLE LOWER SYSTEM LEAK WITH NOMINAL FLOW RATE GIVEN IN RULE {A5-153E}.1, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[110900-7239]

If the predicted MECO time is extended due to low ascent performance or an abort requirement such that interconnecting is necessary to meet shutdown requirements, the pneumatic system and the helium system of any failed engine can be interconnected to a running engine as soon as practical. The minimum tank pressure which will support a zero-g shut down of an engine with two good regulators and no helium leak is given in the helium curves for a non-isolatable lower system leak with nominal flow rate in rule {A5-153E}.1, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS. Since an engine with extended burn time has a constant helium usage, the curve for an engine with a non-isolatable lower system helium leak is used to define the minimum zero-g requirement. @[090894-1676A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

6. IN THE NO-COMM CASE, THE CREW WILL PERFORM HELIUM SYSTEM INTERCONNECTS AT A SYSTEM PRESSURE OF 1150 PSIA OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050400-7195A]

In the loss of comm case, crew action is taken at 1150 psia. 1150 psia is the C&W limit. The alarms and tones annunciated at 1150 psia are a good reminder to the crew that action needs to be taken. If the tank pressure reaches this value and continues to fall, the engine HPOTP IMSL purge redline limit may be violated. Action is taken at 1150 psia to preclude an early engine out situation while making as much use of available helium as possible. The engine IMSL seal limit should not be violated until the pressure decays below approximately 518 psia at the engine interface for the Phase II SSME (ref. SODB Vol. 3, Section 4.3.1) or 576 psia at the engine interface for the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME (ref. SSME test 901-835 and the 09-13-95 PSIG). @[050495-1767B] @[020196-1812] @[100997-6298] @[121197-6472A] @[110900-7239]

- B. IF THE INTERCONNECT CUES IN PARAGRAPH A ARE MET, THE INTERCONNECT OF THE PNEUMATIC HELIUM SYSTEM OR THE HELIUM SYSTEM OF ANOTHER ENGINE WILL BE PERFORMED PER THE FOLLOWING CONDITIONS: @[090894-1676A] @[100997-6298]

If an engine helium supply is depleting due to a leak, or helium shut down requirements are not met due to extended burn times or single regulator operation, interconnecting other helium systems will be allowed in some situations to sustain the operation of an engine.

1. WITH THREE ENGINES ON:

ONLY THE PNEUMATIC HELIUM SYSTEM WILL BE INTERCONNECTED AND THE ENTIRE SYSTEM WILL BE USED IF REQUIRED.

The entire pneumatic helium system will be used to sustain the operation of an engine, since sufficient helium margin should be available in the other two helium systems and the pneumatic accumulator to satisfy the zero-g requirements for pre-valve actuation, SSME pogo system post-charge, shutdown and entry environmental purges, and entry MPS manifold pressurization. @[090894-1676A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

2. WITH TWO ENGINES ON: @[050400-7195A]
- a. INTERCONNECTING THE PNEUMATIC HELIUM SYSTEM AND THE HELIUM SYSTEM OF THE PREVIOUSLY SHUT DOWN ENGINE WILL BE PERFORMED.

For the two engine on case, interconnecting is allowed from the previously shut down engine and the pneumatic system. This will not only maximize the leaking engine run time but may also re-establish zero-g shutdown capability. @[110900-7239]

- b. INTERCONNECTING THE HELIUM SYSTEM OF THE NON-LEAKING RUNNING ENGINE WILL BE PERFORMED BY TAKING THE INTERCONNECT VALVE OF THE NON-LEAKING RUNNING ENGINE TO OUT OPEN FOR 15 SECONDS (ONE TIME ONLY) AND THEN BACK TO THE GPC POSITION IF ALL OF THE FOLLOWING CONDITIONS ARE SATISFIED:
- (1) THE INTERCONNECTS PER PARAGRAPH B.2.a WILL NOT ALLOW THE LEAKING ENGINE TO SUPPORT SINGLE ENGINE ABORT CAPABILITY TO A LANDING SITE (SINGLE ENGINE LIMITS OR SINGLE ENGINE RTLS BOUNDARY), AND
- (2) THE TOTAL FLOWRATE OF THE LEAKING SYSTEM HAS NEVER BEEN GREATER THAN 0.30 LBM/SEC.

Margin in the non-leaking, running SSME MPS helium supply will be used to support the operation of another SSME with a leaking supply. Interconnecting in this case will result in one MPS helium supply supporting two SSME's, one at an off-nominal flowrate. Consequently, the interconnect of a running supply will only be performed if the total flowrate of the leaking supply has never been greater than 0.30 lbm/sec. The 0.30 lbm/sec total flowrate requirement is a generic value which will provide at least 15 seconds, and at most 1.5 minutes, of additional runtime for the SSME with the leaking supply. Total flow rates above 0.30 lbm/sec make it extremely likely that either a second SSME will fail prior to reaching a certified abort boundary, or that helium available to the last SSME will be depleted to a level which is below MECO requirements. By not interconnecting for large leaks, three SSME out contingency aborts are avoided and a crew survival path is maintained by two SSME out abort coverage. @[100997-6298] @[121197-6472A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

Numerous assumptions had to be made in order to cover this case with a generic rule. All the variables were assigned generic values and discussed at Ascent Entry Flight Techniques #135 on October 18, 1996. The assumptions were as follows. The maximum allowable flowrate of the leaking system was derived for the RTLS abort case since three out black zones occur at a later MET than on a TAL. The first SSME shuts down at liftoff and a non isolatable lower system leak develops on one of the remaining engines at the same time. There is a total of 134 pounds of helium available from both the leaking engine and the one that shut down. Of an initial 13 pounds of helium in the pneumatic system, 10 are available to support the leaker. Single engine operation of the last engine must be maintained, while preserving the zero g shutdown helium requirement, until an RTLS MECO time of 10:45 MET, which assumes 109 SSME throttles. Given this MECO time, there are 14 excess pounds of helium available from the running engine to support the leaking helium supply, resulting in a total of 158 pounds of helium available for the leaking engine. Assuming 2 1/2 minutes is the maximum run time needed for single engine completion of an RTLS contingency abort, the leaking engine must support a run time of 8:15 MET (MECO time minus 2 minutes 30 seconds). Assuming that 8 pounds of helium are required to support the shutdown of the leaking engine, the remaining 150 pounds would support the engine's operation until 8:15 MET as long as the leak rate is not greater than 0.30 lbm/sec. AEFTP was also made aware that a real-time or non-real-time redefinition of any of these variables might result in an outcome which varies from current predictions. However, in any case it is agreed that helium from the last SSME should be interconnected to a leaking supply in an attempt to reach a runway, as long as three SSME out black zones are protected. ©[100997-6298]

The running, non-leaking SSME supply will only be interconnected for 15 seconds. This will keep the SSME running while the pneumatic system is repressurized. The interconnect action also increases the likelihood that the last running SSME with a non-leaking MPS helium supply will retain sufficient helium in its supply to support guided MECO once the second SSME with a leaking MPS helium supply shuts down. ©[121197-6472A] ©[050400-7195A]

The interconnect is broken by taking the interconnect switch of the engine with the non-leaking helium system to the GPC position. If the leaking helium supply has been depleted due to a tank leak, or an upper system leak exists, breaking the interconnects in this manner allows the pneumatic system to remain interconnected to the engine with a leaking helium supply in order to support its shutdown. ©[100997-6298]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

3. WITH ONE ENGINE ON: @[050400-7195A]

INTERCONNECTING THE PNEUMATIC HELIUM SYSTEM AND THE HELIUM SYSTEMS OF ALL PREVIOUSLY SHUT-DOWN ENGINES WILL BE PERFORMED.

- C. THROTTLE MANAGEMENT FOR TWO ENGINES ON WITH A NON-ISOLATABLE MPS HELIUM LEAK IN ONE OF THE RUNNING SSMEs WILL BE PERFORMED PER THE FOLLOWING: @[050495-1753A] @[100997-6298]

With three engines on, there are no regions where a subsequent engine out will not allow the remaining engines to perform an abort to a landing site. Therefore, 109 percent SSME throttles are not required for that case.

1. NOMINAL/ATO:

109 PERCENT SSME THROTTLES IS NOT REQUIRED FOR THESE CASES.

The only region where an abort cannot be performed to a landing site with the leaking engine out usually occurs between the PRESS-TO-ATO boundary and the SINGLE ENGINE LIMITS boundary. Since the time between these boundaries is less than 1.5 minutes, it is extremely unlikely that an interconnect from a running engine to a running engine will be required. Consequently, the maximum time spent at 109 throttles (at most 1.5 minutes) will not significantly reduce the predicted MECO time. @[050495-1753A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

2. TAL:

THE SSME'S WILL BE IMMEDIATELY THROTTLED TO 109 PERCENT POWER LEVEL AFTER THE ISOLATION PROCEDURE IS COMPLETED AND MPS HELIUM LEAK IS DETERMINED TO BE NON-ISOLATABLE. IF SINGLE ENGINE TAL 104 ABORT CAPABILITY IS ACHIEVED OR IS PREDICTED TO BE ACHIEVED WITHOUT INTERCONNECTING A RUNNING ENGINE SUPPLY, SSME THROTTLES MAY BE RETURNED TO 104 PERCENT POWER LEVEL. @[100997-6298] @[050400-7195A]

For this case, the additional risk associated with operating the main engines at 109 power level is acceptable in order to provide the crew and vehicle a chance to reach a runway (i.e., SE LIMITS). Commanding the engines to 109 percent power level, while the vehicle is in an abort gap with a helium leak on one of two running SSME supplies, maximizes the use of the remaining helium by reducing the time required to achieve abort capability to a landing site. Furthermore, the increased power level does not increase helium usage in the engine HPOTP IMSL purge package (usage remains unchanged from 67-109 percent power level) and should have no negative effect on the size of the leak in the MPS helium system. Operationally, the increased internal engine pressures and temperatures at 109 percent do increase the likelihood of having an SSME failure (ref. AEFTP #108 charts, 12/17/93). However, because the run time remaining on the last engine to MECO cannot be determined (its helium supply was compromised), the main engines will remain at 109 percent power level until fine count is reached and the software throttles back the engines, the crew initiates manual throttles at the 2 percent propellant remaining in the ET cue (reference rule {A5-112}, MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN,), or until the manual MECO (reference rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS). @[090894-1676A] @[ED]

If single engine TAL 104 abort capability is achieved, or is predicted to be achieved, after throttling the SSME's to 109 percent power level and without interconnecting a running, non-leaking SSME helium supply, sufficient helium will be available in the non-leaking MPS helium system to complete a single engine abort at 104 or 109 percent power level and eliminate the possibility of having to return to 109 percent power level should the engine with the helium leak shut down prior to single engine TAL 104. Additionally, since the time between the single engine limits and single engine TAL 104 boundaries is short, it is advisable to leave the throttles at 109 percent to preclude additional work for the crew should an engine fail in this region. Single engine TAL 104 is when the Flight Dynamics Officer determines that 109 percent power level is no longer required for single engine abort completion. Per the rationale above, it is desirable that the SSME throttle setting be returned to 104 percent whenever possible. @[ED] @[050495-1767B] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

3. RTLS:

THE SSME'S WILL BE IMMEDIATELY MANUALLY THROTTLED TO 109 PERCENT POWER LEVEL AFTER THE ISOLATION PROCEDURE IS COMPLETED AND THE MPS HELIUM LEAK IS DETERMINED TO BE NON-ISOLATABLE. IF IT IS DETERMINED BY THE MCC THAT THE ABORT CAN BE COMPLETED WITHOUT COMPROMISING THE NON-LEAKING SUPPLY OF A RUNNING SSME, MAIN ENGINE THROTTLES WILL BE RETURNED TO AUTO PRIOR TO POWERED PITCH AROUND INITIATION. OTHERWISE, AUTO SSME THROTTLES WILL BE RESELECTED AT THE COMPLETION OF POWERED PITCH AROUND.

@[050495-1753A] @[100997-6298] @[050400-7195A]

If a non-isolatable MPS helium leak exists in the supply of one of two running SSME's while performing an RTLS abort, the likelihood that the associated SSME will shut down early, prior to reaching single engine abort capability, increases significantly. The probability that the shut down requirements of the last SSME are violated at MECO also increases significantly. Both possibilities are further compounded on the RTLS case by predicted MECO times which may extend by as much as 3 minutes longer than the nominal uphill MECO. Furthermore, since the maximum SSME operating time is defined at liftoff by the prelaunch loading of MPS helium, the SSME burn time cannot be extended to alleviate these concerns. The only available option is to use a higher main engine power level in order to minimize the predicted MECO time.

Analysis by flight design indicates that using 109 percent throttles on an RTLS abort can decrease the MECO time by as much as 55 seconds, assuming 109 is maintained throughout the trajectory (reference Ascent Abort Panel briefing charts, 10/6/94, "RTLS MECO Time Reduction for MPS Helium Leaks"). The resulting decrease in predicted MECO time may be the difference between a crew bailout and an intact abort landing. However, it must be noted that the trade off of using 109 percent throttles during the RTLS flyback phase is that, the ET separation QBAR is decreased by approximately 1.5 psf with respect to the designed RTLS condition, and the ET separation MPS propellant residuals are increased by approximately 0.5 percent over the designed RTLS condition. Since manual throttles must be maintained until the initiation of powered pitch around in order to stay at 109 throttles during flyback, the GPC's will not perform mass control throttling (auto throttles required) and the resulting separation conditions are slightly off-nominal. These conditions are considered acceptable when compared to violations which may occur on an alternative contingency abort. @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL] (CONTINUED)

To minimize violations of the designed QBAR and residual constraints for this case, SSME throttles will be returned to the AUTO position prior to powered pitch around initiation if the MCC determines that the abort can be completed without compromising the non-leaking helium supply of a running SSME while in auto throttles. This action allows the GPC's to perform mass control throttling during flyback, thereby controlling ET separation conditions. If the MCC cannot determine abort capability prior to powered pitch around initiation, then manual throttles at 109 percent are maintained until powered pitch around is complete. Although fine mass control will not be performed, returning to auto throttles after powered pitch around completion minimizes crew actions during the pitch around maneuver and allows the engines to remain at 109 percent power level until the fine count throttle command is received from guidance near MECO. ©[050400-7195A]

Flight design analysis indicates that for cases involving manual throttling after powered pitch around initiation, the ET separation QBAR and MPS residual violations are minimized when the 109 percent SSME throttle setting is used during flyback. For these cases, there are no LO₂ NPSP concerns since there are always MPS residuals in the ET, and significant NPSP violations only occur during LO₂ low level cutoff. Consequently, SSME shut down from the fine count throttle setting is a preferred, not a mandatory, condition. ©[050495-1753A] ©[050400-7195A]

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS**

A. IF ALLOWABLE HELIUM INTERCONNECTS, PER RULE {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], WILL NOT SATISFY ZERO-G SHUTDOWN REQUIREMENTS PER PARAGRAPH E, BUT WILL SATISFY SHUTDOWN REQUIREMENTS AT THE CUES BELOW, THE AFFECTED ENGINE WILL BE SHUT DOWN MANUALLY (PUSH-BUTTON ONLY IF POSSIBLE), AS FOLLOWS: @[090894-1676A]

1. MCC DECISION (PRIME)

a. NOMINAL/ATO/AOA

(1) THREE ENGINES ON: VI = 23 KFPS

(2) TWO ENGINES ON: VI = 24.5 KFPS

b. TAL

TWO OR THREE ENGINES ON VI = 22.5 KFPS

c. RTLS

TWO OR THREE ENGINES ON: ALPHA = -1 DEGREES
@[032395-1759A]

In this case, the engine will run with the helium system leak, but the helium supply pressure may not be able to support the zero-g shutdown requirements at MECO. The required helium supply pressure for a safe shutdown will depend upon the number of helium regulators operating, the helium leak rate, and type of shutdown (i.e., hydraulic or pneumatic). If the requirements for a pre-MECO hydraulic, pneumatic, or single regulator shutdown will be satisfied subsequent to the cues mentioned in paragraph C, manual action is taken to shut the engine down while still protecting shutdown requirements. The engine is shut down approximately 30 seconds before MECO at a velocity which equates to MECO minus 30 seconds. This gives guidance time to adjust to the late engine out and converge on the proper MECO targets. The only exception to this is the RTLS abort where the engine is shut down during powered pitch down (alpha equals -1 degree). @[032395-1759A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS (CONTINUED)

The shutdown pushbutton is used for engine shutdown instead of the AC power switches in order to shut the engine down hydraulically. A pre-MECO hydraulic shutdown requires less helium than a pre-MECO pneumatic shutdown and also retains post-MECO LO₂ dump capability through the affected engine. It also avoids the zero fault tolerant pneumatic shutdown mode. ©[090894-1676A]

2. ONBOARD DECISION (NO COMMUNICATION) ©[090894-1676A]

- a. IF A NON-ISOLATABLE MPS HELIUM LEAK EXISTS, THE CREW WILL SHUT DOWN THE AFFECTED ENGINE AT THE APPROPRIATE BOUNDARY LISTED IN PARAGRAPH A1.

If a leak develops in an engine helium supply and the crew cannot communicate with the MCC, shutting the affected engine down early may prevent the violation of shutdown helium requirements on that engine. With no communication with the ground the crew has no way to tell when the helium requirements will be violated. The helium margin which exists in each supply at liftoff will very likely keep shutdown requirements from being violated at the cues listed.

- b. IF AN MPS HELIUM SYSTEM IS OPERATING ON A SINGLE REGULATOR, THE CREW CANNOT COMMUNICATE WITH THE MCC, AND THE HELIUM SYSTEM TANK PRESSURE ON THAT SUPPLY IS LESS THAN 2163 (2200) PSIA AT MECO-60 SECONDS, THE CREW WILL SHUT DOWN THE AFFECTED ENGINE AT THE APPROPRIATE CUE LISTED ABOVE IN PARAGRAPH A1. ©[110900-7239]

1963 psia is the minimum engine system tank pressure which will support MECO requirements while operating on a single regulator (ref. paragraph E). In this configuration, approximately 200 psia of helium (10 psia/3 sec x 60 sec) is used between the velocity cues mentioned in paragraph A1 and MECO. Therefore, if the affected engine tank pressure is less than 2163 psia (1963 psia + 200 psia) at MECO minus 1 minute, MECO shutdown requirements will not be satisfied and the engine is shut down pre-MECO. The crew shutdown cue of 2200 psia is derived by adding 20 psia instrumentation error and rounding up to the nearest hundred (1963 psia + 200 psia + 20 psia instrumentation error + 17 psia rounding = 2200 psia). ©[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)

- B. IF AN ENGINE HELIUM SUPPLY DEVELOPS A LEAK WITHIN 60 SECONDS OF MECO, WITH OR WITHOUT COMMUNICATION WITH THE MCC, THE CREW WILL USE THE SHUTDOWN PUSHBUTTON TO SHUT DOWN THE AFFECTED ENGINE PRIOR TO MECO. ©[041196-1876]

When helium system leaks develop late in flight, sufficient time to evaluate MECO capability may not exist. Since pre-MECO engine shutdowns consume less helium than zero-g shutdowns, it is safer to shut the affected engine down prior to MECO. Shutting the engine down soon after a helium system leak occurs also gives guidance software time to converge on the correct MECO velocity targets.
©[090894-1676A]

- C. IF ENGINE AND PNEUMATIC HELIUM SYSTEMS INTERCONNECTS TO AN ENGINE WITH A LEAKING MPS HELIUM SUPPLY ARE INSUFFICIENT TO SUPPORT ENGINE SHUT DOWN AT THE CUES OUTLINED IN PARAGRAPH A1, ENGINE SHUTDOWN PRIOR TO THOSE CUES MUST BE ACCOMPLISHED IN THE FOLLOWING MANNER WHILE TWO OR THREE ENGINES ARE RUNNING: ©[090894-1676A] ©[ED]

1. IF NO RUNNING ENGINE SUPPLIES HAVE BEEN INTERCONNECTED:
 - a. THE LEAKING ENGINE WILL BE ALLOWED TO SHUT DOWN ON THE ENGINE HPOTP INTERMEDIATE SEAL (IMSL) PURGE REDLINE AS LONG AS THE ENGINE HYDRAULIC SYSTEM IS FUNCTIONAL AND THE SSME REDLINE LIMITS ARE ENABLED.

On the Phase II SSME, an HPOTP IMSL purge redline violation will always occur when the intermediate seal pressure falls below 170 psia. However, the minimum helium system/engine interface pressure required to prevent an HPOTP IMSL violation decreases over the duration of engine operation. As the turbine/pump shaft heats up, the intermediate seal gap becomes smaller. Consequently, lower interface pressures will keep the HPOTP IMSL purge pressure above 170 psia. If the helium system regulator outlet pressure at the start of shutdown is below the minimum helium system regulator outlet pressure, the resulting helium purge flow rates may be significantly reduced during the shutdown sequence. If two engine abort capability to a landing site exists, while three engines are running, or single engine abort capability to a landing site exists, while two engines are running, a leaking engine will be allowed to shut down on the HPOTP IMSL purge redline. Although minor engine erosion may occur during the shutdown sequence due to reduced helium pressure, the shutdown will be contained and engine run time is maximized. ©[050495-1767B]

On the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, an HPOTP IMSL purge redline violation will always occur when the intermediate seal pressure falls below 159 psia. The alternate HPOTP used on these engines has a true controlled gap IMSL package. Due to this feature, the minimum helium system/engine interface pressure required to prevent an HPOTP IMSL violation does not change over the duration of engine operation. ©[050495-1767B] ©[020196-1812] ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)

- b. IF A HYDRAULIC SHUTDOWN CANNOT BE PERFORMED, MANUAL SHUTDOWN WILL BE PERFORMED AT THE MINIMUM REQUIRED PNEUMATIC SHUTDOWN HELIUM INTERFACE PRESSURE PER PARAGRAPH E1 OR E2 OF THIS RULE.

If hydraulic shutdown capability is lost for any reason, the pneumatic shutdown requirements must be manually protected in order to prevent a catastrophic shutdown from occurring. @[090894-1676A] @[100997-6298]

- 2. IF A RUNNING SSME WITH A NON-LEAKING HELIUM SUPPLY HAS BEEN INTERCONNECTED TO A RUNNING SSME WITH A LEAKING MPS HELIUM SUPPLY (ABORT GAP). @[090894-1676A]

For this case, the desired single engine abort capability is unattainable. However, a contingency abort may still be performed. Getting as far down range as possible prior to MECO improves ET separation conditions and decreases orbiter pull-out loads; hence, both engines will be allowed to run as long as possible. Shutting the leaking engine down before the good engine may allow both engines to shut down in a contained manner, since the leaking engine will be shut down under g's and therefore consume less helium during the sequence.

- a. THE LEAKING ENGINE WILL BE SHUT DOWN AT AN HPOTP IMSL PURGE PRESSURE (ON ALL QUALIFIED SENSORS) OF:

PHASE II SSME: 40 PSIA

BLOCK I, IIA, AND II SSME: 60 PSIA

@[100997-6298] @[121197-6472A]

Phase II SSME: Shutting down the engine with the leaking supply at an HPOTP IMSL pressure of 40 psia keeps that engine running as long as feasible (a positive barrier pressure exists as measured between the IMSL and SECONDARY SEAL cavities) while the vehicle is in an abort gap. 40 psia, as measured by the IMSL transducers, equates to approximately 25 psia in the IMSL cavity. The nominal pressure in the secondary seal cavity is 12 psia. This results in a pressure differential of 13 psia across the carbon seals. A similar barrier pressure margin exists across the carbon seal to the oxygen (pump side) drain. Allowing the engine with the leaking MPS helium supply to run to an IMSL pressure of 40 psia is a worst case scenario which assumes that the desired abort boundary has not been achieved, and that the turbopump seal packages are intact. @[050495-1767B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME: Shutting down the engine with the leaking supply at an HPOTP IMSL pressure of 60 psia keeps that engine running as long as feasible (a positive barrier pressure exists between the IMSL and the O₂ and H₂ cavities) while the vehicle is in an abort gap. 60 psia, as measured by the IMSL transducers, equates to approximately 42 psia in the IMSL cavity. The nominal pressure in the O₂ cavity is 16 psia and the nominal pressure in the H₂ cavity is 25 psia. This results in a pressure differential of 26 and 17 psia across the carbon seals. Allowing the engine with the leaking MPS helium supply to run to an IMSL pressure of 60 psia is a worst case scenario which assumes that the desired abort boundary has not been achieved and that the engine seal packages are intact.

@[050495-1767B] @[020196-1812] @[100997-6298] @[121197-6472A]

- b. THE NON-LEAKING, RUNNING ENGINE WILL BE ALLOWED TO RUN UNTIL MECO OR 1150 PSIA, WHICHEVER COMES FIRST. IF A MANUAL SHUTDOWN IS REQUIRED, IT WILL BE WITH THE SHUT DOWN PUSHBUTTON ONLY. @[090894-1676A] @[100997-6298]

Although 1288 psia is the minimum helium system tank pressure which will support zero-g shut down of an engine with two good regulators and no helium system leak, the last engine will be allowed to run until the MPS supply pressure reaches the crew C&W limit of 1150 psia. Allowing the engine to run to 1150 psia provides a clear engine shutdown cue for the crew (C&W alarm at 1150) and also takes advantage of any instrumentation error/margin which may exist in the onboard measurement system and the ground predicted shut down requirements respectively. @[100997-6298]

Reference Rule {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], for interconnect procedures.

- D. IF AN MPS HELIUM SYSTEM IS OPERATING ON A SINGLE REGULATOR AND DOES NOT MEET THE ZERO-G SHUTDOWN REQUIREMENTS OF THE ASSOCIATED ENGINE AS PREDICTED BY THE MCC, THE ENGINE WILL BE SHUT DOWN PER PARAGRAPHS A OR C ABOVE, WHILE PROTECTING THE SINGLE REGULATOR SHUTDOWN REQUIREMENTS OF PARAGRAPH E.6 BELOW.

When an MPS helium system is operating on a single helium regulator, the supply may not meet the MECO (zero-g) shutdown requirements of the affected engine. If it is predicted that the MECO requirements, as stated in paragraph E.6 below, will be violated, the engine must be shut down early according to paragraphs A.1, C.1 or C.2 above. @[090894-1676A]

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS (CONTINUED)

A lower system MPS helium leak is a leak downstream of the system regulators. The resulting leak rate should be constant. Lower system leaks are isolatable only when they occur between the regulator and the downstream check valve.

The zero-g line represents the minimum supply pressure to support a hydraulic or pneumatic shutdown at MECO (zero-g) with two system regulators, with or without a lower system MPS helium leak. This requirement is the ICD value of 630 psia interface pressure at shutdown plus 7 seconds (ref. SSME-to-Orbiter ICD 13M15000). The pneumatic shutdown line represents the minimum supply pressure to support a pre-MECO pneumatic shutdown with two system regulators, with or without a lower system leak. This requirement is based on an analytical value of 529 psia interface pressure at shutdown plus 7 seconds. The redline shutdown curve is the minimum supply pressure at which the HPOTP IMSL purge redline will be violated with one or two system regulators, with or without a lower system leak. For the Phase II SSME, this value is 518 psia interface pressure at shutdown and is based on an analysis and minimal test data (reference SODB data request R1-1507). For the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, this value is 576 psia interface pressure at shutdown and is based on SSME test 901-835 (reference SODB data request R1-1640). The minimum pressure which will support the expected shutdown mode and mass flow rate should always be protected. These curves include 20 psia instrumentation error. ©[090894-1676A] ©[020196-1812] ©[121197-6472A] ©[110900-7239]

FLIGHT RULES

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS (CONTINUED)

An MPS upper system helium leak is a leak upstream of the system regulators. The resulting leak rate should decay over time. Upper system leaks are isolatable only when they occur between the helium isolation valve and the downstream regulator.

The zero-g line represents the minimum supply pressure to support a hydraulic or pneumatic shutdown at MECO (zero-g) with two system regulators, with or without an upper system leak. This requirement is the ICD value of 630 psia interface pressure at shutdown plus 7 seconds (ref. SSME-to-Orbiter ICD 13M15000). The pneumatic shutdown line represents the minimum supply pressure to support a pre-MECO pneumatic shut down with two system regulators, with or without an upper system leak. This requirement is based on an analytical value of 529 psia interface pressure at shutdown plus 7 seconds. The redline shutdown curve is the minimum supply pressure at which the HPOTP IMSL purge redline will be violated with one or two system regulators, with or without an upper system leak. For the Phase II SSME, this value is 518 psia interface pressure at shutdown and is based on analysis and minimal test data (reference SODB data request R1-1507). For the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, this value is 576 psia interface pressure at shutdown and is based on SSME test 901-835 (reference SODB data request R1-1640). The minimum pressure which will support the expected shutdown mode and mass flow rate should always be protected. These curves include 20 psia instrumentation error. @[050495-1767B] @[121197-6472A] @[110900-7239]

3. IF THE ENGINE CAN SHUT DOWN HYDRAULICALLY BUT HPOTP IMSL REDLINE SHUT DOWN CAPABILITY IS LOST FOR ANY REASON, A MANUAL SHUTDOWN MUST PROTECT THE MINIMUM INTERFACE PRESSURES FOR A PRE-MECO HYDRAULIC SHUT DOWN AS SHOWN ABOVE IN PARAGRAPH E. @[090894-1676A]

If both HPOTP IMSL purge pressure transducers have failed or the redline limit software is not available for any reason, a redline engine shutdown will never occur. Manual action must be taken above the minimum hydraulic shutdown interface pressure.

4. IF A PNEUMATIC SHUT DOWN IS REQUIRED FOR ANY REASON, A MANUAL SHUT DOWN MUST PROTECT THE MINIMUM INTERFACE PRESSURES FOR A PRE-MECO PNEUMATIC SHUTDOWN PER PARAGRAPH E.

For all four SSME types (Phase II, BLOCK I, BLOCK IIA, and BLOCK II), it takes significantly more helium to support a pre-MECO pneumatic shutdown than it does to support a pre-MECO hydraulic shutdown. Consequently, pre-MECO pneumatic shutdown capability must be manually protected for all cases where hydraulic engine function has been lost or for which a pneumatic shutdown will occur. @[050495-1767B] @[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

5. IF THE PNEUMATIC SYSTEM ALONE WILL BE USED TO SUPPORT THE SHUTDOWN HELIUM REQUIREMENT OF AN ENGINE, AND THE ENGINE SYSTEM HAS TWO OPERATIONAL REGULATORS AND NO DOWNSTREAM HELIUM LEAK, THE FOLLOWING NUMBERS MUST BE PROTECTED:

- a. ZERO-G
 - 2800 (2820) PSIA
(3 ENG S/D) @[110900-7239]
 - 2357 (2377) PSIA

- c. PRE-MECO HYDRAULIC:
 - PHASE II SSME - 600 (620) PSIA
 - BLOCK I, IIA, AND II SSME - 639 (659) PSIA

@[050495-1767B] @[020196-1812] @[121197-6472A] @[110900-7239]

If the MPS supply system has an upper system leak, the pneumatic system will be interconnected to the engine as late in the flight as is practical, but above the minimum tank pressure required to support engine shut down. After the interconnect is performed a determination is made as to whether or not the leak is an upper system leak or a tank leak. If the leak is found to be a tank leak, the pneumatic tank only numbers must be protected. The leak in the tank may deplete all of the engine system helium before the pneumatic tank and engine tank equalize in pressure. If this is the case, the pneumatic tank alone must support engine shutdown. @[090894-1676A]

 - BLOCK I, IIA, AND II SSME - 679 (699) PSIA
- @[050495-1767B] @[020196-1812] @[121197-6472A] @[110900-7239]

The requirements for engine shutdown in the single regulator mode are represented by three distinct pressures. The single regulator must now flow two times nominal mass in order to meet shutdown requirements. A higher initial helium tank pressure is needed to meet this demand. @[050495-1767B] @[ED] @[100997-6298]

Rules {A5-5}, SUSPECT ENGINE; {A5-102}, AUTO/MANUAL SHUTDOWN; {A5-103}, LIMIT SHUTDOWN CONTROL; {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES; and {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], reference this rule. @[121197-6482B] @[111298-6785A]

FLIGHT RULES

A5-154

LH₂ TANK PRESSURIZATION [CIL]

THE ET LH₂ TANK ULLAGE PRESSURE WILL BE MANUALLY CONTROLLED USING THE LH₂ ULLAGE PRESSURE SWITCH WHEN THE LH₂ ULLAGE PRESSURE IS < 27.7 (28.0) PSIA. THE PRESSURIZATION WILL BE CONTROLLED SO THAT THE ULLAGE PRESSURE DOES NOT EXCEED 35 (34.0) PSIA TO AVOID THE LOW CRACKING PRESSURE OF THE TANK VENT/RELIEF VALVE. @[101096-4474A]

The pressurization flow control system consists of three tank ullage pressure sensors, signal conditioners for the orbiter flow control valve electronics, and three gaseous hydrogen flow control valves. Each ullage pressure sensor is wired to a signal conditioner which in turn controls the GH₂ pressurant flow from its respective engine. Each control system is single string; i.e., ullage pressure no. 1 feeds only the electronics for the center SSME, no. 2 to the left SSME, and no. 3 to the right SSME. The flow control valves are used to maintain the LH₂ tank ullage pressure between 32 and 34 psia. The signal conditioners use 33.0 psia as the set point for the ullage pressure. Failure of one flow control valve to the closed position (low flow) does not cause the ullage pressure to drop below 28.0 psia or violate the SSME NPSP ICD. However, the pressure cannot be maintained above 28.0 psia when two flow control valves fail closed. Additionally, failure of one flow control valve to the open position (high flow) does not cause the ullage pressure to rise to the LH₂ tank vent valve relief setting of 36 psia (reference December 22, 1995 PSIG and Rockwell action item 951208-02). @[021199-6791A]

There are several failure modes associated with the LH₂ tank pressurization flow control system. This flight rule addresses the case of two ullage pressure sensors failed high (i.e., above the ullage pressure where the flow control valve is commanded closed) which will cause their respective flow control valves to remain closed. The remaining flow control system will not maintain the tank pressure. When the true tank pressure decays to 28.0 psia on the remaining good sensor, a class 3 BFS alert will be set. (The 28.0 psia value was reviewed and approved as DCR 3581A and DCR 3586 at the July 11, 1996 SASCB.) An LH₂ ullage pressure of 28.0 psia is the value at which manual action will be taken. This pressure includes crew response time and one sigma dispersions of the instrumentation error: 0.21 psia (reference Booster SCP 2.2.1). Additionally, this lower value of 28.0 psia protects the minimum ullage pressure to support the NPSP requirement of 27.7 (reference December 22, 1995 PSIG and Rockwell action item 951208-02, chart 1-18). In response to the alert, the crew will use the LH₂ ullage pressure switch to open the flow control valves by overriding the electronics on all flow control valves. The tank pressure should then increase. However, the pressure could go through the control band and reach the tank vent valve relief setting of 36 ± 1 psig. Therefore, the value of 34.0 psia was chosen as the value at which the crew would close the flow control valves before venting could occur. If venting occurs while the vehicle is in first stage, a fire could propagate along the side of the external tank (reference PRCB presentation February 10, 1987 and the 32nd PSIG). The high flow setting of the -1301 FCV's (70 percent instead of 100 percent used with the -0361) allows for manual action to be taken prior to staging. For this failure case, venting GH₂ is not a concern due to a gradual pressure recovery when the switch is placed in the high flow position during first stage (reference May 8, 1996 PSIG and action item-941005-03 Rev 3). @[101096-4474A] @[021199-6791A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-154 **LH2 TANK PRESSURIZATION [CIL] (CONTINUED)**

Other failure modes of the GH₂ pressurization system include: a mechanical failure of two flow control valves, a flow restriction in either an SSME GH₂ repressurization path or in the main pressurization line, a hole in the side of the LH₂ tank or a vent valve not closed. However, the LH₂ ullage pressure switch cannot correct conditions caused by these failure modes. For these cases, all three ullage pressures could decay below 28.0 psia since the sensors are accurately reading the decaying tank pressure. If the pressure decay continues, the minimum NPSP of the engines will be violated. ©[101096-4474A] ©[021199-6791A]

Rules {A4-56H}, PERFORMANCE BOUNDARIES, and {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, reference this rule. ©[071494-1646A]

A5-155 **LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP** ©[040899-6818A]

- A. MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED UPON RECOGNITION OF EITHER AN LH₂ ULLAGE LEAK OR FOR ANY ORBITER GH₂ PRESSURIZATION SYSTEM ANOMALY EXCEPT ONE GH₂ FLOW CONTROL VALVE FAILED CLOSED.

For LH₂ net positive suction pressure (NPSP) decaying below the ICD requirement, the engines will eventually violate their high pressure fuel turbopump (HPFTP) turbine discharge temperature (TDT) redlines. Low LH₂ NPSP causes the fuel turbopumps to cavitate, resulting in turbine overspeed and increased discharge temperatures. Cavitation is possible on all SSME's; therefore, the main engine limit shutdown software will be manually enabled to allow any number of engines to shut down for HPFT TDT redline exceedance.

- B. ORBITER GH₂ PRESSURIZATION SYSTEM ANOMALY

IF ULLAGE PRESSURE IS STEADILY DECAYING BELOW THE CONTROL BAND AND IS NOT THE RESULT OF AN ULLAGE LEAK (PER RULE {A5-9}, LH₂ ULLAGE LEAK), THE ENGINES WILL BE MANUALLY THROTTLED PER THE STEPS GIVEN BELOW. THE MANUAL THROTTLE STEPS WILL BE BASED ON THE SETTINGS LISTED IN THE TABLE BELOW WHEN THE LH₂ NPSP DROPS BELOW 3.5 PSI OR THE HPFTP TDT'S INCREASE TO WITHIN 75 DEG R OF THEIR REDLINES. TO PREVENT THE VEHICLE ACCELERATION FROM EXCEEDING 3.0 G'S AFTER MANUAL THROTTLING IS INVOKED, THE CREW WILL MANUALLY THROTTLE BACK TO MAINTAIN 3.0 G'S. ©[ED] ©[040899-6818A] ©[031500-7181A] ©[ED]

FLIGHT RULES

A5-155

LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP (CONTINUED)

ONCE INITIATED, MANUAL THROTTLES WILL BE MAINTAINED UNTIL MECO. A MANUAL MECO WILL BE REQUIRED.

A GH₂ pressurization system anomaly could be caused by either multiple flow control valves failed closed or a plugged GH₂ pressurization leg. Coverage of the highly unlikely GH₂ plugged pressurization leg failure mode is a result of PRCB Directive S050270DP, "Main Propulsion System (MPS) Critical Items List (CIL) Submittal Waiver Request," November 9, 1998. ©[040899-6818A]

Underspeeds resulting from two GH₂ flow control valves failed closed or a plugged GH₂ pressurization leg for specific engine configurations, or three GH₂ flow control valves failed closed in all cases, will potentially result in loss of crew and vehicle due to either early engine shutdowns (due to LH₂ NPSP) or ET structural failure. Manually throttling to a lower throttle setting increases the supplied NPSP by lowering LH₂ pressure losses across the LH₂ manifolds and lines and also reduces the SSME NPSP requirement for engine operation. The combination of higher supplied NPSP and reduced NPSP requirement enables continued engine operation. Once initiated, manual throttles are maintained until MECO in order to prevent the auto throttle up to the mission power level that would occur following an SSME failure. Since the NPSP drops with this throttle up, maintaining manual throttles protects against the potential loss of additional SSME(s). ©[051500-7181A]

The severity of the LH₂ NPSP loss is not only dependent upon the GH₂ pressurization system failure mode but also upon the engine configuration and power level for a particular mission. Analysis shows that two GH₂ flow control valves failed closed on a nominal, ATO, or AOA mission using three Block I or Phase II SSME's at 104 percent will not result in a LH₂ NPSP degradation which requires throttling (reference February 19, 1997 PSIG, Action Item 970205-01). Analysis also shows that missions using specific combinations of Block I and Block II SSME's may require throttling if two flow control valves are failed closed. Further analysis suggests that throttling may be expected for those missions using three Block IIA/II SSME's if two flow control valves are failed closed or one of the SSME's pressurization legs becomes plugged such that there is 0 percent flow from that leg.

A GH₂ pressurization leg refers to the series of hardware in the GH₂ pressurization line that carries flow from each SSME's LPFTP turbine outlet to the 2-inch pressurization line that provides ullage pressure to the ET LH₂ tank. Each engine contains a check valve, a filter, and a flow control valve (reference SSSH 10-12). The hardware in these lines could potentially fail closed or, in the most extreme case, become plugged by contamination. ©[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-155

LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP (CONTINUED)

There are three possible scenarios resulting in a plugged GH₂ pressurization system leg. The first scenario involves the filter upstream of the flow control valve becoming plugged, resulting in 0 percent flow to the associated valve. The second and third scenarios are an obstruction, or mechanical failure, of the check valve upstream of the flow control valve or an obstruction of the flow control valve itself. This would result in 0 percent flow being provided from that engine to the 2-inch pressurization line. Since flow from all three pressurization legs is required to maintain ullage pressure above 32.6 psia, all three flow control valves will be commanded open as the system attempts to maintain pressure in the ET LH₂ tank. However, since flow in a single leg is obstructed, ullage pressure will steadily decay below the control band as the fuel volume in the ET LH₂ tank decreases. ©[040899-6818A]

The value of 3.5 psi for the LH₂ NPSP was chosen as the primary cue to avoid LH₂ NPSP regions where severe cavitation occurs and HPFTP turbine temperatures increase exponentially. The HPFTP is expected to run to a LH₂ NPSP of 1.0 to 2.0 psi before cavitation becomes critical. The ground LH₂ NPSP computation assumes a 3 sigma worst case LH₂ inlet temperature of 37.2 deg R from liftoff until MECO. The use of this worst case temperature provides for 2 sigma protection (i.e., a 0.8 psi bias) in the ground NPSP computation. The ground computation uncertainties are a result of measurement inaccuracies in ullage pressure, head pressure, frictional losses, and vapor pressure used in the derivation of NPSP. On average, the actual vehicle NPSP will be 0.8 psi higher than the NPSP value displayed by the MCC ground computation. HPFTP TDT's were selected as a backup cue in case an HPFTP starts to severely cavitate at a higher LH₂ NPSP value than expected. Both temperature limits (channels A and B) are calculated by subtracting 75 deg R from the redlines. Larger margins from the redline may overlap the nominal operating temperature range and provide false cues for action (ref. PSIG Flight Rule Reviews on 2/25/88, 3/23/88, and 11/17/93). ©[071494-1646A]

The cue of 3.0 g's of acceleration was selected to ensure protection of vehicle acceleration limits (3.0 g). Various vehicle configurations or GH₂ pressurization system failure modes may or may not result in exceedance of vehicle acceleration limits. However, if a 3.0 g acceleration limit is used as an auto or manual throttling cue for all cases, vehicle structural limits are protected at all times. Reference Rule {A2-61}, Q-BAR/G-CONTROL. Three-g is not used as a cue for the first manual throttle step since leaving throttles in auto will throttle at 3.0 g's. Once manual throttles are taken for an NPSP or HPFTP TDT cue, throttles will remain in manual and 3.0 g's will be protected in addition to the NPSP and HPFTP TDT cues. The shuttle crews are trained that after selecting manual throttles, if the vehicle acceleration exceeds 3.0 g's, they will need to manually throttle to maintain 3.0 g's. ©[031500-7181A]

Throttling in three steps was selected to minimize crew/MCC impact and workload. The steps approximately divide the action equally into thirds. The first step, 95 percent, was originally chosen to avoid the Rocketdyne HPFTP impeller resonance region (i.e., 88 to 92 percent). This is no longer a concern as a result of a redesign of the impeller. The throttle setting of 95 percent was retained for training simplicity. The second step, 80 percent, is midway between the first step and the minimum power level. The last step, 67 percent, is the minimum power level and further commanded power reduction is not possible. ©[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-155

LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP (CONTINUED)

C. LH₂ ULLAGE LEAK @[040899-6818A]

MANUAL THROTTLES WILL BE SELECTED IMMEDIATELY FOLLOWED BY A TAL ABORT TO THE MOST IN-PLANE SITE (GO TAL SITE OR ACLS). AFTER TAL SELECTION, THE THROTTLES WILL BE RETURNED TO AUTO.

Throttling for low LH₂ NPSP due to an LH₂ ullage leak (reference Rule {A5-9}, LH₂ ULLAGE LEAK), or an open LH₂ vent/relief valve, delivers less ullage pressurization gas causing LH₂ NPSP to decay faster than keeping the engines at 104 percent. @[ED]

GPC software automatically throttles the engines down if TAL is selected above an I-loaded inertial velocity. To prevent the software from throttling the engines down when there is an LH₂ ullage leak, manual throttles are selected prior to selecting TAL. Once TAL is selected, the throttles will be returned to AUTO where they will stay at 104 percent until 3 g's are reached. Three-g throttling may cause engine shutdowns, but this is an accepted risk to avoid vehicle structural damage. @[071494-1646A]

Since there is no way to accurately predict when engine shutdown will occur for this case, it is important to reach multiple engine-out capability and an acceptable MECO as soon as possible. The earliest multi-engine out abort site, either ACLS or TAL, will always be the preferred one for this case (reference rule {A4-56}, PERFORMANCE BOUNDARIES).

The main engine limit shutdown software will be manually enabled upon recognition of this failure to protect against multiple engine shutdowns without limits enabled.

Rules {A2-64}, MANUAL THROTTLE CRITERIA; {A2-61}, Q-BAR/G-CONTROL; {A2-301}, CONTINGENCY ACTION SUMMARY; {A4-56}, PERFORMANCE BOUNDARIES; {A4-59}, MANUAL THROTTLE SELECTION; {A5-9}, LH₂ ULLAGE LEAK; {A5-103}, LIMIT SHUTDOWN CONTROL; {A5-154}, LH₂ TANK PRESSURIZATION [CIL]; and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES, reference this rule. @[092195-1770A] @[040899-6818A] @[ED]

FLIGHT RULES

A5-156

ABORT PREFERENCE FOR SYSTEMS FAILURES

A. LH₂ ULLAGE LEAK @[040899-6818A]

IF LOW LH₂ NPSP OCCURS DUE TO AN EXTERNAL TANK LH₂ ULLAGE LEAK, A TAL ABORT WILL BE PERFORMED TO A TAL OR ACLS BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY. @[ED]

B. GH₂ PRESSURIZATION SYSTEM ANOMALIES

IF THE LOW LH₂ NPSP OCCURS DUE TO THREE GH₂ FLOW CONTROL VALVES FAILED CLOSED, A TAL ABORT WILL BE PERFORMED TO A TAL OR ACLS BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY. THIS IS THE ONLY GH₂ PRESSURIZATION SYSTEM ANOMALY FOR WHICH AN ABORT WILL BE PERFORMED. REFERENCE RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP.

A TAL abort is preferred over RTLS because TAL MECO conditions are satisfied sooner than RTLS MECO conditions. If an LH₂ ullage leak occurs, throttling will not be performed for low LH₂ NPSP (see rationale for Rule {A5-155C}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP). Once an ullage leak occurs, it is possible for the leak to worsen. In this case, the NPSP may deteriorate much faster than the failed closed flow control valve case. There is no method to predict when engine shutdown will occur. It is important to reach multiple engine-out capability and MECO conditions as soon as possible. The earliest MECO conditions and multiple engine-out capabilities are available during a TAL abort or an abort to an ACLS. If an intact abort is not performed, the risk of a bailout or other contingency condition will increase. @[021199-6791A]

An abort will not be performed for two flow control valves failed closed or for a plugged GH₂ pressurization system leg. The flow control valves are normally open valves (must be powered closed). The close power will cycle the valves as required to satisfy the ullage pressure control band (reference Rule {A5-154}, LH₂ TANK PRESSURIZATION [CIL]). It is assumed that the failure will occur during power cycling. With two valves failed closed, the third valve will not be power-cycled. Therefore, the third valve will remain open (unpowered) and nominal MECO conditions may be achieved by implementing Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. For a plugged GH₂ pressurization leg, the other two flow control valves will operate and nominal MECO conditions may be achieved by implementing Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. If three flow control valves are failed closed, a TAL abort will be selected. @[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-156

ABORT PREFERENCE FOR SYSTEMS FAILURES (CONTINUED)

C. ENGINE-TO-ENGINE HELIUM INTERCONNECT

A TAL ABORT TO EITHER A TAL OR ACLS, BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY, WILL BE PERFORMED IF THE HELIUM SYSTEM FROM A RUNNING ENGINE IS INTERCONNECTED TO A LEAKING ENGINE HELIUM SUPPLY IN ORDER TO ACHIEVE INTACT ABORT CAPABILITY (REF. RULE {A5-152B}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]) ©[090894-1676A]

Because of the severity of the helium leak which requires the implementation of Rule {A5-152B}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], adequate helium may not be available to support three-engine operation to nominal MECO. In this case, it is possible that a non-leaking engine as well as the leaking engine could shut down due to inadequate helium. Therefore, it is important to reach multiple engine-out capability and MECO conditions as soon as possible. This will be accomplished by performing a TAL abort or an abort to an ACLS. ©[090894-1676A] ©[021199-6791A]

Rule {A5-9}, LH₂ ULLAGE LEAK, references this rule. ©[040899-6818A] ©[ED]

FLIGHT RULES

A5-157**ET LOW LEVEL CUTOFF SENSOR FAILED DRY**

THE FAILURE TO THE DRY STATE OF THREE OR MORE ET PROPELLANT LOW LEVEL SENSORS ON THE SAME TANK WILL REQUIRE A TAL ABORT TO BE PERFORMED (TO A TAL, OR ACLS IF NO TAL SITE IS AVAILABLE) IF UPHILL CAPABILITY DOES NOT EXIST (REF. RULE {A4-56H}.1, PERFORMANCE BOUNDARIES). A PREFLIGHT EVALUATION WILL BE REQUIRED TO DETERMINE UPHILL CAPABILITY FOR THIS FAILURE. ©[021397-4824]

NOTE: THREE OR MORE "DRY" INDICATIONS WILL CAUSE PREMATURE MECO IF THE LOW LEVEL ARM COMMAND IS PRESENT PRIOR TO REACHING THE REQUIRED MECO TARGET. TWO SENSORS INDICATING "DRY" WILL NOT REQUIRE AN ABORT.

Propellant low level shutdown software is provided to protect the vehicle from an uncontrolled engine failure which would be caused by the depletion of either LO₂ or LH₂ propellant to a running engine. The software logic requires two qualified sensors to indicate dry after the arming mass is reached in order to start the low level timer and issue the MECO command. On the first pass after the arming mass is reached, the software will disable one dry low level sensor. On the next pass, the software will command MECO if two other low level sensors on the same tank are failed dry. Therefore, three sensors dry when the arming mass is reached will result in an early MECO which may require a TAL or ACLS abort. The failure of two sensors will not cause a premature MECO when the arming mass is reached, since one will be disabled. The crew will be required to abort TAL (or ACLS if no TAL site is available) on some performance-critical missions (as determined by flight design) to prevent a MECO from occurring in a region where no abort capability exists. ©[021397-4824]

Rule {A2-301}, Note 31, CONTINGENCY ACTION SUMMARY, references this rule.

FLIGHT RULES

MPS MANAGEMENT: POST-MECO

A5-201 MPS DUMP INHIBIT [CIL] @[020196-1813A]

A. INSIGHT INTO ENGINE INLET CONDITIONS AVAILABLE:

IF A PROPELLANT LEAK IS DETECTED PRE-MECO ON ANY ENGINE WHICH SHUTS DOWN (MANUAL OR CONTROLLER INITIATED) PRIOR TO MECO, IT WILL BE ISOLATED FROM DUMPING IMMEDIATELY FOLLOWING MECO. THIS DUMP INHIBIT DECISION WILL BE BASED ON THE FOLLOWING:

1. LO₂ INLET PRESSURE < 40 PSIA,

FOR A DUMP INHIBIT OF THE LO₂ SYSTEM, AN EARLY APU SHUTDOWN WILL BE REQUIRED FOR TAL AND RTLS ABORTS (REFERENCE FLIGHT RULE {A16-205A}, EARLY APU SHUTDOWN).
@[020196-1813A]

2. LH₂ INLET PRESSURE < 30 PSIA.

FOR A DUMP INHIBIT OF THE LH₂ SYSTEM, AN EMERGENCY POWERDOWN/MODE V EGRESS WILL BE REQUIRED FOR TAL AND RTLS ABORTS (REFERENCE FLIGHT RULES {A16-12B}.2, EMERGENCY POWERDOWN). AN EARLY APU SHUTDOWN WILL OCCUR AS A RESULT OF THE EMERGENCY POWERDOWN. @[020196-1813A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-201

MPS DUMP INHIBIT [CIL] (CONTINUED)

For nominal, RTLS, TAL, ATO, and AOA missions, the dump inhibit will be performed immediately post-MECO on the affected SSME if insight into the engine inlet conditions is available and the above criteria are met. The dump inhibit is performed by manually closing the associated pre valve and powering down that engine's controller. To minimize dump and vacuum inert impacts, only the associated pre valve will be closed on the side which was determined to be leaking. The engine controller is powered off to close the bleed and hydraulic valves. These actions will prevent excessive leakage of propellant into the aft compartment during the MPS propellant dump, thereby minimizing a potentially hazardous condition in the aft compartment (reference the PSIG Flight Rule Review of 2/25/88). Causes for early shutdown include redline limit shutdown, multiple loss of controller avionics, and manual shutdown for a MPS helium leak, a hydraulic or electrical lockup, or a command path failure. Since flight data indicates that the pump inlet pressures drop below the above limits after MECO, an engine propellant leak cannot be detected if a low level cutoff occurs. The low pressure fuel pump discharge pressure can be used as a backup to the LH₂ inlet pressure and would also use 30 psia as the dump inhibit criterion. If a breach of one or more of the LH₂ propellant lines has occurred, the possibility exists of uncontained/uncontrolled LH₂ propellant in the aft, which constitutes a flammability and explosion hazard on a RTLS or TAL abort. This condition requires the most expeditious powerdown of the vehicle (emergency powerdown) and crew egress (Mode V) possible. An LO₂ leak is not considered as hazardous as an LH₂ leak and therefore does not require an emergency powerdown and Mode V egress. However, both kinds of leaks do warrant an early APU shutdown after an RTLS or TAL abort in order to eliminate an ignition source in a hydrogen or oxygen enriched environment. These postlanding actions are not required after a nominal, ATO, or AOA mission since no uncontained residuals will remain in the aft compartment at the time of landing.

Rules {A16-12B}.2, EMERGENCY POWERDOWN, and {A16-205A}, EARLY APU SHUTDOWN, reference this rule. ©[020196-1813A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-201

MPS DUMP INHIBIT [CIL] (CONTINUED)

B. INSIGHT INTO ENGINE INLET CONDITIONS UNAVAILABLE:

1. NOM/ATO/AOA:

FOR ANY ENGINE WHICH SHUTS DOWN (MANUAL OR CONTROLLER INITIATED) PRIOR TO MECO, THE MPS DUMP INHIBIT WILL BE PERFORMED IMMEDIATELY POST-MECO ON THE PROPELLANT SYSTEM(S) ON WHICH INSIGHT HAD BEEN LOST. THIS ACTION WILL BE TAKEN ON A TIME PERMITTING BASIS TO MINIMIZE POTENTIAL LEAKAGE. THE LPFP DISCHARGE PRESSURE CAN BE USED AS A BACKUP CUE TO ASSESS LH2 INLET CONDITIONS.

Loss of insight into the inlet pressures (and the LPFP discharge pressure for the fuel side) results in the inability to assess the inlet conditions. Therefore, the dump will be inhibited for any engine shut down prior to MECO for the nominal case, an ATO, or an AOA if the inlet condition(s) cannot be assessed (at the time of shutdown) due to avionics failures since a contained shutdown cannot be guaranteed. In the case where there was no leakage, any residuals trapped in the engine by the dump inhibit procedure will have time to bleed out prior to landing.

2. TAL/RTLS:

THE MPS DUMP INHIBIT WILL NOT BE PERFORMED.

Due to the extremely low probability of a noncatastrophic, uncontained shutdown, and the additional failure to lose insight, the cases of survivable shutdowns with leakage hidden due to loss of insight on a TAL and RTLS will not be covered. If the MPS dump is inhibited for the RTLS and TAL cases due to loss of insight and no leakage existed, it would induce an unnecessary risk of trapped LH₂ residuals (approximately 26 lbs. LH₂ on a RTLS and approximately 8 lbs. LH₂ on a TAL abort, at touchdown). These amounts of LH₂ are enough to cause a venting concern for the convoy and preclude normal convoy operations and would require as a minimum an expedited powerdown and Mode V egress per Rule {A16-11F}, EXPEDITED POWERDOWN. However, if leakage was assumed, an emergency powerdown and Mode V egress would be performed per paragraph A of this rule. ©[020196-1813A]

FLIGHT RULES

A5-202

ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL]

A. NOMINAL

IF AN ET/ORBITER 17-INCH DISCONNECT VALVE IS NOT VERIFIED CLOSED, ET SEPARATION WILL BE DELAYED UNTIL MECO PLUS 6 MINUTES TO ALLOW THRUST DECAY FROM THE OPEN VALVE AND THUS PREVENT RECONTACT BETWEEN THE ET AND ORBITER. THE MPS PROPELLANT DUMP WILL BE AUTOMATICALLY PERFORMED DURING THE WAIT PERIOD. FOR AN UNDERSPEED AT MECO WHICH REQUIRES THE OMS-1 BURN TO BE PERFORMED PRIOR TO MECO PLUS 6 MINUTES, ET SEPARATION WILL BE PERFORMED AT OMS-1 TIG MINUS 1 MINUTE 30 SECONDS OR IMMEDIATELY IF REQUIRED, AND THE MPS DUMP WILL BE MANUALLY DELAYED UNTIL AFTER SEPARATION. @[030994-1618B]

BOTTOM-SUN WILL BE REQUIRED FOR THERMAL CONDITIONING (REFERENCE RULE {A10-243}, ET UMBILICAL DOOR CLOSURE DELAY FOR DISCONNECT VALVE FAILURE [CIL]). @[021199-6795A]

B. RTLS/TAL

ET SEPARATION IS AUTOMATIC FOR 17-INCH DISCONNECT VALVE FAILURE.

The ET separation sequence software in the GPC's will inhibit ET separation automatically if it does not receive at least one of the two close position indications from each of the orbiter 17-inch disconnect valves. The closed position indicators may not show closed for real valve failures or loss of insight. This prevents a recontact problem which could occur between the ET and the orbiter after separation due to the large venting force (>10,000 lbf) of the open 17-inch valve (reference SODB, volume 1, section 3.4.3.1).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-202

ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL] (CONTINUED)

The crew will perform a manual separation 6 minutes after the nominal separation time. This waiting period allows the tank and the Orbiter manifold to vent to a level where the venting force < 1800 lbf, which is considered safe for separation (reference SODB, volume 1, section 3.4.3.1). For underspeeds at MECO, which require an OMS-1 to be performed prior to MECO plus 6 minutes, ET separation has to be performed 1 minute 30 seconds prior to OMS-1 ignition. The 1 minute 30 second time was selected to ensure that the crew had sufficient time to prepare for the OMS-1 ignition (reference SODB, volume 1, section 3.4.3.1). The MPS dump will be manually delayed by placing the MPS Propellant Dump Sequence Switch in the STOP position if the separation time would occur during the scheduled MPS dump. The switch is taken back to the GPC position after the ET SEP -Z translation to allow the automated MPS dump to commence. The MPS dump is delayed since performing the MPS dump during ET separation is not a certified separation mode. Time criticality during an RTLS and TAL aborts necessitates an automatic ET separation for OI-22 and subsequent software. The RTLS ET separation software allows 6 seconds of venting. Recontact damage will be risked on an RTLS to avoid rapid degradation of ET separation conditions and possible loss of control. The TAL ET separation software allows 15 seconds of venting to avoid recontact while minimizing the time to OPS 3 transition. TAL aborts incorporate an I-loaded software timer expiration (MSID V97U9717C) to sequence automatic ET separation while RTLS aborts use a hardcoded software constant for separation.

The LO₂ MPS manifold repressurization valves are not commanded open after a 17-inch LO₂ disconnect failure to prevent excessive loss of helium during the MPS dump. The LH₂ MPS manifold repressurization valves are not opened during this timeframe.

Rule {A10-243}, ET UMBILICAL DOOR CLOSURE DELAY FOR DISCONNECT VALVE FAILURE [CIL], references this rule. ©[021199-6795A]

FLIGHT RULES

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]

A. AN MPS PROPELLANT MANIFOLD OVERPRESSURE CONDITION (> 312 (249) PSIA FOR LO_2 OR > 66 (60) PSIA FOR LH_2) WILL BE RELIEVED BY THE FOLLOWING METHODS:

1. PRE-MPS DUMP

THE MPS DUMP WILL AUTOMATICALLY BE STARTED IMMEDIATELY IF THE LH_2 MANIFOLD PRESSURE IS BETWEEN 60 AND 90 PSIA AND NOT COMMFAULTED. @[092701-4867A]

2. POST-MPS DUMP, PRE-FIRST AUTOMATED VACUUM INERT

THE LH_2 OUTBOARD FILL/DRAIN AND TOPPING VALVES WILL AUTOMATICALLY OPEN IF:

- a. THE LH_2 MANIFOLD PRESSURE IS BETWEEN 60 AND 90 PSIA AND NOT COMMFAULTED AND
- b. THE LH_2 BACKUP DUMP VALVES SWITCH WAS NOT TAKEN TO OPEN.

THE LH_2 OUTBOARD FILL/DRAIN AND TOPPING VALVES WILL AUTOMATICALLY CLOSE AT MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES). IF THE OUTBOARD FILL/DRAIN DOES NOT CLOSE, THE SOFTWARE WILL COMMAND THE LH_2 INBOARD FILL/DRAIN VALVE CLOSED. @[111094-1730A] @[021199-6792B]

3. POST-FIRST AUTOMATED VACUUM INERT @[092701-4867A]

THE AFFECTED LO_2 OR LH_2 OUTBOARD FILL/DRAIN VALVE WILL BE MANUALLY OPENED IMMEDIATELY. THIS VALVE WILL BE CLOSED AFTER THE SYSTEM HAS BEEN INERTED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

Because of the characteristics of the LO₂ system, it is highly unlikely that a real overpressure condition will occur without multiple (> 2) system failures prior to the start of the MPS dump (nominally at MECO + 2 minutes). Therefore, no crew action is taken for LO₂ manifold pressure above C&W (249 psia). Heat soak back will vaporize any fluid propellants, increasing the pressure in the lines. On the LO₂ side, the pressure can be relieved by either the MPS dump or vacuum inerting. On the LH₂ side, the pressure can be relieved by MPS dump, vacuum inerting, or opening the LH₂ backup dump valves in OPS 1. An automatic MPS dump will be performed to avoid reaching proof pressure (66 psig) if the software limit (greater than 60 psia and less than 90 psia) is reached before the scheduled MPS dump occurs. If the LH₂ manifold pressure C&W limit of 65 psia is reached, the crew will open the LH₂ backup dump valves and both LH₂ inboard and outboard fill/drain valves per the Ascent Pocket Checklist procedure. If the LH₂ manifold pressure is between 60 and 90 psia after the MPS dump terminates but prior to the first automated vacuum inert start (dump start + 17 minutes, approximately MECO + 19 minutes) and the LH₂ backup dump valves switch on panel R2 was not taken to OPEN, an automated contingency LH₂ vacuum inert will be started by the software and relieve the pressure. This contingency inert will be performed by opening the LH₂ topping and LH₂ outboard fill/drain valves (the LH₂ inboard fill/drain valve remains open following the MPS dump). If the LH₂ manifold pressure is between 60 and 90 psia after the MPS dump terminates but prior to the first automated vacuum inert start and the LH₂ backup dump valves switch on panel R2 was taken to OPEN, an automated contingency LH₂ vacuum inert will not be started by the software because manual action has already been taken. ©[092701-4867A]

If either the LO₂ or LH₂ C&W limit is reached after the first automated vacuum inert, the affected LO₂ or LH₂ outboard fill/drain valve will be opened manually to relieve the pressure. Only the outboards are opened since the inboards should already be open. This is only performed for true high pressure in the affected manifold and not for instrumentation failures. Procedures in the Orbit Pocket Checklist have the crew open all the fill/drain valves since the crew does not have time to determine which system has the overpressure condition. The LO₂ manifold pressure C&W limit (249 psia) is approximately midway between the relief (190 psig) and proof (312 psig) pressures (ref. SODB, volume I, section 4.3). The LH₂ manifold pressure C&W limit (65 psia) is set to avoid having system delays in starting the MPS dump allow the LH₂ manifold pressure to exceed the C&W limit. Rule {A5-205C}, NOMINAL, AOA, AND ATO MPS DUMP FAILURES, references this rule. ©[111094-1730A] ©[021199-6792B] ©[092701-4867A] ©[ED]

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

- B. IF THE LH₂ RELIEF ISOLATION VALVE FAILS CLOSED POST-MECO AND ANY OMS BURN TIG IS PRIOR TO THE START OF THE FIRST AUTOMATED VACUUM INERT AT MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) : ©[021199-6792B] ©[090999-7035] ©[092701-4867A]
1. THE LH₂ BACKUP DUMP VALVES WILL BE MANUALLY OPENED PRIOR TO THE OMS BURN. THE LH₂ BACKUP DUMP VALVES WILL AUTOMATICALLY CLOSE AT THE COMPLETION OF THE FIRST AUTOMATED VACUUM INERT AT MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES).
 2. THE AUTOMATED LH₂ MANIFOLD REPRESSURIZATION FOLLOWING THE SECOND AUTOMATED VACUUM INERT WILL BE MANUALLY INHIBITED BY TAKING THE LH₂ MANIFOLD PRESS SWITCH TO CLOSE PRIOR TO THE MM 106 TRANSITION. THE LH₂ MANIFOLD PRESS SWITCH WILL BE TAKEN TO GPC AFTER THE MM 106 TRANSITION + 3 MINUTES.

If the LH₂ relief isolation valve does not open, the LH₂ manifold cannot be relieved through the relief valve. The nominal pressure buildup post-MECO is not expected to reach the manifold relief setting with a nominal MPS dump and nominal vacuum inerts. If the manifold pressure builds up greater than 60 psia, the software will automatically start the MPS dump or an automated contingency LH₂ vacuum inert (through the LH₂ fill/drain valves) to relieve the pressure. The LH₂ backup dump valves will be manually opened if an OMS burn is expected to occur prior to the nominal first automated vacuum inert start time of MPS dump start + 17 minutes (approximately MECO + 19 minutes). The OMS burn will increase the sublimation of the LH₂ residuals, resulting in a pressure buildup that may reach the relief setting. Although the software will automatically provide pressure relief if needed, the LH₂ backup dump valves are opened to prevent the pressure rise from nearing the proof pressure of the manifold (66 psig). The valves will be left open until the end of the first automated vacuum inert when they will automatically close. The second automated vacuum inert will be allowed to proceed normally except for the LH₂ manifold repressurization. The repressurization is manually inhibited by taking the LH₂ manifold press switch to close because there is no manifold relief capability. This will be performed prior to the MM 106 transition because the second automated vacuum inert and subsequent manifold repressurization will initiate at the MM 106 transition. The LH₂ manifold press switch will be taken to GPC after the MM 106 transition + 3 minutes (corresponding to the completion of the second automated vacuum inert and subsequent manifold repressurization) in order to avoid powering the valve until it is nominally checked in the Deorbit Prep timeframe. ©[092701-4867A]

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

- C. IF AUTOMATIC LH₂ VENT, DUMP, AND RELIEF CAPABILITY IS LOST AS A RESULT OF DUAL GPC/FA MDM FAILURES (GPC'S/FA MDM'S 1 AND 3, 1 AND 4, OR 3 AND 4), THE CREW WILL MANUALLY OPEN THE LH₂ FEEDLINE RELIEF ISOLATION VALVE IMMEDIATELY POST-MECO. ©[090999-7035]

Certain dual GPC/FA MDM failure combinations occurring during ascent will prevent the LH₂ relief isolation valve as well as the LH₂ backup dump valves and LH₂ fill/drain valves from opening after MECO. Without a relief path, the LH₂ manifold pressure will rapidly rise to a dangerous pressure level in seconds. During the STS-1 flight, where the LH₂ backup dump valves were not commanded open at 11.4 seconds after MECO as they are now, the LH₂ manifold pressure went from 34 psia before 17-inch disconnect closure to 50 psia within 15 seconds and subsequently relieved until the start of the MPS dump. The LH₂ manifold burst pressure is 83 psig. The crew can manually open the LH₂ feedline relief isolation valve with a single switch throw on panel R4. Pressure rise on the LO₂ side is not a major concern as a result of the slower pressure rise rate, higher manifold burst pressure, and the available leak path through the SSME oxidizer pump seal packages. For any dual GPC/FA MDM failures, the onboard procedure has the crew take both the LO₂ and LH₂ feedline relief isolation valve switches to open for procedural simplicity. ©[030994-1618B] ©[021199-6792B] ©[092701-4867A]

FLIGHT RULES

A5-204

MANUAL MPS DUMP @[092701-4867A]

THE MPS DUMP WILL BE MANUALLY DELAYED BY TAKING THE MPS DUMP SEQUENCE SWITCH TO "STOP" UNTIL AFTER ET SEPARATION FOR THE FOLLOWING FAILURE CASES IN ORDER TO AVOID PERFORMING THE MPS DUMP DURING ET SEPARATION:

- A. AFT RCS LEAK.
- B. FORWARD RCS LEAK.
- C. MPS FEEDLINE DISCONNECT FAILURE(S) WITH AN OMS-1 TIG PRIOR TO MECO + 6 MINUTES. @[090999-7035]

To prevent orbiter recontact with the ET, the MPS dump is delayed until after ET separation for RCS leaks and the feedline disconnect failure(s). With an RCS leak, the potential exists for the MPS dump forces to overwhelm the reduced RCS control authority during ET separation; therefore, the MPS dump is delayed until after separation by taking the MPS dump sequence switch to stop. With a feedline disconnect failure and an OMS-1 TIG prior to MECO + 6 minutes, the MPS dump is delayed per Rule {A5-202}, ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL], to prevent dump forces from interfering with the separation sequence (dump and vent forces could cause recontact). Analysis certifying the MPS dump during ET separation (SSEIG minutes, April 26, 1999) is not valid in these cases because the analysis assumed 1) the only RCS jets that are failed are those affected by a GPC 4 failure, and 2) the MPS dump can occur no earlier than 1.4 seconds after ET structural separation. @[090999-7035] @[092701-4867A] @[ED]

Taking the MPS dump sequence switch to stop for an ET toggle switch failure along with an LH2 manifold pressure transducer bias between 60 and 90 psia is not covered per the direction of the PRCB (PRCBD # S050270EF) on July 1, 1999. Since the most likely time that the ET toggle switch failure (FMEA/CIL's 05-6-2237-02 and 05-6-2237-03) can occur is post MECO, the crew would not have time to inhibit the MPS dump prior to MECO + 20 seconds (dump start time for the LH2 transducer failure). The PRCB also considered the combination of these two failures to be too unlikely to be specifically covered by crew procedures or by the Flight Rules. Rule {A5-205}, NOMINAL, AOA, AND ATO MPS DUMP FAILURES, references this rule. @[090999-7035] @[092701-4867A] @[ED]

FLIGHT RULES

A5-205

NOMINAL, AOA, AND ATO MPS T DUMP FAILURES

@[092701-4867A] @[ED]

- A. MPS DUMP SWITCH FAILURE - IF THE MPS DUMP SEQUENCE SWITCH IS NEEDED TO DELAY THE MPS DUMP AND IS UNAVAILABLE DUE TO A CONTROL BUS FAILURE, THE AFFECTED CONTACT WILL BE COMM FAULTED BY POWER CYCLING THE APPROPRIATE MDM PER THE TABLE BELOW. @[021397-4825]

<u>SW CONTACT</u>	<u>CONTROL BUS</u>	<u>MDM</u>
A	AB3	FF1
B	BC3	FF2

The MPS dump sequence switch can no longer be used to manually control the dump if the switch fails redundancy management. The MPS dump sequence switch is only used to delay the automated MPS dump until after ET separation for an aft RCS leak, a forward RCS leak, or an ET separation inhibit due to feedline disconnect failures with an OMS-1 TIG prior to MECO + 6 minutes per Rule {A5-204}, MANUAL MPS DUMP. If the MPS dump sequence switch is needed to delay the MPS dump and one of the contacts is failed due to loss of either control bus AB3 or BC3, the affected contact could be taken out of the switch RM logic by power cycling either MDM FF1 or FF2. @[111094-1720B] @[021397-4825] @[092701-4867A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-205

NOMINAL, AOA, AND ATO MPS T DUMP FAILURES
(CONTINUED)

- B. LH2 DUMP FAILURES - AN LH2 DUMP WILL BE PERFORMED BY MANUALLY OPENING THE LH2 BACKUP DUMP VALVES PRIOR TO THE END OF THE MPS DUMP FOR THE FAILURE TO OPEN EITHER THE LH2 INBOARD OR OUTBOARD FILL/DRAIN VALVE. THE LH2 BACKUP DUMP VALVES WILL BE MANUALLY CLOSED BETWEEN MECO + 7 MINUTES AND MECO + 10 MINUTES BY TAKING THE LH2 BACKUP DUMP VALVE SWITCH TO CLOSE THEN GPC. OTHERWISE, THE LH2 MANIFOLD REPRESSURIZATION FOLLOWING THE SECOND AUTOMATED VACUUM INERT WILL BE MANUALLY INHIBITED BY TAKING THE LH2 MANIFOLD PRESS SWITCH TO CLOSE PRIOR TO THE MM 106 TRANSITION. THE LH2 MANIFOLD PRESS SWITCH WILL BE TAKEN TO GPC AFTER THE MM 106 TRANSITION + 3 MINUTES. ©[092701-4867A]

The LH₂ portion of the MPS dump is a 120-second unpressurized dump through the LH₂ fill/drain valves, the LH₂ topping valve, and the LH₂ backup dump valves. If the LH₂ outboard fill/drain valve fails closed prior to the start of the MPS dump, approximately 57 lbm of hydrogen will remain at the end of the MPS dump. If the LH₂ inboard valve fails closed, approximately 6 lbm of hydrogen will remain. For these cases, the LH₂ backup dump valves will be taken to the open position prior to the end of the MPS dump. This will allow all but approximately 5 lbm of hydrogen to be vented off before the LH₂ backup dump valves are manually closed.

If no other crew action is taken, the LH₂ backup dump valves will remain open until the termination of the first automated vacuum inert (dump start + 19 minutes, approximately MECO + 21 minutes). At the termination of the first automated vacuum inert, the LH₂ backup dump valves will automatically close until the start of the second automated vacuum inert at the MM 106 transition. At the termination of the second automated vacuum inert, all but 0.24 lbm of hydrogen will be vented. This amount of hydrogen residual is sufficiently high to cause concern regarding the automatic manifold press checkout because the manifold pressure is expected to reach approximately 41 psia which is high enough to open the LH₂ feedline relief valve. In order to avoid opening the LH₂ feedline relief valve (the vent port is located near the vertical stabilizer), the automatic manifold press checkout will be manually inhibited by taking the LH₂ manifold press switch to close. This will be performed prior to the MM 106 transition because the second automated vacuum inert and subsequent manifold repressurization will initiate at the MM 106 transition. The LH₂ manifold press switch will be taken to GPC after the MM 106 transition + 3 minutes (corresponding to the completion of the second automated vacuum inert and subsequent manifold repressurization) in order to avoid powering the valve until it is nominally checked in the Deorbit Prep timeframe. ©[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-205

NOMINAL, AOA, AND ATO MPS T DUMP FAILURES (CONTINUED)

If the crew closes the LH₂ backup dump valves between MECO + 6 minutes, 40 seconds and MECO + 10 minutes, (prior to the start of the first automated vacuum inert), the hydrogen residuals following the second automated vacuum inert will be between 0.09 lbm and 0.10 lbm, respectively. For simplicity, the crew action to take the LH₂ backup dump valve switch to close then GPC will be performed between MECO + 7 minutes and MECO + 10 minutes. It is believed that these residuals are insufficient to cause hydrogen to relieve on orbit. All residuals are based on Boeing IL SHA0-01-014 / SI-01-044 dated February 19, 2001. ©[092701-4867A]

Manual control of the LH₂ backup dump valves is only available in OPS 1. If the hydrogen residuals were not properly inerted in OPS 1, the manifold pressure may rise above the 83 psig burst pressure of the manifold. This scenario would require the crew to pro to OPS 303 (via OPS 301) in order for the software to automatically open the LH₂ backup dump valves. Once the manifold pressure returns to normal, the vehicle may be transitioned back to OPS 2. For this reason, the hydrogen residuals are managed in OPS 1 via the LH₂ backup dump valve switch.

Currently, no ops code exists to open the LH₂ backup dump valves via real-time command (RTC), and due to the fact that the pressure will rise from the max relief setting to the burst pressure in a relatively short amount of time (approximately 1.0 hour), the decision was made not to pursue a GPC memory read/write (GMEM). In the case of an AOA, the manifold pressure should not reach burst pressure prior to the OPS 303 transition. ©[111094-1720B]

C. LO₂ DUMP FAILURES - AN INCOMPLETE LO₂ DUMP MAY REQUIRE A MANUAL LO₂ VACUUM INERT TO BE PERFORMED PER RULE {A5-206}, MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA).
©[111094-1730A] ©[021397-4825]

The LO₂ is dumped through the SSME main oxidizer valves. There is no secondary dump path available during the MPS dump. However, after MPS dump termination, residuals will vent through the engine high pressure oxidizer pump seals, and the relief system will protect the manifold from overpressurization. ©[092701-4867A]

FLIGHT RULES

A5-206

MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA)

- A. FOR NOMINAL/ATO MISSIONS, A MANUAL LO₂ VACUUM INERTING MAY BE PERFORMED BY THE CREW IF THE LO₂ MANIFOLD PRESSURE IS GREATER THAN 30 PSIA AFTER THE SCHEDULED TERMINATION OF THE FIRST AUTOMATED VACUUM INERT. MANUAL LO₂ VACUUM INERTING WILL NOT BE PERFORMED UNTIL THE LO₂ MANIFOLD PRESSURE VENTS BELOW 30 PSIA. @[111094-1718A] @[092701-4867A]

LO₂ vacuum inerting can be delayed because the LO₂ prevalues remain open after the MPS dump which allows the pressure to vent through the engine high-pressure oxidizer pump seals. After the pressure decays below 30 psia, the software or crew can then perform vacuum inerting without any vehicle control problems. The software can only perform the automated LO₂ vacuum inert between MPS dump start +17 minutes (approximately MECO + 19 minutes) and MPS dump start + 19 minutes (approximately MECO + 21 minutes).

For a nominal and ATO mission, there should be sufficient time to allow the pressure to decay and then perform the LO₂ vacuum inert if required. The manual vacuum inert may not be necessary depending on the effectiveness of the pressure relief through the engine high-pressure oxidizer pump seals. On an AOA, there may not be sufficient time to vent below 30 psia, however, no action would be required because the LO₂ manifold will be inerted automatically in MM 304 by the MPS entry dump sequence.

LO₂ manifold pressure will be less than 30 psia if the MPS dump was performed successfully. However, if two or three engine main oxidizer valves were not able to open for the MPS dump, the residual oxidizer could result in a manifold pressure greater than 30 psia. Opening the LO₂ fill/drain valves when the manifold pressure is greater than 30 psia will cause the vehicle to roll significantly as was experienced during an MPS dump detailed test objective on STS 51-D. The roll was due to the oxidizer flow force at the LO₂ outboard fill/drain valve and flow impingement on the wing.

- B. FOR A BCE STRING 2C FAILURE, A MANUAL LO₂ VACUUM INERT WILL BE PERFORMED AFTER MPS DUMP START + 22 MINUTES (APPROXIMATELY MECO + 24 MINUTES) IF THE LO₂ MANIFOLD PRESSURE IS CONFIRMED TO BE LESS THAN 30 PSIA.

The loss of BCE STRING 2C commfaults the LO₂ manifold pressure sensor. The MPS dump sequence will not perform the LO₂ portion of the first automated vacuum inert if the manifold pressure sensor is commfaulted. Any LO₂ inlet pressure sensor can be used by the MCC as a backup to the LO₂ manifold pressure if the corresponding LO₂ prevalue is open. The crew's manifold pressure meter on panel F7 should also be available to determine the LO₂ manifold pressure. The BCE STRING X procedure in the Ascent Pocket Checklist directs the crew to perform the MPS vacuum inert procedure for the STRING 2C failure. @[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-206

MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA) (CONTINUED)

- C. ON A SYSTEMS AOA, A MANUAL VACUUM INERT MAY BE REQUIRED IF OPS 3 IS ENTERED PRIOR TO INITIATION OF THE FIRST AUTOMATED VACUUM INERT. @[092701-4867A]

On a systems AOA, there may not be sufficient time for the software to initiate the first automated vacuum inert and the crew must manually perform the vacuum inert to insure no residuals, since no entry dump/inert will be performed.

- D. MANUAL LH₂ VACUUM INERTING WILL BE PERFORMED BY MANUALLY OPENING THE LH₂ INBOARD AND OUTBOARD FILL/DRAIN VALVES FOR THE FAILURE TO OPEN THE LH₂ BACKUP DUMP VALVES. THE FIRST MANUAL VACUUM INERT WILL BE PERFORMED AS CLOSE TO THE AUTOMATIC SEQUENCE AS POSSIBLE, BETWEEN MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) AND MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES). THE SECOND MANUAL VACUUM INERT WILL BE PERFORMED POST OMS-2 AND PRIOR TO THE MM 106 TRANSITION. @[092195-1791]

If either of the LH₂ backup dump valves do not open during the MPS dump or automated vacuum inert(s), the system will be manually inerted using the LH₂ fill/drain valves in order to minimize residuals in the LH₂ manifold. The first manual vacuum inert will be performed as close to the automatic sequence timing as possible (to minimize hydrogen residuals). The second manual vacuum inert will be performed prior to the MM 106 transition in order to allow the automatic manifold press checkout and to minimize hydrogen residuals. By performing the manual vacuum inert(s), the hydrogen residuals will be sufficiently low to allow for the automatic manifold press checkout. The MCC will direct the crew to perform the manual vacuum inerting procedure in the Ascent Pocket Checklist for both vacuum inerts. @[ED] @[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-206 MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA) (CONTINUED)

- E. IF A MANUAL VACUUM INERTING IS REQUIRED, THE MCC WILL REQUEST, WHENEVER POSSIBLE, THAT THE CREW PERFORM THE PROCEDURE ON THE AFFECTED SYSTEM(S) ONLY LO₂/LH₂. IF POSSIBLE, THE MER MPS ENGINEER WILL BE CONSULTED PRIOR TO SCHEDULING A MANUAL VACUUM INERT. ©[111094-1718A] ©[092701-4867A]

Although several crew LO₂/LH₂ vacuum inerting procedures are integrated in order to cover single failure cases which affects both systems, it is preferable that the procedures be performed on only the affected system(s) whenever possible. Performing the manual vacuum inert for only the affected system will minimize cycling of the MPS fill/drain valves and should, consequently, maximize the useful life of the MPS hardware. ©[111094-1718A] ©[ED]

Vacuum inerting will be repeated if propellants are believed to remain in the manifolds. Because there are several potential causes for propellant residuals, because of the significant technical resources available to the MER MPS engineer, and because it is likely that there will be a significant period of time to discuss the situation, the Booster Flight Control Team will consult with the MER MPS engineer if at all possible. Based on reviews of Boeing IL SHA0-01-014 / SI-01-044 dated February 19, 2001, LH₂ manifold pressures above 40 psia will be considered high enough to perform a manual vacuum inert of the LH₂ manifold. ©[092701-4867A]

A5-207 LH₂ PRESSURIZATION VENT CONTROL

AFTER THE ET/ORBITER UMBILICAL DOOR IS CLOSED, THE LH₂ PRESSURIZATION LINE VENT WILL NOT BE OPENED TO AVOID VENTING LH₂ INTO THE UMBILICAL CAVITY. ©[021199-6793]

Damage to the door or cavity may occur if the LH₂ pressurization line vent is opened while line pressure is high and the vent door is closed (ref. SODB, volume I, section 3.4.3.1-6).

FLIGHT RULES

A5-208

POST-MECO AND ENTRY HELIUM ISOLATION @[ED]

- A. MPS ENGINE OR PNEUMATIC HELIUM REGULATOR PRESSURE > 800 (810) PSIA AND THE: @[021199-6787B]
1. VENT DOORS CLOSED: CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE ASAP.
 2. VENT DOORS OPEN: CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE AS TIME PERMITS.

Analysis indicates an MPS helium regulator failed open can cause an overpressurization of the aft compartment in approximately 17 seconds if the vent doors are closed. This overpressurization will not result in a loss of the vehicle. However, the safety factor for the 1307 Bulkhead will be reduced to 1.31 during entry and structural damage will likely occur which will require the vehicle to be taken out of service for thorough inspection and refurbishment as necessary (reference Rockwell International Analysis PCIN R76186, July 15, 1988).

Crew action is required above 800 psig when the relief valve begins to flow helium into the aft compartment. Since any action will be taken where the ambient pressure is near zero psia, 800 psia will be equivalent to 800 psig. Crew caution and warning is set to 810 psia for the MPS helium regulator pressures. 810 psia is sufficiently close to 805 psia (the relief valve cracking pressure of 800 psig plus 5 psia for transducer accuracy) that action can be taken at the crew caution and warning cue while still maintaining adequate margin to 850 psig where the relief valve goes full open.

With the vent doors open, no action is required. The vent doors close on a TAL at ET SEP command. During an RTLS, the vent doors close at the MM 602 transition. During the nominal or ATO entry, the vent doors close at the transition to MM 304. During an AOA, the vent doors are manually closed just prior to the MM 304 transition. For all of these entry profiles, the vent doors open at Mach 2.4.

Entry MPS helium regulator shifts are most likely to occur during periods of high flow demand such as when the MPS helium isolation valves open at the transition to MM 303 or when the MPS helium blowdown valves open at Mach 5.3. For simplicity, the crew procedure for MPS helium regulator shifts call for the immediate isolation of the associated MPS helium isolation valve(s) on entry prior to Mach 2.4. After Mach 2.4, MCC may direct the crew to close the associated MPS helium regulator valves, time permitting. Training in the nominal helium leak isolation procedure will allow the crew to react to the caution and warning system in less than 15 seconds. @[021199-6787B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-208

POST-MECO AND ENTRY HELIUM ISOLATION (CONTINUED)

- B. FOR ALL OTHER POST-MECO AND ENTRY HELIUM OR PNEUMATIC SYSTEM LEAKS, THE SYSTEM WILL BE ISOLATED AS TIME PERMITS. POST-ISOLATION, AN ATTEMPT WILL BE MADE TO MANUALLY RECONFIGURE THE MPS HELIUM SYSTEM TO SUPPORT THE ENTRY PURGE IF TIME PERMITS. @[021199-6787B]

If a leak occurs on an engine or pneumatic helium system, the affected system will be isolated as time permits. Helium is required for manifold pressurization during the MPS dump and entry, for valve actuation, and for the entry aft compartment purge. Since the crew has no insight into the configuration of the MPS helium system interconnect valves, it is likely that the crew will need assistance from MCC in order to isolate any post-MECO helium leak. These procedures may be complicated and will be performed as time permits.

For nominal missions, if a leak occurs prior to the MPS dump, the leak may be isolated and the helium system subsequently reconfigured to support the MPS dump. On entry, if time permits after the leak is isolated, the helium system may be manually reconfigured to support the entry purge. The entry purge is highly desirable for the nominal end of mission but is considered mandatory during aborts. If a hazardous gas leak is evident in the aft compartment or OMS pods, the entry purge will be required. Also, contamination may be ingested into the evacuated MPS manifolds if the helium pressurization is not performed. The contamination in the lines would require cleaning before the next flight which would increase the vehicle's turnaround time.

During an RTLS abort, post-MECO isolation may not be performed. Because of the limited flight duration and the crew workload, there may not be adequate time to reconfigure the MPS helium system to support the entry purge.

- C. IF ALL CAUTION AND WARNING IS LOST FOR ANY MPS HELIUM REGULATOR PRESSURE TRANSDUCER(S):
1. NOMINAL/ATO:
 - a. PRIOR TO MACH 2.4: MCC WILL HAVE THE CREW CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE(S).
 - b. AFTER MACH 2.4: NO ACTION REQUIRED. @[021199-6787B]
 2. AOA/TAL/RTLS: NO ACTION REQUIRED. @[021199-6787B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-208

POST-MECO AND ENTRY HELIUM ISOLATION (CONTINUED)

Without hardware or software caution and warning, it is unlikely that MCC could diagnose an MPS helium regulator failed open and tell the crew to close the associated MPS helium isolation valve before the aft compartment is overpressurized (17 seconds). For a nominal or ATO entry, if hardware and software caution and warning is unavailable, the crew will preemptively close the associated MPS helium isolation valve(s). Caution and warning may be lost due to the loss (or bias) of the MPS helium regulator pressure transducer, loss of the associated OI DSC or OI MDM, or loss of the BFS.

After the vent doors open at Mach 2.4, the overpressurization of the aft compartment is no longer a concern and preemptively closing the MPS helium isolation valve(s) to protect for a potential MPS helium regulator failed open is not required. Preemptive helium isolation is also not required on the AOA, TAL, or RTL entry. Protecting for the additional, unrelated failure of an MPS helium regulator following the loss of caution and warning will not be performed because of the relatively short exposure period and high crew workload during aborts.

Preemptive closure of MPS helium isolation valves for the loss of caution and warning will require an MCC call except for a failure of the BFS GPC. The BFS FAIL crew procedure in the Entry Pocket Checklist and Ascent/Entry Systems Procedures directs the crew to close the MPS helium B isolation valves and the pneumatic helium isolation valves since caution and warning for these pressure transducers is only available in the BFS. This procedure does not differentiate between a nominal and abort entry profiles. ©[021199-6787B]

FLIGHT RULES

A5-209**ENTRY MPS HELIUM PURGE/MANIFOLD PRESSURIZATION**

@[022802-5080] @[ED]

THE ENTRY MPS HELIUM PURGE AND MANIFOLD PRESSURIZATION FUNCTIONS ARE HIGHLY DESIRABLE TO PURGE THE AFT COMPARTMENT OF ANY HAZARDOUS FLUID BUILDUP AND TO PREVENT AIR INGESTION INTO THE MPS LO₂ AND LH₂ MANIFOLDS. IF THIS FUNCTION IS LOST, THEN THE FOLLOWING ATTEMPTS WILL BE MADE, TIME PERMITTING, TO RECOVER THEM:

A. NOMINAL/AOA:

EFFORTS TO RECOVER THE ENTRY MPS HELIUM PURGE AND LO₂ AND LH₂ MANIFOLD PRESSURIZATION WILL ONLY BE ATTEMPTED IF IT WILL NOT IMPACT CRITICAL CAPABILITY IN OTHER ORBITER SYSTEMS. FOR CRITICAL POWER/COOLING CASES (I.E., LOSS OF TWO FUEL CELLS OR TWO FREON LOOPS), THE ENTRY PURGE AND MANIFOLD PRESSURIZATION WILL BE INHIBITED PER CREW PROCEDURES.

B. RTLS/TAL:

1. FOR THE ENTRY MPS HELIUM PURGE, RECOVERY EFFORTS WILL ONLY BE ATTEMPTED IF IT WILL NOT IMPACT CRITICAL CAPABILITY IN OTHER ORBITER SYSTEMS.
2. FOR THE MPS LH₂ MANIFOLD PRESSURIZATION, IF THE SITUATION PERMITS, THE FUNCTION WILL BE RECOVERED (BY A SWITCH THROW, PORT MODE, OR RESTRING) IN ORDER TO AVOID INGESTION OF AIR INTO THE LH₂ MANIFOLD.

NOTE: FAILURE TO PRESSURIZE THE LH₂ MANIFOLD WITH MPS HELIUM REQUIRES AN EXPEDITED POWERDOWN AND MODE V EGRESS PER RULE {A16-11F}, EXPEDITED POWERDOWN.

@[022802-5080]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-209

**ENTRY MPS HELIUM PURGE/MANIFOLD PRESSURIZATION
(CONTINUED)**

The MPS entry helium purge is used to purge the aft compartment of hazardous fluids (e.g., LH₂, LO₂, N₂H₄, NH₃, or hydraulic oil) during entry. For nominal and AOA entries, hazardous MPS propellants will have had time to be fully inerted as part of the MPS dump sequence; and therefore, the importance of the purge is low. On RTLS and TAL entries, residual MPS propellants may be present, thereby increasing the importance of the purge. If the presence of hazardous fluids is suspected due to system leaks or failures, the purge may help to reduce the potential for combustion by reducing the hazardous fluid concentrations in the aft compartment. The effectiveness of the MPS entry purge is unknown; therefore, critical capability in other Shuttle systems should not be traded off to regain the purge. At the Ascent Entry Flight Techniques Panel Meeting (AEFTP #168 on 10/27/00), it was decided that if it was deemed appropriate by the flight control team to regain the purge, a temporary port mode (to latch the purge valve commands) could be attempted, but a restring was determined to not be warranted due to the unknown effectiveness of the purge. The decision to port mode will depend upon the specific flight phase and failure scenario present in the orbiter as established in Flight Rule {A2-5}, PORT MODING/RESTRINGING GUIDELINES. ©[022802-5080]

It is desirable to pressurize the MPS propellant manifold during entry because failure to do so will result in the ingestion of air into the MPS propellant lines requiring additional turnaround time to clean the contaminated manifolds. Also, loss of the LH₂ manifold pressurization on RTLS and TAL aborts will result in the creation of an explosive mixture in the LH₂ manifold as air is ingested and mixes with the hydrogen residuals. This scenario will require an expedited powerdown per Flight Rule {A16-11}, EXPEDITED POWERDOWN. At the AEFTP Meeting (AEFTP #168 on 10/27/00), it was decided that the recovery technique for the loss of LH₂ manifold pressurization could be a switch throw, temporary port mode (to latch the LH₂ manifold pressurization commands), or restring. In general, a switch throw will be attempted before a port mode, which will be attempted before a restring; however, the recovery technique used will depend upon the specific flight phase and failure scenario present in the orbiter as established in Flight Rule {A2-5}, PORT MODING/RESTRINGING GUIDELINES. The importance of the LO₂ manifold pressurization function is insufficient to justify recovery actions during an RTLS or TAL entry (contamination/reflight issue).

To accomplish a safe entry on a nominal or AOA entry with the loss of two Freon loops or the loss of two fuel cells, critical power and cooling capability must be conserved via power reductions in all orbiter systems. MPS valves that are normally closed valves will be positioned to the CLOSE position in order to conserve power (as documented in the Orbit Pocket Checklist, Entry Pocket Checklist, Contingency Deorbit Prep, and Systems AOA Procedures Flight Data File). This reconfiguration will save approximately 218.4 watts. ©[022802-5080]

FLIGHT RULES

A5-210

ENTRY MPS PROPELLANT DUMP FAILURES [CIL]

@[020196-1813A]

A. NOMINAL/ATO: @[110900-7240]

NO ACTION IS REQUIRED.

During nominal/ATO missions, automatic software or crew procedures will insure dumping and/or inerting of the LO₂ and LH₂ residuals prior to entry. A complete LH₂ dump can be done if either the LH₂ backup dump valves or LH₂ fill/drain valves are open. A complete LO₂ dump can be done if two or three SSME's perform LO₂ dumps, or if the LO₂ fill/drain valves are both open (reference Rockwell Internal Letter no. 287-104-87-004, dated January 8, 1987). The LH₂ backup dump valves are the only dump path opened during the nominal/ATO entry MPS dump sequence, and no action is required in the event that these valves do not open.

B. AOA/TAL:

IN MM 304, IF GPC/MDM FAILURES CAUSE ALL LH₂ DUMP PATHS TO BE LOST (INCLUDING THE LH₂ BACKUP DUMP VALVES), THE AFFECTED LH₂ FILL/DRAIN VALVE(S) WILL BE MANUALLY OPENED. IF THE SOFTWARE CANNOT CLOSE THE LH₂ OUTBOARD FILL/DRAIN OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES, THE LH₂ OUTBOARD FILL/DRAIN VALVE WILL BE MANUALLY CLOSED AT A RELATIVE VELOCITY (V_{REL}) OF 5300 FT/SEC.

In the LH₂ system, there are single GPC/MDM failures which result in the loss of GPC control of the LH₂ fill/drain valves and the LH₂ topping valve. In these cases, the affected LH₂ fill/drain valve(s) will be manually opened on a TAL only if the LH₂ backup dump valves are not open. Sufficient time exists to dump LH₂ residuals through the backup LH₂ valves for AOA or TAL aborts, leaving approximately 3 lbs of hydrogen residuals (per Rockwell International internal letter 287-100-94-164, dated August 9, 1994). There are also combinations of GPC/MDM failures which result in the loss of all LH₂ dump paths. On a TAL abort, the crew will manually open the affected LH₂ fill/drain valve(s). The LH₂ backup dump valves cannot be manually opened in these cases because the switch is software driven and only read in OPS 1. The LH₂ outboard fill/drain valve will be closed in order to preserve helium for the aft compartment purge and to prevent the combination of atmospheric O₂ with the residual LH₂ in the manifold. The velocity cue used to close the LH₂ outboard fill/drain valve represents the nominal closing time and corresponds to an altitude at which possible ignition of residual LH₂ can occur.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-210

ENTRY MPS PROPELLANT DUMP FAILURES [CIL]
(CONTINUED)

C. RTLS: @[110900-7240]

IN MM 602, IF GPC/MDM FAILURES CAUSE THE LH₂ OUTBOARD FILL/DRAIN DUMP PATH TO BE LOST (DUE TO A FAILURE OF THE LH₂ OUTBOARD FILL/DRAIN, OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES), THE AFFECTED LH₂ FILL/DRAIN VALVE(S) WILL BE MANUALLY OPENED. IF THE SOFTWARE CANNOT CLOSE EITHER THE LH₂ OUTBOARD FILL/DRAIN VALVE OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES, THE LH₂ OUTBOARD FILL/DRAIN VALVE WILL BE CLOSED AT A V_{REL} OF 3800 FT/SEC.

NOTE: AN EXPEDITED POWERDOWN/MODE V EGRESS WILL BE REQUIRED IF A DUMP PATH THROUGH THE LH₂ OUTBOARD FILL/DRAIN VALVE CANNOT BE ACQUIRED (REFERENCE RULE {A16-11F}, EXPEDITED POWERDOWN). @[020196-1813A]

In the LH₂ system, there are GPC/MDM failures which result in the loss of GPC control of the LH₂ fill/drain valves and the LH₂ topping valve. The failure of the LH₂ outboard fill/drain valve will result in an incomplete LH₂ dump on RTLS aborts. Analysis has shown that approximately 40.8 pounds of LH₂ residuals will remain in the MPS LH₂ manifold if the only LH₂ dump path is through the backup LH₂ valves (reference Rockwell internal letter 287-100-04-164, dated August 9, 1994). Venting LH₂ residuals will preclude normal convoy operations (reference rule {A16-11F}, EXPEDITED POWERDOWN). In order to avoid this ground hazard, the affected LH₂ fill/drain valve(s) will be opened. The LH₂ outboard fill/drain valve will be closed in order to preserve helium for the aft compartment purge and to prevent the combination of atmospheric O₂ with the residual LH₂ in the manifold. The velocity cue used to close the LH₂ outboard fill/drain valve represents the nominal closing time and corresponds to an altitude at which possible ignition of residual LH₂ can occur.

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES**A6-3 OMS ENGINE (CONTINUED)**

- D. PROPELLANT LEAK DOWNSTREAM OF BALL VALVES, PC < 76 (80) PERCENT, AND OMS RM ENGINE SELECT DOWN ARROW (∇) ON MANEUVER EXECUTE DISPLAY OR FUEL INJECTION TEMP > 260 DEG F.

A propellant leak large enough to cause low Pc and decayed acceleration, as indicated by the down arrow or fuel injector temperature high, during a burn results in the loss of the affected engine. (Reference SODB, volume I, paragraphs 3.4.3.3 and 3.4.4.3.)

- E. PREVIOUS FUEL OR OXIDIZER DEPLETION CUTOFF.

Although WSTF tests with a fuel depletion cutoff did not damage an OMS engine, there is significant risk that engine damage may occur during shutdown. This is due to the loss of engine cooling when fuel no longer passes through the cooling jacket around the combustion chamber. Uncontained damage did not occur during WSTF tests but zero-g effects are unknown.

It is not desirable to reuse an OMS engine following an oxidizer depletion cutoff. A period of time is required for oxidizer from a different propellant source to reach the engine during the first engine start following oxidizer depletion cutoff. During this time, unburned fuel accumulates in the combustion chamber because of the very low vapor pressure of monomethylhydrazine. When the oxidizer reaches the injector, extremely rough combustion will result. Uncontained engine damage could result.

There have not been any tests to verify reuse of an engine which has experienced a previous oxidizer or fuel depletion cutoff.

Reference: SODB 3.4.3.3. Rule {A6-106}, OMS ENGINE BURN TO DEPLETION, references this rule.

- F. PRE-MECO PC ? 76 (80) PERCENT CONFIRMED BY ENGINE BALL VALVE POSITION < 47 (70) PERCENT OR OXIDIZER INLET PRESSURE > 235 (227) PSIA.

The crew will get a class 2 alarm at Pc < 76 (80) percent, but there is no MNVR EXEC display or ENG SEL down arrow pre-MECO to indicate loss of acceleration. Therefore, oxidizer inlet pressure or ball valve position is checked for an additional indication of an engine failure. The rationale used for paragraphs A and C (CAUTION: SODB, volume III, contains engineering estimates for non-nominal evaluation. Data may not be supported by test.) applies here also. (Reference SODB, volume I, 3.4.3.3, table 3.4.3.3 and SODB request response R921.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-3 OMS ENGINE (CONTINUED)

G. OXIDIZER RESTRICTION: PC < 76 (80) PERCENT, OMS RM ENGINE SELECT DOWN ARROW ("?") ON MANEUVER EXEC DISPLAY, AND OXIDIZER INLET PRESSURE > 235 (227) PSIA.

The engine can also fail if the oxidizer injector is restricted, which causes the upstream oxidizer inlet pressure to increase. Operating at this low oxidizer inlet pressure will result in an engine failure indicated by low Pc and acceleration. (Reference SODB, volume I, paragraph 3.4.3.3. A request has been submitted for inlet pressure verification.)

H. OMS BALL VALVE POSITION > 0 PERCENT (FAILED OPEN RANGE LOWER LIMIT) AND < 47 (70) PERCENT POSTBURN AND INSTRUMENTATION FAILURE CANNOT BE POSITIVELY IDENTIFIED.

ENGINE SERIAL #	OMS BALL VALVE FAILED OPEN RANGE LOWER LIMIT	
	BV1 %	BV2 %
101	6	5
105	3	5
106	4	6
107	6	6
108	4	5
109	4	6
110	3	4
111	6	3
113	4	4
114	5	3
115	3	3
116	2	4
117	5	4

@[110900-7251] @[1112102-ED]

For failure definition purposes, the OMS ball valves are considered a functionally integral part of the OMS engine. OMS ball valve position indicators are single-point instrumentation on the series ball valves. To distinguish an instrumentation failure from a hardware failure, it is necessary to examine the time-ordered history of the anomaly.

The normal position of the ball valves when not operating is 0 percent open (decimals of percent open are rounded). If the ball valves are failed to < 47 percent, the affected OMS Pc will be < 80 percent which is the level at which the engine is considered failed. (Refer to rationale of Rule {A6-108}, OMS BALL VALVE FAILURE MANAGEMENT.) The position indicators have an instrumentation accuracy of 5 percent.

FLIGHT RULES

A8-19

YAW JET DOWNMODE

- A. IF NO YAW JETS ARE AVAILABLE ON EITHER LEFT OR RIGHT SIDE, THE NO-YAW-JET DAP MODE WILL BE SELECTED IF ABOVE MACH = 1.

The no-yaw-jet mode for emergencies is a certified flight control mode from Q -bar = 20 psf through landing. This mode should be selected between Q -bar = 20 psf and Mach 1 (yaw jets inhibited) if no-yaw-jets are available on a side. In the low Q -bar regime (Q -bar < 20), vehicle response will be sluggish and pilot workload increased, but control will be better than with the baseline DAP. Once selected, it is not necessary to deselect the no-yaw-jet mode. Flight Rule {A6-305}, AFT RCS REDLINES, defines when to engage no-yaw-jet based on aft RCS quantity. Reference DA8-88-20 (FT), Entry Flight Techniques Meeting #41.

- B. IN OPS 3, IF THE AEROJET DAP BASELINE MODE IS SELECTED AND ADDITIONAL LATERAL CONTROL MARGIN IS REQUIRED, THE WRAPAROUND DAP MODE WILL BE ENABLED IF ABOVE MACH 1. @[021998-6485B]

The aerojet DAP wraparound mode is normally enabled for EOM, AOA/ATO, and contingency payload return entry but is not enabled for TAL abort entries, due to lack of certification for TAL aborts. The wraparound DAP is not available in OPS 6. If lateral control margin is reduced due to three yaw jets failed on one side or aileron trim saturation, a loss of control may occur. In addition, if LVAR 9 aerodynamic uncertainties are experienced (a low-probability potential below Mach 6), excessive jet firings and high RCS propellant usage may result. Enabling wraparound mode eliminates these problems by providing increased aileron authority. Reference DA8-88-20 (FT), Entry Flight Techniques Meeting #41, and Ascent/Entry Flight Techniques Panel meeting #141 minutes. @[021998-6485B]

Rules {A6-206}, RCS MANIFOLD/LEG LEAK REPRESSURIZATION, and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule. @[ED]

FLIGHT RULES

A8-20

ENTRY ELEVON SCHEDULE SELECTION CRITERIA

THE AUTO ELEVON SCHEDULE WILL NOMINALLY BE SELECTED INDEPENDENT OF X-AXIS CENTER-OF-GRAVITY (X CG) LOCATION WITH THE FOLLOWING EXCEPTIONS:

- A. THE FIXED ELEVON SCHEDULE WILL BE SELECTED AS REQUIRED ON A FLIGHT-SPECIFIC BASIS IN ORDER TO SUPPORT AERODYNAMIC PTI'S. IF AERO PTI'S ARE SCHEDULED AND IT IS SUBSEQUENTLY DECIDED NOT TO EXECUTE THEM, THEN THE AUTO SCHEDULE WILL BE SELECTED.
- B. IF THE NO-YAW-JET MODE OF THE AEROJET DAP IS REQUIRED DURING ENTRY, THE FIXED SCHEDULE WILL BE SELECTED IF IT IS I-LOADED WITH THE AFT SCHEDULE. IF EITHER THE FORWARD OR MID SCHEDULE IS LOADED, THE AUTO SCHEDULE WILL BE SELECTED.

The smart body flap logic incorporated with OI-20 software eliminates the need for selecting elevon schedules based on the X CG for entry. The smart body flap is enabled anytime the auto schedule is selected and will maintain the elevons on a schedule that is similar to the previous mid-CG schedule but will allow the elevons to move off-schedule, within limits, in order to thermally protect the body flap and main engines.

The fixed elevon schedule maintains the body flap logic used prior to OI-20 and allows one of the three previously used schedules (fwd, mid or aft) to be loaded into this slot. It is planned to use this schedule to support aero PTI's as required on a flight-specific basis.

Low RCS propellant quantity or loss of yaw jets may require that the no-yaw-jet mode of the Aerojet DAP be selected during entry. Selecting a schedule with more positive elevon deflection (down) increases the control authority of the elevons by moving them into the airstream. For flights in which aero PTI's are not planned, the aft schedule will be loaded into the fixed slot and this schedule will be selected if the no-yaw-jet mode is required even though this may thermally impact the main engine nozzles (turnaround issue). The auto elevon schedule is certified for use with the no-yaw-jet mode; however, the aft schedule provides better control authority (ref. A/E FTP #76, held 3/15/91). The fwd schedule is not certified for use with the no-yaw-jet mode. The RCS critical entry cue card contains the procedural callout for selecting the correct schedule to be used with the no-yaw-jet mode.

A8-21 THROUGH A8-50 RULES ARE RESERVED

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

2. G1 GYRO BIAS UPLINK MAY BE USED FOR IMU REALIGNMENT SUBJECT TO THE FOLLOWING CONSTRAINTS:
 - a. IRAMS IS REQUIRED TO CALCULATE GYRO BIAS UPLINK TERMS.

IRAMS is required to monitor individual IMU prelaunch misalignment and calculate gyro bias uplink values to correct the misalignment.

- b. THE LAUNCH WINDOW MUST SUPPORT THE 15 MINUTES REQUIRED TO GENERATE AND VERIFY THE GYRO BIAS UPLINK. THE GYRO BIAS TERMS (AS COMPUTED BY THE IMU PREFLIGHT CALIBRATION) WILL BE ON-BOARD, AND THE PERFORMANCE WILL BE VERIFIED PRIOR TO LIFT-OFF. IT IS HIGHLY DESIRABLE TO VERIFY THE PERFORMANCE PRIOR TO RESUMING THE COUNT AT T MINUS 5 MINUTES.

Five minutes is required for the uplink decision and implementation process. This process consists of the MER/MCC decision that an uplink is required; coordination of required compensation values between MER and MCC; uplink load generation; uplink load verification; coordination between MER, MCC and KSC prior to uplink execution; uplink execution; and 1 minute for torquing out IMU misalignment. An additional 10-minute monitoring/verification period is required after the realignment is complete prior to committing to launch.

A8-58

ADI LOSS

AN ADI IS CONSIDERED FAILED ONLY IF THE ATTITUDE BALL IS FAILED (N/A FOR MEDS VEHICLES). @[040899-2459B]

The entry-critical parameters required by the crew can be monitored using the attitude ball (or sphere). While rate and error needles are desirable (especially for monitoring vehicle control), the attitude ball is sufficient in providing the required information. As a result, an ADI will be considered failed only if the attitude sphere is not providing accurate or stable attitude reference. This rule is needed for making decisions regarding early flight termination, night landings, and IFM. (Ref. Rules {A8-1001E}, GNC GO/NO-GO CRITERIA, for dedicated displays and {A8-18}, LANDING SYSTEMS REQUIREMENTS.) (Ref. Entry Flight Tech. Panel #34, 8/21/87.)

FLIGHT RULES

A8-59

IMU BITE FAILURE DEFINITION

FOR PURPOSES OF EARLY MISSION TERMINATION AND LANDING SITE DOWNMODING, AN IMU WITH A BITE SHOULD BE CONSIDERED FAILED WITH THE FOLLOWING EXCEPTIONS:

- A. TRANSMISSION WORD 2 BITE
- B. TRANSMISSION WORD 1 BITE
- C. TEMPERATURE SAFE BITE
- D. TEMPERATURE READY BITE @[011295-1752A]

IF REAL-TIME ASSESSMENT DETERMINES THE BITE TO BE FALSE OR NO IMPACT, THEN THE IMU WILL NO LONGER BE CONSIDERED FAILED.

At the three-level, redundancy management (RM) will not downmode an IMU with a BITE because there is no risk of incorporating bad data. At the two-level, RM will downmode the IMU with the BITE should the attitude or velocity disagree by more than the RM threshold.

A BITE is an indication that the IMU has experienced a failure and may be operating outside of spec. BITE will almost always indicate an actual problem with the IMU. In most cases, data can be used to determine whether or not the BITE is real. There is, however, the possibility of a failure in the BITE circuitry itself - termed false BITE. Also, it cannot necessarily be determined whether or not an IMU will continue to operate in a consistent manner while outside of spec. For several BITE's, performance will remain unknown until data is observed during entry. It is logical, therefore, to assume that the BITE logic has correctly identified a real failure and to consider the unit failed. Since RM provides for BITE's, there is no requirement for manual deselection of the affected IMU.

A next PLS should be declared after the second BITE (or the first BITE at the two-level) to reduce the risk of losing the last IMU. Reference Rule {A2-207}, LANDING SITE SELECTION, for runway priorities. @[102402-5804C]

The Transmission Word 2 Fail BITE (loss of slew) only impacts the IMU if an IMU/IMU alignment is required. Even if an IMU/IMU is required, other options exist to fully recover the IMU.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES (CONTINUED)

As with the NOM/ATO/TAL cases, it is preferable to leave the nongimballing engine running through single-engine press to MECO and accept the risk of the loss of a gimballing engine to this point. Due to the possibility of SSME failures resulting from valve drift on the engines in hydraulic lockup, the time to single-engine press should be minimized, since engine failures prior to this point can result in loss of vehicle and crew bailout. Unfortunately, shutting an engine down at single-engine press on an RTLS with two stuck throttles can lead to undesirable results.

For the contingency case in which two hydraulic system failures, in addition to another independent failure, result in a three-engine RTLS with two SSME throttles stuck high, it is possible for g forces to get as high as 3.9g. Therefore, if both stuck throttles are above 85 percent, an engine must be shut down before MECO-20 seconds in order to avoid the possibility of exceeding 3.5g. However, analysis has shown that shutting down the nongimballer with 85 seconds of MECO in this scenario leaves more than 2 percent propellant remaining in the ET at MECO, resulting in orbiter/ET recontact after ET SEP. Therefore, MECO-2 minutes was selected as an operationally convenient shutdown cue that would eliminate both the recontact and the g-load concerns. One drawback to shutting down at this point (or any later point) is that guidance commands a large pitch-up. Although the vehicle adequately follows the guidance commands, this pitch transient causes the dedicated displays to pass through the singularity point, degrading the crew's capability to monitor vehicle control. The only way to avoid this pitch transient would be to shut the engine down just after powered pitcharound (PPA), which would extend the time to single-engine press by more than 1 minute, compared to shutting down at MECO-2 minutes. Since the pitch transient is due to a guidance command and not a control problem and since the risk of engine failure due to valve drift was considered to be a greater concern than the momentary loss of crew monitoring capability, it was decided that MECO-2 minutes is the optimal shutdown time. (Reference Ascent/Entry Flight Techniques Panel #105, 10/22/93.)

For the case in which at least one throttle is stuck at or below 85 percent, there is no threat of exceeding 3.5g. Depending on the throttle levels of the stuck engines, it also may not be acceptable, from a performance standpoint, to shut down the nongimballing engine before single-engine press. Since shutting down after single-engine press can result in an undesirable pitch transient and is not required to protect for excessive g-loads, it is preferable to leave all three engines running to MECO for this case. The only risk incurred with this philosophy is that the window of exposure to the failure of a gimballing engine remains open until MECO for this case.

The 85-percent throttle level provides an operationally convenient breakpoint which ensures that a shutdown will never be performed if the engine is needed to achieve the desired MECO targets, while also ensuring that an engine will always be shut down if any threat of exceeding 3.5g exists. For scenarios in which engines are stuck at intermediate throttle settings, acceptable results can sometimes be obtained regardless of whether or not an engine is shut down.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES
(CONTINUED)

For all RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of a early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection. ©[082593-1464C]

C. SHUTDOWN MATRIX:

FAILED HYDRAULIC SYSTEM	NONGIMBALLING ENGINE	ENGINES WITH STUCK THROTTLES
1 AND 3	CENTER	CENTER AND RIGHT
1 AND 2	LEFT	CENTER AND LEFT
2 AND 3	RIGHT	LEFT AND RIGHT

The failure of two hydraulic systems will cause two engines to lock up hydraulically and eliminate TVC capability on one of these two engines. The engine shutdown matrix identifies which engines have lost TVC and/or throttle capability.

Rules {A4-59}, MANUAL THROTTLE SELECTION; {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES); {A5-103}, LIMIT SHUTDOWN CONTROL; and {A2-301}, CONTINGENCY ACTION SUMMARY, reference this rule. ©[092195-1770A] ©[ED]

A8-115

GPS SYSTEM MANAGEMENT

CERTIFIED SINGLE STRING GPS WILL BE CONSIDERED TO BE FUNCTIONING PROPERLY AND AVAILABLE FOR USE DURING ON-ORBIT AND ENTRY OPERATIONS GIVEN THE FOLLOWING CRITERIA: ©[092602-5643]

- A. NO COMMFAULT, HARDWARE, OR POWER FAILURES
- B. NO EXTENDED PERIODS OF HIGH FOM
 - 1. ORBIT FOM LIMITS - CAN BE > 175 FT (FOM > 2) FOR NO MORE THAN 5 MIN.
 - 2. ENTRY FOM LIMITS - CAN BE > 650 FT (FOM > 5) FOR NO MORE THAN 3 MIN.
- C. PERIODS OF TRACKING LESS THAN FOUR SATELLITES LIMITED TO NO MORE THAN 5 MIN.

GPS is certified to be used for on orbit as well as an additional entry navaid with the consideration given to the above criteria for evaluating the status and availability of GPS. The above limits for FOM and periods of tracking less than four satellites were established to meet the requirements for on-orbit state vector maintenance as well as loss of service requirements for entry certification. Antenna pointing, structural blockage, and other constellation and environmental surroundings should be considered as having a possible impact on the GPS's ability to track satellites and maintain low FOM conditions. These specifications will be used to consider mission duration impacts, single-fault tolerance, and zero-fault tolerance for orbit and entry operations. (Ref. AEFTP #176 July 27, 2001, #185 June 28, 2002)

GNC GO/NO-GO CRITERIA (CONTINUED)

NOTES:

- [1] RESERVED
- [2] THE AVAILABILITY OF A GOOD REPLACEMENT UNIT MAY BE USED TO SATISFY THE MINIMUM REQUIREMENTS FOR NEXT PLS OPPORTUNITY. (REPLACEMENT MAY OCCUR SUBSEQUENT TO NEXT PLS DECISION POINT.)
- [3] + X ONLY. REQUIRED ONLY IF RCS DEORBIT REQUIRED.
- [4] EITHER TWO OF THREE PER SIDE OR THREE OF THREE ON EITHER SIDE IS REQUIRED.
- [5] FOR FOUR OR MORE CHANNELS DOWN, REQUIRE ALL SYSTEMS NEEDED FOR AN EMERGENCY AUTOLAND (ADTA, MLS, AA-N₂). REF. RULE {A8-17}, EQUIPMENT REQUIRED FOR EMERGENCY AUTOLAND.
- [6] ROTATIONAL PULSE OR DISC RATE DAP MODE IS REQUIRED IN APPROPRIATE AXES FOR -Z COAS (PITCH AND ROLL) AND HUDS (PITCH AND YAW). @[111298-6750]
- [7] ENGINE IS NO-GO IF TVC CAPABILITY IS LOST AS DEFINED IN RULE {A8-53}, OMS TVC LOSS.
- [8] REF. RULE {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL], FOR MDF AND NEXT PLS. REF. RULE {A2-301}, CONTINGENCY ACTION SUMMARY, FOR FIRST DAY PLS.
- [9] SAME SURFACE.
- [10] REQUIRED ONLY IF COAS AND/OR HUD IS REQUIRED. ANY LOCATION ACCEPTABLE.
- [11] ONE FAILED YAW JET AND ORBITER CG OUTSIDE NOMINAL EOM BOUNDARY IS CAUSE FOR NEXT PLS ENTRY PROVIDED THAT THE CG CANNOT BE RESTORED BY RECONFIGURATION, PAYLOAD DEPLOYMENT, ETC.
- [12] ENTER PLS IF POSITION FEEDBACK FAILURE(S) RESULTS IN TWO FCS CHNLS FAILED. @[102402-5804C]
- [13] RESERVED
- [14] MDF IF SINGLE-FAULT TOLERANCE CAPABILITY EXISTS WITH THE REMAINING ENTRY NAVAIDS (TACAN OR SINGLE STRING GPS) AND COMMAND DELTA STATE CAPABILITY. IF HIGH-SPEED C-BAND RADAR IS NOT SCHEDULED AND NOT AVAILABLE TO BE SCHEDULED FOR ENTRY (REF. RULE {A3-1}, GROUND AND NETWORK DEFINITIONS) THEN DEORBIT NEXT PLS. @[041196-1914] @[092602-5718]
- [15] ENTER NEXT PLS (NOT FIRST DAY PLS) IF ALL FOUR ENTRY NAVAIDS (THREE TACANS AND SINGLE STRING GPS) ARE FAILED AND COMMAND DELTA STATE CAPABILITY EXISTS.
- [16] REFERENCE RULE {A2-207}, LANDING SITE SELECTION, FOR RUNWAY PRIORITIES.
- [17] RESERVED
- [18] RESERVED @[102402-5804C]
- [19] THIS ASSUMES MANUAL CALIBRATION INSTRUMENTS ARE CALIBRATED AND VERIFIED. ANY UNCALIBRATED/UNVERIFIED INSTRUMENT SHOULD BE CONSIDERED FAILED FOR MISSION DURATION DETERMINATION. @[111298-6750]
- [20] N/A FOR MEDS CONFIGURED VEHICLES. @[040899-2459B]
- [21] REFERENCE RULE {A8-115}, GPS SYSTEM MANAGEMENT. @[092602-5718]

Reference Rule {A2-102}, MISSION DURATION REQUIREMENTS.

Rules {A8-4}, FAULT TOLERANCE PHILOSOPHY; {A2-301}, CONTINGENCY ACTION SUMMARY; and {A8-58}, ADI LOSS, reference this rule.

When failure(s) require a next PLS entry but do not require a first day PLS entry, the rationale is that the risks associated with performing a first day PLS entry are greater than those associated with remaining on orbit until the next PLS opportunity.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)****A. CONTROLLERS and SWITCHES**

If necessary or desirable, most entry-critical controllers and switches can be reconfigured in OPS 8 and/or OPS 2 (ref. Rule {A8-6} CONTROLLERS/FCS SWITCHING FAULT TOLERANCE).

LH, RH RHC

For the loss of two RHC channels on the same controller, MDF is required. Subsequent failures can be tolerated on orbit, either by RM or by channel reconfiguration. For four or more RHC channels failed, the next failure results in the loss of at least one RHC, and possibly both. For five channels failed, a next PLS is required since the RHC's are zero-fault tolerant for manual flight of the vehicle. There are no first day PLS requirements for RHC channel failures, since an IFM will be done to recover the failed RHC.

LH THC

There are no first day PLS requirements for the left THC since an IFM will be performed to regain RCS deorbit capability, if required.

AFT RHC, THC

Loss of aft station capability does not require early mission termination since these systems are not available for entry (ref. Rule {A8-9}, AFT STATION GNC REDUNDANCY).

LH, RH RPTA

There are no mission duration impacts. Although manual control capability is desirable, RPTA control is not required for a safe entry.

LH, RH SBTC

For three SBTC channels failed on one side (loss of that SBTC) and one failed on the other side, MDF is required. The next failure, unless a commfault, will result in the loss of manual speedbrake operations. Reference A/E FTP #128, 12/8/95. ©[102402-5804C]

LH, RH BF UP and DN SW

There are no mission duration impacts since the body flap can be manually driven UP for any number of body flap UP/DOWN switch failures. Manual control is only required for off-nominal CG or aero conditions, to use the body flap as a trim device and allow better elevon control authority.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

LH, RH PANEL and RHC TRIM SW

These switches are not considered critical for entry and do not impact mission duration.

LH, RH BFS ENGAGE SW

Failures associated with the BFS engage switches do not require early mission termination (ref. Rule {A8-11}, LOSS OF BFS).

LH, RH FCS MODE AUTO SWITCH

For three or more FCS MODE AUTO switch (PITCH and ROLL/YAW) contacts failed (at least two failed one side, one failed other side), a next PLS is required. The system is zero-fault tolerant since the next failure results in no capability to mode the flight control system to AUTO.

LH, RH FCS MODE CSS SW

Failures in these switches are not considered critical and do not require early mission termination. RHC hot stick (to manual control) is available any time in OPS 3.

LH, RH FCS MODE BF A/M SW

The body flap will be in AUTO under most flight conditions, but manual (MAN) may be required (off-nominal CG or aero conditions). For two BF AUTO/MAN (A/M) switch contacts failed, changing the body flap flight control mode is single-fault tolerant, and MDF is required. For three or more contacts failed (at least two failed one side, one failed other side), a next PLS is required. At least two contacts on each side, or all three contacts on one side, are required to maintain single-fault tolerance on these switches.

LH, RH FCS MODE SB A/M SW

The SB A/M switch is used to mode the speedbrake from MAN to AUTO only, since MAN is achieved with the SBTC takeover switch. If the crew is required to take over MAN speedbrake and subsequent failures result in the loss of capability to mode back to AUTO, the crew can remain in manual with no added workload.

LH, RH SBTC TAKEOVER SW

Reference rationale for LH, RH SBTC rationale.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

ENTRY MODE

This switch is not considered critical for entry. For a failure of the switch during entry (LO GAIN or NO-YAW-JET), the AUTO position can be selected on SPEC 51, OVERRIDE, in MM 304/305.

ABORT MODE SW

This switch is used to select the bailout function and early mission termination is not required.

ORBIT DAP PBI's

If the COAS is required for entry IMU alignment, then MDF is required by definition of COAS/STAR TRACKER requirements. If any of the required switches is zero-fault tolerant (and the COAS is required for entry IMU alignment), then a next PLS will be declared.

B. TVC and DRIVERS

SSME ACT CHNL and SSME SEC DELTA P

These systems are not required for performing a safe entry (impacts to postlanding configuration and turnaround activities only).

SRB ACT CHNL and SRB SEC DELTA P

These systems are not used for entry, and mission duration impacts do not apply.

L, R OMS PITCH and YAW TVC

The two OMS engines and the four +X RCS jets constitute three means of deorbit capability. If failures of the left and/or right OMS TVC in combination with failures of the +X RCS jets result in the loss of two out of three deorbit methods, then a next PLS (or first day PLS) is required (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL], and Rule {A8-3}, LOSS OF GNC SYSTEM).

FORWARD RCS JETS

The forward RCS jets are not considered critical for entry. Reduction of mission duration is not required for failures of these jets.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)**L, R RCS JETS LEFT and RIGHT (YAW JETS)

For one yaw jet failed and the orbiter CG outside of the nominal EOM boundary (ref. Rule {A4-153}, CG PLANNING), a next PLS is required due to the potential for elevon saturation. A full complement of yaw jets is required to ensure vehicle control within the contingency CG envelope. The loss of three yaw jets on the same side results in significantly degraded flight control in the low Q-bar regime ($Q\text{-bar} < 20$ psf). Therefore, a next PLS is required after two yaw jet failures, without regard to vehicle CG. There are no first day PLS requirements for the loss of these jets because the no-yaw-jet mode is certified ($Q\text{-bar} > 20$ psf) for flight control (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]; Rule {A8-19}, YAW JET DOWNMODE; and EFTP, 1/15/88).

L, R RCS VERNIER JETS

The loss of these jets has no impact on mission duration.

L, R RCS JETS UP and DOWN

For the loss of any two jets on the same side that fire in the same direction (two LEFT UP firing, for example), a next PLS (or first day PLS) is required. These jets are critical for vehicle pitch and roll control during entry, and entering next PLS reduces the risk for the next failure which could impact vehicle control (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]).

L, R RCS JETS AFT (+X JETS)

If failures of the left and/or right OMS TVC in combination with failures of +X RCS jets result in the loss of two out of three deorbit methods, then a next PLS (or first day PLS) is required. There are no mission duration requirements for loss of these jets alone (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)

C. AEROSURFACES

FCS CHANNELS

For one channel failed (any surface) the FCS is single-fault tolerant, with the exception of certain “smart failures” during specific windows of entry, and there are no mission duration impacts (ref. Rule {A8-4}, FAULT TOLERANCE PHILOSOPHY). The risk of sustaining a second failure in the FCS affecting the same aerosurface (ASA, MDM, or actuator) while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, MISSION DURATION REQUIREMENTS. After the first failure, there are certain failures in the FCS command channels (ASA, servo valve, actuator) which could reduce flight control margins (2-on-1 force fight) for short periods during entry until the MCC and crew can isolate the bad channel. However, the risk of sustaining one of these failures at the three-level on the FCS command channels during entry is the same regardless of when entry occurs (i.e., the window-of-exposure is the same regardless of flight duration). For two channels failed on the same aerosurface, a next PLS (or first day PLS) will be declared. PLS landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. Loss of three command channels on any aerosurface is an uncertified flight mode. ©[121296-4610] ©[102402-5804C]

BF ACT CHNL

For one of three bodyflap (BF) channels failed, BF control is single-fault tolerant, and there are no mission duration impacts (ref. Rule {A8-4}, FAULT TOLERANCE PHILOSOPHY). The risk of sustaining a second BF channel failure while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, MISSION DURATION REQUIREMENTS. For two channels failed, next PLS is required since BF control is zero-fault tolerant. It is required to maintain control of the BF in order to avoid off-nominal flying configurations and to prevent damage to the main engine bells and/or the body flap itself. There are no first day PLS requirements for BF channel failures. ©[121296-4610]

ELEVON/BF POS FDBK

For two elevon or body flap position feedbacks failed on the same surface, MDF is required since the system is single-fault tolerant. For three feedbacks failed on the same surface, the system is fail critical and a next PLS (or first day PLS) is required. However, if the affected port is bypassed, then the FCS channel loss criteria will apply (ref. A/E FTP #45, 6/17/88).

RUDDER and SPDBK POS FDBK

The position feedbacks for these surfaces are not used in the aerojet DAP but are used for surface position indications on the SPI. Although desirable, these indications are not considered critical for entry and there are no mission duration impacts associated with them. However, if the affected port is bypassed, then the FCS channel loss criteria will apply (ref. A/E FTP #45, 6/17/88).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

ELEVON PRI DELTA P

For two elevon primary delta pressure indications failed on the same surface, MDF is required since the system is single-fault tolerant. For three failed, a next PLS is required because the system is zero-fault tolerant. The effector system requires at least one primary pressure feedback loop in an actuator since the ASA relies on these pressure indications to provide command stability (ref. SODB, volume I, paragraph 3.4.5.1-4).

SECONDARY DELTA P

The aerosurface and SSME/SRB actuator secondary delta pressure transducers provide fault detection (RM) in the ASA's and ATVC's, respectively. If RM is lost, the system can still be managed (MCC required) and any failed channels can be manually bypassed if required. FCS channel loss criteria will apply for transducer failures that degrade the FCS performance/redundancy.

D. SENSORS

LATERAL AA

For two lateral axis AA's failed, an MDF is required and, for three failed, a next PLS (or first day PLS), is required. Landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. The lateral axis AA feedback is used in the aerojet DAP for turn coordination by preventing rolloff during bank maneuvers. The lateral feedback is also used for NWS control during rollout (ref. A/E FTP #45, 6/17/88). ©[102402-5804C]

NORMAL AA

The normal AA feedback is used for ADI pitch error and alpha error indications only prior to MM 305. In MM 305, the normal AA feedback is used by guidance to provide Nz commands to the flight control system. However, failures in these feedbacks do not require reduction in mission duration because the crew can fly CSS in the pitch axis in MM 305, thereby removing the normal feedback from the command loop.

ORBITER RGA

For two orbiter RGA's failed, MDF is required because the system is single-fault tolerant on orbit. For three failed, a next PLS (or first day PLS) is required because the system is zero-fault tolerant on orbit. Landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. (ref. A/E FTP #45, 6/17/88). ©[102402-5804C]

SRB RGA

These systems are not used for entry, and mission duration impacts do not apply.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-1001****GNC GO/NO-GO CRITERIA (CONTINUED)****IMU**

*For the loss of one IMU, the system is single-fault tolerant, with the exception of certain “smart failures” during specific windows of deorbit and entry, and there are no mission duration impacts (ref. Rule {A8-4}, **FAULT TOLERANCE PHILOSOPHY**). The risk of sustaining a second IMU failure while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, **MISSION DURATION REQUIREMENTS**. Also, high-speed C-band radar is mandatory for entry at the IMU two-level (ref. Rule {A3-1}, **GROUND AND NETWORK DEFINITIONS**). There are single-point failures that can result in either an unresolvable dilemma at the two-level, or bad selected data due to a transient output which is not present long enough for IMU RM to operate and declare a failure. For these cases, the onboard state vector and/or vehicle flight control could be significantly impacted during critical deorbit or entry phases. However, the risk of sustaining one of these failures at the two-level during entry is the same regardless of when entry occurs (i.e., the window-of-exposure is the same regardless of flight duration). Additionally, it is expected that the IMU entry two-level redundancy management (RM), including the use of BITE, will correctly isolate and reconfigure the system (prime selecting the good IMU) for at least 98 percent of all failures. For two IMU’s failed, a next PLS (or first day PLS) is required. The system is zero-fault tolerant because navigation and flight control require one IMU for entry. Landing site selection will be determined per Rule {A2-207}, **LANDING SITE SELECTION**. ©[041196-1914] ©[121296-4610] ©[ED] ©[102402-5804C]*

STAR TRACKER/COAS/HUD ©[111298-6750]

*If only one instrument for aligning the IMU’s remains, enter next PLS. It is important to note that in considering the availability of manual alignment instruments, an instrument can only be considered available if it has been calibrated and verified. An instrument that is not calibrated and verified should not be used to perform IMU alignments. Only the CDR HUD is considered calibrated at launch (except on OV-104). This calibration should be verified before using the HUD to perform IMU alignments. Refer to Flight Rule {A8-108}, **HUD/COAS SYSTEM MANAGEMENT**.*

The only exception to the PLS rule is the case where the -Z COAS is the only instrument remaining for performing IMU alignments. Since the probability of a COAS failure is considered extremely remote (COAS is a simple mechanical apparatus), the mission can be extended beyond next PLS to MDF.

If a manual alignment instrument is required, it is necessary to have the appropriate digital auto pilot (DAP) modes available. The DAP modes are required to allow the crew to mark accurately on a star. ©[111298-6750]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)ATT REF PB

The ATT REF PB is required for IMU alignments using the COAS or HUD. If the COAS and/or HUD is required for the entry and only a single ATT REF PB remains, a next PLS is required. It should be noted that only the forward station ATT REF PB's are supported in OPS 3; and, if only the aft PB remains, the alignment will have to be performed in OPS 2. ©[111298-6750]

TACAN AND SINGLE STRING GPS

*For three of four Entry Nav aids (TACAN's and/or Single String GPS) failed, the system is single-fault tolerant (assuming command delta state capability exists), and MDF is required. For three of four LRU's failed, enter next PLS if high-speed C-band radar is not scheduled and not available to be scheduled for entry (ref. Rule {A3-1}, **GROUND AND NETWORK DEFINITIONS**). For all four Entry Nav aids failed, a next PLS is required to protect for the loss of CONUS site capability. Entry with no TACAN's or GPS could require a GCA and/or a command delta state uplink to correct navigation errors, and declaring next PLS minimizes exposure to landings that do not have these options. Consideration must be given to Data and Power Bus configurations to ensure that fault tolerance exists for remaining TACAN and GPS LRU's. If fault tolerance does not exist, then a PLS landing is required (ref. EFTP #28, #29, #30, #176, #185). ©[041196-1914] ©[092602-5718]*

TACAN MODE SW, ANT SEL, CHNL SEL

The TACAN mode switch, antenna select, and channel select are not critical for entry. If the switch failures render the TACAN(s) unusable, then the TACAN loss criteria will apply.

ADTA

*For two ADTA's failed, the system is zero-fault tolerant and MDF is required. With the next failure (three ADTA's failed), air data (AD) will not be incorporated into G&C except for specific off-nominal circumstances, and a next PLS (or first day PLS) is required. Landing site selection will be determined per Rule {A2-207}, **LANDING SITE SELECTION**. The incorporation of AD to G&C is required for auto flight control and very desirable for manual. It is highly desirable to protect against the last ADTA failure so that it can be used if necessary. Without AD, the crew will fly theta limits for pitch control (ref. A/E FTP #45, 6/17/88, ENTRY FTP #34, 8/21/87, and A/E FTP #187, 9/20/02). ©[102402-5894C] ©[102402-5804C] ©[102402-5804C]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)MSBLS

There are no requirements for early mission termination for MLS failures, since in most cases a safe landing can be performed without the use of MLS (ref. Rule {A8-18}, LANDING SYSTEMS REQUIREMENTS). However, for one MLS failed and MLS redundancy required (ref. Rule {A3-202}, MLS), high-speed C-band radar should be scheduled as required (ref. Rule {A3-1}, GROUND AND NETWORK DEFINITIONS). ©[041196-1914] ©[ED]

RA

The radar altimeters are used for altitude source from 5k feet to the ground and are highly desirable for night landings and/or low ceilings. However, there are no mission duration impacts for RA failures. (Ref. Rule {A8-18}, LANDING SYSTEMS REQUIREMENTS.) ©[072398-6646]

E. DEDICATED DISPLAYS

LH & RH ADI

Declare MDF when only one forward ADI remains since only a single display source of bank angle (phi) and vehicle rates and errors remains. Bank angle is required during MM 304 for controlling drag and H-dot in the event of bad guidance. Similarly, vehicle rates and attitude errors are required in the event of guidance or flight control problems. Given the availability of replacement units for both the ADI and DDU (aft station), two failures are required in order to have only a single remaining ADI in the forward station.

AFT ADI

There is no requirement for this display during entry. (Ref. Rule {A8-9}, AFT STATION GNC REDUNDANCY.)

HUD/AMI

Equivalent air speed (EAS), displayed on the HUD and AMI, is a critical parameter from TAEM to touchdown. As a result, declare PLS for loss of three of the four sources for this parameter, and MDF for loss of two of the four sources for this parameter.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)HUD/AVVI

Altitude (H), displayed only on the HUD and AVVI from TAEM to touchdown, is a critical parameter required by the pilot during the approach and landing phases of the entry. Thus, declare PLS for loss of three of the four sources for this parameter, and MDF for loss of two of the four sources for this parameter.

While H-dot, displayed only on the AVVI in MM 304, is an important parameter, early flight termination will not be declared for the loss of one AVVI. It is not reasonable to declare early flight termination to protect for the extremely remote scenarios (if they exist at all) where H-dot would be required to fly a manual MM 304 entry.

HUD/FWD ADI

Phi (bank angle) and one of gamma (flight path angle) or theta (pitch) are required from TAEM through the approach phase of entry. These parameters are only available to the pilot on the HUD and forward ADI. Thus, declare PLS for loss of three of the four sources for these parameters, and MDF for loss of two of the four sources for these parameters.

HUD

The HUD is highly desirable but not mandatory for night landings; therefore, an MDF is not required.
©[111298-6750]

HSI

For low ceilings (<10k feet) or night landings, the HSI is desirable, but not required, for accurate heading and course information. Since MLS is required under both of these situations, accurate approach information is available. In addition, rough course alignment and heading is provided by the Horizontal Situation Display (HSD). As a result, early flight termination is not required for loss of HSI(s). (Ref. Rules {A8-18}, LANDING SYSTEMS REQUIREMENTS; {A3-202}, MLS; and {A2-6}, LANDING SITE WEATHER CRITERIA [HC].)

SPI and G-METER

Though desirable, these displays are not required.

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES

AC POWER DISTRIBUTION AND CONTROL SYSTEMS MANAGEMENT

A9-151 AC INVERTER MANAGEMENT

NORMALLY, ALL AC INVERTERS AND BUSES WILL BE POWERED DURING FLIGHT. IF AN INVERTER FAILS, IT WILL BE DISCONNECTED FROM BOTH THE AC AND DC BUSES.

All nine ac inverters are utilized by orbiter equipment. The dc power to a failed inverter will be disconnected since the inverter could act as a load. Also, the output capacitor acts as a load of 2.95 amps on the other two phases of the ac bus supplying power to coupled three-phase loads (ac motors).

A9-152 AC BUS SENSORS SWITCH MANAGEMENT

TO PRECLUDE INADVERTENT AC BUS DISCONNECT, THE AC BUS SENSORS WILL BE PLACED IN THE "MONITOR" POSITION DURING ASCENT (UNTIL MM 105). ALSO, DURING ASCENT PRIOR TO MECO, IF ANY AC PHASE BUS FAILS, OR IF A MAIN ENGINE SHUTS DOWN, OR IF AN SSME CONTROLLER LOSES REDUNDANCY, THEN ALL THREE AC BUS SENSOR SWITCHES WILL BE PLACED TO "OFF". POST OMS-1, THE AC BUS SENSORS WILL NOMINALLY BE PLACED IN "AUTO TRIP" AND REMAIN IN THAT POSITION FOR THE REMAINDER OF THE FLIGHT (THROUGH WHEEL STOP). @[110900-3510]

AC sensors are put to MONITOR during powered flight to prevent an inadvertent tripoff that would cause SSME controller auto switchover from the affected bus to a secondary SSME controller on another ac bus. If a main engine shuts down, or SSME controller redundancy is lost, or a failure occurs in the AC system, the ac sensor switches will be put to OFF so that no failure in the ac bus sensor could cause further complications. If a failure occurs in an AC system during the entry timeframe, the affected AC bus sensor can be taken "OFF" to protect for critical equipment redundancy. @[110900-3510]

Rule {A5-111A}, AC BUS SENSOR ELECTRONICS CONTROL [CIL] references this rule. @[ED]

A9-153 AC BUS LOADING

WHEN POSSIBLE, AC BUS LOADING WILL BE SELECTED TO PROVIDE SEPARATE POWER SOURCES TO REDUNDANT EQUIPMENT AND TO BALANCE BUS LOADS.

The highest level of power redundancy should be maintained. It is advisable to maintain near equal loading on all buses in the event that, if a single FC powers two main buses, it will not be overstressed.

FLIGHT RULES

A9-154

AC LOAD MANAGEMENT DURING ASCENT

- A. ONLY THE FOLLOWING AC SWITCHABLE LOADS, WHOSE RECOVERY CANNOT BE DELAYED UNTIL POST-MECO, MAY BE RECONFIGURED PRE-MECO:
1. FREON PUMPS (IF ONLY ONE FREON LOOP AFFECTED, SWITCH WITHIN 6 MINUTES; IF BOTH FREON LOOPS AFFECTED, SWITCH ASAP)
 2. RAD BYPASS VALVES (ONLY FOR LOSS OF FES OR FREON LOOP(S) AFFECTED)
 3. RAD ISOLATION VALVES (FOR AN UNEXPLAINED LEAKING LOOP ATTEMPT ISOLATION ASAP; IF LEAK RATE CAN SUPPORT MECO AND AC CRITICAL, DELAY ACTION UNTIL POST-MECO) @[040899-2568A]
 4. AVIONICS BAY FANS (SWITCH WITHIN 3 MINUTES IF A POWERED GOULD TACAN IS LOCATED IN AFFECTED AV BAY. IF AV BAY 3A UPGRADED FOR ENHANCED COOLING, THE FAN WILL NOT BE SWITCHED.)
 5. OMS/RCS VALVES
 6. APU/HYD WSB CONTROLLER (ONLY AFTER HIGH TEMP FDA ALERT)
 7. H₂O LOOP PUMPS (ONLY IN THE EVENT OF AVIONICS AIR TEMP FDA)
 8. CREW SEAT OPERATIONS (ONLY IF CONSIDERED MANDATORY BY THE CREW) @[040899-2568A]
- B. AC CIRCUIT BREAKERS WHICH HAVE OPENED WILL NOT BE RESET PRE-MECO UNLESS THE FUNCTION IS CRITICAL AND:
1. THE MCC HAS CONFIRMED THAT THE CB(S) DID NOT OPEN BECAUSE OF A SHORT, OR:
 2. THE MCC CONFIRMS THAT BOTH SSME CONTROLLERS ON THE AFFECTED BUS HAVE BEEN LOST, OR:
 3. LOSS OF THE FUNCTION IS CONSIDERED TO BE A GREATER RISK THAN LOSS OF THE TWO AFFECTED SSME CONTROLLERS.

CRYO

a. Continue Nominal Ascent

If all but one of the cryo tanks fails during ascent, an abort is not required because the remaining tank will support a first day PLS entry.

b. Invoke Minimum Duration Flight

If a single tank fails, the amount of consumables will determine the length of the mission. After a single tank failure, at least two more failures are required before loss of crew/ vehicle.

c. Enter Next PLS

If two tanks fail, a PLS is called because the risk has increased that similar failures will occur in the remaining tanks. Loss of cryo is loss of crew/vehicle.

FLIGHT RULES

A10-23

APU ENTRY START TIME (CONTINUED)

B. AN APU WILL HAVE ITS ENTRY START TIME DELAYED FOR THE FOLLOWING:

FAILURE/CONSTRAINT	START TIME
1. LOSS OF WSB COOLING CAPABILITY	TAEM
2. APU LUBE OIL OUTLET OR GEARBOX BEARING TEMPERATURES EXCEEDED LIMITS SPECIFIED IN RULE {A10-22F}, APU START/RESTART LIMITS, DURING ASCENT	NO EARLIER THAN TAEM (IF NEEDED TO MAINTAIN TWO SYSTEMS)
3. APU WILL ONLY OPERATE WITH THE AUTO SHUTDOWN FUNCTION INHIBITED	TAEM (UNLESS NEEDED EARLIER TO MAINTAIN TWO SYSTEMS)
4. APU DOES NOT HAVE GG INJECTOR COOLING (IF APPLICABLE TO SINGLE APU ONLY)	EI-13
5. GEARBOX OR GN ₂ REPRESS BOTTLE HAS KNOWN EXTERNAL LEAK WHICH WILL NOT SUPPORT ENTIRE ENTRY OR GN ₂ REPRESS VALVE IS FAILED CLOSED	NO LATER THAN MACH 1.0
6. HYDRAULIC SYSTEM LEAK	NO EARLIER THAN TAEM BASED ON LEAK RATE
7. FREON LEAK INTO A HYDRAULIC SYSTEM	TAEM
8. HYDRAULIC SYSTEM RESERVOIR PRESSURE LOST	AFTER OTHER APU'S RUNNING AT NORMAL PRESSURE
9. HYDRAULIC SYSTEM RESERVOIR TEMPERATURE > 162° (154°) F PRIOR TO DEORBIT APU START.	TAEM

@[051194-1619B] @[ED] @[ED]

1, 2. *The loss of lube oil cooling will limit APU run time to approximately 11 minutes, based on data from previous flights. The time period from TAEM through landing is more critical for APU/hydraulic system availability since the system will be needed for heavy aerosurface activity, landing gear deployment, and braking during that period.*

If WSB cooling was lost for the hydraulic fluid (due to a failure of the bypass valve), the impact to the system is not so much overheating of the hydraulic system, but rather possible premature depletion of the water supply for the water boiler, resulting in the loss of APU cooling. Bypass valve failures during entry on STS-7 and STS 61-C caused significant depletion in the water supply. The hydraulic fluid temperature sensors demanded spraying, but the bypass valve failure did not allow the fluid to receive any cooling and spraying continued. The APU start time should be delayed to move the time at which the hydraulic fluid temperatures will demand spraying to as close to TAEM as possible.

Reference Rule {A10-22F}, APU START/RESTART LIMITS.

3. *Since inhibiting the auto shutdown logic does remove one layer of protection, starting the APU at TAEM will reduce the amount of time this protection is not present. However, if another APU/ hydraulic system is failed or failing, this APU may be started earlier than TAEM to maintain two systems. In this case, it would not be necessary to start the APU any earlier than EI minus 13 minutes.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-23

APU ENTRY START TIME (CONTINUED)

4. *If an APU is started at TIG minus 5 minutes and then a one-orbit waveoff is declared, the APU will have to be shut down. Without injector cooling, this APU could not be restarted to support entry as it would not have had time to cool (reference Rule {A10-22A}, APU START/RESTART LIMITS). For this case, the APU should be started after the deorbit burn as a waveoff is no longer a possibility.*

5. *If gearbox GN₂ leakage occurs, the GN₂ repressurization bottle will repressurize the gearbox at APU start. GN₂ will leak, requiring further represses and eventually depleting the bottle. By delaying the start of the APU until Mach 1.0, atmospheric pressure would prevent further leakage from the gearbox while the APU is running and actually would tend to back pressurize the gearbox. It is not possible to distinguish between an oil leak and a GN₂ leak when the APU is not running. If the drop in pressure is due to oil leakage, low oil pressure will be seen at startup, bearing temperatures will rise rapidly, and the APU will have to be shut down.*

If the GN₂ bottle develops a leak or the repress valve fails closed, typical GN₂ leakage from the gearbox may not support the entire entry. In this case, delay the start of the APU until it will support through wheelstop or Mach 1.0, where atmospheric pressure will prevent GN₂ leakage from the gearbox. With an evacuated repress bottle, if a gearbox repress is required, the valve will come open and the oil/GN₂ from the gearbox will flow into the bottle. The pressure would equalize at a lower value, the valve will remain open, and the oil/GN₂ will continue to leak. Below Mach 1, the repress valve most likely will not be activated. If it is, there will be some atmospheric pressure in the bottle that will reduce the amount of flow from the gearbox. ©[021199-6814]

Reference Rules {A10-1A}.5, APU LOSS DEFINITIONS, and {A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE.

6. *See Rule {A10-72}, HYDRAULIC LEAKS, for rationale.*

7. *Analysis by RI/Downey has determined that when Freon and hydraulic fluid are mixed, the bulk modulus of the hydraulic fluid is maintained within an acceptable range as long as fluid temperatures are limited to below 150 deg F. To prevent excessive temperature buildup in a hydraulic system with a Freon leak into it, the associated APU start should be delayed until no earlier than TAEM. The temperature rise from TAEM to wheelstop is not expected to exceed 100 deg F. ©[021199-6814]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-122 LOSS OF WSB(S) ACTIONS (CONTINUED)

2. FOR DEPLOYABLE PAYLOAD FLIGHTS, PAYLOAD DEPLOY AND/OR JETTISON WILL BE SCHEDULED TO ALLOW FOR DEORBIT ON DAY 2.

The loss of a WSB system does not indicate the immediate loss of an APU/hydraulic system, though the APU can only run about 11 minutes before reaching temperature limits. The APU associated with the lost WSB will be started late during entry to support landing (reference Rule {A10-23}, APU ENTRY START TIME). Assuming the other APU/hydraulic/WSB systems are good, three APU/hydraulic systems will be available to support the latter part of entry and landing.

For the loss of two WSB's, entry should be made at the next PLS opportunity after deployable payloads have been deployed. It is desirable to deploy the payloads since this will improve the vehicle capability to maneuver and land safely if an APU or hydraulic system fails during entry. Jettison of deployable payloads that, for some reason, cannot be deployed should be considered as a means of last resort to improve the vehicle entry and landing capability.

If the APU/hydraulic system not associated with the lost WSB's fails or if the remaining WSB fails, one of the APU/hydraulic systems with limited run time must be started. Starts and restarts of both limited lifetime APU/hydraulic systems must be managed to allow for at least one system running at all times. Accomplishing this may be an impossible task if the good APU/hydraulic system fails at the worst possible time, i.e., prior to the deorbit burn. A next PLS entry should be performed for the loss of two WSB's in order to minimize the amount of time the vehicle is exposed to the next failure that would result in the orbiter being down an APU/hydraulic system and two water spray boilers.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

A10-123 THROUGH A10-140 RULES ARE RESERVED

FLIGHT RULES

LANDING/DECEL SYSTEMS MANAGEMENT

A10-141

NOSE WHEEL STEERING (NWS)

- A. NWS IS DEFINED AS "REQUIRED" IF IT IS NEEDED TO MAINTAIN DIRECTIONAL CONTROL DURING ROLLOUT: @[102402-5804C]
1. FOR RTLS/TAL/AOA (KSC) LANDINGS.
 2. AT ANY LANDING SITE IF THERE ARE KNOWN DIRECTIONAL CONTROL PROBLEMS (MLG OR NLG TIRE PREDICTED TO BE BELOW THE MINIMUM ACCEPTABLE PRESSURE AT TOUCHDOWN, UNCOMMANDED BRAKE PRESSURE, OR PEAK CROSSWINDS ABOVE THE SURFACE WIND LIMITS).

EFFORTS WILL BE TAKEN TO REGAIN NWS AS SPECIFIED IN THE REFERENCED FLIGHT RULES.

NWS provides the most effective means of preventing runway departure at any site where lateral margins are very limited, especially if a subsequent directional control problem develops. Ames VMS testing (July/August 1988, May/June 1989) demonstrated that differential braking and rudder inputs may not always provide adequate directional control capability when directional control problems are known to exist, even for runways with wide lateral margins. The forward position of the nose wheel provides a long moment arm (relative to the vehicle CG) for very effective vehicle steering. Therefore, NWS can overcome high frictional forces that may develop between a flat tire and a runway surface and also overcome the high frictional forces caused by uncommanded brake pressure. Moreover, excessive energy dissipated through differential braking can lead to subsequent loss of tire pressure (overtemperature of fuse plugs, post wheelstop). In all cases, NWS is much more effective for directional control than differential braking. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-141 NOSE WHEEL STEERING (NWS) (CONTINUED)**

B. NWS WILL BE TURNED OFF FOR ENTRY IF, DURING THE OPS 8 CHECKOUT, TWO OF THREE STEERING POSITION TRANSDUCERS DO NOT INDICATE -0.42 ± 0.31 VOLTS (GROUND) OR 0.0 ± 0.75 DEGREES (ONBOARD). @[102402-5804C]

The NWS system requires at least two good steering position transducers for reliable nose wheel position SOP operation. If none of the steering position transducers have been comm faulted (all three inputs available), the nose wheel position SOP will midvalue select from the three position transducer values, regardless of their failure status. If one transducer is failed or biased, one of the two good transducers will always yield the midvalue of the three, and the SOP will always select a good value. If two transducers are failed or biased, one of these two may yield the midvalue, and the SOP would then select an erroneous value. However, Ames VMS data (July/August 1988) confirmed that, for this scenario, the selected value will exceed the nose wheel position comparison limits when compared against the DAP-commanded nose wheel position and rate. The nose wheel position SOP will then generate a nose wheel position error and downmode to castor. @[102402-5804C]

C. NWS1 WILL BE USED AS THE PRIMARY MEANS OF DIRECTIONAL CONTROL. IF NWS1 HAS FAILED: @[102402-5804C]

1. BEFORE NGTD: NWS2 WILL BE SELECTED AND USED AS THE MEANS OF DIRECTIONAL CONTROL.
2. POST-NGTD: NWS2 CAN BE SELECTED AND USED AS THE MEANS OF DIRECTIONAL CONTROL.

Although both NWS1 and NWS2 modes of nosewheel steering provide identical functions and capabilities, NWS1 provides more downlisted system status parameters; NWS1 is, therefore, preferred over NWS2. @[102402-5804C]

If NWS is determined to be failed during the OPS 8 checkout or anytime prior to nose gear touchdown (ground speed enable flag set true), selecting NWS2 will provide the best alternative for rollout directional control. Ames VMS testing (July/August 1988) demonstrated that switching NWS modes during rollout was an effective procedure, particularly for MDM hardover failure cases.

However, SAIL testing (April 1991) demonstrated that for certain scenarios where the NWS1 channel downmoded to free castor (post-NGTD), the NWS system did not recover after selecting NWS2. In these cases, the NWS2 channel was selected coincident with a large rudder pedal command (DR 100737 and 106206). The NWS system was never perceived to have recovered as it downmoded to castor unnoticeably 240 milliseconds after selection. Although the NWS software may not recover if the alternate NWS channel is selected on rollout, NWS2 can still be safely selected post-NGTD and is likely to regain control if a large rudder pedal input is not present at selection. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-141 NOSE WHEEL STEERING (NWS) (CONTINUED)**

- D. NWS WILL BE TURNED OFF FOR LOSS OF ANY OF THE FOLLOWING, UNLESS NWS IS REQUIRED: @[102402-5804C]
1. TWO LATERAL AA'S
 2. TWO LEFT OR TWO RIGHT RPTA CHANNELS
 3. RIGHT DDU (TWO POWER SUPPLIES - A, B, OR C)
 4. TWO STEERING POSITION TRANSDUCERS @[102402-5804C]

Once two lateral AA's or RPTA's have failed, there are potential vehicle control risks if NWS is selected. A hardover or high bias of one of these remaining components could result in loss of vehicle control. For runways with wide lateral margins, where differential braking and rudder inputs can provide adequate vehicle control, the use of NWS is not warranted at the risk of a third AA or RPTA failure, provided there are no known directional control problems. However, for abort landing sites (without wide lateral margins), the risk of runway departure due to a subsequent directional control problem outweighs the potential for a third AA or RPTA failure during the small window of rollout, and NWS should be selected.

Results of a NWS test matrix performed using the NASA Ames VMS in May/June 1991 indicate that vehicle control can be difficult to nonrecoverable after a third AA or RPTA hardover failure has occurred (Cooper/Harper ratings from 5 to 10). The matrix also demonstrated that, although landing with a known directional control problem (failed tire) without NWS is unsatisfactory (Cooper/Harper ratings between 5 and 8), this condition is sometimes controllable. Again, the risk of runway departure due to a known directional control problem outweighs the potential for a third AA or RPTA failure during rollout, and NWS should be selected. @[102402-5804C]

FLIGHT RULES

SECTION 11 - COMMUNICATIONS

SYSTEM MANAGEMENT RULES

A11-1 COMMUNICATIONS DURING ASCENT

THERE ARE NO COMMUNICATIONS FAILURES FOR WHICH THE ASCENT PHASE WILL BE TERMINATED.

Termination of the ascent phase implies an immediate return; i.e., an RTLS, AOA, or TAL/TPL. Continuing to orbit is the most benign environment for the orbiter and crew. In addition, there is a high probability of restoring at least one communications link once on orbit; and, if communication is not restored, the orbiter is capable of a safe day 1 return without any further contact with the MCC.

A11-2 S-BAND/UHF LAUNCH REQUIREMENT

S-BAND PM VOICE WILL BE PRIME FOR LAUNCH. THE UHF SYSTEM WILL BE CONFIGURED IN TRANSMIT/RECEIVE MODE AS BACKUP TO THE S-BAND PM SYSTEM.

The S-band PM system is the only system available for launch that can provide redundant real-time telemetry, command, ranging, and duplex voice required for ascent phase support. SSME engine interface unit (EIU) data uses the S-band FM system and is redundantly recorded on Ops recorder 1. C-band skin tracking provides a redundant tracking source, and the UHF system provides an additional simplex voice source.

FLIGHT RULES

A11-3

UPLINK HANDOVER DURING ASCENT FROM KSC

UPLINK HANDOVER FROM MIL TO PDL WILL OCCUR BEFORE THE LINE-OF-SIGHT FROM THE ORBITER TO MIL INTERSECTS THE SRB PLUME. THE CARRIER WILL REMAIN ON PDL UNTIL POST-SRB STAGING. AT THAT TIME IT WILL BE HANDED BACK TO MIL TO REGAIN S-BAND TRACKING.

During ascent it is highly desirable to provide S-band ranging data to the MCC as an additional tracking source for trajectory evaluation. S-band ranging is available from MIL/MILX but not PDL. Ascents from KSC necessarily result in the line-of-site from the orbiter to MIL/MILX intersecting the SRB plume. The SRB plume characteristics are such that severe S-band attenuation (approaching 60 dB) and erratic phase shifts will adversely affect the S-band PM link, resulting in poor uplink lock conditions and intermittent downlink data. To avoid the plume, the orbiter antennas are optimized for PDL from lift-off and the uplink is handed to PDL just before plume intersection until after SRB staging. This loss of S-band ranging and somewhat weaker signal margin during this time period is considered preferable to intermittent S-band uplink and downlink lock conditions, since downlink vectors and C-band tracking are still available for trajectory monitoring. ©[092602-5734]

A11-4

ORBITER DATA PRIORITY DURING ASCENT/ENTRY

ORBITER DATA WILL TAKE PRIORITY OVER PAYLOAD DATA DURING ASCENT/ENTRY. PCMMU SWITCHES FOR THE PURPOSE OF RECOVERING ORBITER DATA WILL BE PERFORMED AT THE EXPENSE OF PDI PAYLOAD DATA.

OI MDM port failures and internal PCMMU failures affecting downlink or crew display of orbiter data can be recovered by power cycling the active PCMMU or by switching to the alternate PCMMU. During ascent/entry phases, when the SM major function for PCMMU reloading is unavailable, the PDI data downlinked to the MCC would be lost as the PCMMU defaults to Format 129 upon powerup and this format allocates no bandwidth to PDI data. The intent of this rule is to document that monitoring of orbiter data during ascent/entry takes precedence over remoting payload data to remote POCC's. PDI data displayed to the crew will not be affected.

FLIGHT RULES

A11-11

S-BAND FM USAGE

- A. THE S-BAND SYSTEM SHALL BE REQUIRED TO TRANSMIT MAIN ENGINE DATA DURING ASCENT PHASE.

The S-band FM system provides the only real-time source of main engine interface unit (EIU) high rate data. It is sufficiently important enough to require downlinking in real time as well as being redundantly recorded onboard.

- B. FOR THE REMAINDER OF THE FLIGHT, THE S-BAND FM SYSTEM WILL BE USED FOR TV, OPS RECORDER DUMPS, SOLID STATE RECORDERS DUMPS (SSR), REAL-TIME PAYLOAD DATA, AND PAYLOAD RECORDER DUMPS.

@[102402-5735]

The S-band FM system provides a wideband downlink to GSDTN sites (not for TDRS) which can be configured for any one of several inputs (e.g., Ops or Payload recorder dumps, SSR's, TV, and real-time analog, or digital payload data). Individual mission requirements will dictate when these inputs will be required to use the FM system for a particular flight and what the time-sharing plan will be.

@[102402-5735]

FLIGHT RULES

A11-12

S-BAND PM USAGE

- A. THE S-BAND PM SYSTEM 2 LRU'S WILL NOMINALLY BE SELECTED VIA COMMAND FOR THE ENTIRE FLIGHT. ONBOARD SWITCHES WILL BE IN THE SYSTEM 1 LRU CONFIGURATION.

Since the S-band system is the prime orbiter communications system, it is desirable that switchover capability to the redundant system be reachable from the CDR or PLT seats during ascent/entry and other high activity phases. The design of panel and command hybrid driver logic within the GCIL allows the entire S-band PM system (NSP, XPNDR, antenna electronics, Power Amp, Pre Amp) to be switched to the redundant string with a single switch on panel C3. The redundant string is selectable via the panel C3 switch (nominally string 1). The choice of system 1 or 2 is arbitrary; however, the Flight Data File has long been written assuming this configuration.

- B. THE GROUND WILL BE PRIME FOR OPERATION OF THE S-BAND PM SYSTEM.

The orbiter S-band PM system must be configured differently for TDRS, GSTDN or SGLS modes continuously as required during the flight. This is a routine, repetitive task necessary during both crew awake and crew sleep periods in order to maximize data retrieval and is best done by MCC to free the flightcrew for more mission-unique tasks. Additionally, through telemetry indications from the orbiter and using voice reports and other indications from TDRS, GSTDN, and SGLS sites, the MCC has better overall visibility into the total air/ground communications network and is better suited for operating the total system, especially during non-nominal conditions.

- C. S-BAND PM ANTENNA MANAGEMENT WILL BE VIA GPC AUTOMATIC ANTENNA SELECTION.

S-band PM antenna management can be done either manually by the crew or ground or via GPC automatic selection. As long as the GPC's knowledge of attitude and position is accurate, it is less error prone to enable automatic selection. This has the added benefit of greatly reducing crew or ground workload for what is largely a routine function.

FLIGHT RULES

A11-13

S-BAND PAYLOAD USAGE

- A. THE S-BAND PAYLOAD SYSTEM 1 LRU'S WILL NORMALLY BE USED TO SUPPORT PAYLOAD OPERATIONS. ONBOARD SWITCHES WILL MATCH THE DESIRED CONFIGURATION.

The S-band payload system consists of redundant PI/PSP strings. Although there are exceptions on some flights, the flightcrew is typically much more involved with the usage of this system than in the S-band PM system, the management of which is primarily a ground function. The switch setup for S-band PM is unmatched from that commanded so that the crew need throw a minimum number of switches to restore communications in the event of onboard failure. In the case of the S-band payload system, it is preferable to have the switches match the commanded configuration so that the crew can easily track the current status since they are the prime system operators.

- B. THE S-BAND PAYLOAD INTERROGATOR (PI) CHANNEL SELECT THUMBWHEELS WILL BE CONFIGURED SO THAT INADVERTENT PI ACTIVATION WILL NOT INTERFERE WITH THE S-BAND PM SYSTEM. THE STANDARD SETTING FOR ASCENT/ENTRY SHALL BE CHANNEL 910.
@[102402-5737]

Although the PI may be unpowered, a single-point failure exists that can inadvertently result in PI activation. Should this occur when the selected channel is one that interferes with the S-band PM uplink or downlink, a loss of uplink or downlink PM lock may occur disrupting the prime mode of communications. The cause of this unexpected disruption would be difficult to detect, result in confusion, and the workaround would not be obvious even if the alternate UHF link were available. Therefore, it should be avoided. Channel 910 is safe for ascent/entry since it cannot cause any interference. @[102402-5737]

FLIGHT RULES

A11-14 CREW ALERT SPC'S

DURING TIME PERIODS WHEN ALL CREWMEMBERS SLEEP SIMULTANEOUSLY, A CREW ALERT SPC WILL BE ROUTINELY USED TO ALERT THE CREW TO COMMUNICATIONS SYSTEMS PROBLEMS. THE SPC WILL TIME OUT APPROXIMATELY HALFWAY THROUGH THE SLEEP PERIOD IN THE EVENT OF A LOSS OF UPLINK COMMAND.

The crew alert commands result in an onboard class 3 alarm. When loaded into the SM SPC buffer during time periods when all crewmembers are sleeping, it can be used to alert the crew that uplink S-band command and probably voice capability has been lost. The crew alert commands are uplinked at the beginning of a sleep period and timetagged to execute midway through the sleep period. Should no loss of command occur, these commands are cleared from the SPC buffer before execution. If uplink command is lost, it is possible that uplink voice or even downlink voice and telemetry may be lost as well since common components are used. Single-point failures in the S-band PM system exist making this possible. UHF provides a redundant voice source but is often deactivated during crew sleep periods due to ground interference. Therefore, the crew alert commands are used to warn the crew of a possible loss of all monitoring capability and all communications capability. This is considered serious enough to wake the crew.

A11-15 ELBOW CAMERA/PAYLOAD INTERFERENCE [CIL]

FOR THOSE MISSIONS WHERE AN ELBOW CAMERA/PAYLOAD INTERFERENCE PROBLEM EXISTS, THE ELBOW CAMERA WILL NOT BE ACTIVATED UNLESS THE INTERFERENCE PROBLEM IS ELIMINATED. THIS APPLIES EVEN IF THE RMS IS DEPLOYED.

FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT RULES ANNEX.

Due to the geometry of the elbow camera 25-degree mounting wedge when the MPM is stowed, the maneuvering envelope of the camera intrudes upon the maximum payload envelope. A potential interference problem exists with a payload manifested at the same X location as the elbow camera. The interference could prevent stowing the MPM's and require an RMS jettison or EVA to close PLBD's.

FLIGHT RULES

A11-16

KU-BAND MANAGEMENT

THE ORBITER KU-BAND SYSTEM WILL BE OPERATED IN THE "BETA PLUS MASK" MODE WITH A LIMIT OF 21 DEGREES UNLESS A PAYLOAD EXTENDS BEYOND THE PAYLOAD BAY DOOR ENVELOPE. IN THIS CASE, FLIGHT-SPECIFIC KU MASKING IS DEFINED IN RULE {A2-325}, IFM PROCEDURES ON EXPERIMENTS WITH TOXIC HAZARDS. ©[ED] ©[102402-5742]

The Ku-band masking is used to protect a payload in the payload bay from the Ku main beam RF radiation. A limit of 21 degrees in the "Beta Plus Mask" mode will protect the entire bay up to the payload bay door moldline and prevent any part of the bay being exposed to a level greater than 10 volts per meter (the ICD limit). This masking mode also provides the maximum comm coverage while still providing the required protection. ©[102402-5742]

If a payload instrument is present which extends beyond the payload bay door moldline, then this masking may not protect the payload from levels higher than the ICD level. The required mode and beta limit is then dependent on the location of the payload in the bay and on the dimensions of the payload. Thus, the limit must be calculated for the specific mission case. ©[102402-5742]

Note that the beta mask function does not apply to Ku radar operation. The radar mode uses the old microprocessor mask which is equivalent to beta plus mask with a limit of -90 degrees. This is more restrictive (i.e., more protection) than 21 degrees. ©[ED]

Rule {A2-118}, RNDZ/PROX OPS COMMUNICATION SYSTEMS MANAGEMENT, references this rule. ©[061396-1961]

FLIGHT RULES

A11-17

PI CHANNELS AND S-BD FREQUENCIES COMPATIBILITIES

IN ORDER TO PREVENT MUTUAL INTERFERENCE BETWEEN THE PAYLOAD INTERROGATOR (PI) AND THE S-BAND PM SYSTEM, THE FOLLOWING PI CHANNELS AND S-BAND PM FREQUENCIES COMPATIBILITY TABLE WILL BE FOLLOWED FOR ALL PI OPERATIONS: @[090894-1648B]

COMPATIBLE PI CHANNELS AND S-BAND PM FREQUENCIES	
WHEN USING PI CHANNEL	USE S-BAND PM FREQUENCY
001-407	HIGH
408-433	NOT COMPATIBLE WITH LOW OR HIGH *
434-883	LOW
899-909	HIGH
910-920	LOW

* PI INTERFERENCE WITH SSA FORWARD LINK TEST SHOWS THAT THERE IS A POTENTIAL FOR DEGRADED SSA FORWARD LINK ACQUISITION AND; THEREFORE, THIS PI/S-BD PM COMBINATION (408-420/421-433) WILL NOT BE USED. EXCEPTIONS MAY BE MADE ON A FLIGHT SPECIFIC BASIS BY DETAILED ANALYSIS.

The S-Band PM system and Payload Interrogator selectable frequencies overlap and if not properly selected could interfere with each other. The consequence of selecting channels other than those noted in the table above are unknown and potentially compromise S-Band PM communications and/or communications with a detached payload. Reference ESTL report EE7-93-214. @[090894-1648B]

A11-18

COMSEC USAGE

IN ORDER TO PROTECT THE ORBITER FROM UNAUTHORIZED COMMANDS, THE S-BAND SYSTEM UPLINK WILL NORMALLY BE ENCRYPTED FOR ALL FLIGHTS.

Configuring the S-band uplink for encryption protects against unauthorized commands being received via both the S-band and Ku-band systems as the COMSEC equipment interfaces with the NSP which is common to both systems. Uplinks bypassing the NSP can still be received via the alternate (216 kbps) Ku-band channel, but this channel (intended for OCA and high rate payload data) does not interface with the GPC's or other critical orbiter systems. @[111298-6778] @[012402-5068]

FLIGHT RULES

A11-59

FM SYSTEM IFM GROUND RULE

FOLLOWING A CONFIRMED LOSS OF DOWNLINK IN ONE S-BAND TRANSPONDER, CONSIDERATION WILL BE GIVEN TO IMPLEMENTING AN IFM PROCEDURE TO ALLOW THE USE OF THE FM SYSTEM AS A REDUNDANT TELEMETRY SOURCE FOR ENTRY.

Following a transponder loss, no redundancy remains for downlink telemetry. The IFM regains this redundancy using the FM system, and implementation of the IFM should be considered prior to entry. The IFM procedure to allow the use of the S-band FM system for downlink voice and telemetry results in disconnecting flight cables and terminating the use of one of the Ops recorders. The NSP's must be switched when real-time and dump data share the FM downlink. This is compatible only with ground stations, not TDRS. For these reasons it is desirable to troubleshoot the transponders to determine alternate capabilities before considering the IFM which nominally requires about 2-1/2 hours of crew time. As transponder troubleshooting necessarily requires a ground station or TDRS to confirm status, the ground should direct the procedure rather than the crew if the remaining capability makes this feasible. The ground is required because compatible configurations are necessary onboard and at the STDN to ensure valid checks.

A11-60

LOSS OF TDRS TRACKING CAPABILITY

LOSS OF TDRS TRACKING CAPABILITY WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of TDRS tracking would require call up of contingency use S-band tracking stations that are obligated to provide support in the event of such an orbiter or ground system failure. These stations, supplemented as required by C-band radars, can provide satisfactory support to continue nominal orbital operations and entry preparations.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-61

LOSS OF S-BAND PREAMPS AND POWER AMPS

LOSS OF BOTH S-BAND PREAMPLIFIERS AND/OR BOTH POWER AMPLIFIERS WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of either both preamps or both power amps results in loss of all TDRS S-band capability. Ku-band still remains but does not provide a tracking source and is unavailable following antenna stowage during deorbit prep. A total loss of TDRS S-band would require call up of the contingency ground stations that are obligated to provide support in the event of such an orbiter failure. These stations would be a combination of the NASA Spacecraft Tracking and Data Network (STDN), DOD remote tracking stations (RTS), and C-band radars. These stations can provide satisfactory support to continue nominal orbital operations and nominal entry preparations. ©[102402-5741]

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-62

LOSS OF ANTENNA ELECTRONICS

THE FLIGHT WILL BE CONTINUED FOR LOSS OF THE S-BAND ANTENNA ELECTRONICS.

Loss of both S-band antenna electronics results in the inability to select S-band antennas (i.e., only one antenna could be used). All communications functions would remain, but severe attitude constraints would have to be imposed to maintain TDRS S-band. TDRS Ku-band would be unaffected, and ground station (GSTDN) S-band would be slightly degraded due to reduced (but still acceptable) circuit margins. Since the attitude timeline would be affected, it is reasonable to assume that mission activities would be impacted. As long as productive mission objectives can still be accomplished, the mission need not be shortened. Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-65

AUDIO CENTRAL CONTROL UNIT (ACCU)

THE ACCU IS CONSIDERED LOST IF TWO-WAY VOICE ON THE FOLLOWING LOOPS IS INOPERABLE:

- A. AIR/GROUND 1.
- B. AIR/GROUND 2.
- C. AIR/AIR.

These are the only loops that interface with the communications equipment (both air/ground and EVA). Only Intercom and Page loops remain. Therefore, a subsequent failure in the alternate ACCU would result in the loss of all orbiter communications. One-half of the ACCU BYPASS IFM (J4) should be performed as described in Rule {A11-66}, LOSS OF ACCU's.

Rule {A11-66}, LOSS OF ACCU's, references this rule.

FLIGHT RULES

A11-66

LOSS OF ACCU'S

- A. FOR THE LOSS OF ONE ACCU, ONE-HALF OF THE ACCU BYPASS IFM (J4) WILL BE PERFORMED AS SOON AS PRACTICAL AND THE NOMINAL FLIGHT COMPLETED. IF UNSUCCESSFUL A NEXT PLS LANDING WILL BE PERFORMED.

Refer to Rule {A11-65}, AUDIO CENTRAL CONTROL UNIT (ACCU).

- B. FOR THE LOSS OF BOTH ACCU'S, THE IFM WILL BE COMPLETED AND AN MDF WILL BE PERFORMED.

The primary difference between A and B above is that loss of an ACCU is only loss of one source of redundancy while loss of total IFM is loss of two sources.

Loss of one ACCU is one failure away from loss of all air/ground voice. The IFM, when installed, provides two sources of air/ground voice. Implementing the J4 half of the IFM allows normal use of the remaining ACCU but with the following lost capabilities:

1. PS, OS, and AIRLOCK ATU's.
2. TACAN 3 tones.
3. C&W B tones via ACCU (Middeck Speaker Unit). @[102402-5743]
4. NSP 2 voice record channel 1.
5. NSP 1 voice record channel 2.
6. NSP 1 Air/Ground 2 loop.
7. PLT ATU is limited to only the Air/Ground 1 loop in NSP 2 and only in hot mike mode.

The extent of these lost capabilities is of minor mission impact and does not constitute grounds for shortening the mission. For vehicles 103 and 104 only one crewmember in the airlock will have hardline communications which has a minor procedural impact. Should the remaining ACCU fail after the J4 IFM, the CDR and PLT ATU's (only) will still retain an S-band communications capability although it will be nonredundant. The IFM should then be completed restoring dual S-band communications redundancy. Since redundancy is available, an immediate (next PLS) landing is not necessary, but the dwindling communication capabilities justify that the flight be continued only until MDF.

Rule {A11-65}, AUDIO CENTRAL CONTROL UNIT (ACCU), references this rule.

FLIGHT RULES

A13-155

ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

E. LEVEL 0

THE FLIGHT DECK CREW WILL TURN OFF THE CABIN AND IMU FANS.
THE CLEANUP CREW WILL TAKE ACTIONS a AND b LISTED IN
PARAGRAPH B.

A level-0 substance may or may not be containable by the crew. Crew exposure would result in only slight transient (less than 30 minutes) irritation.

No protective gear is required.

See paragraph B, level-3 rationale, for the reason for stopping the airflow in the spill area.

If the spill is not containable by the crew, the MCC will determine other procedures for containment or for a workaround.

All payload substances are reviewed by the Payload Safety Review Panel; those not listed as level-4 through 1 are considered nonhazardous (level 0).

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE

@[092701-4872]

THE FLIGHT-SPECIFIC ANNEX WILL LIST ALL EXPERIMENT/SAMPLES CONTAINING LEVEL-4 THROUGH LEVEL-1 PAYLOAD HAZARDOUS SUBSTANCES. REFERENCE RULE {A13-154}, HAZARDOUS SPILL LEVEL DEFINITIONS. THE FOLLOWING ACTIONS WILL BE TAKEN IN THE EVENT THAT A HAZARDOUS SUBSTANCE IS RELEASED INTO THE SPACEHAB/ORBITER ATMOSPHERE. @[111501-4971]

A. LEVEL 4

1. ORBITER

REFERENCE RULE {A13-155A}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. THE CREW SHALL SAFE AND ISOLATE THE SPACEHAB MODULE PER RULE {A2-329}, SPACEHAB DEACTIVATION/ENTRY PREP. @[ED]

A level-4 hazardous substance is defined as either a gas, a volatile liquid, or fumes that are not containable by the crew. Crew exposure could result in a systemic toxicity, severe irritation, and/or tissue damage. The driving factor that distinguishes a level-4 substance from a level-3 substance is noncontainability.

The immediate priorities for a level-4 spill in the orbiter are prevention of crew exposure to the substance and configuration of the atmospheric revitalization system (ARS) for environmental scrubbing. All crewmembers will don and activate Quick Don Masks to avoid any detrimental effects.

The Spacehab module cannot be used as a safe haven for the crew because the module ARS is incapable of controlling humidity, O₂, N₂, and CO₂ concentrations.

2. SPACEHAB MODULE

IF HAZARDOUS SPILL OCCURS IN THE SPACEHAB MODULE, EVACUATE ALL CREWMEMBERS TO THE ORBITER EXCEPT THE SAFING CREW. THE FLIGHTDECK CREW WILL TURN OFF ALL SPACEHAB FANS. THE EVACUATING CREW WILL CLOSE THE MAN PL ISOL VLV. THE SAFING CREW WILL PERFORM THE FOLLOWING ACTIONS: @[021600-7102A]

- a. DON/ACTIVATE SEBS
- b. OPEN CABIN DEPRESS VALVE (CDV)
- c. EVACUATE THE MODULE
- d. CLOSE THE SPACEHAB HATCH

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-11

EXPEDITED POWERDOWN

AN EXPEDITED POWERDOWN IS DEFINED TO ALLOW ACCOMPLISHMENT OF ET DOOR OPENING (RTLIS/TAL ONLY), OMS/RCS-SAFING, NOMINAL GPC POWERDOWN FOLLOWED IMMEDIATELY BY AN EMERGENCY POWERDOWN. ©[012402-5079]

AN EXPEDITED POWERDOWN AND MODE V CREW EGRESS WILL BE ACCOMPLISHED FOR:

- A. LOSS OF ALL COMMUNICATIONS (INCLUDING VISUAL SIGNALS AND MCC RELAY) BETWEEN CREW AND CONVOY ELEMENTS.

NOTE: RULE {A16-8}, CREW EGRESS METHOD DETERMINATION (FOR MODE V EGRESS) GOVERNS THE MODE V EGRESS METHOD THE CREW WILL USE. ©[041196-1881A]

Crew safety could be compromised with the loss of communication between the crew and convoy personnel. Possible orbiter problems that occur during landing and rollout not reflected in orbiter systems would not be available to the crew (i.e., tire fire, explosive/flammable conditions, etc.).

- B. LOSS OF ALL TELEMETRY (MCC AND LCC) AND ONBOARD SYSTEMS MONITORING (BFS, C&W PANEL, AND FDA) VISIBILITY. IF COMM IS AVAILABLE TO CREW, MCC WILL DETERMINE IF MODE V IS REQUIRED.

As long as insight into critical vehicle systems and communication with the crew are maintained, normal postlanding operations can continue. Critical systems information is available at KSC (LCC) that allows the LCC to be an acceptable source for orbiter systems monitoring.

- C. A NONISOLATABLE OMS, RCS, OR APU FUEL LEAK OR FOR AN ISOLATED LEAK WHEN THERE HAS BEEN INSUFFICIENT TIME FOR FUEL SUBLIMATION (RTLIS, TAL, AOA, OR POST-DEORBIT IGNITION). FOR THESE CASES, A MODE V CREW EGRESS WILL BE IMPLEMENTED. RCS JET LEAKS AND APU SEAL CAVITY DRAIN LEAKS ARE EXEMPTED FROM THIS CATEGORY.

Leaking OMS, RCS, or APU fuel poses a toxicity and fire hazard. An expedited powerdown should be performed in order to minimize the danger to the flightcrew and ground operations personnel. If a fuel leak occurs and is isolated during an RTLIS, TAL, AOA, or post-deorbit ignition, there is insufficient time for the fuel to sublimate, and an expedited powerdown is prudent.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A16-11 EXPEDITED POWERDOWN (CONTINUED)**

An isolated RCS jet leak does not pose a risk to the orbiter/crew with continued postlanding operations. In the event of an APU fuel pump seal failure, the APU seal cavity drain dumps hydrazine overboard. Once the APU is shut down, the leak is isolated.

Rules {A16-10C} and D, NORMAL POSTLANDING OPERATIONS, and {A6-206}, RCS MANIFOLD/LEG LEAK PRESSURIZATION, reference this rule. [ED]

- D. A CONFIRMED OR SUSPECTED FIRE FOR WHICH A FIRE SUPPRESSION BOTTLE HAS BEEN DISCHARGED DURING ENTRY.

Vehicle damage can pose hazards to crew safety after a fire is extinguished, especially if its location is unknown. Wires melted together could cause any number of hazards (e.g., inadvertent GPC commanding causing fuel valves to open, etc.). In addition, if the fire occurred in an avionics bay several hours (minutes for a cabin fire) before landing, the crew should exit the vehicle to avoid breathing Halon and toxic combustion byproducts which slowly leak out of the avionics bay and panels.

- E. A NON-ISOLATABLE H₂ LEAK GREATER THAN 6.5 LB/HR (5.5 LB/HR FOR SPACEHAB/PAYLOAD RETURN).

Leaking H₂ poses a possible fire hazard in the midbody. An H₂ concentration of 4 percent represents the lower ignitable limit of H₂ (deflagrates or burns rapidly).

Rule {A16-205F}, EARLY APU SHUTDOWN, references this rule. [072398-6577]

Normally, KSC is prime for recommending an expedited powerdown/crew egress based on detected H₂ concentrations. For known H₂ leaks prior to touchdown, this rule identifies the H₂ leak rate criteria to be used by MCC in determining whether an expedited powerdown/crew egress should be performed prior to KSC assessment (i.e., for large leaks). These leak rates are based on a 4 percent concentration 35 minutes after wheels stop.

For leak rates below 6.5 (5.5) lb/hr, KSC is prime for determining whether or not an expedited powerdown is required, based on actual detection of H₂. The MCC H₂ leak rate prediction is based on the initial size of the leak once detected, a homogenous mixing in the midbody, and no consideration for venting or leakage of H₂ from the midbody at wheel stop.

DOCUMENTATION: ECLS Console Handbook, SCP 4.6.2, and KSC OMI S0026, Revision L.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-11

EXPEDITED POWERDOWN (CONTINUED)

F. AN INCOMPLETE MPS LH₂ DUMP (NEGATIVE INERT) OR FAILURE TO PRESSURIZE THE MPS LH₂ MANIFOLD ABOVE ATMOSPHERIC PRESSURE ON AN RTLS OR TAL ABORT. ©[012402-5079]

Failure(s) in the MPS LH₂ system during the MPS dump and inert will result in an incomplete LH₂ dump (negative inert) on RTLS and TAL aborts. Analysis (reference Rockwell Internal Letter no. 287-100-94-186 dated October 12, 1994) has shown that the loss of a dump path or the loss of helium pressurization (during the MPS dump) will trap between approximately 0.8 to 40.8 pounds of LH₂ residuals in the MPS LH₂ manifold depending on the specific scenario. Loss of a dump path may be caused by failure of one of the following LH₂ valves: outboard or inboard fill/drain valve, backup dump valves, topping valve, pre valve, or SSME fuel bleed valve. Loss of helium pressurization may be caused by numerous reasons such as: relief isolation valve fails closed, relief valve fails open, inboard fill/drain fails open, clogged orifice, etc. In these failure cases, concern exists for crew and convoy safety because analysis (reference Boeing Internal Letter SHA0-01-043 dated April 26, 2001) predicts the MPS LH₂ manifold will exceed its relief setting and venting of hydrogen residuals (potentially explosive mixture) will occur as early as 10.8 minutes after touchdown. In addition, nominal leakage in the MPS system could lead to the buildup of an explosive mixture of hydrogen in or around the aft compartment.

©[012402-5079]

After discussion at the Ascent/Entry Flight Techniques Panel (AEFTP #168 on October 27, 2000) and subsequent discussions with KSC ground operations and KSC safety, it was decided that the appropriate action for MPS dump failures on RTLS and TAL aborts is to perform an expedited powerdown. Rationale for this decision is based on the potential hazard to the flight crew and ground personnel due to uncertainties in the hazards of the trapped hydrogen residuals. Although, residuals due to a failure in the MPS system on a TAL abort can be lower than the residuals on a nominal RTLS abort, an expedited powerdown will still be performed on the TAL because of the limited ground operations equipment available to assess and manage the situation at the TAL site. Expedited powerdown actions are not required for AOA aborts or nominal missions because sufficient time exists on orbit to fully inert the MPS LH₂ manifold of all LH₂ residuals.

©[012402-5079]

After discussion at the AEFTP Meeting (AEFTP #168 on October 27, 2000) and subsequent discussions with KSC ground operations and KSC safety, it was also decided that the failure to pressurize the MPS LH₂ manifold above atmospheric pressure on RTLS and TAL aborts would result in the ingestion of air into the LH₂ manifold resulting in the creation of an explosive mixture (reference Boeing Internal Letter SHA0-01-043 dated April 26, 2001). The hazards of an explosive mixture in the MPS manifold that the flight crew and ground operations personnel would be exposed to are difficult to quantify. However, these hazards represent an unnecessary risk, and, therefore, this scenario warrants an expedited powerdown.

Rules {A5-210}, ENTRY MPS PROPELLANT DUMP FAILURES, {A5-201}, MPS DUMP INHIBIT [CIL], and {A5-209}, ENTRY MPS HELIUM PURGING FOR CRITICAL VEHICLE POWER/COOLING, reference this rule. ©[030994-1604B] ©[030994-1617] ©[090894-1730A] ©[012402-5079]

©[ED]

FLIGHT RULES

A16-12

EMERGENCY POWERDOWN

AN EMERGENCY POWERDOWN WILL BE IMPLEMENTED POST-ROLLOUT FOR THE FOLLOWING CONDITIONS OR AS REQUESTED BY THE FLIGHT DIRECTOR OR CONVOY COMMANDER :

An emergency powerdown will be performed if Orbiter systems cannot support continued operations or if orbiter conditions compromise crew safety. The normal egress mode is preferred if allowed by system conditions. Loss of cooling will allow an orderly egress to continue.

If conditions exist that compromise crew safety (fire, smoke, explosive conditions, etc.), a MODE V egress is warranted. Based on knowledge of Orbiter conditions and systems indications, the Flight Director and Convoy Commander are able to recognize problems and recommend the appropriate action/egress mode.

A. NORMAL EGRESS (SIDE HATCH, CONVOY CREW ASSIST) :

1. LOSS OF BOTH FREON COOLANT LOOPS.

If both loops are lost, the emergency powerdown is required because there is absolutely no cooling of the vehicle. The fuel cell stack temperature will reach the specification limit of 250 degrees F within approximately 50 minutes. In addition, the electrolyte concentration will reach the 25 percent operational limit in approximately 75 minutes. At this point, continued operation of the fuel cells is questionable. This assumes a simultaneous purge of all three fuel cells and a 12.54 kWh (4.18 kWh/fuel cell) power level. If the failure occurred on orbit, the situation would be time-critical postlanding. Purging H₂ into the atmosphere should be avoided if at all possible (ref. Rule {A16-301}, CONTAMINATION/ FLAMMABILITY/TOXICITY). Without the purge, the fuel cells will flood in approximately 18 minutes based on an 8.0 kWh (2.67 kWh/fuel cell) power level (ref. Rules {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]; and {A2-205}, EMERGENCY DEORBIT). Upon completion of the emergency powerdown, a normal crew egress can be performed.

DOCUMENTATION: Dual Freon Loop Failure Entry Analysis, Rockwell International IL 388-301-79-018, and SODB table 3.4.4.1-1.

2. LOSS OF BOTH H₂O COOLANT LOOPS.

If both loops are lost, the emergency powerdown is required because there is no cooling to water and air cooled equipment in the cabin. If the failure occurred on orbit, avionics equipment and GPC's would be cycled to their thermal limits in order to maintain as much redundancy as possible during critical mission phases. Since this failure scenario does not contain any hazard to the crew, an orderly, normal egress can be accomplished.

DOCUMENTATION: MDTSCO analysis 1.1-ECLSS-09, Dual Water Coolant Loop Failed Entry Contingency.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A16-12****EMERGENCY POWERDOWN (CONTINUED)**

3. LOSS OF BOTH NH₃ SYSTEMS WHEN CRITICAL TEMPERATURES ARE (RULE {A16-51}, NO GROUND COOLING/EARLY VEHICLE POWER TERMINATION) EXCEEDED.

Postlanding, orbiter cooling is provided by the heat sink capacity remaining from the on-orbit radiator coldsoak, the NH₃ system, and the ground-cooling cart. In the event that the ground-cooling cart is not available, NH₃ must supply the cooling once the radiator coldsoak has been used. Therefore, subsequent loss of both NH₃ systems will eventually lead to loss of all vehicle cooling, and loss of all vehicle cooling has the same result as described in the loss of both Freon loops in paragraph A.1.

DOCUMENTATION: Engineering judgment.

B. MODE V EGRESS:

1. WHEEL WELL FIRE OR BRAKE FIRE THAT POTENTIALLY WILL PROPAGATE TO THE WHEEL WELL. EGRESS WILL BE BASED ON CONVOY COMMANDER RECOMMENDATION.
2. EXPLOSIVE/FLAMMABLE CONDITIONS (REF. RULE {A16-301}, CONTAMINATION/FLAMMABILITY/TOXICITY).
3. SMOKE, FIRE, OR OBVIOUS STRUCTURAL DAMAGE.
4. INTOLERABLE CABIN CONDITIONS.

NOTE: RULE {A16-8}, CREW EGRESS METHOD DETERMINATION (FOR MODE V EGRESS) GOVERNS THE MODE V EGRESS METHOD THE CREW WILL USE. @[041196-1881A]

It is preferable to perform a normal egress. However, if cabin conditions warrant, a MODE V egress may be performed. An emergency powerdown should be implemented for the conditions listed in paragraph B1, 2, 3 above in order to eliminate electrical ignition/isolate volatile propellant sources that could make the vehicle anomalous condition worse. A confirmed MPS LH₂ leak is considered to be an explosive/flammable condition (ref. rule {A5-201}, MPS DUMP INHIBIT [CIL]). @[030994-1604B]
@[ED]

DOCUMENTATION: Engineering judgment.

Rule {A16-10E}, NORMAL POSTLANDING OPERATIONS, references this rule.

FLIGHT RULES

A16-13 **SIDE HATCH OPENING CONSTRAINT**

IF CABIN PRESSURE EXCEEDS LANDING SITE ATMOSPHERIC PRESSURE BY MORE THAN 3.2 PSID, THEN THE CABIN VENT VALVES WILL BE USED TO DEPRESSURIZE THE CABIN TO BRING THE PRESSURE DIFFERENTIAL BELOW 3.2 PSID BEFORE ATTEMPTING TO OPEN THE SIDE HATCH.

An unisolatable leak into the cabin could result in cabin pressure being as much as 16 psid greater than landing site atmosphere pressure (the cabin relief valves relieve at 16 psid). Rockwell International has verified side hatch structural capability to vent excess cabin pressure postlanding only as high as 3.2 psid. The 3.2 psid pressure differential was selected for verification because it is the maximum expected to be encountered at the highest altitude landing site (White Sands) under normal cabin pressure conditions.

DOCUMENTATION: Side Hatch Structural Capability to Release Cabin Pressure Following Rollout, Rockwell International Internal Letter No. 280-106-82-016, May 7, 1983.

A16-14 THROUGH A16-50 RULES ARE RESERVED

FLIGHT RULES

A16-204

WINDWARD APU OPERATION CONSTRAINT

TO AVOID EXCEEDING VERTICAL TAIL STRUCTURAL TEMPERATURE LIMITS, THE WINDWARD APU(S) WILL NOT BE OPERATED LONGER THAN THE ALLOWABLE POSTLANDING APU RUN TIME, OBTAINED FROM THE POSTLANDING OPERATIONS PLOT.

If the postlanding run time exceeds the allowable run time, vertical tail overtemperature and subsequent structural damage can occur if the APU plume has ignited. There are no constraints to run time if the APU plume has not ignited; however, due to the difficulty in visually determining whether the plume is burning or not, the worst case is assumed.

Reference SPDB 3.2.1.1.

FLIGHT RULES

A16-205

EARLY APU SHUTDOWN

AN APU (OR APU'S) WILL BE SHUTDOWN ASAP POST-WHEEL STOP:

- A. IF A FUEL OR OXIDIZER LEAK IS SUSPECTED OR DETECTED IN THE MPS, OMS, RCS, OR ANY APU, EVEN IF THE LEAKS HAVE BEEN ISOLATED (DOES NOT APPLY FOR RCS JET LEAKS). ©[030994-1604B]

The requirements for APU operations postlanding, SSME repositioning, and hydraulic load test are not considered mandatory. In cases where fuel or oxidizer leaks are suspected or detected, the APU's should be shut down ASAP to reduce chances of the leak developing into a greater flammability hazard, brought on by the operation of hot, rotating machinery. Note that an APU fuel tank N₂ leak is considered a fuel leak.

APU's will not be shut down early for RCS jet leaks since these types of leaks are isolated and external to the orbiter. No flammability hazard exists for continued APU operations with known RCS jet leaks.

Rules {A5-201}, MPS DUMP INHIBIT [CIL], and {A6-206}, RCS MANIFOLD/LEG LEAK PRESSURIZATION, reference this rule. ©[030994-1604B] ©[ED]

- B. IF A FIRE IS OBSERVED IN A WHEEL WELL OR TIRE/BRAKE AREA. THE HYDRAULIC LANDING GEAR EXTEND AND BRAKE ISOLATION VALVES WILL BE CLOSED PRIOR TO SHUTTING DOWN THE APU'S.

A fire in the wheel well or landing gear area could involve hydraulic fluid. Closing the landing gear isolation valves will isolate the fluid from the gear area, thus preventing any further feeding of the fire. The APU's should be shut down in an effort to reduce high-pressure flow of hydraulic fluid to the gear area should an isolation valve fail to close.

- C. IF THERE IS A NON-ISOLATABLE LEAK IN ITS ASSOCIATED HYDRAULIC SYSTEM.

The APU should be shut down postlanding to minimize hydraulic leakage into the aft compartment. Postlanding operations requiring hydraulic power are not mandatory and can be performed if there are two remaining good systems.

- D. IF THE APU SHIFTS TO HIGH SPEED WITH NORMAL SPEED SELECTED.

The APU should be shut down postlanding to protect against a possible uncontained overspeed. Postlanding operations requiring the APU's are not mandatory and can be performed if there are two remaining good systems.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-254

CABIN O2 CONCENTRATION (CONTINUED)

The 36-hour decision point for which upper limit to apply to oxygen concentration at 8.0 psi is arbitrary. A reason for having two upper limits while at 8.0 psi is to avoid extended operations at high O₂ concentration levels. Leak rates which allow less than 36 hours will be large enough to keep the oxygen concentration from remaining above 35 percent for long periods of time. (Ref. Rule {A13-53A}.2, MINIMUM PPO2 CONSTRAINTS.). @[090894-1673A]

Documentation: PRCB PCIN 41004, NASA TR-255-001.

Rules {A17-53}, FIRE AND POST-FIRE ACTIONS; and {A13-152C}, CABIN ATMOSPHERE CONTAMINATION, reference this rule.

FLIGHT RULES

A17-255

8 PSIA EMERGENCY CABIN CONFIGURATION

THE 14.7 PSIA CABIN REGULATOR INLET VALVES WILL BE CLOSED AND THE CABIN WILL BE ALLOWED TO BLEED TO 8 PSIA ONLY IF: @[090894-1673A]

- A. CABIN LEAK: O₂/N₂ CONSUMABLES ARE INSUFFICIENT TO ALLOW THE ORBITER TO EFFECT A NEXT PLS ENTRY AT 14.7 (10.2 IF ALREADY IN 10.2 PSIA OPS) PSIA CABIN PRESSURE PLUS A 24-HOUR FLIGHT EXTENSION AT 8 PSIA.

Operation at 14.7 psia is preferred because, at 8 psia, a powerdown is required and the crew must wear the LES helmet. However, if inadequate consumables exist to allow both a 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin pressure to the next PLS opportunity and 1 extension day at 8 psia, the cabin will be immediately reconfigured to the 8 psia emergency configuration (i.e., 14.7 cabin regulators closed and associated powerdowns performed).

If it is determined that enough consumables exist to allow the 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin pressure to the next PLS plus the 24-hour extension day at 8 psia, then the 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin will be maintained to the next PLS opportunity to attempt a normal entry. If entry cannot be performed at the PLS opportunity, then the cabin must be reconfigured to the 8 psia emergency configuration for the remainder of the mission and an entry performed prior to consumables depletion @[090894-1673A]

DOCUMENTATION: Engineering judgment.

Rule {A17-254}, CABIN O₂ CONCENTRATION, references this rule.

- B. CABIN/AV BAY FIRE OR LEVEL 4 HAZARDOUS SPILL: THE CREW IS REQUIRED TO WEAR THE LES/QD, FOR AN EXTENDED PERIOD OF TIME TO PROTECT THEMSELVES AGAINST A CONTAMINATED CABIN ATMOSPHERE. @[090894-1673A]

A cabin depress to 8 psi and continuous purge at 8 psi will manage O₂ concentration below maximum levels as well as decrease the concentration of discharged Halon and any potentially toxic gases that were produced by a fire or hazardous elements that were spilled into the cabin atmosphere. This action could extend the time on orbit so as to avoid an ELS entry (ref. Rule {A17-53}, FIRE AND POST-FIRE ACTIONS, and {A13-155}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE). @[ED]

DOCUMENTATION: Engineering judgment @[090894-1673A]

Rule {A17-254}, CABIN O₂ CONCENTRATION, references this rule.

FLIGHT RULES

A17-256**O₂ BLEED ORIFICE MANAGEMENT**

THE O₂ BLEED ORIFICE WILL BE INSTALLED IN AN LEH VALVE QUICK DISCONNECT (QD), PRESLEEP ON FLIGHT DAY 1, IF PPO₂ LEVELS ARE BELOW 3.20 PSIA AND REMOVED DURING DEORBIT PREPARATION ACTIVITIES ON ENTRY DAY.

The O₂ bleed orifice, sized specifically for metabolic consumption of O₂ based on crew size, is installed to keep the 14.7 cabin regulator inlets in the low flow region of the regulator. This eliminates nuisance O₂/N₂ FLOW HIGH alarms caused by WCS cycles and O₂/N₂ flow switchovers. Normally, the bleed orifice is installed presleep on flight day 1, if PPO₂ levels permit. Due to oxygen introduced into the cabin via LES flow during ascent, however, the PPO₂ may be elevated to such a degree that bleed orifice installation is not necessary until postsleep on flight day 2. Delaying the installation will allow metabolic consumption to lower PPO₂ to nominal levels.

The bleed orifice is not used during ascent/entry since the PCS system is deactivated and there is no concern of generating nuisance flow alarms.

DOCUMENTATION: Flight data.

A17-257**N₂ SYSTEM MANAGEMENT**

BOTH N₂ SYSTEMS WILL NORMALLY BE OPERATED AS ONE SYSTEM.

Nominal operations for N₂ systems 1 and 2 has both systems fully open (i.e., supply valves, regulator inlet valves, etc.) so N₂ will be depleted simultaneously from all tanks. One of the drawbacks of operating both nitrogen systems as a single system is the possibility of losing more than one system's nitrogen quantity in the event of a massive tank leak. However, by operating both systems fully open, the risk is removed of a supply valve failing closed and cutting off one N₂ system for the remainder of the mission. The likelihood of a supply valve failing closed is considered greater than the possibility of a massive tank leak, and therefore the system is operated to protect against failure of one, or both, of the N₂ supply valves failing closed. Also, by depleting nitrogen equally from both systems, the quantity of N₂ remaining in a good system is maximized.

DOCUMENTATION: Engineering judgment.

Rule {A17-202B}, 8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY, references this rule.

FLIGHT RULES

A17-258

LOSS OF CABIN INTEGRITY T_{MAX} DEFINITION AND TIG SELECTION

- A. T_{MAX} IS DEFINED AS THE LATEST DEORBIT TIG THAT WILL ALLOW A LANDING BEFORE THE DEPLETION OF N_2 CONSUMABLES. IF CONSUMABLES WILL BE DEPLETED BEFORE A PLS LANDING, AN ELS LANDING WILL BE EFFECTED.
- B. THE MINIMUM ACCEPTABLE CABIN PRESSURE PRIOR TO ATMOSPHERIC REPRESSURIZATION IS 8 PSIA. THE PCS SHALL BE CONFIGURED TO MAINTAIN 8 PSIA. NOTE: EXTENDED TIME ON ORBIT AT A LOWER CABIN PRESSURE WILL BE SACRIFICED TO MAINTAIN A CABIN PRESSURE OF 8 PSIA.
- C. A DEORBIT TIG FOR LOSS OF CABIN PRESSURE INTEGRITY SHALL OCCUR AT OR BEFORE T_{MAX} .

T_{max} is defined as the deorbit TIG that synchronizes touchdown with the depletion of N_2 consumables. Note that T_{max} is independent of landing site availability and does not account for cooling certification violations due to loss of cabin pressure.

The T_{max} prediction is based on an assumed 8-psia emergency regulator maximum flowrate of 125 lb/hr of N_2 each (while the spec max flow is 75 lb/hr, OMRSD testing shows that the actual average max flow is about 125 lb/hr). It also assumes that the time from TIG to touchdown is 60 minutes and that O_2 is managed between 2.2 and 3.0 psia (ref. Rules {A17-254}, CABIN O_2 CONCENTRATION, and {A13-53}, MINIMUM PPO2 CONSTRAINTS). N_2 depletion is defined in Rule {A17-204}, N_2 SUPPLY, as tank pressure below 200 (375) psia. [ED]

The vehicle avionics are not certified to withstand cabin pressures below 8 psia due to cooling requirements. Also, a cabin pressure of 8 psia is the minimum pressure which will allow the crew to function normally for any length of time without a prebreathe. Reference Rule {A13-51A}, CABIN PRESSURE. For these reasons, maintaining 8 psia (if possible) is mandatory.

In maintaining 8 psia, N_2 supplies will be exhausted as necessary. No N_2 conservation steps that involve lowering the cabin stabilization pressure below 8 psia will be attempted. Therefore, the time on orbit that could be achieved if the cabin was allowed to stabilize at a lower pressure will be sacrificed to maintain 8 psia.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-705

ATMOSPHERE REVITALIZATION SYSTEM (ARS) FAN @[021600-7106B] @[111501-5101A]

- A. FOR LOSS OF A SINGLE PHASE, THE ARS FAN MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER.

The ARS fan was operated on two phases during preflight testing. The ARS fan may be operated but not started on only two phases. @[111501-5101A]

If the ARS fan is operating on the SH INV and phase A fails, the fan will stop working because phase A of the SH INV provides the sync pulse required for SH INV phases B and C to operate. However, the fan will continue to operate on the SH INV on two-phase power if phase A continues to operate with either phase B or phase C. @[021600-7106B]

- B. FOR LOSS OF THE ARS FAN, AN IFM WILL BE PERFORMED (BASED ON PPCO₂, ETC.) TO CHANGE OUT THE FAN. UNTIL THE IFM IS PERFORMED, ALLOWABLE CREW TIME IN THE MODULE IS LIMITED BY DEWPOINT, PPO₂, AND PPCO₂ RESTRICTIONS PER RULE {A17-701}, MODULE ATMOSPHERIC CONTROL. @[101096-4494]

Without the ARS fan, air exchange with the orbiter is degraded. In the Spacehab RDM, smoke detection in the forward subfloor volume is considered lost when the ARS fan is not operating with the mixing box cap installed. As long as one HFA fan is operating, smoke detection capability can be regained throughout the RDM by removing the mixing box cap. Reference Rule {A17-757}, RDM MIXING BOX CAP.

- C. (SM/LDM ONLY) THE ARS FAN SHALL NOT BE OPERATED WITH THE PL ISO VALVE CLOSED UNLESS THE ASCENT/DESCENT INLET STUB IS OPEN OR THE FLEX DUCT IS REMOVED. @[021600-7106B]

Operation of the ARS fan with the PL ISO valve closed and flex duct connected in the Spacehab single or logistics double module configurations may cause failure of the ARS fan. Reference Rule {A17-756}, SM/LDM ASCENT/DESCENT INLET STUB. @[021600-7106B]

- D. (RDM ONLY) THE ARS FAN SHALL BE DEACTIVATED PRIOR TO POWERING ON A SECOND HFA FAN.

Preflight testing by Boeing has shown that the HFA fans will operate in a degraded mode if a second HFA fan is powered up while the ARS fan is operating. Reference Rule {A17-704}, CABIN/HFA FAN. No immediate damage to the fans is associated with operation in this mode, only degraded system performance (> 30 percent reduction in HFA flow).

DOCUMENTATION: Boeing RDM Certification Acceptance Review Presentation, October 4-5, 2000, ECS Special Topic. @[111501-5101A]

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS

THE FOLLOWING FAN CONFIGURATION WILL BE USED FOR NOMINAL SPACEHAB SM/LDM OR RDM OPERATIONS FOR ASCENT, ON-ORBIT, AND ENTRY: @[111501-5000]

A. ASCENT

1. SM/LDM:

a. UNPOWERED SPACEHAB MODULE

- (1) ARS FAN - ON, CONFIGURED TO SPACEHAB INVERTER POWER, BUT NOT OPERATIONAL SINCE THE SPACEHAB INVERTER IS UNPOWERED
- (2) CABIN FAN - OFF, CONFIGURED TO SPACEHAB INVERTER POWER
- (3) AFT MODULE FAN - OFF (LDM ONLY)

When the Spacehab module is unpowered for ascent, all subsystem equipment is OFF. Although the ARS fan is configured ON, it is not operational because its power source is configured to an unpowered Spacehab inverter. This configuration simply allows the ARS fan to be activated by commanding its power source from Spacehab inverter to orbiter AC.

b. POWERED SPACEHAB MODULE

- (1) ARS FAN - ON, USING SPACEHAB INVERTER POWER
- (2) CABIN FAN - OFF, BUT CONFIGURED TO SPACEHAB INVERTER POWER
- (3) AFT MODULE FAN - OFF (LDM ONLY)

IF THE ARS FAN FAILS, IT WILL BE COMMANDED OFF AND THE CABIN FAN COMMANDED ON ASAP POST MAIN ENGINE CUTOFF (MECO). FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.

@[ED] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

The ARS or cabin fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. The cabin fan is unpowered, but configured to inverter power to allow it to serve as a backup in case the ARS fan fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 1 (SM GPC not available), the fans will be reconfigured via ground command post MECO. The aft module fan uses Spacehab DC power and is not powered for ascent. @[111501-5000]

2. RDM: @[111501-5000]
 - a. HFA FAN 1 - ON, USING SPACEHAB INVERTER POWER
 - b. HFA FAN 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER
 - c. ARS FAN - ON, CONFIGURED TO ORBITER AC, BUT NOT OPERATIONAL SINCE ORBITER AC IS NOT AVAILABLE TO PAYLOADS FOR ASCENT

IF HFA FAN 1 FAILS, IT WILL BE COMMANDED OFF AND HFA FAN 2 COMMANDED ON ASAP POST MAIN ENGINE CUTOFF (MECO). FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.
@[ED] @[ED]

The Spacehab RDM is always powered for ascent. An HFA fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. HFA fan 1 is preferred over HFA fan 2 because contingency commanding is only available to turn HFA fan 1 OFF and HFA fan 2 ON. HFA fan 2 is unpowered but configured to inverter power to allow it to serve as a backup in case HFA fan 1 fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 1 (SM GPC not available), the fans will be reconfigured via ground command post MECO. The ARS fan is not operational during ascent; however, it is configured ON, but to orbiter AC power which is not available during ascent. In this configuration, the ARS fan can be activated whenever power is applied to the payload AC 2 bus in the event of a failure that prevents Spacehab commanding.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

B. ON-ORBIT

1. SM/LDM:

- a. ARS FAN - ON, USING ORBITER AC POWER
- b. CABIN FAN - ON, USING ORBITER AC POWER
- c. AFT MODULE FAN - ON, USING SPACEHAB DC POWER (LDM ONLY)

IF ORBITER AC POWER IS UNAVAILABLE, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[111501-5000] @[ED]
@[ED]

2. RDM: @[111501-5000]

- a. ARS FAN - ON, USING ORBITER AC3 POWER
- b. HFA FAN 1 - ON, USING SPACEHAB INVERTER POWER
- c. HFA FAN 2 - ON, USING ORBITER AC2 POWER

FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]
@[ED]

All subsystem fans for Spacehab SM/LDM or RDM are nominally operating on-orbit to obtain the best air circulation throughout the module. It is highly desired to power the ARS fan from orbiter AC in order to maintain fan operation in case of an inadvertent loss of the Spacehab inverter. Powering any of the fans via the Spacehab inverter(s) or orbiter AC is acceptable and is preferred over not running the fans. In the RDM, HFA fan 1 is powered by the Spacehab inverters and HFA fan 2 is powered by orbiter AC to maintain airflow in case of a failure of either power source, as well as to off load orbiter AC 2. Operation of both HFA fans from the same power source is acceptable, but will impact troubleshooting in the case of a failed fan.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

C. ENTRY

1. SM/LDM:

- a. ARS FAN - ON, USING SPACEHAB INVERTER POWER
- b. CABIN FAN - OFF, CONFIGURED TO ORBITER AC
- c. AFT MODULE FAN - OFF (LDM ONLY)

IF THE ARS FAN FAILS, IT WILL BE COMMANDED OFF AND THE CABIN FAN COMMANDED ON USING ORBITER AC POWER ASAP PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN RULE {A9-155}, AC INVERTER THERMAL LIFE. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. ©[ED] ©[ED]

The ARS or cabin fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. The cabin fan is unpowered but configured to orbiter AC power to allow it to serve as a backup in case the ARS fan or Spacehab inverter fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 3 (SM GPC not available), the fans will be reconfigured via ground command. The aft module fan uses Spacehab DC power and is not powered for entry. ©[111501-5000]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A17-706 SPACEHAB FAN CONFIGURATIONS (CONTINUED)**

2. RDM: @[111501-5000]
- a. HFA FAN 1 - ON, USING INVERTER POWER
 - b. HFA FAN 2 - OFF, CONFIGURED TO ORBITER AC
 - c. ARS FAN - OFF

IF HFA FAN 1 FAILS, IT WILL BE COMMANDED OFF AND HFA FAN 2 COMMANDED ON USING ORBITER AC POWER ASAP PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN RULE {A9-155}, AC INVERTER THERMAL LIFE. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]
@[ED]

An HFA fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. HFA fan 1 is preferred over HFA fan 2 because contingency commanding is only available to turn HFA fan 1 OFF and HFA fan 2 ON. HFA fan 2 is unpowered, but configured to orbiter AC to allow it to serve as a backup in case HFA fan 1 or the Spacehab inverter fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 3 (SM GPC not available), the fans will be reconfigured via ground command. The ARS fan is OFF during entry and is not considered a viable option to regain smoke detection should both HFA fans fail (reference Rule {A17-601}, SPACEHAB FIRE/SMOKE DETECTION LOSS). @[111501-5000]

A17-707 THROUGH A17 750 RULES ARE RESERVED

FLIGHT RULES

A18-553

SPACEHAB SUBSYSTEM PUMP OPERATIONS @[111501-5012]

- A. FOR LOSS OF A SINGLE PHASE, THE SUBSYSTEM WATER PUMP MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER.

The Subsystem Water Pump was operated on two phases during preflight testing. The Subsystem Water Pump may be operated but not started on only two phases.

If the Subsystem Water Pump is operating on the Spacehab INV and phase A fails, the pump will stop working because phase A of the Spacehab INV provides the sync pulse required for Spacehab INV phases B and C to operate. However, the Subsystem Water Pump will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C.

- B. THE FOLLOWING SUBSYSTEM WATER PUMP CONFIGURATION WILL BE USED FOR NOMINAL SPACEHAB SM/LDM OR RDM OPERATIONS FOR ASCENT/ENTRY AND ON-ORBIT:

1. ASCENT/ENTRY

a. POWERED SPACEHAB MODULE

- (1) SUBSYSTEM WATER PUMP 1 - ON, USING SPACEHAB INVERTER POWER
- (2) SUBSYSTEM WATER PUMP 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

FOR FAILURE OF WATER PUMP 1, WATER PUMP 2 WILL BE COMMANDED ON ASAP POST-MECO OR DURING ENTRY. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

Subsystem water pump 2 is configured to inverter power to allow it to serve as a backup in case pump 1 fails. Without switching pumps, module heat rejection is lost. Subsystem water pump 1 can only be powered from the Spacehab inverter. Pump 2 can be powered from Spacehab inverter or orbiter AC power. Since no on-board command capability exists in OPS 1 (Single Module General Purpose Computer (SM GPC) not available), the pumps will be reconfigured via ground command post MECO or during entry. @[111501-5012]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-553

SPACEHAB SUBSYSTEM PUMP OPERATIONS (CONTINUED)

- b. UNPOWERED SPACEHAB MODULE (SM/LDM ASCENT ONLY)
@[111501-5012]

SUBSYSTEM WATER PUMP 2 IS CONFIGURED ON AND TO ORBITER POWER, BUT THE PUMP WILL NOT BE OPERATING SINCE ORBITER AC POWER IS NOT AVAILABLE TO PAYLOADS DURING ASCENT.

When the Spacehab module is unpowered for ascent, this configuration allows the Spacehab Subsystem Pump to be activated whenever power is applied to the payload AC bus in the event of a failure that prevents Spacehab commanding. Spacehab is always powered for entry.

2. ON-ORBIT

- a. SUBSYSTEM WATER PUMP 2 - ON, USING ORBITER AC
- b. SUBSYSTEM WATER PUMP 1 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

PUMP 1 WILL BE COMMANDED ON FOR FAILURE OF PUMP 2. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

A subsystem water pump is required to provide heat rejection for the module. Operation of either pump on Spacehab inverter power is acceptable, but orbiter AC power is preferred to maintain pump operation in case of a Spacehab Main Power Kill. Subsystem pump 2 is preferred because pump 1 cannot be configured to orbiter AC power. @[111501-5012]

FLIGHT RULES

A18-556

RDM CENTRALIZED EXPERIMENT WATER LOOP (CEWL)

A. LOST IF: @[111501-5013]

1. PUMP ACCUMULATOR QUANTITY IS ? 0 (3.4) PERCENT AND SYMPTOMS OF PUMP CAVITATION ARE PRESENT.

Spacehab has identified this percentage as an indication of accumulator failure; 3.4 percent is the range of uncertainty of the quantity sensor.

2. THERE ARE SYMPTOMS OF PUMP CAVITATION AND THE PUMP INLET PRESSURE IS LESS THAN 20 PSIA.

Pump will operate erratically and may cavitate at pressures less than specified value.

B. FOR LOSS OF THE CEWL, POWER WILL BE REMOVED FROM EXPERIMENT COMPONENTS BEING COOLED BY THE CEWL IF REQUIRED TO MAINTAIN THERMAL LIMITS.

C. THE CEWL INLET QD'S SHALL BE CAPPED FOR ASCENT/ENTRY AND UNCAPPED PRIOR TO ACTIVATING THE CEWL PUMP.

The CEWL inlet QD's, when uncapped, provide pressure relief capability for the CEWL when active. This pressure relief capability is a safety requirement to prevent temperature induced over pressurization of the CEWL in case of loss of flow. Ascent/Entry loads may cause water to leak into the Spacehab subfloor from the CEWL inlet QD's if not capped.

Reference: Hazard Report RDM HR-5. @[111501-5013]

FLIGHT RULES

A18-557

RDM CEWL PUMP OPERATIONS

- A. FOR LOSS OF A SINGLE PHASE, THE CEWL PUMP MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER. @[111501-5013]

The CEWL pump was operated on two phases during preflight testing. The CEWL pump may be operated but not started on only two phases.

If the CEWL pump is operating on the Spacehab Aft INV and phase A fails, the CEWL pump will stop working because phase A of the Spacehab INV provides the sync pulse required for Spacehab INV phases B and C to operate. However, the CEWL pump will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C.

- B. THE ON-ORBIT CEWL PUMP CONFIGURATION FOR NOMINAL OPERATIONS IS AS FOLLOWS:

1. CEWL PUMP 1 - ON, USING ORBITER AC POWER
2. CEWL PUMP 2 - OFF, CONFIGURED TO SPACEHAB AFT INVERTER POWER

FOR FAILURE OF CEWL PUMP 1, CEWL PUMP 2 WILL BE AUTOMATICALLY COMMANDED ON. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.
@[ED]

CEWL pump 1 is considered the prime pump since an automatic switchover capability exists in the Aft Power Distribution Unit (APDU) logic to power on CEWL pump 2 in case of a pump 1 failure. This capability does not exist from pump 2 to pump 1. Pump 2 is configured to an alternate power source to allow it to be powered in case the power source to pump 1 fails. Orbiter AC is considered the preferred source for the prime pump. Operation of either CEWL pump by Spacehab Aft Inverter or orbiter AC is acceptable. Whenever CEWL cooled experiments are operating, a CEWL pump is required to provide heat rejection. @[11105-5013]

A18-558 THROUGH A18-600 RULES ARE RESERVED

NASA - JOHNSON SPACE CENTER
FLIGHT RULES

A18-605

RDM ROTARY SEPARATOR (RS) OPERATIONS

- A. THE RS SENSORS SHALL BE POWERED PRIOR TO RS ACTIVATION.
@[111501-5013]

The RS sensors can be powered by orbiter AC or Spacehab inverter power. The sensors must be active before RS activation to prevent RS automatic switchover.

- B. THE RS MAY BE OPERATED, BUT NOT STARTED USING ONLY TWO-PHASE POWER.

The RS was operated on two phases during preflight testing. The RS may be operated but not started on only two phases.

If the RS is operating on the Spacehab Aft INV and phase A fails, the RS will stop working because phase A of the Spacehab INV provides the sync pulse required for phases B and C to operate. However, the RS will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C. @[111501-5013]

- C. THE RS CONFIGURATION FOR ASCENT/ENTRY WILL BE AS FOLLOWS:
@[111501-5013]

1. RS 1 - ON, USING SPACEHAB INVERTER POWER
2. RS 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

RS 1 WILL BE AUTOMATICALLY COMMANDED OFF AND RS 2 COMMANDED ON, IF RS 1 FAILS. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

RS 1 is the prime RS since an automatic switchover capability exists in the APDU logic to power on RS 2 in case of an RS 1 failure. RS 2 is configured to inverter power to allow it to serve as a backup in case of an RS 1 failure. This automatic switchover capability does not exist to turn on RS 1 if RS 2 fails. Therefore, as long as RS 1 is operational, it will always be prime. RS 2 operating would indicate failure of RS 1. An operational RS is required to maintain moisture removal capability in the Spacehab module. Unlike fans and pumps, the backup RS is not configured to orbiter AC because it is not critical for entry and the RS switches automatically without opportunity for flight controller intervention. @[111501-5013]

THIS RULE CONTINUED ON NEXT PAGE

NASA - JOHNSON SPACE CENTER
FLIGHT RULES

A18-605 **RDM ROTARY SEPARATOR (RS) OPERATIONS (CONTINUED)**

D. THE RS CONFIGURATION FOR ON-ORBIT OPERATIONS WILL BE AS FOLLOWS:

1. RS 1 - ON, USING SPACEHAB INVERTER POWER
2. RS 2 - OFF, CONFIGURED TO ORBITER AC POWER

RS 1 WILL BE AUTOMATICALLY COMMANDED OFF AND RS 2 COMMANDED ON, IF RS 1 FAILS. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.
©[ED]

RS 1 is the prime RS since an automatic switchover capability exists in the APDU logic to power on RS 2 in case of an RS 1 failure. This automatic switchover capability does not exist to turn on RS 1 if RS 2 fails. Therefore, as long as RS 1 is operational, it will always be prime. RS 2 operating would indicate a failure in RS 1. It is preferred for RS 1 to remain on Spacehab aft inverter power from the ascent configuration. RS 2 is commanded to orbiter AC to allow RS 2 to be powered by an alternate source in case of a Spacehab aft inverter failure. Operation of either RS from Spacehab inverter power or orbiter AC power is acceptable. An operational RS is required to maintain moisture removal capability in the Spacehab module. The Spacehab inverters are the preferred source of power for the prime RS in order to off load orbiter AC power. ©[111501-5013]

SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX

ALL FLIGHTS

VOLUME A

FINAL

PREFACE

THIS DOCUMENT, VOLUME A, FINAL, DATED JUNE 20, 2002, IS THE GENERIC VERSION OF THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES AND IS INTENDED TO BE USED IN CONJUNCTION WITH THE SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX (NSTS-18308) WHICH CONTAINS THE FLIGHT SPECIFIC RULES. INCLUDED IN THIS PUBLICATION ARE FLIGHT RULE CHANGES APPROVED IN FLIGHT RULES CONTROL BOARD (FRCB) MEETINGS 137, 138, AND 139 HELD ON MARCH 28, APRIL 25, AND MAY 23, 2002, RESPECTIVELY.

THIS DOCUMENT USES A NEW RULE NUMBER SYSTEM DESIGNED TO FACILITATE NEW DATABASES FOR MAINTAINING CONFIGURATION MANAGEMENT OF JOINT SHUTTLE-ISS ANNEXES, SPACE SHUTTLE OPERATIONAL FLIGHT RULES, VOLUME A; ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME B; JOINT SHUTTLE/ISS GENERIC OPERATIONAL FLIGHT RULES, VOLUME C; AND SOYUZ/PROGRESS/ISS JOINT FLIGHT RULES, VOLUME D.

IT IS REQUESTED THAT ANY ORGANIZATION HAVING COMMENTS, QUESTIONS, OR SUGGESTIONS CONCERNING THESE FLIGHT RULES CONTACT DA8/W. PRESTON DILL, FLIGHT DIRECTOR OFFICE, BUILDING 4 NORTH, ROOM 3039, PHONE 281-483-5418.

ALL FLIGHT RULES ARE AVAILABLE ON THE INTERNET. THE URL IS: **HTTP://MOD.JSC.NASA.GOV/DA8**. NO ID OR PASSWORD WILL BE REQUIRED TO ACCESS ANY OF THE RULES PROVIDED THE USER IS ACCESSING FROM A TRUSTED SITE (ALL NASA CENTERS, CONTRACTORS, AND INTERNATIONAL PARTNERS). IF UNABLE TO ACCESS, USERS NEED TO SEND AN E-MAIL NOTE TO DA8/M. L. GRIFFITH (MARY.L.GRIFFITH1@JSC.NASA.GOV) WITH THEIR FULL NAME, COMPANY, IP ADDRESS, AND A JUSTIFICATION STATEMENT FOR ACCESS.

THIS IS A CONTROLLED DOCUMENT AND ANY CHANGES ARE SUBJECT TO THE CHANGE CONTROL PROCEDURES DELINEATED IN APPENDIX B. THIS DOCUMENT IS NOT TO BE REPRODUCED WITHOUT THE WRITTEN APPROVAL OF THE CHIEF, FLIGHT DIRECTOR OFFICE, DA8, LYNDON B. JOHNSON SPACE CENTER, HOUSTON, TEXAS.

APPROVED BY:

MILTON HEFLIN
CHIEF, FLIGHT DIRECTOR OFFICE

JON C. HARPOLD
DIRECTOR, MISSION OPERATIONS

RONALD D. DITTEMORE
MANAGER, SPACE SHUTTLE PROGRAM

FLIGHT RULES

SECTION 1 - OPERATIONS POLICY, GENERAL AND DEFINITIONS

OPERATIONS POLICY

A1-1 FLIGHT RULE PURPOSE

THE FLIGHT RULES OUTLINE PREPLANNED DECISIONS DESIGNED TO MINIMIZE THE AMOUNT OF REAL-TIME RATIONALIZATION REQUIRED WHEN NON-NOMINAL SITUATIONS OCCUR FROM THE START OF THE TERMINAL COUNTDOWN THROUGH CREW EGRESS OR GROUND SUPPORT EQUIPMENT (GSE) COOLING ACTIVATION, WHICHEVER OCCURS LATER.

Self-explanatory.

A1-2 REAL-TIME OPERATING POLICY

- A. MISSION SUCCESS RELATED REAL-TIME DECISIONS WILL BE MADE WITHIN THE FRAMEWORK OF THE ESTABLISHED SHUTTLE OPERATING BASE DOCUMENTED AS FOLLOWS:
1. PERMISSION DECISIONS - STS OPERATIONAL FLIGHT RULES AND STS OPERATIONAL FLIGHT RULES FLIGHT-SPECIFIC ANNEX DEVELOPED USING THE SYSTEM PERFORMANCE CAPABILITIES DOCUMENTED IN THE SHUTTLE OPERATIONAL DATA BOOK (SODB).
 2. PROGRAM CERTIFIED CAPABILITY - REAL-TIME INTERPRETATION OF THE REQUIREMENTS WILL BE MADE CONSISTENT WITH AUTHORITY DEFINED HEREIN.
- B. CREW SAFETY RELATED DECISIONS WILL BE MADE WITHIN THE FRAMEWORK OF ESTABLISHED SHUTTLE OPERATING BASE (PARAGRAPH A ABOVE) WHEN PRACTICAL. WHEN TIME OR CIRCUMSTANCES DO NOT ALLOW STAYING WITHIN THE OPERATING BASE, THE RESPONSIBLE AUTHORITY MAY CHOOSE TO TAKE ANY NECESSARY ACTION TO ENSURE THE SAFETY OF THE SHUTTLE AND CREW.
- C. WHERE POSSIBLE CONTINGENCY MANAGEMENT WILL BE EMPLOYED TO PROVIDE FOR LANDING AT THE PRIMARY OR SECONDARY LANDING SITE AND TO PROVIDE THE MAXIMUM POSSIBLE GUIDANCE, NAVIGATION, AND CONTROL CAPABILITY FOR ENTRY AND LANDING.

Self-explanatory.

Rule {A1-5}, FLIGHT DIRECTOR AUTHORITY, references this rule.

FLIGHT RULES

A1-3 PROGRAM LIFETIME OPERATING POLICY

SYSTEMS MANAGEMENT FOR NOMINAL OPERATION WILL OBSERVE THE PROGRAM (MULTIPLE FLIGHT) LIFETIME OPERATING LIMITS AND/OR CONSTRAINTS PER THE SODB. HOWEVER, THOSE LIMITS AND/OR CONSTRAINTS MAY BE VIOLATED FOR CONTINGENCY OPERATIONS AS FOLLOWS:

- A. SINGLE-FLIGHT CONTINGENCY MANAGEMENT LIMITS AND/OR CONSTRAINTS MAY BE USED IF AGREED TO PREFLIGHT OR WITH THE CONCURRENCE OF THE MISSION MANAGEMENT TEAM (MMT) IN REAL TIME.
- B. IF THE SINGLE-FLIGHT LIMITS MUST BE VIOLATED, THE BEST ENGINEERING JUDGMENT ON THE LIMITS/CONSTRAINTS THAT PROVIDE THE HIGHEST PROBABILITY OF SUCCESSFUL RECOVERY OF THE CREW AND ORBITER WILL BE USED.

Self-explanatory.

A1-4 MISSION MANAGEMENT TEAM (MMT) AUTHORITY

DURING FLIGHT, THE MMT CHAIRMAN IS RESPONSIBLE FOR NEAR REAL-TIME POLICY DECISIONS AND WILL BE CONSULTED AS SOON AS POSSIBLE WHENEVER OPERATIONS OUTSIDE THE SHUTTLE OPERATING BASE ARE REQUIRED.

Self-explanatory.

FLIGHT RULES

A1-5

FLIGHT DIRECTOR AUTHORITY

- A. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR OVERALL DIRECTION OF SHUTTLE FLIGHTS FROM SOLID ROCKET BOOSTER (SRB) IGNITION UNTIL CREW EGRESS OR GSE COOLING ACTIVATION, WHICHEVER OCCURS LATER:
1. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR REAL-TIME IMPLEMENTATION OF OPERATIONS WITHIN THE FRAMEWORK OF THE SHUTTLE OPERATING BASE (REFERENCE (REF.) RULE {A1-2}, REAL-TIME OPERATING POLICY).
 2. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR PROVIDING RECOMMENDATIONS AND/OR OPTIONS TO THE MMT FOR NEAR REAL-TIME DECISIONS WHEN OPERATING OUTSIDE THE FRAMEWORK OF THE MISSION RULES OR THE SHUTTLE OPERATING BASE.
- B. THE FLIGHT DIRECTOR, AFTER ANALYSIS OF THE FLIGHT CONDITION, MAY CHOOSE TO TAKE ANY NECESSARY REAL-TIME ACTION REQUIRED TO ENSURE THE SAFETY OF THE CREW AND SHUTTLE.
- C. THE FLIGHT DIRECTOR WILL PROVIDE THE DEFINITIVE LAUNCH WINDOW OPEN, CLOSE, RENDEZVOUS PANE CHANGE AND LOX DRAINBACK TIME. ©[041097-4911A]
- D. THE FLIGHT DIRECTOR WILL INITIATE THE ABORT REQUEST COMMAND FROM THE MCC.
- E. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR CALLING A LAUNCH "HOLD" FOR ALL PROBLEMS THAT JEOPARDIZE THE ABILITY TO SAFELY MONITOR AND RECOVER THE ORBITER AND CREW AFTER LAUNCH. THIS INCLUDES PROBLEMS IN THE FOLLOWING AREAS: MISSION CONTROL CENTER (MCC), SPACECRAFT TRACKING AND DATA NETWORK (STDN), LANDING AREA FACILITIES, AND ABORT LANDING AREA WEATHER.
- F. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR OVERALL CONTROL OF THE MCC COMMAND UPLINK CAPABILITY.
- G. THE FLIGHT DIRECTOR IS RESPONSIBLE FOR POSTLANDING ORBITER SYSTEMS CONFIGURATION AND SAFING THROUGH CREW EGRESS OR GSE COOLING ACTIVATION, WHICH EVER OCCURS LATER. ©[041097-4911A]

Self-explanatory.

FLIGHT RULES

A1-6 SHUTTLE COMMANDER AUTHORITY

- A. THE COMMANDER WILL ASSUME RESPONSIBILITY FOR CONDUCT OF THE FLIGHT WITHIN THE FRAMEWORK OF THE FLIGHT RULES, IF UNABLE TO COMMUNICATE WITH MCC.
- B. THE COMMANDER MAY INITIATE SUCH ACTION AS HE DEEMS ESSENTIAL FOR CREW SAFETY.

Self-explanatory.

Rule {A2-251}, BAILOUT, references this rule.

A1-7 FLIGHT CONTROL ROOM (FCR) SURGEON AUTHORITY

- A. THE FCR SURGEON WILL BE CONSULTED ON ALL CONDITIONS WHICH DEAL WITH CREW HEALTH.
- B. THE FCR SURGEON IS RESPONSIBLE FOR EVALUATION OF ANY CHANGE IN CREW HEALTH STATUS AND MAKING RECOMMENDATIONS TO THE FLIGHT DIRECTOR REGARDING ANY REQUIRED CHANGES IN MISSION DURATION OR CREW ACTIVITIES.

A1-8 WEATHER DECISION AUTHORITY

- A. THE JOHNSON SPACE CENTER (JSC) MCC FLIGHT DIRECTOR IS RESPONSIBLE FOR LAUNCH ABORT LANDING AND END-OF-MISSION WEATHER DECISIONS AND ASSOCIATED RECOMMENDATIONS TO THE MMT CHAIRMAN.
- B. THE KENNEDY SPACE CENTER (KSC) LAUNCH DIRECTOR IS RESPONSIBLE FOR THE LAUNCH DECISION FOR WEATHER ACCEPTABILITY AT THE LAUNCH PAD FOR ASCENT TRAJECTORY AND ASSOCIATED RECOMMENDATIONS TO THE MMT CHAIRMAN.

Self-explanatory.

FLIGHT RULES

A1-9

POSTLANDING DECISION AUTHORITY

A. FLIGHT DIRECTOR

THE FLIGHT DIRECTOR IS RESPONSIBLE FOR POSTLANDING ORBITER SYSTEMS CONFIGURATION AND SAFING THROUGH CREW EGRESS OR GSE COOLING ACTIVATION, WHICHEVER OCCURS LATER. THIS INCLUDES:

1. IN-FLIGHT CONTINGENCIES.
2. OFF-NOMINAL AND CONTINGENCY LANDING OPERATIONS (THROUGH CREW EGRESS) AS LONG AS COMMUNICATIONS EXIST BETWEEN THE ORBITER AND MCC-HOUSTON (MCC-H).

The flight director will support postlanding operations by ensuring correct configuration of orbiter systems to allow convoy activities to proceed. Assessment of the external environment to allow safe crew egress and continued postlanding operations is the responsibility of convoy personnel.

B. CONVOY COMMANDER

THE CONVOY COMMANDER IS RESPONSIBLE FOR THE ORBITER SAFETY INSPECTION/HAZARD ASSESSMENT AND ASSOCIATED IMPACT TO CREW EGRESS AND CONVOY OPERATIONS. THE FLIGHT DIRECTOR WILL BE NOTIFIED OF ANY EXPLOSIVE, FLAMMABLE, OR TOXIC CONDITIONS THAT WILL PRECLUDE/DELAY NORMAL CREW EGRESS.

The orbiter inspection/hazard assessment will be accomplished by on-site convoy personnel who are in the best position to determine if unsafe conditions exist (explosive, flammable, toxic, smoke, etc.). Violation of identified "safe criteria" will result in termination of convoy activities and crew egress as recommended by the convoy commander (reference Postlanding Operations Maintenance Instruction (OMI) for hazard assessment criteria).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A1-9

POSTLANDING DECISION AUTHORITY (CONTINUED)

C. LANDING RECOVERY DIRECTOR (LRD)/GROUND OPERATIONS MANAGER (GOM)

THE LRD OR THE GOM IS RESPONSIBLE FOR THE COORDINATION OF DECLARED POSTLANDING MODE V THROUGH MODE VII EGRESS/ESCAPE MODES PLUS ORBITER POSTLANDING ACTIVITIES POST-MCC HANDOVER.

Coordinating contingency operations at any time during a mission should be accomplished by the person in charge with the most current, reliable information and communications capabilities that ensure the proper resources are employed to save life and property. During a landing at an augmented landing site (ALS), (primary landing site (PLS), secondary landing site (SLS), or transoceanic abort landing (TAL) site), the LRD/GOM is best able to coordinate this effort. At a Department of Defense (DOD) emergency landing site (ELS), this coordination is best handled by the on-scene commander. In certain situations, however, the Flight Director is in the best position to coordinate contingency operations. These are as follows:

- a. For in-flight emergencies, the flight director (in conjunction with the flightcrew) is best able to determine when a contingency situation exists and is responsible for conduct of the flight until crew egress.*
- b. When outside the operating radius of an ALS or DOD ELS, the flight director, again in conjunction with the crew, is in the best position to coordinate contingency operations and to see that the appropriate actions are initiated up to and including crew egress.*

FLIGHT RULES

A1-10

POSTLANDING EMERGENCY DECLARATION

OFFICIAL DECLARATION OF A POSTLANDING EMERGENCY (MODE V THROUGH MODE VII) CAN BE MADE BY THE LRD, FLIGHT DIRECTOR, GOM, CONVOY COMMANDER, OR FLIGHTCREW. IN ADDITION FOR ELS LANDINGS, THIS DECLARATION MAY BE MADE BY THE DOD ON-SCENE COMMANDER. TIME AND CIRCUMSTANCES PERMITTING, COORDINATION WITH THE FLIGHT DIRECTOR WILL BE ACCOMPLISHED.

A postlanding emergency (Mode V through Mode VII) should be declared so that everyone involved is aware of the situation and can take the proper actions or precautions to protect both equipment and life. For this reason, the first of the following individuals that would discover that the emergency exists would make the declaration: LRD, flight director, GOM, convoy commander, on-scene commander, or flightcrew. Any of the above individuals have the communication capabilities to ensure that everyone involved is aware of the emergency. If time is available and the circumstances allow, coordination with the flight director will ensure that the most current information concerning the status of the crew and the orbiter is available for dealing with the emergency.

FLIGHT RULES

A1-11 **SEARCH AND RESCUE RESPONSIBILITY**

FOR MODE VII, SEARCH AND RESCUE RESPONSIBILITY REVERTS FROM THE LOCAL SITE COMMANDER TO THE APPROPRIATE SEARCH AND RESCUE (SAR) PLAN, WHEN IMPACT IS:

- A. FOR EDWARDS (EDW), OUTSIDE THE BOUNDARIES OF THE BASE.
- B. FOR NORTHRUP (NOR), GREATER THAN 25 NM RADIUS OF THE WHITE SANDS SPACE HARBOR (WSSH) TACAN.
- C. FOR KSC, GREATER THAN 25 NM RADIUS OF THE KSC TACAN, EXCLUDING THE ATLANTIC OCEAN.

Within the local contingency area for KSC, the DOD will support NASA's rescue/recovery operations by providing two helicopters configured for Medivac.

At Edwards Air Force Base (EAFB), the Commander of Air Force Flight Test Center (AFFTC) has complete responsibility for all efforts involving astronaut recovery, fire fighting, and security. The DOD will provide support as necessary.

At WSSH, the DOD has varying degrees of responsibility and basically will provide support for search and rescue within the limitations of their equipment.

All of the above support is provided within the limits of the site as described in this rule. Outside of that limit, search and rescue operations will be conducted in accordance with applicable SAR plans. These plans identify the areas of responsibility and the controlling agencies.

A1-12 **ORBITER EMERGENCY LANDING SITE (ELS) AUTHORITY**

FOR ELS LANDINGS, THE FLIGHTCREW HAS ON-SCENE RESPONSIBILITY FOR THE ORBITER UNTIL ARRIVAL OF THE KSC RAPID RESPONSE TEAM (APPROXIMATELY LANDING PLUS 24 HOURS). THE LANDING AND RECOVERY DIRECTOR (LRD) IS RESPONSIBLE FOR ANSWERING ORBITER HANDLING QUESTIONS FROM ELS PERSONNEL.

For a landing at an ELS, the crew will have the responsibility for the orbiter until the KSC Rapid Response Team is able to arrive. The crew will have a checklist to follow and may be able to obtain help from the U. S. Embassy in securing and protecting the orbiter. Communications to the ELS will be provided as best as possible through the JSC Landing Support Officer (LSO), and any questions that the ELS personnel may have regarding the handling of the orbiter will be provided by the person responsible for the recovery, the LRD at KSC.

FLIGHT RULES

A1-13

MCC REAL-TIME COMMAND COORDINATION POLICY

- A. THE FLIGHT DIRECTOR WILL APPROVE ALL COMMAND OPERATIONS.
©[092293-1547]

The flight director is responsible for the integrity of the command system/process and for insuring that all commands to the shuttle are safely and properly executed.

- B. ROUTINE COMMAND OPERATIONS CAN BE PERFORMED WITHOUT A "GO" FROM THE FLIGHT DIRECTOR FOR EACH ROUTINE FUNCTION.

Thousands of routine commands must be sent to the vehicle each flight to manage comm systems, instrumentation systems, recorders, video systems, etc. Requiring flight director approval for these operations continuously is not appropriate and prevents efficient operations. Risk associated with these routine commands is considered low. The flight director may identify critical time periods where even routine commands require coordination.

- C. NONSTANDARD COMMAND ACTIVITY (NOT OPERATING PER A REVIEWED, APPROVED, AND PUBLISHED PROCEDURE OR ANY EXECUTION OF A PROCEDURE THAT IS NOT ROUTINELY PERFORMED EACH MISSION) MUST BE REVIEWED BY THE FLIGHT CONTROL TEAM AND BE APPROVED BY THE FLIGHT DIRECTOR.

Nonstandard command activity contains increased possibilities for command errors. Flight control team review and flight director approval are the techniques used to reduce the possibility of command errors. These techniques must be utilized whenever a procedure is developed or modified in real time because the standard preflight command procedure review has not been accomplished. These techniques must also be used on infrequently used or modified procedures in order to assure that the procedures are current and compatible with recent changes in shuttle hardware and software as well as ground hardware and software.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A1-13

MCC REAL-TIME COMMAND COORDINATION POLICY
(CONTINUED)

- D. ANY REAL-TIME MODIFICATIONS TO PREFLIGHT APPROVED COMMAND PROCEDURES MUST BE REVIEWED BY THE FLIGHT CONTROL TEAM AND APPROVED BY THE FLIGHT DIRECTOR.

Modified procedures need to be reviewed just as the procedures specified in paragraph C above require review.

- E. COMMANDS SHALL ONLY BE BUILT BY CERTIFIED FLIGHT CONTROLLERS AND EXECUTED BY COMMAND CERTIFIED FLIGHT CONTROLLERS.

Command certification is required to reduce command error risk by insuring that personnel are properly trained and certified to accomplish the necessary command functions without error.

- F. ANY ANOMALIES IN COMMAND OPERATIONS WILL BE BROUGHT TO THE ATTENTION OF THE FLIGHT DIRECTOR IMMEDIATELY.

The flight director is responsible for command operations and any deviations from command operations. The flight director is also responsible for maintaining the integrity and safety of command operations. The flight director must be notified immediately of any problems or off-nominal activity with respect to any procedure to assure corrective action coordination and safe resumption of command activity.

- G. THE FLIGHT DIRECTOR WILL EXERCISE POSITIVE CONTROL AND BE DIRECTLY INVOLVED THROUGH STATUS AND APPROVAL AT MAJOR STEPS IN ALL NONSTANDARD COMMAND PROCEDURES.

When executing nonstandard or critical commands which create more risk to the vehicle/command operations than routine commanding, the flight director will provide another level of operational awareness and control to assure the safe and proper execution of the required command functions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A1-13

MCC REAL-TIME COMMAND COORDINATION POLICY
(CONTINUED)

H. INCO IS THE PRIME UPLINK OPERATOR AND ALL FLIGHT CONTROL POSITIONS WILL COORDINATE THEIR COMMAND ACTIVITIES THROUGH INCO.

The INCO and the INCO MPSR perform the majority of all commanding to the shuttle and are aware of the systems/uplink and downlink status. Because multiple command operations/operators can lead to command execution problems and errors, all command activities will be coordinated through INCO and the INCO MPSR to reduce the possibility of having command problems.

I. FLIGHT CONTROLLERS REQUESTING COMMAND ACTIVITIES ARE RESPONSIBLE FOR:

1. PROPERLY GENERATING THE COMMAND DATA
2. CLEARLY COMMUNICATING THE COMMAND REQUEST AND COMMANDS TO THE FLIGHT CONTROLLER EXECUTING THE COMMANDS (AS WELL AS THE FLIGHT CONTROL TEAM/FLIGHT DIRECTOR IF REQUIRED)
3. REMAINING IN COMMUNICATION WITH THE EXECUTING FLIGHT CONTROLLER THROUGHOUT THE COMMAND SEQUENCE
4. VERIFYING THE PROPER EXECUTION OF THE REQUIRED COMMANDS PRIOR TO PROCEEDING TO THE NEXT COMMAND (VIA COMMAND TRACK DISPLAYS OR END ITEM FUNCTIONS)
5. REPORTING THE RESULTS OF THE COMMAND TO THE FLIGHT DIRECTOR

Responsibilities of the flight controllers must be established to assure that command activities are performed in a safe and proper manner. The INCO and flight control team/flight director may not know all of the ramifications of a particular command sequence and must be informed clearly of the procedure and expectations and risks associated with it.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A1-13

MCC REAL-TIME COMMAND COORDINATION POLICY
(CONTINUED)

- J. COMMAND ACTIVITIES TO THE SHUTTLE OR PAYLOADS DURING PERIODS OF CREW SLEEP WILL ONLY BE ALLOWED IN THE FOLLOWING CASES:
1. THE COMMANDS HAVE BEEN PREVIOUSLY COORDINATED WITH THE CREW, EITHER INDIVIDUALLY OR AS PART OF A PAYLOAD COMMAND PLAN.
 2. THE COMMANDS ARE NECESSARY TO PREVENT NUISANCE ALARMS THAT WILL DISTURB THE CREW SLEEP.
 3. THE COMMANDS ARE THE ROUTINE/CONTINUOUS COMMANDS REQUIRED FOR COMMUNICATIONS CONFIGURATION (E.G., RECORDERS, VIDEO, COMM SYSTEMS MANAGEMENT).
 4. STATE VECTOR UPDATES REQUIRED TO MAINTAIN SHUTTLE EMERGENCY DEORBIT CAPABILITY.

In order to mitigate the risk of unanticipated command effects, only necessary commands will be sent during crew sleep periods. Special testing or comm related DTO's are not considered necessary commanding, as well as any other command operations that could result in disturbing the crew and/or disruption of mission activities.

- K. ALL TYPES OF COMMANDS WILL BE COORDINATED WITH THE ORBITER FLIGHTCREW AND MCC FLIGHT DIRECTOR PRIOR TO BEING TRANSMITTED WITH THE EXCEPTION OF:
1. ROUTINE ORBITER COMMUNICATIONS COMMANDS (TRANSPARENT TO CREW).
 2. NONHAZARDOUS PAYLOAD COMMANDS (PREFLIGHT APPROVED).

With the exception of routine communications systems commands and nonhazardous commands, most command uplinks directly affect the systems being used by the flightcrew for control of the vehicle or payload. To ensure that the flightcrew has current status of vehicle or payload systems in the event of loss of communications, and to ensure that the flightcrew and ground are not in competition for use of a particular orbiter or payload facility, the flightcrew shall be informed of the transmission of command uplinks.

A1-14 THROUGH A1-50 RULES ARE RESERVED

FLIGHT RULES

GENERAL

A1-51 VEHICLE SYSTEM LIMITS

SYSTEMS LIMITS LISTED IN THESE RULES INCLUDE THE ACTUAL VEHICLE LIMITS FOLLOWED BY A NUMBER IN () WHICH IS THE NUMBER BIASED FOR INSTRUMENTATION INACCURACIES AND REPRESENTS THE NUMBER ON WHICH FLIGHT CONTROL ACTION WILL BE TAKEN. IN THE EVENT ONLY ONE NUMBER IS INDICATED, IT WILL BE ASSUMED THAT INSTRUMENTATION INACCURACY CANNOT BE INCORPORATED OR IS IRRELEVANT. IN THOSE CASES WHERE TWO SETS OF ENGINEERING UNITS ARE INDICATED, THE SECOND SET WILL BE SEPARATED FROM THE FIRST BY A SLASH; I.E., XX DEG F/YY DEG C (XX DEG F/YY DEG C).

Self-explanatory.

A1-52 INTERIM OR UNCONFIRMED LIMITS

FLIGHT RULE LIMITS THAT ARE CONSIDERED TO BE INTERIM OR UNCONFIRMED NUMBERS WILL BE UNDERLINED IN THIS PUBLICATION AND IN ALL SUBSEQUENT REVISIONS UNTIL THE NUMBERS ARE CONFIRMED BY THE RESPONSIBLE NASA ORGANIZATION.

Self-explanatory.

A1-53 MANDATORY INSTRUMENTATION REQUIREMENTS

UNLESS STATED OTHERWISE, MANDATORY INSTRUMENTATION REQUIREMENTS CAN BE SATISFIED BY EITHER ONBOARD OR TELEMETRY CAPABILITY.

Self-explanatory.

FLIGHT RULES

A1-54

FAILURE DEFINITION APPLICATION

FAILURE DEFINITIONS IN THIS DOCUMENT REFER TO LIMITS TO BE APPLIED FOR GO/NO-GO DECISIONS TO CONTINUE BEYOND A PREFERRED DAILY LANDING OPPORTUNITY. SYSTEMS MAY BE USED IN A DEGRADED MODE AS SPECIFIED BY THE MANAGEMENT RULES OR AS DICTATED BY FLIGHT NEED.

Self-explanatory.

A1-55

CONFLICTING FLIGHT RULES

- A. RULES WHICH ARE KNOWN TO HAVE FLIGHT SPECIFIC EXCEPTIONS OR OPTIONS WILL BE NOTED IN THIS DOCUMENT (NSTS-12820) AND DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX (NSTS-18308).
- B. RULES FROM THE "ALL FLIGHTS" DOCUMENT FOR WHICH EXCEPTIONS ARE PROPOSED WHICH HAVE NOT BEEN PREVIOUSLY IDENTIFIED AS EXCEPTIONS OR OPTIONS MUST BE PROCESSED AND APPROVED AS A PERMANENT CHANGE OR AS A DEVIATION TO THE ALL FLIGHTS DOCUMENT.

Flight-specific exceptions or options to the All Flights rules are at the discretion of the lead flight director provided that the All Flights rules permit them. If the All Flights rule does not make provisions for an exception, a change request (CR) must be written to change the rule, and the CR may be approved as either a change or deviation. The annotation in the Annex rationale should reflect the type of rule approval, i.e., stating, "This rule is a flight-specific exception or option (as applicable) to Flight Rule xx.yy-zz." or, "This rule is a flight-specific deviation from Flight Rule xx.yy-zz."

FLIGHT RULES

A1-56

INSTRUMENTATION ONBOARD VS. GROUND READOUT PHILOSOPHY

WHERE DISCREPANCIES EXIST BETWEEN ONBOARD AND GROUND READOUTS, DEDICATED ONBOARD METERS WILL BE CONSIDERED PRIME OVER GROUND READOUTS. FOR GENERAL PURPOSE COMPUTER (GPC)-DRIVEN DATA, THE MOST REASONABLE (IF IT CAN BE DETERMINED) OR THE MOST CONSERVATIVE READOUT WILL BE USED. LOSS OF INSTRUMENTATION WHICH PRECLUDES IMPLEMENTATION OF A FLIGHT RULE WILL NOT NECESSARILY CAUSE FLIGHT TERMINATION.

The purpose of this rule is to minimize the possibility of invoking a flight rule as a result of transducer failures, shifts, or errors introduced in the communications path from the vehicle to the MCC. In general, if the same transducer drives both an onboard meter and a telemetry input, the onboard meter readout, if reasonable, should be more accurate since it is closer to the source. In cases of GPC-driven data (no meter or other analog display), when two readouts (both onboard or onboard and ground) differ but are still reasonable, the more conservative of the two is used as it results in the safest course of action. If a mandatory instrumentation parameter exists which, if lost, would result in invoking a flight rule, it is specifically identified in these rules. In general, instrumentation failures will not cause flight termination since critical systems failure can be monitored by redundant means.

A1-57

FLIGHT-CRITICAL MODING

WHERE REDUNDANT CAPABILITIES ARE PROVIDED TO EXECUTE FLIGHT-CRITICAL SWITCHING OR MODING, THE PATHS WILL BE CONFIGURED TO PREVENT LOSS OF A TOTAL CAPABILITY FOR LOSS OF A SINGLE GPC, DATA PATH, OR POWER SOURCE.

Self-explanatory.

FLIGHT RULES

A1-58 SHUTTLE OPERATIONAL DATA BOOK (SODB), VOLUME III, DATA USE

IN CONTINGENCY SITUATIONS, SODB, VOLUME III, DATA IS USED WITH THE BEST ENGINEERING JUDGMENT RECOGNIZING THAT SOME OF THE DATA CONTAINS ENGINEERING ESTIMATES FOR NON-NOMINAL PERFORMANCE EVALUATION AND MAY NOT BE SUPPORTED BY TEST DATA.

A1-59 ACTIVITIES DURING YEAR END ROLLOVER/LEAP SECOND INCORPORATION

IF POSSIBLE, CRITICAL PHASES OF MISSIONS WILL NOT BE PERFORMED DURING AN OCCURRENCE OF A MASTER TIMING UNIT (MTU) YEAR END ROLLOVER OR AN INCORPORATION OF A LEAP SECOND.

Whenever an MTU year end rollover or leap second incorporation occurs during a flight, the MCC has to perform several off-nominal procedural workarounds including reconfiguring the data dump handler (DDH) (which directly affects near real-time telemetry (NRT) processing and retrieval), manually processing the GSFC TDRS state vectors, and altering the build process for stored program commands (SPC's). Additionally, the 1-second bias to the data as a result of a leap second incorporation during ascent/entry is deemed undesirable by the ground navigation and tracking personnel. Tracking data in the high speed phases of ascent/entry would be 1 second out of sync with the mission operations computer (MOC), and the MCC would have to manually implement a bias to account for the 1 additional second; if this bias is not implemented, the tracking data would be essentially useless. Per the ground navigation personnel, implementation of this bias is not a trivial task. For year end rollover, the same concerns apply, but to a greater degree. Therefore, because of the dependency of several critical mission phases on accurate time, these phases should not be performed during an MTU year end rollover or leap second incorporation. However, if other factors prevent a rescheduling of these critical phases (e.g., weather, next PLS conditions), the risk of performing these critical phases during MTU year end rollover or leap second incorporation will be accepted.

A1-60 THROUGH A1-100 RULES ARE RESERVED

FLIGHT RULES

GENERAL DEFINITIONS

A1-101 **AS SOON AS PRACTICAL (ASAP)**

AS SOON AS PRACTICAL (I.E., AS SOON AS POSSIBLE AND REASONABLE)

Self-explanatory.

A1-102 **HIGHLY DESIRABLE (HD)**

A SPACE TRANSPORTATION SYSTEM (STS) OR GROUND SUPPORT ELEMENT THAT ENHANCES ACCOMPLISHMENT OF THE FLIGHT. CONSIDERATION WILL BE GIVEN TO HOLDING THE COUNT FOR THE REPAIR OF AN HD ELEMENT, IF CONVENIENT, BUT IN NO CASE WILL THE LAUNCH BE SCRUBBED.

Self-explanatory.

A1-103 **MANDATORY (M)**

AN STS OR GROUND ELEMENT THAT IS REQUIRED TO ENSURE CREW SAFETY, IMPLEMENT LAUNCH GO/NO-GO CRITERIA, LAUNCH ABORT, OR EARLY FLIGHT TERMINATION FLIGHT RULES.

Self-explanatory.

FLIGHT RULES

A1-104

FLIGHT PHASE

- A. PRELAUNCH - PRIOR TO SRB IGNITION.
- B. ASCENT - SRB IGNITION THROUGH ORBITAL MANEUVERING SYSTEM 2 (OMS-2) CUTOFF.
- C. ORBIT - OMS-2 CUTOFF TO DEORBIT MANEUVER IGNITION.
- D. DEORBIT PREPARATION - FROM DEORBIT TIME OF IGNITION (TIG) -3.5 HRS TO DEORBIT TIG.
- E. EXTRAVEHICULAR ACTIVITY (EVA) - START OF AIRLOCK DEPRESSURIZATION THROUGH REPRESSURIZATION AND VERIFICATION OF AIRLOCK INTEGRITY.
- F. ENTRY - DEORBIT MANEUVER IGNITION THROUGH ROLLOUT.
- G. POSTLANDING - ROLLOUT THROUGH CREW EGRESS.
- H. TURNAROUND OPERATIONS - POST CREW EGRESS.

Self-explanatory.

FLIGHT RULES

A1-105

THROTTLE SETTINGS

- A. NOMINAL THROTTLE - MAXIMUM SPACE SHUTTLE MAIN ENGINE (SSME) THROTTLE SETTING LEVEL THAT IS ALLOWED DURING A NOMINAL (NOT LOW PERFORMANCE) ASCENT.
- B. ABORT THROTTLE - MAXIMUM CERTIFIED SSME THROTTLE SETTING LEVEL TO BE USED FOR OFF-NOMINAL (LOW PERFORMANCE) ASCENT AND INTACT ABORT MODES.
- C. MAX THROTTLE - MAXIMUM SELECTABLE SSME THROTTLE SETTING LEVEL.

Self-explanatory.

A1-106

LANDING SITES

- A. PRIMARY LANDING SITE (PLS) - THE PERMISSION SELECTED, NOMINAL END-OF-MISSION (EOM) LANDING SITE OR THE CONUS (EDW, KSC, NOR) LANDING SITE SELECTED DAILY IF REQUIRED FOR EARLY MISSION TERMINATION ("NEXT PLS"). SEE RULE {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS. @[113095-1800]
- B. SECONDARY LANDING SITE (SLS) - BACKUP TO THE PRIMARY EOM LANDING SITE USED WHEN THE PRIME EOM LANDING SITE DOES NOT MEET ACCEPTABLE CONDITIONS.
- C. EMERGENCY LANDING SITES (ELS) - LANDING SITES, CARRIED IN THE ONBOARD SOFTWARE OR AVAILABLE FOR UPLINK FROM THE MCC, NOT SUPPORTING PLANNED EOM OR INTACT ABORTS. SEE RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA. @[113095-1800]
- D. ABORT-ONCE-AROUND (AOA) SITE - THE SITE SELECTED PERMISSION FOR LANDING IN THE EVENT OF AN AOA ABORT. (REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS). @[121593-1590]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A1-106 LANDING SITES (CONTINUED)

- E. ALTERNATE AOA SITE - THE BACKUP TO THE PRIME AOA SITE; USED WHEN THE PRIME AOA SITE DOES NOT MEET ACCEPTABLE CONDITIONS (REF. RULES {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS, AND {A2-2}, ABORT LANDING SITE REQUIREMENTS). @[121593-1590]
- F. TRANSOCEANIC ABORT LANDING (TAL) SITE - THE SITE(S) SELECTED PERMISSION FOR LANDING IN THE EVENT OF A TAL ABORT.
- G. ALTERNATE TAL SITE - THE BACKUP TO THE PRIME TAL SITE; USED WHEN THE PRIME TAL SITE DOES NOT MEET ACCEPTABLE CONDITIONS (REF. RULE {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS).
- H. AUGMENTED CONTINGENCY LANDING SITE (ACLS) - A TAL SITE, WHICH IS NO-GO FOR TAL DUE TO WEATHER, REDUNDANCY, OR TOUCHDOWN/ROLLOUT CONDITIONS, THAT IS USED TO FILL CONTINGENCY POWERED FLIGHT PERFORMANCE GAPS AND PROVIDE COVERAGE FOR CERTAIN ASCENT SYSTEMS FAILURES REQUIRING EARLIEST LANDING TIME. WEATHER (EXCEPT AS NOTED BELOW) AND TOUCHDOWN/ROLLOUT CONDITIONS ARE NOT CONSIDERED FOR THESE SITES, AND MINIMUM REQUIRED NAV/LANDING AIDS ARE REDUCED TO A SINGLE-STRING TACAN OR DME, WITH SINGLE-STRING MLS REQUIRED FOR REDUCED CEILING AND VISIBILITY LIMITS AS DEFINED IN RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. FOR NIGHT LANDINGS, RUNWAY EDGE LIGHTING IS ALSO REQUIRED. @[102793-1560] @[113095-1800]

Self-explanatory.

FLIGHT RULES

A1-107

LANDING OPPORTUNITIES

- A. ENTER FIRST DAY PLS - THE PLANNED OPPORTUNITY FOR LANDING ON THE DAY OF LAUNCH IF A SITE IS AVAILABLE, REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS, OTHERWISE LAND ON FLIGHT DAY 2 PLS. @[121593-1590]
- B. ENTER NEXT PLS - THE NEXT LANDING OPPORTUNITY AT THE PRIMARY LANDING SITE, WHICH SATISFIES LIGHTING, WEATHER, AND CREW CONSTRAINTS.
- C. ENTER ASAP - ENTER AS SOON AS PRACTICAL TO THE NEXT AVAILABLE LANDING SITE (PLS, SLS, OR ELS).
- D. ENTER IMMEDIATELY - ENTER IMMEDIATELY TO AN UNSPECIFIED LANDING AREA.

For some systems failures, the risk of staying on orbit beyond the first flight day is considered to be high enough to justify the increased risk associated with a day 1 entry. These failures are defined in Rule {A2-301}, CONTINGENCY ACTION SUMMARY.

This set of failures is a subset of the larger group of failures that require entry at the next PLS. This larger set includes all systems failures where deorbit will be planned for the next opportunity to the primary landing site which meets required weather and lighting constraints and allows the crew to have adequate rest and perform a nominal deorbit prep. These failures are listed in the individual sections of this book and are consolidated in Rule {A2-1001}, ORBITER SYSTEMS GO/NO-GO.

Enter ASAP and immediately are self-explanatory. They only apply to the most critical of circumstances where staying on orbit would mean probable loss of the orbiter and crew. These failures are also listed in Rule {A2-301}, CONTINGENCY ACTION SUMMARY.

FLIGHT RULES

A1-108

CREW EGRESS/ESCAPE MODES

- A. MODE I - UNAIDED PRELAUNCH EGRESS AND ESCAPE. @[041196-1881A]
- B. MODE II - AIDED PRELAUNCH EGRESS AND ESCAPE, THE FLIGHT CREW IS ASSISTED BY THE CLOSEOUT CREW.
- C. MODE III - AIDED PRELAUNCH EGRESS AND ESCAPE, THE FLIGHT CREW IS ASSISTED BY FIRE/RESCUE PERSONNEL.
- D. MODE IV - AIDED PRELAUNCH EGRESS AND ESCAPE, THE FLIGHT CREW AND CLOSEOUT CREW ARE ASSISTED BY FIRE/RESCUE PERSONNEL.
- E. MODE V - UNAIDED POSTLANDING EGRESS AND GROUND-AIDED ESCAPE/EVACUATION.
 - 1. HATCH ON MODE V - NORMAL HATCH OPENING.
 - 2. HATCH JETTISON MODE V - PYROTECHNIC HATCH JETTISON (IMMINENT CREW HAZARD).
 - 3. ESCAPE PANEL MODE V - PYROTECHNIC JETTISON OF WINDOW 8 ESCAPE PANEL (HATCH EGRESS IMPOSSIBLE). @[041196-1881A]
- F. MODE VI - AIDED POSTLANDING EGRESS, ESCAPE, AND EVACUATION WITHIN AN AREA ACCESSIBLE BY THE GROUND CONVOY ELEMENTS. @[041196-1881A]
- G. MODE VII - AIDED POSTLANDING EGRESS, ESCAPE, AND EVACUATION AT A LOCATION INACCESSIBLE BY THE GROUND CONVOY ELEMENTS.
- H. MODE VIII - BAILOUT DURING CONTROLLED, GLIDING FLIGHT. @[041196-1881A]

Self-explanatory.

FLIGHT RULES

A1-109

CREW MEDICAL (MED) CONDITIONS

- A. MED 0 - PATIENT SEVERELY INJURED BEYOND REASONABLE EXPECTATION OF SURVIVAL OR DECEASED.
- B. MED 1 - CONDITION CRITICAL, PATIENT REQUIRES IMMEDIATE CARE AND EVACUATION.
- C. MED 2 - CONDITION FAIR TO POOR, PATIENT'S NEED FOR CARE IS NOT SO ACUTE, BUT WILL REQUIRE CARE BEFORE EVACUATION.
- D. MED 3 - CONDITION GOOD TO FAIR, PATIENT WITH INJURIES WHICH DO NOT REQUIRE HOSPITALIZATION; SOME MEDICAL CARE MAY BE NEEDED, BUT NOT ON A TIME CRITICAL BASIS.

These medical codes are the standard triage codes used by the DOD triage teams and the KSC triage teams. Triage codes should be in universal agreement so accurate reporting of crew medical conditions can occur.

FLIGHT RULES

A1-110

REMOTE MANIPULATOR SYSTEM (RMS)

- A. STOW/DEPLOY - ROLL THE MANIPULATOR POSITIONING MECHANISM (MPM) INBOARD/OUTBOARD WHILE THE RMS IS CRADLED AND LATCHED.
- B. CRADLE/UNCRADLE - MOVE THE RMS TO/FROM ITS RETENTION LATCHES.
- C. BERTH/UNBERTH - USE THE RMS TO ATTACH/DETACH A PAYLOAD TO/FROM THE PAYLOAD BAY OR PALLET STRUCTURE.
- D. CONTROL MODES:
 - 1. MANUAL AUGMENTED - POINT OF RESOLUTION (POR) IS MANEUVERED BY CONTROL INPUTS VIA THE REMOTE HAND CONTROLLERS (RHC'S).
 - 2. AUTO - POR IS MANEUVERED BY THE GPC TO PREPROGRAMMED POINTS.
 - 3. OPERATOR COMMANDED - COMPUTER COMMANDED MODE WITH POR MANEUVERED TO A POINT LOADED BY THE CREW.
 - 4. SINGLE - JOINTS ARE DRIVEN ONE AT A TIME BY "PLUS" AND "MINUS" DRIVE COMMANDS FROM THE DISPLAYS AND CONTROLS (D&C) PANEL. THE UNDRIVEN JOINTS ARE HELD IN POSITION BY THE GPC.
 - 5. DIRECT - SAME AS "SINGLE" WITH THE EXCEPTION THAT THE UNDRIVEN JOINTS ARE HELD IN POSITION BY THE BRAKES.
 - 6. BACKUP - SAME AS "DIRECT" WITH THE EXCEPTION THAT NO DISPLAYS ARE AVAILABLE AND POWER IS SUPPLIED BY MAIN BUS B VICE MAIN BUS A.

Self-explanatory.

FLIGHT RULES

A1-111 **TIME REFERENCE DEFINITIONS**

DAY - ANY 24-HOUR PERIOD

END-OF-MISSION (EOM) ± - TIME REFERENCE RELATING TO THE EOM WHERE THE PLANNED LANDING TIME IS ZERO.

FLIGHT DAY (FD) - TIME REFERENCE RELATING TO A CREWMEMBER'S WORK/REST CYCLE. FD 1 BEGINS AT LAUNCH WITH SUBSEQUENT FD'S BEGINNING AT CREW WAKE UP AND CONTINUING THROUGH CREW SLEEP.

MISSION ELAPSED TIME (MET) - TIME REFERENCE RELATING TO MET, WHERE LAUNCH IS 0/00:00 (D/HH:MM).

Self-explanatory.

A1-112 **MULTIFUNCTION ELECTRONIC DISPLAY SUBSYSTEM**

FOR THE MEDS CONFIGURATION: @[040899-2459B]

FLIGHT RULES THAT REFERENCE MCDS ARE ACTUALLY REFERENCING MEDS.

- A. FLIGHT RULES THAT REFERENCE A DEU ARE ACTUALLY REFERENCING AN IDP.
- B. FLIGHT RULES THAT REFERENCE A DU ARE ACTUALLY REFERENCING AN MDU.
- C. FLIGHT RULES THAT REFERENCE PANEL F6, F7, AND F8 FLIGHT INSTRUMENT TAPES AND SUBSYSTEM METERS ARE ACTUALLY REFERENCING THE FUNCTION OF THOSE TAPES AND METERS DISPLAYED ON AN MDU.
- D. FLIGHT RULES THAT REFERENCE A FLIGHT INSTRUMENT (ADI, HSI, SPI, ETC) ARE ACTUALLY REFERENCING THE FUNCTION OF THOSE INSTRUMENTS DISPLAYED ON AN MDU.

This flight rule allows existing flight rules to be compatible with MEDS configured vehicles and also allows existing rules to be used with a mixed fleet of MCDS and MEDS. @[040899-2459B]

FLIGHT RULES

SECTION 2 - FLIGHT OPERATIONS

PRELAUNCH

A2-1 **PRELAUNCH GO/NO-GO REQUIREMENTS**

LAUNCH WILL BE NO-GO IF THE FOLLOWING CONDITIONS ARE NOT SATISFIED:

- A. MINIMUM STS SUBSYSTEMS CAPABILITY (REF. LAUNCH COMMIT CRITERIA (LCC)).

The vehicle must satisfy certain minimum subsystems capabilities to be GO for launch. Prelaunch OMI's implement checkout requirements specified in the OMRSD. In general, these are designed to demonstrate operation of all testable subsystems within prescribed limits. Any deviation must be accounted for, either by repair, replacement, or a waiver from the MMT. Launch commit criteria are designed to ensure those systems that are monitorable operate within acceptable limits during the final hours in the launch countdown. In certain areas, launch may be permitted with certain equipment losses provided those are well understood to be isolated occurrences and not symptomatic of a potentially generic problem. These instances will be specified in the LCC document.

- B. MINIMUM ONBOARD INSTRUMENTATION REQUIREMENTS (REF. LCC).

The vehicle must satisfy minimum onboard display/control capability via crew display/control equipment as well as minimum telemetry/instrumentation requirements to be GO for launch. These capabilities are required to allow ground and crew monitoring and control of the vehicle systems for critical failures and crew capability to fly the vehicle should it become necessary. These are documented in the Launch Commit Criteria.

- C. VEHICLE PERFORMANCE MARGINS (REF. RULE {A4-1A}, PERFORMANCE ANALYSIS).

The vehicle must satisfy the propellant reserve performance margins (ref. Rule {A4-1A}, PERFORMANCE ANALYSIS) in order to be GO for launch. These margins are protected to assure that sufficient propellant reserves cover loading and systems usage dispersions during ascent.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-1 PRELAUNCH GO/NO-GO REQUIREMENTS (CONTINUED)

- D. ACCEPTABLE STRUCTURAL LOADS AND DAY-OF-LAUNCH I-LOAD UPDATE (DOLILU) ASSESSMENT (REF. NSTS-08329, VOL. VIII, DOLILU OPERATIONS SUPPORT PLAN (DOSP)). @[091098-6622C]

The generation of the DOLILU I-loads must be consistent with certification groundrules and the launch day environment, and vehicle structural loading must remain within acceptable boundaries to be GO for launch. The assessment is performed at several points in the pre-launch timeframe using balloon-measured upper-level wind data. The DOLILU process launch decision criteria applied to this assessment is specified in the DOSP. @[091098-6622C]

- E. MINIMUM GROUND INSTRUMENTATION REQUIREMENTS.

SUFFICIENT GROUND INSTRUMENTATION SUPPORT SHALL BE OPERATIONAL AT LAUNCH TO SATISFY A/G VOICE, TELEMETRY, TRACKING, AND COMMAND REQUIREMENTS FOR ASCENT AND REQUIRED ABORT LANDING SITES, REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS. SPECIFIC EQUIPMENT REQUIREMENTS ARE DEFINED IN FLIGHT RULES SECTION 3.

FOR FIRST DAY PLS LANDING SITES ONLY, EQUIPMENT OUTAGES ARE ALLOWED ONLY IF CRITICAL EQUIPMENT ETRO IS PRIOR TO FIRST DAY PLS DEORBIT DECISION TIME, OR IF FIRST DAY PLS IS NOT REQUIRED, ETRO MUST BE PRIOR TO SECOND DAY PLS DEORBIT DECISION TIME.

Detailed requirements and the facilities necessary to provide support and redundancy for ascent and ascent aborts vary from phase to phase and even within each phase. In general, the requirements are broken down into A/G voice, telemetry, tracking, and command capabilities as high-level requirements. These, in turn, determine the facilities support requirements which are detailed in section 3 for each capability and facility. For mandatory ascent abort landing sites, full capabilities must be functional prior to launch. If an ascent abort landing site is not required, then full capabilities are highly desirable, and loss of any capability will not lead to a launch hold. For a required first day PLS site, equipment outages are allowed if repairs can be guaranteed complete prior to landing. In any event, all required equipment must be planned to be functional at one CONUS site by second day PLS time, or launch is NO-GO.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-1

PRELAUNCH GO/NO-GO REQUIREMENTS (CONTINUED)

- F. ACCEPTABLE LANDING CONDITIONS FOR REQUIRED ABORT LANDING SITES, REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS. IF AN ABORT LANDING SITE IS NOT MANDATORY, ACCEPTABLE LANDING CONDITIONS ARE STILL HIGHLY DESIRABLE AT THAT SITE. CONDITIONS WHICH MUST BE MET ARE:
1. NO VIOLATIONS OF THE LANDING SITE WEATHER CRITERIA (REF. RULES {A4-2}, LANDING SITE CONDITIONS, AND {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). @[111094-1622B]
 2. FOR ALL LANDINGS BUT FIRST OR SECOND DAY PLS, NO VIOLATION OF ENTRY ANALYSIS LIMITS INCLUDING:
 - a. APPROACH AND LAND TRANSITION (REF. RULE {A4-156}, HAC SELECTION CRITERIA)
 - b. NORMALIZED TOUCHDOWN DISTANCE (REF. RULE {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION)
 - c. TIRE SPEED/ROLLOUT/BRAKING LIMITS (REF. RULE {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS)
 - d. NZ AND Q-BAR CONSTRAINTS (REF. RULE {A4-207}, ENTRY LIMITS) @[072795-1788B]
 3. ACCEPTABLE GROUND NAVAIDS (REF. RULES {A3-201}, TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY; {A3-202}, MLS; AND {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). @[111094-1622B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-1

PRELAUNCH GO/NO-GO REQUIREMENTS (CONTINUED)

4. ACCEPTABLE LANDING AND VISUAL AIDS (REF. RULE {A3-203}, LANDING AID REQUIREMENTS).
5. ACCEPTABLE CURRENT AND PREDICTED RUNWAY CONDITIONS (REF. RULE {A4-111}, RUNWAY ACCEPTABILITY CONDITIONS).
@[111094-1622B]
6. ACCEPTABLE COMMUNICATIONS FROM THE MCC TO THE REQUIRED ASCENT ABORT SITES. (REF. RULES {A3-52E}, MCC INTERNAL VOICE, AND {A3-156}, MCC/ASCENT ABORT SITE INTERFACE).
@[111094-1716A]

Prelaunch, the MCC must be able to communicate with the ascent abort landing sites. This insures that there has not been a change in weather or nav/landing aid status. It also insures that anomalies can be passed to the ground support team and that the runway and airspace are clear for a safe landing. This can be accomplished by insuring that at least one of the communications capabilities listed below are available:

- a. Longline (LFPI)
- b. INMARSAT
- c. Commercial Telephone @[111094-1716A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-1****PRELAUNCH GO/NO-GO REQUIREMENTS (CONTINUED)**

7. DAYLIGHT LANDING UNLESS CREW SPECIFICALLY TRAINED FOR NIGHT LANDING AND RELATED LANDING AIDS FUNCTIONAL (REF. PARAGRAPHS 3 AND 4 ABOVE). EXCEPTIONS ARE ALLOWED FOR AOA (IF NOT REQUIRED) AND FIRST DAY PLS.

Acceptable landing conditions and aids requirements rationale for each of the requirements may be found in the referenced rule. A TAL site is highly desirable if RTLS/two-engine press capability overlap exists since TAL is preferred over RTLS (ref. Rule {A2-52}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES) for an engine out performance. TAL capability also provides for performance gap management and extended coverage during ascent for systems aborts that require abort modes other than first day PLS. Rules {A1-106E} and {A1-106G}, LANDING SITES, reference this rule.

For all abort landings, the entry analysis using the forecast and measured (ref. Rule {A4-112}, UPPER AND LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA) environmental data must be predicting a safe landing. For first day PLS, prelaunch analysis is not generally performed due to the length of time from prelaunch data collection until actual landing; similarly, only forecast weather is used for first day PLS status, not prelaunch observations. ©[111094-1622B]

If AOA is not required for performance reasons, then systems AOA is an extreme contingency case and crew pilot pool night training is considered adequate. Lighting at first day PLS is not a design groundrule; lighted launch, TAL, and first day PLS cannot all be accomplished for some high inclination missions. Therefore, pilot pool night training is considered acceptable for systems AOA or first day PLS. Also for first day PLS, crew workday is not protected.

Predictions of weather and or equipment availability at the first day PLS site are less accurate due to the time involved (4.5 to 10.5 hours after launch). The requirements to use a first day PLS site are based on performance and systems redundancy requirements. If a first day PLS site is not available, the single engine out abort boundaries are adjusted to ensure that a stable orbit is achieved which will support a delay in landing until flight day 2 when more landing sites and better conditions will be available. The redundancy requirements are considered an acceptable risk (multiple failures of proven highly reliable equipment occurring in short periods of time). Acceptance of this risk allows an on time launch when all conditions other than those at the first day PLS site are acceptable.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-1 PRELAUNCH GO/NO-GO REQUIREMENTS (CONTINUED)

- G. THE LAUNCH WILL BE NO-GO IF PRELAUNCH, U.S. SPACE COMMAND ORBIT CONJUNCTIONS (COMBO ANALYSIS), OR EASTERN RANGE (ER) COLLISION AVOIDANCE (COLA) CONFLICTS ARE PREDICTED. LAUNCH HOLD TO THE NEXT EVEN MINUTE IS UTILIZED TO CLEAR CONFLICTS (REF. RULE {A4-3}, ORBIT CONJUNCTIONS/CONFLICTS, AND LCC 5.6). ©[051194-1605]

Responsibility for calling launch holds based on COLA's lies with ER/KSC, while computation of misses between orbits (COMBO) conflict responsibility lies with JSC based on data provided by U. S. Space Command.

U.S. Space Command and ER perform several prelaunch analyses to determine if any such orbital conjunctions may result. The U.S. Space Command COMBO analysis is performed assuming an on-time launch while the ER COLA analysis evaluates the entire launch window. Also, ER analyses are performed only against mannable space vehicles (such as Mir) for the first orbit after liftoff, while U.S. Space Command provides data to JSC for analysis of the entire U.S. Space Command orbiting object catalog for a period of 2 hours after liftoff. If clearance limits are exceeded for a launch at the planned time, the launch must be held until adequate clearance can be assured. For practical considerations, such holds will extend to the even minute. ©[051194-1605]

- H. ACLS'S ARE NOT REQUIRED FOR LAUNCH COMMIT.

These sites are for contingency cases only and are therefore not required for launch.

- I. POSTLAUNCH SEARCH AND RESCUE (SAR) OPERATIONS - THE LAUNCH WILL NOT BE HELD BASED ON SAR WEATHER OR THE FAILURE OF ANY EQUIPMENT THAT WOULD BE USED TO SUPPORT A POSTLAUNCH SAR OPERATION.

Establishing weather/sea state criteria across the total trajectory/range for SAR operations is prohibitive, and we would be NO-GO for launch most of the time. Additionally, the weather and sea state along the total trajectory will probably not be known. Delaying the launch to accommodate repair of a SAR aircraft or other piece of equipment, or to allow improvement in weather conditions in areas for which we may not have an adequate forecast anyway, is not the prudent action. The DOD response for bailout support may be affected.

FLIGHT RULES

A2-2

ABORT LANDING SITE REQUIREMENTS

CONTINUOUS SINGLE SSME OUT INTACT ABORT COVERAGE IS REQUIRED THROUGHOUT POWERED FLIGHT (REF. NSTS 07700, VOLUME X, PARAGRAPHS 3.2.1.1.4 AND 3.2.1.5.1.1 THROUGH 3.2.1.5.1.3). PRELAUNCH ANALYSIS MUST DEMONSTRATE THIS CONTINUOUS SINGLE SSME OUT INTACT ABORT COVERAGE EXISTS OR LAUNCH IS NO GO PER RULE {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS. @[041196-1801A]

THIS CONTINUOUS SINGLE SSME OUT INTACT ABORT COVERAGE MUST INCLUDE SYSTEMS FAILURE TOLERANCE AND BOTH SYSTEMS AND ENVIRONMENTAL PERFORMANCE DISPERSIONS AS REQUIRED.

THIS CONTINUOUS SINGLE ENGINE OUT INTACT ABORT COVERAGE MUST BE TO A FULLY ACCEPTABLE LANDING SITE THROUGHOUT POWERED FLIGHT. THERE CAN BE NO PRELAUNCH PREDICTED SINGLE SSME OUT ABORT GAP BETWEEN LAST RTLS AND FIRST TAL NOR BETWEEN LAST RTLS OR LAST INTACT TAL CAPABILITY (TO A GO TAL SITE) AND FIRST PRESS CAPABILITY, AND NO GAP IN SINGLE SSME OUT PROTECTION FOLLOWING FIRST PRESS CAPABILITY NO MATTER WHICH OF THE FOLLOWING CRITERIA IS USED TO DEFINE PRESS CAPABILITY. @[041196-1801A]

- A. AN RTLS LANDING SITE IS REQUIRED FOR LAUNCH COMMIT.
- B. A TAL LANDING SITE IS REQUIRED FOR LAUNCH COMMIT UNLESS THERE IS RTLS AND TWO ENGINE PRESS CAPABILITY OVERLAP. THEN A TAL LANDING SITE IS HIGHLY DESIRABLE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-2

ABORT LANDING SITE REQUIREMENTS (CONTINUED)

- C. AN AOA LANDING SITE IS HIGHLY DESIRABLE. AN AOA LANDING SITE IS REQUIRED FOR LAUNCH COMMIT ONLY IF BOTH OF THE FOLLOWING CONDITIONS ARE MET:
1. AN INTACT SINGLE ENGINE OUT ABORT GAP EXISTS BETWEEN THE LATER OF LAST TWO ENGINE TAL TO A GO TAL SITE OR LAST TWO ENGINE RTLS AND TWO ENGINE PRESS CAPABILITY BASED ON ATO/MINIMUM HP SHALLOW DEORBIT (FD1 OR 2), AND [012402-5112B]
 2. TWO ENGINE PRESS CAPABILITY BASED UPON AOA STEEP PROVIDES CONTINUOUS SINGLE ENGINE OUT INTACT ABORT COVERAGE THROUGH MECO.

IF AN ASCENT INTACT ABORT LANDING SITE IS REQUIRED, THEN ALL LANDING SITE REQUIREMENTS, AS SPECIFIED IN THE FLIGHT RULES, MUST BE SATISFIED. IN THE CASE OF LAUNCH COMMIT WITHOUT A TAL OR AOA OR FIRST DAY PLS LANDING SITE, OR WITHOUT ANY COMBINATION OF SITES, THEN A CONTINGENCY OR SYSTEMS ABORT REQUIREMENT WILL BE SATISFIED USING EXISTING RTLS, TAL, ACLS, OR ABORT FROM ORBIT (AFO) CAPABILITY, POSSIBLY TO AN ELS. [041196-1801A] [012402-5112B]

NOTE: IF FIRST DAY PLS IS NO-GO DUE TO EQUIPMENT OUTAGE (REF. SECTION 3), THEN LAUNCH WILL BE GO ONLY IF ALL REQUIRED EQUIPMENT WILL BE AVAILABLE AT ONE OR MORE CONUS SITES PRIOR TO FD 2 PLS DEORBIT DECISION TIME.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-2

ABORT LANDING SITE REQUIREMENTS (CONTINUED)

Continuous single engine out intact abort capability to a landing site meeting all requirements must be achieved to commit to launch (ref. Rule {A4-1D}, PERFORMANCE ANALYSES). Since the only two engine intact abort mode available for the first 2 to 3 minutes of any flight is the RTLS site, GO conditions are mandatory at the RTLS landing site.

TAL is required unless RTLS/two engine press overlaps. Even in those cases, TAL is the preferred abort mode for an engine out during the RTLS/TAL overlap period. Launching without TAL capability should never be a design goal but a real-time fallback if weather or equipment outages at the TAL sites are the only constraints to launch.

The ATO single SSME out press boundary represents the earliest time at which an engine failure will result in the achievement of an acceptable MECO underspeed based on one of four cases: AOA steep capability; ATO/minimum Hp with shallow deorbit on flight day 1 capability; ATO/minimum Hp with shallow deorbit on flight day 2 capability, including OPS 2 use of Fwd RCS (ref. Rule {A2-53}, FORWARD RCS USAGE GUIDELINES); or ET impact in an acceptable area (ref. Rule {A4-55B}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS). If the design press boundary is based on AOA steep but no AOA site is available, then intact capability can still be provided as long as no gap exists between last RTLS or TAL and the press boundary based on ATO/minimum Hp for flight day 1/shallow deorbit. If no first day PLS site is available, then continuous single SSME out intact abort capability can still be provided as long as no gap exists between last RTLS or TAL and the press boundary based on AOA steep (press capabilities based on AOA steep and ATO/min Hp/flight day 1 shallow come only a few seconds apart). If neither an AOA or first day PLS site are available, then launch commit may be allowed if there is no gap between last RTLS or TAL and a press boundary based on ATO OMS-1/minimum Hp OMS-2/shallow deorbit on flight day 2. This boundary assumes the use of the Fwd RCS in OPS 2. Analysis has shown that there is no delay in this press boundary with respect to the flight day 1 press boundary when the Fwd RCS is allowed. ©[012402-5112B]

Even if a first day PLS site is not technically available at launch time, equipment outages may be resolved or weather may improve by deorbit decision time.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-2

ABORT LANDING SITE REQUIREMENTS (CONTINUED)

If a first day PLS landing site is not available, and systems failures requiring early flight termination occur, landing will be supported by RTLS, TAL, and AFO sites. This means that deorbit/landing might be made under ACLS/ELS type conditions: less than normally acceptable weather; lack of nav aids; etc. Systems failures requiring first day PLS are typically multiple failures or structural failures. In some cases, immediate deorbit is required. Should these type failures occur during the on-orbit timeframe, it has always been acceptable to land under ACLS/ELS conditions. In other cases, loss of redundancy in entry critical equipment is cause for a first day PLS. When a first day PLS site is not available, for loss of redundancy that normally calls for first day PLS, the risk of staying on orbit until the next day for improved landing conditions outweighs the risk of loss of critical equipment during the on-orbit wait for 24 hours.

If an abort landing site is required, the sites must fully meet the requirements listed in the flight rules (ref. Rules {A2-1G} and {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS, and {A4-107A}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS) for: landing site weather conditions including visibility, clouds, winds, turbulence, precipitation, runway/lakebed surface conditions, and resources necessary to measure low-level winds and atmospheric data (not PLS); crossrange, rollout margin, brake energy, navigation aids, and lighting (not PLS); touchdown margin (not PLS); and tracking (not AOA or PLS), telemetry, command, and air-ground voice (for PLS equipment outage ETRO must be before deorbit decision time). ©[072795-1772]

Rules {A1-106}, LANDING SITES; {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A3-1}, GROUND AND NETWORK DEFINITIONS; {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX; {A3-201}, TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY; {A4-2}, LANDING SITE CONDITIONS; and {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS, reference this rule. ©[ED]

FLIGHT RULES

A2-3 LAUNCH HOLD

NO MCC COUNTDOWN HOLD WILL BE CALLED AFTER T-31 SECONDS.

After T-31 seconds, launch holds will not be called by the MCC. T-31 seconds is the latest time that an MCC voice call for a launch hold can realistically be acted on in real time. Calling such a hold for MCC-related/non-ground launch sequencer (GLS) recognized problems does not merit the risk of such a launch hold. Backup onboard crew procedures can accomplish most abort functions should the MCC have a problem in the last few seconds before launch. @[061396 4005]

A2-4 LAUNCH DAY CREW TIME CONSTRAINTS

A. THE MAXIMUM TIME THE CREW WILL REMAIN IN THE VEHICLE IS 5 HOURS 15 MINUTES (EXCLUDING SAFING AND EGRESS TIME) (REF. LCC 3.2B), WHICH ALLOWS 2.5 HOURS OF HOLD TIME AFTER THE EARLIEST PLANNED LAUNCH TIME.

It is impractical to keep the crew in the launch-seat posture for an extended period of time. The crew enters the vehicle about 2 hours 45 minutes before launch; thus, a 2.5-hour launch window is preserved.

B. THE SCHEDULED CREW AWAKE TIME ON LAUNCH DAY WILL NOT NORMALLY EXCEED 16 HOURS. PRELAUNCH HOLD TIME AND POSTLAUNCH ORBITER/PAYLOAD CONTINGENCIES REQUIRING THE USE OF BACKUP TIMELINES WILL BE ACCOMMODATED AS LONG AS THEY DO NOT EXTEND THE CREW DAY BEYOND 18 HOURS.

Abnormally long days will result in crew fatigue and increase the potential for procedural errors that could affect safety or compromise mission success. Without a waiver, crew awake time on launch day will not be permission scheduled for greater than 16 hours. Since the crew is awake about 4 hours 55 minutes before launch, this allows for up to 11 hours 5 minutes of on-orbit activities before the start of the sleep period. If there is a launch hold or orbiter/payload contingencies require the use of backup timelines for deploy opportunities or off-nominal operations, these adjustments will be accommodated as long as the maximum crew day of 18 hours is not exceeded.

FLIGHT RULES

A2-5

PORT MODING/RESTRINGING GUIDELINES

- A. PORT MODING OR RESTRINGING MAY BE USED PER RULES {A2-254C}, ENTRY STRING REASSIGNMENT; {A2-63B}.2, ASCENT STRING REASSIGNMENT; {A7-5}, PASS GPC BCE FAILURE MANAGEMENT; AND {A7-105}, MDM PORT MODING, TO REGAIN LOST CAPABILITIES DUE TO GPC FLIGHT-CRITICAL BCE FAILURES. THE RECOVERY TECHNIQUE USED WILL DEPEND UPON THE SPECIFIC FLIGHT PHASE AND FAILURE SCENARIO PRESENT IN THE ORBITER. IN GENERAL, PORT MODING WILL BE ATTEMPTED DURING DYNAMIC PHASES OVER RESTRINGING EXCEPT AS NOTED IN THE REFERENCED RULES. [ED]

For flight-critical BCE failures, recovery of lost capability may be attempted via port moding or restringing. Port moding will recover the bypassed FC MDM, but will result in the loss of the other FC MDM on the affected string. Restringing will result in the entire recovery of string capability, but GPC redundancy may be given up.

Port moding is preferred over restringing because of the ease of implementation (crew SPEC entry), port mode reconfiguration is considered to be less hazardous to the PASS redundant set than restring reconfiguration, and the desire to maintain GPC redundancy.

In general, restringing will only be attempted when the appropriate restring criteria is satisfied. Otherwise, port moding may be done to recover lost capability.

- B. A RESTRING WILL BE PERFORMED TO MAINTAIN CRITICAL CAPABILITY FOR THE FOLLOWING POWERDOWNS:
1. LOSS OF AV BAY COOLING (TO RECOVER TWO STRINGS)
 2. LOSS OF CABIN PRESSURE
 3. LOSS OF FLASH EVAPORATOR SYSTEM
 4. LOSS OF TWO FREON LOOPS
 5. LOSS OF TWO FUEL CELLS
 6. LOSS OF TWO H₂O LOOPS

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-5

PORT MODING/RESTRINGING GUIDELINES (CONTINUED)

If powerdowns are required during ascent or entry, the GPC's are intentionally moded to STBY then HALT and powered off to maintain either acceptable orbiter power levels or GPC thermal limits. This rule allows for a restring to be performed for the listed powerdowns.

If GPC failures or multiple LRU failures in a subsystem exist, then the current restring rules will be adhered to. Measures will also be taken to ensure that the least number of strings are reassigned (ref. Rules {A2-63}, ASCENT STRING REASSIGNMENT; and {A2-254}, ENTRY STRING REASSIGNMENT).

Powerdown procedures have been verified and are officially documented as part of the Space Shuttle Flight Data File (FDF).

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] @[052401-4459A]

LIMITS APPLY TO DAY AND NIGHT LANDINGS UNLESS OTHERWISE NOTED. THE WEATHER LIMITS CONTAINED IN THIS RULE MUST BE SATISFIED WITH OBSERVATIONS AT THE GO/NO-GO DECISION TIME AND WITH THE FORECAST FOR THE LANDING TIME WITH THE FOLLOWING EXCEPTIONS: @[111094-1622B] @[021998-6490A]

FIRST - PRELAUNCH EVALUATION OF THE FD1 OR FD2 PLS IS BASED ONLY ON THE FORECAST.

The prelaunch PLS evaluations use only the forecast because the landing time is at least 5-10 hours after launch.

SECOND - CONSIDERATION MAY BE GIVEN TO RELAXING THE REQUIREMENT FOR A GO OBSERVATION AT DECISION TIME IF ANALYSIS CLEARLY INDICATES IMPROVING WEATHER CONDITIONS, AND THE FORECAST STATES THAT ALL WEATHER LIMITS WILL BE MET AT LANDING TIME.

In some weather situations, the observed weather at decision time may be NO-GO although weather conditions are improving. If there is a high level of confidence, based upon the observed weather trends, that the forecast for landing time is for weather to be within limits, consideration may be given to relaxing the GO requirement at decision time. Examples include: rain showers exhibiting predictable dissipation or movement away from the landing site at decision time; and crosswinds exceeding limits that are forecast to decrease diurnally for a landing near or after sunset. @[021998-6490A]

THE APPROACHES TO BOTH THE PRIME AND BACKUP RUNWAYS AT A GIVEN SITE MUST SATISFY THE CEILING, VISIBILITY, PRECIPITATION, AND THUNDERSTORM PROXIMITY LIMITS LISTED BELOW. WHENEVER AVAILABLE, A WEATHER RECONNAISSANCE FLIGHT WILL PROVIDE A LANDING SITE GO/NO-GO RECOMMENDATION. @[ED]

THIS RULE CONTINUED ON NEXT PAGE

A2-6 LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

A. CEILING AND VISIBILITY LIMITS

TABLE A2-6-I - CEILING AND VISIBILITY LIMITS

CEILING / VISIBILITY (K FT)/(SM)			REDUNDANT MLS	SINGLE STRING-MLS	NO MLS
KSC, EDW, NOR, AOA, DAILY PLS SELECTION (ALL SITES)	CONCRETE	DAY	?8/5 (WX RECON REQUIRED)	?10/7	
		NIGHT		NO-GO	
	LAKEBED	DAY		?10/7	
		NIGHT		?15/7	NO GO
RTL, TAL	CONCRETE	DAY	?5/4 RTL >5/5 TAL (WX RECON REQUIRED)	?10/7	
		NIGHT		NO GO	
ACLS / ECAL / ELS			0/0	?8/5	
PREDEORBIT: ONE APU FAILED OR ATTEMPT TWO APU'S PROCEDURE			?10/7		

@[050495-1776A] @[041097-4927A] @[051697-4928B]

1. CEILINGS AND VISIBILITY MUST MEET THE LIMITS LISTED IN TABLE A2-6-I TO BE GO CONDITIONS. THE MLS REQUIREMENTS APPLY TO THE GROUND AND ORBITER EQUIPMENT.

2. FOR EOM AND INTACT ABORTS, WX RECON MUST CONFIRM THAT THE PAPI'S OR AIMPOINT ARE VISIBLE FROM 8K (5K FOR RTL, TAL) TO PREFLARE AND THE BALL BAR IS VISIBLE FROM PREFLARE TO FINAL FLARE FOR CEILINGS BELOW 10K FT AND/OR VISIBILITY LESS THAN 7 STATUTE MILES (SM). WX RECON GO/NO-GO RECOMMENDATION (BASED ON CURRENT CONDITIONS) IS REQUIRED FOR CEILINGS AT OR BELOW 8K FT. WX RECON IS NOT REQUIRED FOR AN ACLS OR DAILY PLS SELECTION. @[050495-1776A] @[051697-4928B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

3. FOR KSC EOM ONLY, NO-GO CONSIDERATION WILL BE GIVEN TO CLOUD LAYERS BELOW 8K FT BEING REPORTED BY GROUND WEATHER OBSERVERS OR WEATHER AIRCRAFT GREATER THAN 2/8 COVERAGE AND LESS THAN OR EQUAL TO 4/8 COVERAGE (SCATTERED) AT THE DEORBIT BURN GO/NO-GO DECISION TIME. ©[111094-1622B] ©[061396-4008] ©[041097-4927A]

The definition of a ceiling is where the cumulative total of cloud cover exceeds more than 50 percent coverage of the sky. Restrictions to visibility include smoke, haze, fog, dust, clouds, and precipitation. The visibility limits are horizontal distances that correspond to slant range visibility from a point on the outer glide slope to the runway threshold. The 7 and 5 SM visibility limits correspond to the 10K and 8K foot altitude points on the outer glide slope respectively. Ceiling and visibility limits ensure that the crew has sufficient time on the outer and inner glide slopes to acquire the runway and the landing aids during preflare and final flare and correct for any navigation dispersions. Therefore, the minimum limits are a function of MLS availability, lighting conditions, and type of runway. Reference Rule {A8-18}, LANDING SYSTEMS REQUIREMENTS, for orbiter MLS requirements.

For RTLS and TAL, the ceiling limits can be reduced to 5K minimum altitude. Testing at AMES/VMS in combination with STA test matrices confirmed guidance was able to correct back to glide slope and centerline by approximately 5K feet assuming flight derived 3-sigma nav errors (+1100 feet in Z and 1400 feet in Y combined with worse case late MLS incorporation) and KSC design winds. STA data indicated acceptable landing parameters could be obtained with ceilings of 3K, 4K, or 5K. The primary difference between 3K and 5K consists of reaction time available on the outer glide slope for the pilot to transition from IFR to VFR conditions prior to initiation of the preflare maneuver at 2,000 ft AGL (3K allows 6 seconds and 5K allows 18 seconds prior to the preflare maneuver). Pilot evaluation concluded that 18 seconds was the minimum acceptable reaction time to safely transition from IMC or VMC prior to the preflare. Since the guidance and navigation capability is similar for RTLS and TAL, the testing applies to both RTLS and TAL. The higher visibility requirement of 5 NM for TAL provides a better view of the majority of the runway length when breaking out of a 5K ceiling. This view of the runway is desirable on a TAL since the CDR is less familiar with the TAL site than the SLF. A WX Recon GO/NO-GO recommendation by the STA is required when dealing with reduced ceilings to confirm the visibility and to also factor in other weather conditions (turbulence, crosswinds, etc.). Weather minimums/maximums are defined assuming that parameter is the only condition present. Combinations near the limits of ceilings, crosswinds, turbulence, and/or visibility need to be assessed by the WX Recon to ensure acceptable landing conditions. ©[050495-1776A] ©[051697-4928B]

Forecast experience and climatological studies indicate that in most KSC weather situations, 2/8 low cloud coverage is a reasonable criteria to expect a continuation of few or scattered (less than or equal to 4/8) low cloud conditions for 1 to 2 hours. Thus, due to the inherent variability and volatility of cloud conditions in the KSC area, strong consideration should be given to this 2/8 low cloud criteria at the deorbit burn GO/NO-GO decision time. However, there are meteorological situations when forecaster confidence of low clouds remaining scattered for touchdown time supports a GO deorbit burn decision when low clouds exceed 2/8 coverage at the deorbit burn GO/NO-GO decision time. ©[061396-4008]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

NO MLS

Without MLS, visual cues provide the only means to correct navigation dispersions remaining from TACAN/ADTA processing. Flight history has shown that the one-sigma position errors in the onboard state when using HAINS IMU's (no piloting dispersions included) just before processing MLS (at approximately 17K feet) are 188 ft u, 232 ft v, 225 ft w, and 374 ft RSS'd. The one-sigma position errors after one cycle of MLS processing are 38 ft u, 37 ft v, 64 ft w, and 83 ft RSS'd. Reference: The Summary of Navigation Errors through STS-88 (STF NAV-99-48500-008, February 4, 1999). Therefore, the crew can rely on guidance commands to a lower altitude when using MLS before beginning transition to visual cues. @[070899-6872A]

REDUNDANT AND SINGLE STRING MLS

The runway and orbiter must have redundant MLS for a night landing except for a lakebed runway. Single string MLS is acceptable because navigation dispersions are more tolerable on the larger area provided by the lakebed environment. If the single-string MLS fails, visual cues provide the only means to correct navigation dispersions. Flight Design and Dynamics personnel in cooperation with the Astronaut Office conducted an analysis to determine the night ceiling limit of 15K feet on the lakebed. The Shuttle Mission Simulator (SMS) and Shuttle Training Aircraft (STA) flew several sessions of night landings with dispersed initial conditions and good navigation. The experience gained from these analyses indicated that a ceiling level of 15K feet would be acceptable. This ceiling level will provide sufficient time for the crew to visually acquire the landing area, assess the need to correct dispersions, and take the necessary actions. If MLS were available, this is the approximate altitude when processing would begin. @[111094-1622B]

INOPERATIVE MLS COMPONENTS

For purposes of this rule, failure of any of the three MLS ground station measurements (azimuth, elevation, or range) constitutes a total failure of that string. Onboard navigation software will not process MLS data if either azimuth or range is unavailable. Although MLS azimuth and range data will be processed in case of ground elevation equipment failure, onboard altitude errors will not be corrected adequately. @[070899-6872A] @[041097-4927A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-6****LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)**

©[ED]

ACLS / ECAL / ELS

The ACLS, ECAL, or ELS limits require accepting additional risk. Emergency deorbit, SSME limits management, and abort gap closure procedures potentially use these sites. Rules {A2-205E} and {A2-205F}, EMERGENCY DEORBIT, and {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS, outline conditions for use of an ELS for emergency deorbit. Rule {A5-103A}.2, LIMIT SHUTDOWN CONTROL, specifies enabling main engine limits at the earliest single-engine capability to reach a prime TAL or ACLS for some cases following an SSME failure. This action precludes exposure to SSME limits-inhibited operation for any longer than necessary. Landing at an ACLS with zero/zero conditions carries less risk than continuing limits-inhibited SSME operation. Rule {A4-56I}.3, PERFORMANCE BOUNDARIES, specifies the use of an ACLS for abort gap closure. It is reasonable to attempt landing at an ACLS with zero/zero conditions if the attempt carries a reasonable probability of success and the only alternative is a bailout.

ONE APU FAILED (OR ATTEMPT TWO APU'S PROCEDURE)

Flight Rules {A2-207}, LANDING SITE SELECTION, and {A10-23}, APU ENTRY START TIME, summarize the conditions and rationale for selecting a landing site with one APU failed and using the ATTEMPT TWO APU's start procedure. With two APU's failed, the loss of hydraulic power causes reduced flight control authority, reduced braking, and loss of nose wheel steering. The APU placards assure safe conditions should the orbiter lose a second APU. ©[111094-1622B]

1. SURFACE WINDS AND TURBULENCE MUST MEET THE LIMITS LISTED IN TABLE A2-6-II TO BE "GO" CONDITIONS. @[ED]
2. THE LEVEL OF TURBULENCE SHOULD BE THE PROJECTED/ESTIMATED LEVEL FOR THE ORBITER (C130 OR T38 MAY BE COMPARABLE TO THE ORBITER; C12, C21, AND STA WOULD BE LESS FOR THE ORBITER).
3. STA GO FOR RTLS CROSSWINDS GREATER THAN 15 KNOTS WILL BE BASED ON A USABLE HUD BELOW 1000 FEET (HUD NOT CAGED AND SIGNIFICANT DIGITS FOR EAS AND ALTITUDE VISIBLE) AND ACCEPTABLE PILOT WORKLOAD IN THE PRESENCE OF LOW LEVEL SHEARS AS EVIDENCED BY HDOT, X-DISTANCE, Y-DISTANCE AND Y-DOT AT TOUCHDOWN. CDR'S HUD AND REDUNDANT MLS REQUIRED TO ENSURE ACCURATE HUD DATA AVAILABLE TO THE CREW. @[041196-1817B]

At KSC and EDW, the official observation measures the magnitude and direction of the wind every second. The peak wind is the highest wind magnitude measured during the preceding 2, 5, or 10 minutes. The average wind is the average of the wind measurements over the preceding 2 minutes. The peak and average winds are broken down into headwind, tailwind, and crosswind components relative to the runway.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

DEFINITION OF GUSTS

The Shuttle Program uses the term gust to define the difference between the peak and average wind. This is different from the meteorological definition of a gust, which is peak to trough. The gust limit applies to the measured wind, not individual wind components. The gust criterion restricts the wind conditions to those that are stable, predictable, and within the orbiter landing performance capability. ©[111094-1622B]

HEADWIND ©[111094-1622B]

The headwind certification limit is 20 knots steady state with a moderate turbulence model (approximately ? 10 knots) (reference ORBITER VEHICLE END ITEM SPECIFICATION FOR THE SPACE SHUTTLE SYSTEM, Part 1, Performance and Design Requirements, Section 10.1.3.3.1.1.3, Orbiter Entry and Landing Phase; Vehicle Design Environment; Steady State Winds (1K - surface), and Section 10.1.3.3.1.2, Design Vehicle Gust Environments). Headwind affects touchdown energy. Flight Rule {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION, documents the acceptable touchdown distance.

TAILWIND

Tailwind affects the landing by causing a longer touchdown distance, higher touchdown ground speed, loss of roll out margin, and higher brake energy. The tailwind certification limit is one-half the landing steady state design wind speed (reference ORBITER VEHICLE END ITEM SPECIFICATION FOR THE SPACE SHUTTLE SYSTEM, Part 1, Performance and Design Requirements, Section 10.1.3.3.1.1.3, Orbiter Entry and Landing Phase; Vehicle Design Environment; Steady State Winds (1K - surface)).

CROSSWIND

Crosswind limits are set due to concerns in the following areas: tire wear, main gear tire/strut loads, and orbiter handling qualities. Currently, the limiting factor for crosswinds is the vehicle certification limit of 20 knots. Previous concerns with orbiter handling qualities in the two point stance were eliminated with the "cost effective" rudder fix combined with beep trim derotation and significantly reduced lateral aerodynamic uncertainties. ©[041196-1817B] ©[052401-4459A]

The crosswind limit is referenced to peak wind (the maximum wind reported for 2/5/10-minute periods) versus average wind since peak winds tend to persist long enough to be significant with respect to orbiter handling qualities during the final approach, TD, and derotation.

With the incorporation of the new modified tire (which provided a thicker and more durable tread) and the September 1994 regrinding of the KSC surface, tire wear concerns up to 20 kts have been alleviated for all shuttle CONUS runway surfaces. ©[041196-1817B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

Main gear tire/strut loads have been certified under nominal conditions (pilot technique and crosswind of 15 kts) with dispersions RSS'd for pilot technique and crosswind up to 20 kts (reference Rule {A10-142}, TIRE PRESSURE [CIL]). AMES VMS testing in August 1995 indicated main gear strut loads were exceeded for landing in crosswinds greater than 20 knots. Additionally, the sideslip at landing in crosswinds greater than 20 knots exceeded all test data on tire capability. @[041196-1817B]

Previous AMES VMS evaluation of orbiter handling qualities as a function of crosswind (no systems failures and no aero uncertainties) have shown HQR's of Level I up to steady state crosswind of 12 kts (plus 2-3 kts of turbulence). HQR's increase from Level I to Level II as crosswind increases from 15 to 17.5 kts. For steady state crosswind in the 20-25 kt region, HQR's range from Level II to Level III. Testing with worse case aerodynamic uncertainties resulted in increased handling qualities rating of approximately 1.

The August 1995 AMES VMS testing used dynamic wind profiles and incorporated the "cost effective" rudder fix. Utilization of dynamic wind profiles (shear and turbulence) can shift HQR's from Level I to Level III for landing. August 1995 AMES VMS testing indicated that the most significant area of vehicle control is main gear touchdown when flown in dynamic wind profiles. Due to the infinite number of potential wind profiles, testing cannot determine acceptable shear or turbulence in the presence of crosswinds between 15 and 20 knots. The only tool available for determining an acceptable wind profile at touchdown with respect to shear and turbulence while remaining within vehicle limits is the STA since it will fly through the existing wind conditions (approximately 40 minutes from predicted RTLS landings). The STA is considered conservative due to the lower wing loading and slower roll response. Since testing at AMES indicated that there are some profiles that provide acceptable HQR's in crosswinds up to 20 knots, utilization of the STA would allow launch on the days where the wind profile is considered acceptable by the STA pilot. The STA GO will be based on usability of the HUD (HUD not caged and significant digits for altitude and airspeed visible) and acceptable pilot work load during landing (low level shears that do not degrade landing parameters Hdot, EAS, X-distance, Y-distance and Y-drift rate). Limited flight test data (STS 51-G, 11 kts peak; STS-30, 11 kts ave, 16-19 kts peak; STS-37, 8 kts ave, 9-10 kts peak) are inconclusive but provide indications of handling qualities degradation with increasing crosswind (STS-30 HQR approximately 5; however, its landing was complicated with a NWS S/W anomaly). @[111094-1622B] @[041196-1817B]

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

Wind forecasting accuracy must also be considered when determining crosswind limits. Analysis of SMG simulation and mission (STS-60 through STS-106) crosswind forecast accuracy presented at AEFTP #173 determined that a 15-kt (17-kt RTLS) peak crosswind limit protected the 20-kt vehicle certification limit in excess of 98 percent of RTLS, TAL, and EOM cases studied. Peak crosswinds exceeding 20 kt were observed in less than 5 percent of all cases (most frequent for KSC mission EOM and RTLS cases, each 4.7 percent). For those rare cases when landing opportunity crosswinds were observed > 20 kts, SMG forecast crosswinds >15 kts in 89 percent of KSC EOM, 100 percent of KSC RTLS, 80 percent of TAL, and 46 percent of EDW EOM cases. In just over half of the Edwards crosswind forecast "busts," peak wind speed was forecast to be 25 kts or more, and a small wind direction forecast error resulted in observed crosswinds exceeding the 20 kt vehicle certification limit. No reasonable crosswind Flight Rule would have protected the remaining EDW EOM forecast "busted" cases. Analysis presented at AEFTP #173 did not consider the requirement for a "GO" observed crosswind at decision time, which is believed to add further protection from exceeding the 20-kt vehicle certification limit. Limiting peak crosswind to 17 kts for an RTLS (typically 12-14 kts average) and requiring a "GO" from the STA pilot on the wind profile provides adequate allowance for aerodynamic uncertainties and weather forecasting dispersions while maintaining landing within vehicle limits and Level I/II handling qualities. @[111094-1622B] @[041196-1817B] @[021998-6490A] @[052401-4459A]

Crosswind limits for EDO flights and night landings include a somewhat arbitrary reduction to 12 knots peak to allow for additional piloting margin due to uncertainties in pilot performance degradation from increased exposure to zero-g and reduced depth perception, respectively. AEFTP #138 reviewed flight data for gross landing parameters (Hdot, TD EAS, Y-position, height over threshold, and drift in the two-point attitude) for mission durations out to 18 days (STS-67, STS-78, and STS-80). No degradation was noted; therefore, the EDO duration was set to bracket current flight data. Data previously presented by SD indicated some performance shift for long duration flights; therefore, the AEFTP decided to maintain the crosswind reduction for flights outside of the tested envelope. Night RTLS is allowed to be 17/15 knots peak since zero-g degradation is not a concern and the pilots are very familiar with the landing site. In addition, the CDR/PLT have recent STA flight approaches to the SLF. Although TAL sites have shorter and narrower runways than RTLS, and pilot familiarity of these runways is generally less than RTLS, there are no significant differences between day and night TAL landings with respect to the peak crosswind limit. Simulation data from the Ames VMS 8/00 session showed acceptable piloting/HQR results (Level II or better) for night TAL landings with crosswinds up to 20 kts. The AEFTP #168 and #173 reviewed Ames VMS results, re-reviewed the vehicle structural certification limit of 20-kts crosswind, and reviewed updated SMG crosswind forecast accuracy statistics. The AEFTP subsequently determined that a 15-kt TAL peak crosswind limit (day and night) would provide adequate protection of the 20-kt vehicle certification limit. Additionally, it follows that the AOA crosswind limit should be the same day and night, since there are no significant differences between TAL and AOA landings with respect to the crosswind limit. Although there is some exposure to zero-g on an AOA, it is not considered significant relative to pilot performance degradation. All other intact aborts, other than RTLS, TAL, and AOA, have significant exposure of the pilot to zero-g and therefore maintain the 12-kt limit for night landings. @[041196-1817B] @[041196-1871B] @[041097-4926] @[021998-6490A] @[052401-4459A]

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)*CROSSWIND DTO*

Reference Rule {A2-261}, ENTRY DTO/AUTOMODE/CROSSWIND DTO GO/NO-GO, for the crosswind DTO requirements. Even though the crosswind DTO limit is 15 knots peak, the 12-knot peak crosswind limit still applies for night landings and mission landing \geq the CDR's flight day 17. ©[041196-1871B]

DRAG CHUTE CROSSWIND LIMITS

Reference Rules {A10-144}, DRAG CHUTE DEPLOY CONSTRAINTS, and {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, for the drag chute requirements.

ONE APU FAILED (OR ATTEMPT TWO APU'S PROCEDURE)

Flight Rules {A2-207}, LANDING SITE SELECTION, and {A10-23}, APU ENTRY START TIME, summarize the conditions and rationale for selecting a landing site with one APU failed and using the ATTEMPT TWO APU's start procedure. With two APU's failed, the loss of hydraulic power causes reduced flight control authority and braking and loss of nose wheel steering. The APU placards assure safe conditions should the orbiter lose a second APU. ©[111094-1622B]

TURBULENCE ©[111094-1622B]

Severe turbulence is undesirable due to controllability concerns. Turbulence information comes primarily from WX RECON and TALCOM aircraft or area pilot reports (PIREP). The type of aircraft is a factor when determining the applicability of a PIREP to the orbiter because an aircraft's response to turbulence is a function of wing loading. The shuttle is sensitive to turbulence-caused trajectory deviations below 3000 feet due to the inability to makeup energy loss and achieve the desired touch down point. The PIREP's follow standard definitions for the intensity of the turbulence. The aircraft reactions for the different types of the turbulence, as found in the DOD flight information handbook, are as follows: ©[041196-1871B]

Light turbulence - turbulence that momentarily causes slight, erratic changes in altitude and/or attitude.

Moderate turbulence - turbulence that causes changes in altitude and/or attitude, but with the aircraft always remaining in positive control.

Severe turbulence - turbulence that causes large, abrupt changes in altitude and/or attitude. It usually causes large variations in indicated airspeed. Aircraft may be momentarily out of control.

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

- e. FOR ANY SHOWER WITHIN 20 MILES OF THE SLF, IF THE SHOWER EXCEEDS PARAGRAPHS 4.c OR 4.d, THEN A 2-NM VERTICAL CLEARANCE FROM THE TOP OF THAT SHOWER AND A 10-NM LATERAL CLEARANCE MUST BE MAINTAINED ALONG THE APPROACH PATHS TO THE OVERHEAD AND STRAIGHT-IN HAC'S AT BOTH ENDS OF THE RUNWAY. @[021998-6490A]
 - f. BOTH ENDS OF THE RUNWAY MEET THE LANDING AND ROLLOUT CRITERIA AND NAVAID REQUIREMENTS SPECIFIED IN RULE {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS.
 - g. CONSIDERATION MAY BE GIVEN TO RELAXING THE REQUIREMENT TO MEET ALL FOUR APPROACHES TO BOTH ENDS OF THE RUNWAY AS SPECIFIED IN PARAGRAPHS 4.e AND 4.f ABOVE. THERE SHOULD BE A HIGH LEVEL OF CONFIDENCE THAT AT LEAST TWO HAC APPROACHES (OVERHEAD AND STRAIGHT-IN TO ONE RUNWAY OR STRAIGHT-IN TO BOTH ENDS OF THE RUNWAY) WILL BE ACCEPTABLE AT RTLS LANDING TIME. TREND MONITORING UTILIZING RADAR AND AIRCRAFT SURVEILLANCE SHOULD INDICATE THAT A STABLE AND PREDICTABLE ENVIRONMENT EXISTS. @[021998-6490A]
5. THE ORBITER SHALL NOT PENETRATE A CUMULUS CLOUD THAT IS ATTACHED TO A SMOKE PLUME PRODUCED BY A FIRE. IF THE CUMULUS CLOUD DETACHES FROM THE SMOKE PLUME, 1 HOUR MUST ELAPSE FROM TIME OF DETACHMENT FOR SAFE PENETRATION BY THE ORBITER. @[111298-6734]

The orbiter is not to encounter precipitation on any approach due to decreased visibility, damage to the TPS, and the potential for triggered lightning. Undesirable aspects of thunderstorms include rain (TPS, structure), hail (TPS, structure, control), severe wind shear (structure), turbulence (control, performance, structure), and natural or triggered lightning (structure, electronic/software systems). Environmental design requirements for the orbiter are based on no in-flight penetration of thunderstorms (ref. Appendix 10-10, Volume X, Space Shuttle Level II Program Specification). The participants in the Weather Rules Workshop held at JSC/MSFC in October 1987 developed the thunderstorm, lightning, and precipitation limits based on scientific knowledge, engineering judgment, and experience.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

The 20 nm and 15 nm radii around the landing site approximate a 10 nm and 5 nm lateral clearance from all HAC's, respectively. Increasing the radial and lateral limits for EOM, AOA, PLS, and ELS adds protection for the uncertainty associated with a longer forecast. The post-commitment clearances balance the risks associated with a runway redesignation and damage from flying through precipitation or probability of incurring a lightning strike. Clearances are lower for detached nontransparent thunderstorm anvils because the probability for triggered lightning is lower. An attached anvil is part of the thunderstorm and must meet the thunderstorm proximity limits if the anvil is nontransparent. At the January and April 1998 meetings of the Lightning Advisory Panel (LAP), the consensus was that transparent anvil clouds do not pose a triggered lightning threat. An anvil may be considered transparent when higher clouds, blue sky, stars, etc. may be seen and identified from below or when terrain, buildings, etc. may be seen and identified from above. Evaluation of anvils is sometimes difficult and inexact, even with modern remote sensing technology. Water droplets observed on the windscreen of weather aircraft when flying through clouds are definitive evidence of precipitation or virga. ©[111298-6734]

At the January and April 1998 meetings of the Lightning Advisory Panel, LAP members stated that applicable research indicated that cumulus clouds formed by fires and smoke pose a threat of triggered lightning if penetrated and should be avoided for up to 1 hour after the cloud detaches from the source fire or smoke. ©[111298-6734]

Figures A2-6-I through A2-6-V depict the thunderstorm/lightning/rainshower proximity limits for a 28.5 degree inclination flight. The maximum heights marked in the corridor insure that the orbiter clears the top of the thunderstorm for the worst case (i.e., orbiter on the western edge of the region). ©[111094-1622B] ©[020196-1808A] ©[ED]

ACLS/ECAL/ELS LIMITS ©[111094-1622B] ©[020196-1808A]

Weather at the site must be acceptable to provide good visibility during final approach, since lateral and longitudinal margins are minimal at ECAL/ELS sites. As long as visibility and ceiling limits are met, there is no constraint for precipitation. Additional constraints to avoid thunderstorms and lightning apply only to the landing site. The definition for "none at site" used in the Shuttle Program will mean that no thunderstorm is over the landing airfield. Note that operational meteorological reporting standards for weather occurring at a site differs slightly from the definition applied for shuttle landings. For thunderstorm and lightning observations (METAR) and forecasts (TAF) used to evaluate the GO/NO-GO status of an ACLS/ECAL/ELS site prior to launch, meteorological reporting standards define "none at site" as: no thunderstorms or lightning within 5 statute miles of the observing (landing) site. ©[111298-6734]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)*RTLS PRECIPITATION LIMITS*

The short forecast interval for RTLS and availability of radar and weather aircraft allow improved estimation of rain shower movement and characterization of the cloud type. The RTLS shower exception specifies conditions under which launch is acceptable when showers are within the area of the SLF on launch day. SMG developed the conditions specified in this rule to meet orbiter design requirements. Additional launch probability is gained by eliminating the avoidance criteria for showers that do not pose a threat due to lightning, hail, visibility, aerodynamic control, or MLS attenuation. Tile damage that occurs if precipitation is encountered is acceptable. Radial, lateral, and vertical avoidance criteria still apply for any storm that poses a threat to the orbiter. Reference A/E FTP # 109 and 111. ©[020196-1808A]

Cloud Top Temperatures and Lightning Avoidance - Clouds that exceed the conditions stated in paragraphs c and d above pose a threat of hail or lightning (natural and triggered). Clouds with < 30 DBZ and tops below the +5 deg C thermal layer do not pose a threat of stored electrical charge. Clouds that have previously extended above the -10 deg C thermal layer must be avoided for 2.5 hours to allow any accumulated charge to dissipate. A 2-nm vertical clearance and a 10-nm lateral clearance must be maintained along the approach paths of the overhead and straight-in HAC's at both ends of the runway for showers exceeding these limits. The Lightning Avoidance Criteria Peer Review Committee reviewed and concurred with these criteria at their KSC meeting in February 1994. ©[021998-6490A]

If the orbiter encounters ice, window damage may occur resulting in reduced visibility (depending on ice population, mass, density, and relative velocity) and RCC coating damage may occur forcing RCC panel replacement. Clouds with tops below the +5 deg C thermal layer are warm enough to assure they do not contain hail.

Light Precipitation - Testing of TPS tiles flown through moderate rainfall (35 to 40 dbz) indicates that significant tile damage will occur if the orbiter encounters ice-free precipitation at velocities below Mach 1 and above touchdown speed. The extent of damage depends on drop size and the angle of incidence between a drop and a tile. Conservative estimates of effects on approach and landing characteristics assuming a worst-case estimate of approximately 2000 damaged tiles (nose and canopy/windshield areas, vertical tail and OMS pod leading edges) show no significant effect on landing performance. A retrim to a slightly higher angle of attack would be the primary noticeable response to flight through rain during landing approach. No structure or control system damage would occur. Testing indicates that damage to RCC does not occur when flown through light rain at speeds below 0.7 Mach. RCC damage is not desirable due to replacement cost and lead time. RCC damage caused by precipitation impact would not affect aerodynamic performance. ©[020296-1808A]

Tile damage could result in a loss of up to 1000 ft of touchdown distance. Typical touchdown distances carry adequate margin to protect this type of energy loss. A dispersed entry that is flown through a shower on a day that predicted touchdown conditions are at the limits specified in Rule {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION, could result in a vehicle touchdown on the underrun. Consideration should be given to not launching on a low energy day where the capability to avoid showers is low. Otherwise, adequate margin exists within the system to support loss of touchdown energy due to tile damage. ©[020196-180]

FLIGHT RULES

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-6

LANDING SITE WEATHER CRITERIA [HC] (CONTINUED)

Water attenuates microwave signals at MLS frequencies; however, MLS performance is not severely affected. Analysis of MLS link performance with a transmitter power output of 1600 W (the minimum acceptable transmitter power output level) shows that MLS acquires at over 9 nm slant range when a rainfall rate of 10 mm/hr (0.4 in/hr) exists along the entire path between the orbiter and the ground MLS station. Since "light" rainfall is less than 0.4 in/hr, nominal MLS acquisition is protected.

Ceiling and visibility criteria specified in paragraph A of this rule still apply and protect for adequate crew visibility of the PAPI's, aimpoint, and ball bar through clouds and precipitation. WX RECON has primary responsibility for assessing visibility through light precipitation from any showers of concern that do not fall within the field of view used by meteorological observers to evaluate visibility. Ground observers are limited to evaluations using fixed landmarks.

Area Coverage/Multiple HAC's - While it is acceptable to encounter showers that meet the criteria specified in this rule, it is still more desirable to avoid them if possible. Limiting the number of showers in the vicinity of the SLF minimizes the chances of encountering a shower. If more than 10 percent coverage exists or is forecast but multiple HAC's are clear and will remain clear of showers, the intent of this constraint has been met.

Movement and Convective Development - Consistent horizontal motion that is linear or near linear and can be tracked is required to accurately forecast future movement. Conditions must be thermodynamically stable. Observed and forecast conditions are the same and expected to remain unchanged throughout the RTLS period.

*Paragraph f defines the clearance requirements of showers with lightning potential (tops greater than +5 deg C or returns greater than 30 dbz) which have not demonstrated air to ground lightning strikes. The clearance requirements for lightning potential are the same as those of actual thunderstorms.
 ©[020196-1808A]*

RTLS OBSERVATIONS

Providing a safe approach at RTLS landing time is of prime importance. Most of these weather criteria are treated as macro type events, so the general landing site area is protected. Given the short forecasting time for an RTLS and the use of sophisticated meteorological tools along with aircraft surveillance, it may be possible to treat a given situation as a "micro" event. In relaxing these criteria, it is important to consider the stability/predictability of the situation and the tools used to monitor the area (radar, satellite, aircraft surveillance). ©[021998-6490A]

DAY-OF-LAUNCH ET LOAD DATA

- A. ACTUAL DAY OF LAUNCH (DOL) ET LOAD DATA FROM THE PLOAD PROGRAM WILL BE USED TO RE-COMPUTE ASCENT PERFORMANCE MARGIN, ARD MASS PROPERTIES, AND ARD FPR BASED ON L-1.75 HOUR (OR LATER) DATA. @[050495-1729D] @[081497-6305A]
- B. IF A REVERT HAS OCCURRED, MCC WILL BE NO-GO FOR LAUNCH UNTIL STABLE REPLENISH HAS BEEN RE-ESTABLISHED AND A NEW PLOAD DATA INPUT HAS BEEN RECEIVED AND EVALUATED (APPROXIMATELY 50 MINUTES FOR AN LO₂ REVERT OR APPROXIMATELY 25 MINUTES FOR AN LH₂ REVERT).
- C. IF PLOAD IS UNAVAILABLE, THE ARD WILL BE CONFIGURED TO REFLECT TARGET TDDP LOAD QUANTITIES AND THE ARD FPR WILL BE RE-CALCULATED WITH INCREASED LOAD UNCERTAINTIES TO ACCOUNT FOR ADDITIONAL DISPERSIONS IN THE ACTUAL LOAD. NOTE: THIS IS VALID ONLY FOR A NOMINAL ET LOADING TIMELINE, UNLESS PROPULSION SYSTEMS COMMUNITY CONCURRENCE IS RECEIVED PER PARAGRAPH D, BELOW.
- D. IF BOTH AN LO₂ REVERT HAS OCCURRED AND PLOAD IS UNAVAILABLE, OR IF FOR ANY OTHER REASON LOAD UNCERTAINTY EXISTS WITHOUT PLOAD DATA, MCC WILL BE NO-GO FOR LAUNCH UNTIL THE PROPULSION SYSTEMS COMMUNITY, AS REPORTED BY THE JSC/USA PSIG REPRESENTATIVE IN THE MER, VALIDATES THAT THE MEASURED ULLAGE PRESSURE DOES NOT EXCEED 0.255 PSI ABOVE THE TDDP NOMINAL LOAD ULLAGE PRESSURE OF 0.781 PSIG. @[092602-5668]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-7

DAY-OF-LAUNCH ET LOAD DATA (CONTINUED)

The PLOAD program is executed at L-1.75 hours to estimate LO₂ and LH₂ loads based on ullage pressures and environmental conditions. This data is provided to the flight dynamics team at about L-1.5 hours (subsequent PLOAD run data during extended launch holds will also be incorporated as it becomes available, if necessary). The predicted end-of-replenish quantities are used to calculate DOL ascent performance margin, fuel bias, ARD Main Engine Propellant (MEP) quantity, and vehicle weights. ARD FPR is also recalculated based on the actual load, since the ET load and mixture ratio component of ARD FPR is a function of predicted fuel bias.

If a revert occurs, launch will not be attempted until a valid PLOAD data point can be evaluated (approximately 50 minutes of stable replenish for ullage pressure stabilization and load data transmittal for an LO₂ revert, approximately 25 minutes for LH₂), to assure an adequate ascent performance margin. The minimum time is that which is required before giving a "GO" to pick up the count at T-9 min or T-5 min. These procedures were approved at the PRCB, January 14, 1992. ©[050495-1729D] ©[081497-6305A]

When PLOAD is not available, it is assumed that the load fits within statistical limits of previous load quantities, which historically have been very close to the targeted load specified in the Trajectory Design Data Package (TDDP). In this case, ARD FPR must protect for historical deviations of the reported load from the target load as well as normal PLOAD uncertainties. The historical deviations (reference NSTS 08209, Shuttle Systems Design Criteria; Volume I, Shuttle Performance Assessment Databook; Section 8, Flight Performance Reserve; Table 8.1, System Dispersions for FPR Computation) are root sum squared with the normal PLOAD uncertainties to provide a total load uncertainty that is used to recompute ARD FPR. This increases the ARD FPR by approximately 70 lbs. ©[081497-6305A]

For any case involving loss of PLOAD data, a nominal stable replenish timeline is necessary to ensure that the load has reached TDDP target conditions. In the very unlikely event that both an LO₂ revert has occurred and the PLOAD program is unavailable, or if for any other reason load uncertainty exists, the propulsion systems community, as reported via the Propulsion Systems Integration Group (PSIG) representative in the MER, must be satisfied that the target MPS inventory has been achieved before a "GO" can be given to pick up the count. The MPS inventory is protected if the ullage pressure is less than 1.036 psi. Ullage pressure above this limit indicates an under-load of a magnitude beyond that covered in the FPR. The value of 1.036 psi is derived by adding the ullage pressure used in deriving the inventory (0.781 psi) to a tolerance that is protected by FPR (0.255 psi). ©[081497-6305A] ©[092602-5668]

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS

THE MCC-H FLIGHT DYNAMICS OFFICER (FDO) IS RESPONSIBLE FOR ALL COMPUTATIONS RELATED TO LAUNCH WINDOW. FINAL CALCULATIONS WILL BE MADE AT APPROXIMATELY L-2 HOURS. THESE WILL USE THE LATEST AVAILABLE BALLOON PERFORMANCE ANALYSIS, LATEST AVAILABLE TARGET TRACKING VECTOR, AND THE FINAL PLOAD ANALYSIS OF ET LOADING. THE FDO SHALL INFORM THE MCC-H FLIGHT DIRECTOR OF THE LAUNCH WINDOW TIMES. THE FLIGHT DIRECTOR SHALL BE THE SINGLE POINT OF COMMUNICATION FOR THE LAUNCH WINDOW TIMES TO KSC VIA THE NTD. THE ASSOCIATED LAUNCH TARGETING/AUTO DEL PSI COMMAND LOADS WILL BE GENERATED AND UPLINKED TO THE VEHICLE IN THIS TIMEFRAME. AFTER THIS TIME, UPDATES TO WINDOW TIMES AND/OR A NEW COMMAND UPLINK WILL BE REQUIRED IF THE PANE SWITCH WINDOW TIME CHANGES BY MORE THAN 5 SECONDS (IN EITHER DIRECTION) BASED ON THE L-2.25 HR BALLOON ANALYSIS AT APPROXIMATELY L-30. @[081497-6263B] @[111298-6693]

- A. LAUNCH WINDOW OPEN AND CLOSE TIMES WILL BE COMPUTED TO THE NEAREST SECOND. ON A GIVEN DAY, A RENDEZVOUS LAUNCH WINDOW MAY BE ONLY ONE PLANAR PANE OR THE COMBINATION OF TWO PLANAR PANES. ONLY THE PLANAR PANE WHERE THE PHASE ANGLE IS ACCEPTABLE WILL BE CONSIDERED PART OF THE COMBINED LAUNCH WINDOW. THIS MAY RESULT IN CUTOUTS IN THE LAUNCH WINDOW. CALCULATION OF LAUNCH WINDOW OPEN, CLOSE, AND PANE SWITCH TIMES WILL PROTECT:
1. MPS AND OMS PERFORMANCE MARGIN FOR MISSION SUCCESS AS DEFINED BY THE ANNEX FLIGHT RULE, SHUTTLE TRAJECTORY AND GUIDANCE PARAMETERS, PARAGRAPHS A AND B. THIS IS ZERO PREDICTED MPS USABLE RESIDUALS ABOVE THE FLIGHT PERFORMANCE RESERVE AND THE REQUIRED SIGMA DISPERSION. THE SIGMA DISPERSION IS DEFINED IN THE ANNEX FLIGHT RULE, SHUTTLE TRAJECTORY AND GUIDANCE PARAMETERS. @[062801-4521]

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS
(CONTINUED)

LAUNCH WINDOW OPEN WILL BE BASED ON LOX DRAINBACK START TIME 4 MINUTES 55 SECONDS BEFORE WINDOW OPENING. LAUNCH WINDOW CLOSE WILL BE BASED ON A HOLD THAT DELAYS LOX DRAINBACK START TIME TO THE MAXIMUM EXTENT POSSIBLE, 4 MINUTES 55 SECONDS BEFORE THE CLOSE OF THE WINDOW. @[081497-6263B]

FOR 51.6 DEGREE INCLINATION MISSIONS, IF THE PERFORMANCE MARGIN IS LESS THAN 200 POUNDS AT THE OPENING OF THE LAUNCH WINDOW, AN ADDITIONAL DELAY, IF AVAILABLE, WILL BE ADDED TO WINDOW OPEN TIME TO PROTECT FOR PERFORMANCE VARIATION DUE TO WIND PERSISTENCE. @[081497-6263B] @[111298-6693]

2. PROTECT CONTINUOUS SINGLE SSME OUT INTACT ABORT CAPABILITY FOR A LAUNCH AT ANY TIME DURING THE WINDOW.
3. RANGE SAFETY ET DISPOSAL AS SPECIFIED BY FLIGHT RULE {A2-62}, ET FOOTPRINT CRITERIA.
4. ET YAW STEERING CERTIFICATION LIMIT AROUND INPLANE LAUNCH TIME FOR THE PLANAR WINDOW(S). @[062801-4521]
5. SHUTTLE TO TARGET VEHICLE OMS-2 PHASE ANGLE WINDOW, ASSUMING NOMINAL MECO CONDITIONS, AS DEFINED BY THE RENDEZVOUS PLAN ASSUMPTIONS DOCUMENTED IN THE FLIGHT RULE ANNEX.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS
(CONTINUED)

6. ACCEPTABLE PERFORMANCE AROUND PANE SWITCH. THE UPLINKED PANE SWITCH TIME WHICH DEFINES THE END OF THE FIRST PANE FOR PERFORMANCE AND AN ASSOCIATED OPENING OF THE SECOND PANE WILL BE COMPUTED BASED ON LOX DRAINBACK STARTING 4 MIN 55 SECONDS PRIOR TO THE PREFERRED LAUNCH TIME AS DEFINED IN PARAGRAPH D BELOW. NOTE THAT THERE MAY BE A LAUNCH WINDOW CUTOFF WHERE THERE IS INSUFFICIENT PERFORMANCE FOR LAUNCH. @[081497-6263B]

B. UNPLANNED HOLDS @[081497-6263B] @[062801-4521]

1. PANE 1 CLOSE AND PANE 2 OPEN WILL BE CALCULATED ASSUMING LOX DRAINBACK (T-4 MINUTES 55 SECONDS) STARTS FOR THE PREFERRED LAUNCH TIME AS DEFINED IN PARAGRAPH D BELOW. PANE 1 CLOSE AND PANE 2 OPEN TIMES WILL BE UPDATED IF LAUNCH IS TO BE ATTEMPTED AT THE WINDOW OPEN TIME.
2. LOX DRAINBACK HOLD TIME REPORTED TO THE NTD WILL BE CALCULATED ASSUMING START OF LOX DRAINBACK 4 MIN 55 SEC PRIOR TO THE PREFERRED LAUNCH TIME AS DESCRIBED IN PARAGRAPH D BELOW. LOX DRAINBACK HOLD TIME WILL BE UPDATED IF LAUNCH IS TO BE ATTEMPTED AT THE WINDOW OPEN TIME. FOR HOLDS BEFORE LOX DRAINBACK STARTS, THIS TIME IS NO LONGER VALID AND IN GENERAL DECREASES. FOLLOWING A SERIES OF HOLDS BEFORE OR DURING LOX DRAINBACK, IF REQUIRED, THE FD WILL COORDINATE A HOLD OR CUTOFF WITH THE NTD TO PREVENT A LAUNCH WITH INSUFFICIENT PERFORMANCE.
3. SSME START BOX TEMPERATURE LIMITS ARE NOT CONSIDERED IN THESE CALCULATIONS. ONCE THE SSME CONTROLLER DETECTS AN OUT OF LIMITS THERMAL CONDITION, AN AUTOMATIC HOLD/CUTOFF WILL OCCUR.

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS
(CONTINUED)

C. ON TWO PLANAR WINDOW PANE DAYS:

1. FOR 28.5-DEGREE INCLINATION MISSIONS, THERE WILL BE A 10-SECOND LAUNCH WINDOW CUTOFF AT THE UPLINKED PANE SWITCH TIME TO ENSURE ONBOARD GUIDANCE/GROUND PROCESSOR SYNCHRONIZATION. THIS CUTOFF WILL START 5 SECONDS BEFORE SWITCH TIME AND CONTINUE TO 5 SECONDS PAST SWITCH TIME. FOR SOME PERFORMANCE CASES, THE SECOND PANE OPENING MAY BE FURTHER DELAYED. A COUNTDOWN HOLD WILL BE CALLED TO AVOID LAUNCHING DURING THESE CUTOFFS.
@[062801-4521] @[022802-5220]
2. FOR 51.6-DEGREE INCLINATION MISSIONS, THERE WILL BE A MINIMUM 10-SECOND LAUNCH WINDOW CUTOFF AT THE UPLINKED PANE SWITCH TIME TO ENSURE ONBOARD GUIDANCE/GROUND PROCESSOR SYNCHRONIZATION AND TO MAXIMIZE THE ASCENT PERFORMANCE MARGIN AT THE OPENING OF THE SECOND PANE. THIS CUTOFF WILL START 5 SECONDS BEFORE SWITCH TIME.
@[081497-6263B] @[062801-4521] @[022802-5220]
 - a. IN THE EVENT OF AN UNPLANNED HOLD OUTSIDE OF DRAINBACK, THE CUTOFF WILL END AT THE LATER OF 5 SECONDS AFTER THE SWITCH TIME OR THE PANE 2 INPLANE TIME.
 - b. IN THE EVENT OF A HOLD INSIDE DRAINBACK, THE CUTOFF WILL END AT THE LATER OF 5 SECONDS AFTER THE SWITCH TIME OR AT THE PANE 2 PERFORMANCE OPEN.

A COUNTDOWN HOLD WILL BE CALLED TO AVOID LAUNCHING DURING THESE CUTOFFS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS
(CONTINUED)

3. WHENEVER POSSIBLE, FLIGHT DAY 3 RENDEZVOUS CAPABILITY WILL BE MAXIMIZED. FD3 CAPABILITY IS ONLY AVAILABLE IN THE FIRST PANE AND SOMETIMES ONLY A PORTION OF THE FIRST PANE. FD3 CAPABILITY WILL BE MAINTAINED TO THE LAST POSSIBLE TIME IN THE COUNTDOWN. @[081497-6263B] @[062801-4521]
4. FLIGHT DAY 2 RENDEZVOUS CAPABILITY IS HIGHLY DESIRABLE IF MDF OCCURS. REGIONS OF THE LAUNCH WINDOW THAT PRESERVE FD2 RENDEZVOUS WILL BE UTILIZED WHENEVER CONVENIENT.

D. PREFERRED LAUNCH TIME

1. DURING THE T-9 MINUTE HOLD, THE LD, NTD, AND FD WILL MAKE A FINAL DETERMINATION ON THE USE OF PREFERRED LAUNCH TIME. IF THERE ARE INDICATIONS THAT THERE IS A SIGNIFICANT CHANCE OF TROUBLESHOOTING REQUIRED AFTER RESUMPTION OF THE COUNTDOWN AT T-9 MINUTES, THE COUNTDOWN CLOCK WILL BE SET TO WINDOW OPENING AS DEFINED BY PARAGRAPH A OF THIS RULE. OTHERWISE, THE COUNTDOWN CLOCK WILL BE SET TO THE PREFERRED (DELAYED) LAUNCH TIME. IF THE WINDOW OPEN LAUNCH TIME IS SELECTED RATHER THAN THE PREFERRED LAUNCH TIME, A NEW LAUNCH TARGET/OMS TARGET UPLINK MAY BE REQUIRED. PANE 1 CLOSE, PANE 2 OPEN, AND LOX DRAINBACK HOLD TIME UPDATES MAY ALSO BE REQUIRED. @[062801-4521]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS
(CONTINUED)

2. FOR 51.6-DEGREE INCLINATION MISSIONS, PREFERRED LAUNCH TIME MAXIMIZES THE MPS PERFORMANCE MARGIN AVAILABLE IN CASE UNFORESEEN IN-FLIGHT PERFORMANCE PROBLEMS OCCUR. IF SHUTTLE TO TARGET VEHICLE OMS-2 PHASE ANGLE CONSTRAINTS ARE SATISFIED, PREFERRED LAUNCH TIME WILL BE THE INPLANE LAUNCH TIME FOR THE FIRST PANE OF THE LAUNCH WINDOW. UNLESS NOTED AS AN EXCEPTION IN THE FLIGHT RULES ANNEX, THE PREFERRED LAUNCH TIME WILL BE NO EARLIER THAN THE INPLANE TIME OF THE FIRST PANE OF THE LAUNCH WINDOW. BY DEFINITION, THIS WILL RESULT IN A DECREASE OF TOTAL LAUNCH WINDOW TIME AVAILABLE. @[081497-6263B] @[062801-4521]
 3. FOR 28.5 DEGREE INCLINATION MISSIONS, PREFERRED LAUNCH TIME MAY BE EARLIER THAN INPLANE TO MAXIMIZE A TOTAL LAUNCH WINDOW CAPABILITY FOR A HOLD PRIOR TO THE START OF LOX DRAINBACK. @[081497-6263B] @[062801-4521]
- E. THE OMS ASSIST DUMP TIMER MAY BE RECOMPUTED AND UPLINKED BASED ON THE L MINUS 8-DAY TRAJECTORY DESIGN DATA PACK (TDDP) TO MAXIMIZE OMS PROPELLANT AVAILABLE FOR ORBIT OPERATIONS. THE OMS ASSIST DUMP TIMER UPDATE IS DESIGNED SUCH THAT THE RESULTING ASCENT PERFORMANCE MARGIN (APM) IS AT LEAST 1100 LBS ABOVE FLIGHT PERFORMANCE RESERVE (FPR) AND FUEL BIAS TO PROTECT FOR DOL UNCERTAINTIES. THIS MINIMUM APM MUST BE ACHIEVED FOR AT LEAST A 5-MINUTE PERIOD CENTERED NEAR INPLANE TIME.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS (CONTINUED)

Launch window calculation for ground up rendezvous is a complex series of calculations accommodating various conflicting requirements. Paragraph A of this rule states the mandatory requirements for defining the launch window and is self-explanatory. On launch day, the latest information is used to ensure the maximum precision in calculations. The FD is the single point of contact with KSC to ensure the launch time is set properly. [081497-6263B] [062801-4521]

Normally, the final launch window times are calculated based on the L-4.5 hour balloon data. These calculations are complete about L-2 hours. An update using the L-2.25 hour balloon is possible at about L-30 minutes. Also, if a revert occurs, new PLOAD calculations may require window time recalculation. New times will be passed and new launch target commands sent only if these calculations result in significant changes. Since a 10-second launch window cutoff exists around the pane switch time to ensure onboard guidance/ground processor synchronization, both the onboard PASS/BFS guidance and the Abort Region Determinator ground processor will always be on the first pane before the cutout, and on the second pane after the cutout. Thus, if the new switch time is more than 5 seconds different than that which is already onboard (i.e., it falls outside the original cutout), either a new command load uplink with a revised pane switch time and associated launch window cutout is required, or the cutout must be extended to the new desired switch time. [081497-6263B] [022802-5220]

Performance varies through the window as a function of launch time because of the orbital mechanics/rendezvous effects - primarily yaw steering. However, performance decreases with delays after the start of LOX drainback (T-4 min 55 sec). For simplicity, all times transmitted to KSC assume that LOX drainback is started for the selected launch time: in general for the preferred time and in off nominal cases for the window open time. For a combination of problems that result in delays to the start of LOX drainback and also holds after the start of LOX drainback, the FDO calculates new window open/close times based on all factors (ascent performance margin, yaw steering costs, and LOX drainback impact). If the need to use these new times arises, the FD is responsible to ensure that launch will occur only when performance is available to support mission success. It is possible that a combination of launch holds before and after the start of LOX drainback could result in an unanticipated single SSME out abort gap opening. This is especially true if an out-of plane TAL site is used. If this is known prelaunch, it will be avoided. If it is unknown until after launch, then Flight Rule {A4-56I}, PERFORMANCE BOUNDARIES, applies. [111298-6693]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS (CONTINUED)

Beginning with OI-29, a flight software modification was made to prevent the PASS and BFS from targeting different launch panes around the pane switch time. At the Ascent/Entry Flight Techniques Panel # 179 on October 19, 2001, a recommendation was accepted to maintain a 10-second launch window cutout to guarantee launch pane agreement between the onboard PASS/BFS guidance and the Abort Region Determinator ground processor. Also, by maintaining a 10-second launch window cutout around the pane switch time, there is a reduced likelihood that a launch target re-uplink is required at L-30 minutes. ©[081497-6263B] ©[022802-5220]

For high inclination missions, at the direction of the SSP, the launch window management plan was modified to delay launch until the Pane 2 inplane time whenever the Pane 2 inplane time is after the uplinked switch time and a hold outside of drainback moves the T-0 time into the second pane. This is consistent with the SSP philosophy to select the inplane time as the preferred launch time. The Pane 2 inplane time will be passed from JSC to the NTD at L-1:30 with the launch window times. There is no change to the launch window management plan for holds inside of drainback. ©[062801-4521]

Flight Day 3 rendezvous capability (as defined by an acceptable phase angle region inside the orbital plane window pane) is extremely important for most flights. However, FD3 capability does not exist for all launch days. FD4 rendezvous capability is available on every launch day since the longer time allows catch up from greater phase angles. Note that even if launch occurs in a FD3 portion of the window, a FD3 rendezvous can always be cheaply turned into a FD4 rendezvous if time constraints require it. For an MDF mission, a FD2 rendezvous is desirable. However, FD2 phase windows are even shorter than FD3 so they are not generally available. When a FD2 window is available, it should be used providing there are no adverse impacts. ©[081497-6263B]

Since historical data indicates a good track record of on-time launches, and mission success margins are greater at the middle of the window rather than the opening, a preferred launch time is defined so that when there are no overriding considerations, the maximum margin for mission success is available in flight. In addition to maximizing mission success margin, SSP reviews have determined that the inplane time maximizes programmatic safety margins. Note that delaying the launch time also improves multiple SSME out contingency abort landing site coverage which is desirable, but not a window length driver. ©[081497-6263B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-8

LAUNCH TIME SELECTION FOR GROUND-UP RENDEZVOUS (CONTINUED)

For performance limited 51.6 deg inclination missions, the launch window open may actually be based on ascent performance. For these cases, 200 pounds of ascent performance margin is desired at the window open to protect for performance variations between the balloon release and launch time. With FDO's launch window/launch performance application, the window open time will be biased, if there is time available in the launch window, to protect this minimum desired performance margin. ©[111298-6693]

OMS assist timer reduction may be used to trade excess ascent performance margin for increased on-orbit OMS. The minimum change to the dump timer is 1 second, which equates to about 40 pounds less OMS propellant dumped. To maintain the earliest possible Press to ATO, any decrease in the OMS assist timer requires a corresponding increase in the ATO timer. The 1100-lbs bias protects for performance losses from SRB PMBT, weight changes, DOL winds, and DOL atmosphere changes between L minus 8 days and liftoff (ref. PRCB SR#1382, October 19, 2000). This performance bias is required to ensure the OMS assist timer will not need to be increased on DOL. If the OMS assist timer were increased on DOL, PROP products and data would not be sufficiently conservative. Once the OMS assist timer is determined, it cannot be recomputed on DOL. PROP and FDO are responsible to report to LDO that there are no issues with the new OMS assist/ATO timers. ©[062801-4521]

FLIGHT RULES

A2-9

LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS

IN THE PRELAUNCH TIMEFRAME: @[092602-5669A]

- A. FOR THE LOSS OF THE FIRST 100 PERCENT ET LOX LIQUID LEVEL CONTROL SENSOR, NO MCC ACTION IS REQUIRED, REGARDLESS OF WHEN THE FIRST SENSOR FAILS.
- B. LOSS OF A SECOND 100 PERCENT ET LOX LIQUID LEVEL CONTROL SENSOR WILL RESULT IN THE TRANSFER OF ET LOX LOADING CONTROL TO THE 100.15 PERCENT SENSOR.
 1. FOR CONTROL TRANSFER TO 100.15 PERCENT SENSOR PRIOR TO L-25 MINUTES:
 - a. ARD AND LAUNCH WINDOW DATA WILL BE BASED ON A 100.15 PERCENT LOX LOADING ESTIMATE (WITH ADJUSTMENT FOR ADDITIONAL DRAINBACK TIME, AS APPLICABLE).
 - b. IF STABLE REPLENISH USING THE 100.15 PERCENT SENSOR IS REACHED PRIOR TO L-1:20 HOURS, THE LOX LOADING ESTIMATE WILL BE GENERATED USING PLOAD. OTHERWISE, "NO PLOAD" LOADING ESTIMATES WILL BE USED PER RULE {A2-7C}, DAY-OF-LAUNCH ET LOAD DATA, DUE TO MCC OPERATIONAL PROCESSING TIMELINE CONSTRAINTS.
 - c. IF LAUNCH WINDOW UPDATES ARE AVAILABLE PRIOR TO L-39 MINUTES, THE FDO WILL COORDINATE UPDATES TO THE KSC LAUNCH WINDOW DATA. OTHERWISE, THERE WILL BE NO UPDATE TO THE KSC LAUNCH WINDOW TIMES.
 - d. ADDITIONAL DRAINBACK TIME SHALL BE INSERTED INTO THE TIMELINE AFTER THE START OF DRAINBACK AS SPECIFIED BY THE DOLILU OPERATIONS SUPPORT PLAN. FD WILL COORDINATE THE INSERTION OF THE ADDITIONAL DRAINBACK TIME, IF ANY, WITH NTD. @[092602-5669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-9

LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS
(CONTINUED)

2. FOR CONTROL TRANSFER TO 100.15 PERCENT SENSOR AFTER L-25 MINUTES: @[092602-5669A]
 - a. LAUNCH WINDOW DATA AND ARD CALCULATIONS WILL NOT BE UPDATED.
 - b. ADDITIONAL DRAINBACK TIME WILL NOT BE INSERTED INTO THE TIMELINE.
 - c. MCC WILL BE NO-GO FOR LAUNCH UNTIL THE PSIG REPRESENTATIVE IN THE MER VALIDATES THAT THE MEASURED ULLAGE PRESSURE DOES NOT EXCEED 0.255 PSI ABOVE THE TDDP NOMINAL LOAD ULLAGE PRESSURE OF 0.781 PSIG

The ET project has determined that the PLOAD LOX loading estimate based on liquid level control using a 100 percent sensor which subsequently fails will remain valid after a switch to the second 100 percent ET LOX liquid level control sensor. Therefore, switching liquid level control from one 100 percent sensor to the second 100 percent sensor does not invalidate the original PLOAD loading estimate.

The ET project has determined that the PLOAD LOX loading estimate based on liquid level control using either 100 percent sensor is not accurate in the event of a later failure of both 100 percent LOX liquid level control sensors and subsequent fill to the 100.15 percent sensor per LCC ET-10. The ET Project has requested DOSS to rerun PLOAD or revert to 100.15 percent MPS inventory loading estimates. A rerun and QA of PLOAD loading updates, nominal mission performance margin, and launch window impacts requires approximately 40 minutes. KSC Ground Operations is unable to accept launch window updates after L-39 minutes. However, FDO and ARD Support should reflect the best possible estimate of the true LOX loading. Therefore these elements will reconfigure to reflect LOX loading to the 100.15 percent MPS inventory values, if the fail over occurs after the latest time to rerun PLOAD (about L-1:20 hour) and prior to L-25 minutes, regardless of whether or not the KSC launch window is updated.

For any level sensor failure after L-25 minutes, no action is required by the MCC. A late sensor failure (either the first or the second) may result in an underload of approximately 1,100 pounds of LOX, which still meets LCC ET-10 launch requirements. This equates to approximately 15 fps of ascent performance margin. A launch with an underload of this magnitude will result in TAL and ATO abort boundary calls being made approximately 15 fps early and slightly increases the chances of a low level cut-off with a small underspeed. The program accepts this risk due to its low probability of occurrence. @[092602-5669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-9

LOSS OF ET LOX LIQUID LEVEL CONTROL SENSORS
(CONTINUED)

In the event of a failure of both 100 percent sensors and fail-over to a fill to the 100.15 percent sensor failure, no additional drainback time will be added to the countdown. Analysis to clear the ET for flight in this condition is valid only through STS-118. ET LOX tank changes being made subsequent to STS-118 will require additional analysis. @[092602-5669A]

Late fail-over to a LOX tank fill controlled by the 100.15 percent (after failure of both 100 percent level sensors) will require verification that the LOX loading is consistent with MPS inventory loading estimates. The MPS inventory is protected if the ullage pressure is less than 1.036 psi. Ullage pressure above this limit indicates an under-load of a magnitude beyond that covered in the FPR. The value of 1.036 psi is derived by adding the ullage pressure used in deriving the inventory (0.781 psi) to a tolerance that is protected by FPR (0.255 psi). @[092602-5669A]

A2-10 THROUGH A2-50 RULES ARE RESERVED

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES

ASCENT

A2-51 STS ABORT CRITERIA

NOMINAL ASCENT WILL BE CONTINUED FOR STS PROBLEMS EXCEPT FOR:

- A. ENGINE PROBLEMS WHERE REQUIRED PERFORMANCE IS NOT AVAILABLE.
- B. LOSS OF DEORBIT MANEUVER CAPABILITY.
- C. LOSS OF ATTITUDE CONTROL.
- D. CONSUMABLES, COOLING, OR SYSTEMS LIFETIME PROBLEMS THAT WILL NOT SUPPORT THE FOLLOWING FIRST DAY PLS DURATIONS:
 - 1. LOW INCLINATION - DEORBIT ORBIT 3, LANDING ORBIT 4.
 - 2. HIGH INCLINATION - DEORBIT ORBIT 7, LANDING ORBIT 8.

In order to maximize probability of mission success, nominal ascent will be continued unless a specific problem arises which, if not acted upon, jeopardizes the orbiter and/or crew. In these cases, either a pre-MECO abort (RTLS, TAL, ATO) or a post-MECO abort (AOA) will be selected. The specifics of which abort will be selected and the priority of available modes are contained in Rule {A2-52}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, for performance-related failures (paragraph A above) and in Rule {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL], for systems problems (paragraphs B to D). If the capability to support a first day PLS landing opportunity is lost, or the particular failure is such that conditions could deteriorate so rapidly that the landing opportunity could be lost, then an AOA will be performed as specified in Rule {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]. First day PLS landing opportunities are selected based on providing sufficient time for pre-deorbit tracking and onboard state vector update while maintaining capability to a CONUS landing site.

Orbit 3 deorbit is typically the last CONUS opportunity for low inclination flights. For high inclination flights, orbit 2 deorbit provides the last ascending first day opportunity to Edwards, while orbit 7 provides the first descending opportunity to Edwards. Orbit 2 deorbit to Edwards is available for both low and high inclinations, but it does not provide sufficient tracking to assure an adequate deorbit state vector. Hence, orbits 3 (low inclination) and 7 (high inclination) are chosen for the PLS opportunities (ref. Ascent Flight Techniques meeting #43).

FLIGHT RULES

A2-52

ASCENT MODE PRIORITIES FOR PERFORMANCE CASES

- A. DURING POWERED FLIGHT, THE ABORT PRIORITIES FOR PERFORMANCE CASES ARE AS FOLLOWS:
1. PRESS-TO-ORBIT (INCLUDING PRESS-TO-MECO AND PRESS-TO-ATO TRAJECTORIES)
 2. TAL
 3. RTLS
 4. TAL TO AN ACLS (MAY REQUIRE MANUAL SSME SHUTDOWN)
 5. AOA SHALLOW USING ARCS TO THE ARCS PRESS QUANTITY AND CG LIMITED BY THE CONTINGENCY CG ENVELOPE

Powered flight abort priorities were established based on providing the highest probability of safe return of the orbiter and crew. If at all possible, as long as steep deorbit capability can be maintained, the desire is to press to orbit before considering a pre-MECO abort since achieving orbit provides the maximum time to assess and react to problems without incurring additional risks associated with powered flight aborts. Following the option of pressing uphill, the TAL abort (assumed to be flown under auto guidance) is next in priority since it provides the earliest contingency avoidance capability for multiple engine failures and is considered to be more benign than RTLS from an operational point of view. The RTLS abort is next in priority and in the performance case would be used only if TAL were not available (i.e., some systems problems may dictate RTLS over TAL when both modes are available).

Pre-MECO, if TAL capability to the prime site is not available and steep AOA cannot be protected, TAL to an ACLS is selected next in priority since the next lower option (AOA shallow) is considered to be unacceptably sensitive to navigation dispersions. Since an augmented site is required, the abort is not expected to be adversely affected by navigation capability. The tradeoff in this case is that only limited OMS dump time is available for TAL's selected late in powered flight, which may result in violation of the nominal aft CG limit (the contingency limit is still protected) and downweight restrictions. On the other hand, a nominal forward CG violation can result from commitment to AOA shallow, so the CG concern by itself becomes less of a factor. Note that the TAL to an ACLS is still performed under auto guidance, but, in some cases, a manual MECO is performed to achieve the TAL site R-V line with TAL selection occurring post-MECO.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-52

ASCENT MODE PRIORITIES FOR PERFORMANCE CASES
(CONTINUED)

- B. PRESS-TO-ORBIT PERFORMANCE DECISIONS WILL BE BASED ON THE ABILITY TO ACHIEVE MECO UNDERSPEED CONDITIONS WHICH SATISFY ESTABLISHED MINIMUM CONSTRAINTS. INCLUDED IN THESE ARE LIMITATIONS ON ET IMPACT LOCATION, POST-MECO PERFORMANCE CAPABILITY, TRAJECTORY ALTITUDE LIMITS, SSME MINIMUM NPSP CONSTRAINTS, AND PROTECTION OF THE CONTINGENCY CG ENVELOPE (REF. RULE {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS).

Reference Rule {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS, for rationale.

- C. MAXIMUM THROTTLES WILL BE USED TO REGAIN INTACT ABORT CAPABILITY AND TO CONTINUE THE EXECUTED TAL TO THE SELECTED SITE (REF. RULES {A4-53}, USE OF MAXIMUM THROTTLES; AND {A4-56F}, {A4-56H}.2, AND {A4-56H}.3, PERFORMANCE BOUNDARIES). @[092195-1770A]

Maximum throttle capability is used only in limited cases and is the highest power level available on a flight. Use of the maximum setting places additional stress on the engine and seriously reduces engine lifetime and so should be used only if absolutely necessary. In line with this philosophy, the maximum throttle setting will only be used if it allows the orbiter to regain intact abort capability or will allow continuation of a TAL abort to the originally-selected site when two SSME's have failed (continuing to the originally-selected site at maximum throttle is preferred over committing to a sizable attitude maneuver on a single engine).

- D. POST-MECO (OPS 1), THE ABORT PRIORITIES ARE AS FOLLOWS:
@[120894-1744B]

1. NOMINAL, STEEP DEORBIT [1]
2. ATO/ATO [2], STEEP DEORBIT [3]

FLIGHT RULES

A2-52

ASCENT MODE PRIORITIES FOR PERFORMANCE CASES (CONTINUED)

Post-MECO abort priorities were established to provide the highest probability of safe return of the orbiter and crew. Again, the priorities are set up to allow the orbiter to achieve the most desirable uphill/orbital capability available based on propellant available and the known MECO conditions. The first priority is to achieve the nominal mission orbital parameters while maintaining steep deorbit capability (1). This is followed by reducing the orbital altitude, but still protecting steep deorbit (2). Steep capability is maintained since commitment to shallow deorbit unnecessarily trades off the deorbit/entry propellant and trajectory dispersion protection inherent in steep targeting for achievement of mission objectives that in many cases can be adequately accomplished at a lower-than-nominal altitude. The next option (3) accepts further reduction in orbit perigee (and hence, orbital lifetime and tracking/navigation quality) in order to achieve at least some on-orbit time. Aft RCS is committed for deorbit burn completion (nominal RCS entry redlines are maintained, however). Forward RCS may be committed for OMS-2 and in OPS 2 at this priority level (ref. Rule {A2-53}, FORWARD RCS USAGE GUIDELINES). Again, these trades are made in order to maintain steep deorbit capability. ATO/ATO (Hp approximately 105 nm) gives orbital lifetime for FD2 deorbit without committing the Fwd RCS. The minimum perigee guarantees a safe deorbit for the FD1 PLS opportunity. Time-to-EI constraints do not apply to minimum perigee determinations. At the next priority level (4), shallow FD1 and FD2 deorbits are allowed. The only remaining method of preserving propellant in addition to that already committed is to allow use of ARCS and violation of the CG to the contingency CG box (priorities 5, 7, and 9). This may allow achievement of minimum orbital conditions or may require a steep or shallow AOA, with the potential in any case of requiring use of a no-go site. ©[012402-5112B]

If an AOA cannot be achieved, the site selection priority will be based on site status (TAL vs ACLS vs ELS) and guidance capability when more than one site satisfies the conditions in Rule {A2-264}, EMERGENCY LANDING FACILITY CRITERIA. Guidance capability will be based on the Descent Design System (DDS) if available or the Downrange Abort Evaluator (DAE). Figure A2-52-I is included for clarity to illustrate the various regions of dissimilar guidance capability. Nominal guidance refers to OPS 3 entry guidance requiring no manual procedures. Low energy guidance refers to the use of automatic low energy guidance, enabled via Item 3 on the Entry TRAJ display. High crossrange procedures consist of enabling low energy guidance and manually flying a 37-degree angle of attack during the second pullout to minimize wing leading edge temperatures. High energy procedures consist of manual pitch and roll inputs during entry and are contained in section 2 of the Ascent Checklist. ©[120894-1774B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-52

ASCENT MODE PRIORITIES FOR PERFORMANCE CASES (CONTINUED)

In general, the regions shown in figure A2-52-1 are preferred in the following priority: Nominal entry guidance capability (region A), low energy guidance capability (region B), low energy guidance with high crossrange procedures (region C), and finally high energy procedures (region D). Nominal entry guidance is preferred over low energy guidance since low energy guidance can take the vehicle to its thermal limits. A site in the high crossrange region (region C) is third in priority since it requires the use of low energy guidance to solve the crossrange problem and pitch CSS to prevent potential thermal violations (reference Rule {A2-55}, USE OF LOW ENERGY GUIDANCE). High energy procedures are last in priority since they are more complicated and may take the vehicle to its structural and thermal limits. Usually a TAL site has priority over an ACLS, which has priority over an ELS. However, priority will be given to an ACLS within nominal guidance capability (region A) over a TAL site within low energy guidance capability (regions B or C). The risk associated with landing at an ACLS is considered less than the risk associated with the use of low energy guidance. If no TAL site or ACLS lies within nominal guidance capability (region A), priority will be given to a TAL site within low energy guidance capability (region B), followed by a TAL site within low energy guidance capability requiring high crossrange procedures (region C), followed by a TAL site requiring high energy procedures (region D). If no TAL site is available, the same priorities will be given to an ACLS. The use of high energy procedures to a TAL site or ACLS was given priority over an ELS within nominal guidance capability since those sites will have landing aids, nav aids, and ground support. If no TAL site or ACLS is available, then an ELS within nominal guidance capability (region A) will be selected. If no ELS lies within nominal guidance capability, then the site within low energy guidance capability (region B) will be selected. Otherwise, an ELS within low energy guidance capability requiring high crossrange procedures (region C) will be selected.

If there is no site within nominal or low energy guidance capability (outside regions A, B, or C), the site (TAL, ACLS, or ELS) with the best chance of a runway landing will be selected. A landing attempt to this site may require the use of high energy procedures (region D) or a lower angle of attack during the first pullout (region E) or high crossrange procedures (region F) (reference Rule {A2-55}, USE OF LOW ENERGY GUIDANCE). Since all three of these regions require manual procedures and may take the vehicle to its thermal and structural limits, they are given the same priority. Site status, difficulty of manual procedures, and proximity to guidance capability will be considered when choosing between sites in regions D, E, and F.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-52

ASCENT MODE PRIORITIES FOR PERFORMANCE CASES (CONTINUED)

Note that these choices can be heavily influenced by landing site status. Since determination of the desired site must be made rapidly, in real time, the engineering judgment of the flight control team will be considered due to the significant tradeoffs which must be made. For example, the preference for ACLS in region A over a TAL site in region B, C, or D could be modified if the ACLS has very bad weather, as opposed to the ACLS being no-go as a TAL site simply due to loss of nav aids redundancy. ©[120894-1774B]

Rules {A2-51}, STS ABORT CRITERIA; {A4-56C}, PERFORMANCE BOUNDARIES; {A4-62}, OMS-1/OMS-2 EXECUTION; and {A6-51}, OMS FAILURE MANAGEMENT [CIL], reference this rule.

E. POST-MECO (OPS 6 CONTINGENCY ABORT), THE DOWNRANGE SITE HAS PRIORITY WHEN CAPABILITY EXISTS TO MULTIPLE SITES WHICH SATISFY THE CRITERIA IN RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA. ©[120894-1744B]

For OPS-6 contingency abort entries (ECAL and Bermuda), powered flight guidance uses an open loop scheme and is therefore not targeted to any particular MECO conditions. In these cases, energy evaluation is not feasible until after the post-MECO pullout maneuver. Even though active guidance begins at transition to OPS 603 at Mach 3.2 (TAEM interface), an accurate energy assessment cannot be made until the trajectory stabilizes. If energy capability overlaps between two sites and both satisfy the criteria in Rule {A2-264}, EMERGENCY LANDING FACILITY CRITERIA, the further downrange site shall be selected to minimize steering requirements caused by large heading errors. ©[120894-1744B]

FLIGHT RULES

A2-53

FORWARD RCS USAGE GUIDELINES

- A. PRE-MECO: FORWARD RCS DELTA V CAPABILITY WILL ONLY BE CONSIDERED FOR OPS-2 BURNS IN SUPPORT OF A FD2 PLS.
 ©[012402-5112B]
- B. POST-MECO: FORWARD RCS WILL BE USED FOR OMS-2 TO OBTAIN THE HIGHEST POSSIBLE ABORT MODE PROVIDED THERE IS SUFFICIENT FORWARD RCS PROPELLANT TO SUPPORT THE TOTAL DELTA V REQUIRED FOR THE BURN.

Pre-MECO, Forward RCS delta V capability is not considered as being available to support or provide an abort capability for AOA or FD1 PLS since flight design and techniques do not assure that time and/or trajectory constraints will not preclude its use. However, it may be considered pre-MECO in support of a FD2 PLS capability, since a FD2 deorbit allows sufficient time to perform OPS-2 Fwd RCS burns and the post-OMS-2 trajectory conditions are better defined (reference A/E Flight Techniques #178). Each Forward RCS burn will be constrained to a maximum burn time of 150 seconds as defined by Flight Rule {A6-153A}, RCS JET MAXIMM BURN TIME.

Post-MECO, the time and trajectory constraints are mitigated by knowledge of the actual trajectory condition, and hence the Forward RCS may then be committed to help achieve the highest-priority abort option. The basic groundrule in Forward RCS commitment for OMS-2 is that Forward RCS critical-burn redundancy is considered sufficient to commit its use at OMS-2 if such usage will result in at least some on-orbit capability (i.e., avoidance of AOA). It is also desirable to avoid any requirement for a flip-around maneuver to complete a burn begun with the Forward RCS, particularly when the burn is considered critical. Therefore, the Forward RCS will only be used for OMS-2 if it can provide all the delta V necessary to establish a safe perigee. An additional advantage of using the Forward RCS in this manner is that usage at OMS-2 (rather than saving it for deorbit completion) may preclude a fast-flip requirement to complete the deorbit burn since extra OMS/ARCS is made available for that maneuver.
 ©[012402-5112B]

FLIGHT RULES

A2-54

RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]

FOR SPECIFIC SYSTEMS FAILURES, AN RTLS, TAL, OR AOA ABORT WILL BE SELECTED TO PROVIDE THE EARLIEST AVAILABLE LANDING TIME OR TO AVOID REQUIRING A LOST CAPABILITY.

NOTE: WHEN THE SAME ITEM APPEARS IN MORE THAN ONE ABORT OPTION, THE EARLIEST ABORT OPTION AVAILABLE IS SELECTED.

A. AN RTLS WILL BE PERFORMED FOR THE FOLLOWING:

1. IMPENDING LOSS OF ALL APU/HYDRAULIC SYSTEMS CAPABILITY.
@[111699-7070B]

At least one APU/HYD system is required to attempt to land the vehicle. If failures are present that are leading to the loss of all systems, the abort mode which affords the earliest landing time is selected (ref. Rule {A10-21A}.4, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS).

If the third APU/HYD system is nominal, it is preferable to continue to orbit rather than performing an abort. Continuing to orbit allows for time to troubleshoot the two failed systems and possibly regain one or both systems for entry. Additionally, going to orbit will provide the time to take the necessary steps to ensure the best possible conditions (i.e., trajectory, landing site, crew and vehicle health, weather conditions, etc.) for a single APU entry. @[111699-7070B]

2. FAILURE OF A FORWARD WINDSHIELD OR SIDE HATCH THERMAL WINDOWPANE (OUTER PANE) [CIL]. @[021998-6493]

An RTLS abort is selected to minimize the thermal stresses on the remaining windowpanes and surrounding structure. Entry heat loads are less on an RTLS than on other abort modes or during a normal landing. This provides a better chance of the remaining panes and surrounding structure surviving entry.

Reference rule {A10-381}, THERMAL WINDOWPANE FAILURE [CIL]. @[021998-6493]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54

RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES
[CIL] (CONTINUED)

3. CABIN LEAK RESULTING IN A DP/DT > -0.15 PSIA/MINUTE.

If a cabin leak develops with a leak rate greater than that specified, then there has been a loss of cabin integrity and the abort mode that affords the earliest landing time should be selected. The -0.15 psia/minute value allows the capability to perform an orbit 3 deorbit and land with a cabin pressure of 8 psi. It is also the value that should cover ascent pressure fluctuations so that an erroneous abort is not called. If the leak rate is less than that specified, continue to MECO and attempt leak isolation. If the leak is not isolated, then an AOA will be performed and there should be enough pad so that if the leak increases the abort can be completed.

4. IMPENDING LOSS OF ALL O₂ (H₂) CRYO.

If the pressure cannot be maintained in at least one cryo tank and manifold, the fuel cells will eventually stop producing electrical power, no matter what the quantity is in the cryo tanks. Since the amount of time available before "blowdown" of the tanks is dependent on a large number of variables, specific numbers cannot be defined for the purpose of selecting the most preferred abort. Thus, this condition warrants the selection of the abort mode that affords the earliest landing time (ref. Rule {A9-261}, IMPENDING LOSS OF ALL CRYO).

5. LOSS OF TWO FREON LOOPS.

With the loss of both Freon loops the vehicle has lost all cooling capacity. Fuel cell life becomes the critical factor. Assuming a purge of all three fuel cells and a 12.54 kW (4.18 kW/fuel cell) power level, stack temperature limits will be reached in about 50 minutes and the electrolyte concentration will reach the operational limit of 25 percent in about 75 minutes. At this point, continued operation of the fuel cell is questionable. Without a purge, the fuel cells will flood in about 18 minutes at a power level of 8.0 kW (2.67 kW/fuel cell). The life of the fuel cell would therefore be somewhere between 18 and 50 minutes, thus requiring an abort mode that affords the earliest landing time. This data is supported by Rockwell analysis and the SODB.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54

RTLIS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES
[CIL] (CONTINUED)

6. LOSS OF ANY TWO MAIN BUSES (PRECLUDES EXTERNAL TANK (ET) DOOR CLOSE).

The loss of two main electrical buses precludes closing the ET doors. An RTLIS will be performed for this failure since it provides a more benign entry heating scenario and allows a better chance of accomplishing a successful landing.

B. A TAL WILL BE PERFORMED FOR THE FOLLOWING:

NOTE: FOR THE PURPOSES OF SYSTEMS ABORTS, A TAL WILL ONLY BE EXECUTED TO A TAL SITE OR AN AUGMENTED CONTINGENCY LANDING SITE.

1. TWO OMS PROPELLANT TANKS LEAKING/FAILED, DIFFERENT SIDES.

If two OMS propellant tanks are leaking or have failed (different sides), a TAL abort will be selected since uphill capability is not available. A TAL abort is preferred over an RTLIS for the following reasons:

- a. *The TAL entry environment (with the exception of thermal) is less severe than GRTLIS. RTLIS ET separation is more demanding because of higher aerodynamic loads; trajectory maneuvers post- ET separation are more time-critical (to maintain reasonable energy level and loads on the vehicle); and 50 degrees angle of attack must be established and maintained.*
- b. *NZ is greater during GRTLIS than TAL entry. This becomes an important factor if the OMS tank landing weight and maneuver constraints are violated. Structural damage to the OMS tank might occur if the OMS maneuver constraint is violated with high NZ.*
- c. *The TAL post-MECO dump allows the single engine roll control propellant to be dumped. As a result, less residual propellant remains postdump; therefore, the chance of pod freezeup and postlanding fire is decreased.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54

RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL] (CONTINUED)

If these failures occur pre-MECO and after last TAL capability to the prime site, a TAL to an ACLS may be performed. If the decision to abort TAL occurs late enough, a manual MECO may be required in order to reach the TAL R/V line. This would be followed by TAL selection post-MECO. There are risks associated with the manual MECO TAL abort not incurred with a pre-MECO TAL selection prior to the last pre-MECO TAL boundary. (1) Manual MECO incurs the risk of missing the targeted MECO VI and creating an under- or over-speed condition. (2) A complete OMS dump is not possible and this may result in violation of landing weight or cg constraints. The risks associated with manual MECO TAL aborts are judged to be less than those associated with continuing toward a nominal MECO with critical systems failures.

If these failures occur after last capability to an ACLS, then post-MECO, if ATO capability does not exist, an AOA or bailout must be performed.

2. LOSS OF TWO OMS HE TANKS THAT WILL NOT SUPPORT HIGHER PRIORITY ABORTS (ATO/SHALLOW, AOA STEEP).

A TAL will be selected for two OMS He tank failures if uphill capability is not available. A TAL abort is preferred over an RTLS for the reasons listed in a. and b. of paragraph B.1 rationale.

If these failures occur pre-MECO and after last TAL capability to the prime site, a TAL to an ACLS may be performed. If the decision to abort TAL occurs late enough, a manual MECO may be required in order to reach the TAL R/V line. This would be followed by TAL selection post-MECO. There are risks associated with the manual MECO TAL abort not incurred with a pre-MECO TAL selection prior to the last pre-MECO TAL boundary. (1) Manual MECO incurs the risk of missing the targeted MECO VI and creating an underspeed or overspeed condition. (2) A complete OMS dump is not possible and this may result in violation of landing weight or cg constraints. The risks associated with manual MECO TAL aborts are considered much less than those associated with continuing toward a nominal MECO with critical systems failures.

If these failures occur after last capability to an ACLS, then post-MECO, if ATO capability does not exist, an AOA or bailout must be performed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54

RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES
[CIL] (CONTINUED)

3. TWO ARCS PROPELLANT TANKS LEAKING, DIFFERENT SIDES, SAME PROPELLANT THAT WILL SUPPORT TAL ET SEPARATION AND ENTRY TO A Q-BAR = 20.

If one pod contains > 75 percent propellant ET separation can be performed (ref. Rule {A6-57}, AFT RCS PROPELLANT TANK FAIL/HELIUM INGESTION). The leak rate after ET separation must still support Q-bar = 20 to guarantee control until NO YAW JET can be engaged. If either leak rate supports TAL, the proper course of action is to abort TAL. If the leak rate does not support TAL, this case becomes the same as two propellant tanks failed.

Two propellant tanks failed same propellant does not allow any type of certified control mode from EI to Q-bar = 20. By pressing uphill, time is gained to allow complex procedure and/or software changes to take place to help provide control until a Q-bar = 20 (i.e., DAP or procedure changes that will allow forward RCS control in pitch and yaw). With the OI-8 NO YAW JET software, a certified entry from a Q-bar = 20 to touchdown is now available. An uphill abort cutting off at minimum Hp which requires the least total delta-V for the insertion and deorbit burns, and ensures orbital lifetime at least two orbits beyond the first day PLS is selected to maximize the amount of OMS remaining to protect for interconnect operations post-deorbit burn.

4. IMPENDING LOSS OF ALL APU/HYDRAULIC SYSTEMS CAPABILITY.
@[111699-7070B]

See rationale for paragraph A.1.

5. CABIN LEAK RESULTING IN A DP/DT > -0.15 PSIA/MINUTE.

See rationale for paragraph A.3.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54 RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES
[CIL] (CONTINUED)

6. IMPENDING LOSS OF ALL O₂ (H₂) CRYO.

See rationale for paragraph A.4.

7. LOSS OF TWO FREON LOOPS.

See rationale for paragraph A.5.

8. LOSS OF RTLS ET SEPARATION CAPABILITY (WHEN AN RTLS WOULD HAVE BEEN CALLED FOR) BASED ON RCS JET FAILURES WHICH STILL ALLOW ET SEPARATION ON A TAL.

Combinations of failures could result in the loss of RCS jets such that an RTLS ET separation could not be accomplished for an RTLS abort case. In this situation, a TAL would be performed and the additional 11 minutes of flight time would have to be accepted.

9. THREE ET LOW LEVEL SENSORS FAILED DRY IN THE SAME TANK AND ARMING MASS WILL NOT SUPPORT AOA STEEP.

If multiple low level sensors fail indicating the "dry" state in the same tank such that at the time the arming mass is reached MECO would occur in a contingency downrange abort region, a TAL will be performed to avoid the downrange contingency abort. If the arming mass supports an AOA capability, assuming -2-sigma ME performance, then an AOA will be performed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54 RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES
[CIL] (CONTINUED)

C. AN AOA WILL BE PERFORMED FOR THE FOLLOWING:

1. TWO OMS PROPELLANT TANKS LEAKING/FAILED, DIFFERENT SIDES, POST-MECO.

See rationale for paragraph B.1.

2. LOSS OF TWO OMS HE TANKS IF ATO SHALLOW CAPABILITY DOES NOT EXIST.

See rationale for paragraph B.2.

3. TWO ARCS PROPELLANT TANKS LEAKING, DIFFERENT SIDES, SAME PROPELLANT, POST-MECO THAT WILL SUPPORT ENTRY TO A Q-BAR = 20.

See rationale for paragraph B.3.

4. IMPENDING LOSS OF ALL APU/HYDRAULIC SYSTEMS CAPABILITY.
@[111699-7070B]

See rationale for paragraph A.1.

5. AN AOA WILL BE PERFORMED FOR A CABIN LEAK RESULTING IN A DP/DT > -0.02 PSIA/MINUTE (GROUND CALL) OR FOR LOSS OF COMMUNICATION A DP/DT > -0.08 PSIA/MINUTE (CREW CALL).

A value of -0.08 psia/minute will be used for crew loss of communication procedures because it creates a C&W alarm, and therefore cues the crew to a possible cabin leak and to crosscheck with a cabin pressure decrease. The C&W dp/dt limit is set at -0.08 psi/minute to prevent nuisance alarms during the period from lift off to MECO when cabin pressure is transient due to LES helmet flow, thermal and external drop effects.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-54

RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL] (CONTINUED)

A leak rate in the range $-0.02 < -EQdp/dt < -0.15$ psi/minute will allow continuing to orbit and then performing leak isolation procedures to determine whether the leak can be stopped. A leak rate of -0.02 would allow a landing at the next PLS. However, an AOA will be performed to provide additional margin should the leak rate increase. This leak rate is small enough to allow conservatism, but also large enough to not be masked by the post-MECO transient (approximately -0.02) so that a NO-GO call for APU shutdown can be made for a real leak. For leak rates < -0.02 , stay time will be determined by Rule {A17-201B}, CABIN PRESSURE INTEGRITY. ©[081497-1873]

6. IMPENDING LOSS OF ALL O₂ (H₂) CRYO.

See rationale for paragraph A.4.

7. LOSS OF TWO FREON LOOPS.

See rationale for paragraph A.5.

8. LOSS OF TWO WATER LOOPS.

An AOA will be performed for the loss of two water loops since the avionics temperatures cannot be managed for the extended period of time required for first day PLS. The avionics can be managed to allow an AOA while maintaining the required temperature levels.

9. THREE ET LOW LEVEL SENSORS FAILED DRY IN THE SAME TANK IF THE EXPECTED -2 -SIGMA CUTOFF VELOCITY SUPPORTS.

See rationale for paragraph B.9. Rules {A2-51}, STS ABORT CRITERIA; {A2-205}, EMERGENCY DEORBIT; {A4-56C}, PERFORMANCE BOUNDARIES; {A9-261}, IMPENDING LOSS OF ALL CRYO; {A10-21A}.2, LOSS OF APU/HYDRAULIC SYSTEM (S) ACTIONS; and {A16-12A}, EMERGENCY POWERDOWN, reference this rule.

A2-55

USE OF LOW ENERGY GUIDANCE (CONTINUED)

OPS 3 VS OPS 6 - For a large MECO underspeed, entry pullout loads determine whether to use OPS 6 Contingency Guidance or OPS 3 Low Energy Guidance. The MCC uses the Downrange Abort Evaluator (DAE) or a real-time plot of flight path angle versus velocity to assess the 3.5 g limit and make a real time call to inform the crew of the best type of entry. For loss of COMM, the crew uses the TAL velocity boundary on the three engine out portion of the contingency abort cue card to determine whether to use an OPS 6 or OPS 3 entry. If three engines fail simultaneously before this velocity boundary, an OPS 6 entry will be used since an OPS 3 entry will result in more than a 3.5 g pullout. This simple velocity boundary is not accurate for performance dispersions or sequential engine failures.

Low Energy Guidance - OPS 3 Low Energy Guidance uses a 42/31 alpha profile and modified roll command logic to extend the orbiter's downrange and crossrange capability during entry and increase the probability of making a landing site that would be unobtainable using nominal entry guidance. A 42-degree alpha is maintained during the initial pullout to avoid thermal damage and minimize the second pullout temperatures. Alpha is lowered to 31 degrees during the second pullout to extend the downrange capability without exceeding the thermal limits. The wing leading edge temperature must not exceed 3320 deg F at any time or 3220 deg F for more than 40 seconds. STSOC Transmittals DFD-92-510-041 and DFD-92-510-107 document the high inclination and generic low alpha thermal assessments. The low energy stretch footprint computed by the Downrange Abort Evaluator (DAE) defines the region where auto low energy guidance will make the site without violating thermal constraints.

Single Engine Limits and gap management take low energy guidance capability into account when determining performance boundaries. Reference Rules {A4-56}, PERFORMANCE BOUNDARIES, and {A5-103}, LIMIT SHUTDOWN CONTROL.

Low Energy Guidance and Manual Pitch Control in the First Pullout - Manual pitch control may be used in conjunction with auto low energy guidance to increase downrange capability by flying a lower alpha in the first pullout. The MCC can evaluate the thermal acceptability of alpha 40 and 37 degrees through the first pullout. Reference A/E FTP #49, 9/15/88; #79, 6/21/91; and #87, 2/21/92.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-55

USE OF LOW ENERGY GUIDANCE (CONTINUED)

High Crossrange in Region of Thermal Concern - For landing sites outside the nominal guidance crossrange capability, using the automatic low energy logic will improve the chance of making a site by trading downrange for crossrange but may exceed thermal limits. While it is known that the area beside the nominal footprint contains small regions that violate thermal limits, the exact definition of the regions is not available. For this reason, the conservative course of action is to plan to fly the second pullout at an alpha of 37 degrees. The MCC will do a real-time thermal evaluation at alpha 42/31 to determine if the second pullout can be completed in auto. Pitch control can be returned to auto when the pullout is complete or on an MCC call.

High MECO Velocities - High MECO velocities that require low energy guidance to make a landing site could exceed thermal limits during the second pullout. Flying the second pullout at an alpha of 37 degrees will avoid any thermal problem. The MCC will do a real-time thermal evaluation at alpha 42/31 to determine if the second pullout can be completed in auto. Pitch control can be returned to auto when the pullout is complete or on an MCC call.

Rule {A4-56}, PERFORMANCE BOUNDARIES, references this rule. @[120894-1663]

A2-56

ABORT GAP

ASCENTS WILL BE CONTINUED TO ORBIT WITH INTACT ABORT GAPS PROVIDED THREE-SSME UPHILL PERFORMANCE REMAINS ACCEPTABLE. REFERENCE RULE {A4-56I}, PERFORMANCE BOUNDARIES, FOR GAP CLOSURE OPTIONS AND UPHILL PERFORMANCE CRITERIA. @[ED]

Powered flight can continue through an intact abort gap provided three-engine performance is assured. Mission design and flight rules preclude launching with a known single-engine-out abort gap; however, one may arise during powered flight due to performance problems such as an SSME throttle stuck in the first-stage throttle bucket or Pc sensor shifts. In these cases, if performance with the existing SSME configuration is still able to achieve acceptable MECO conditions, then the risk of losing an SSME in the abort gap is accepted rather than commit to a three-engine pre-MECO abort. This risk is reasonable because the actual need for an abort has not yet arisen; the abort itself (RTLS or TAL) carries risks of its own; and the abort in most cases will not recover single-engine-failure protection. Also, the gap will normally be closed to the extent possible (ref. Rule {A4-56I}, PERFORMANCE BOUNDARIES); hence, any remaining gap will probably be of short duration. @[ED]

FLIGHT RULES

A2-57

CONTINGENCY ASCENTS/ABORTS

CONTINGENCY ASCENTS/ABORTS RESULT FROM THOSE SITUATIONS WHERE STRUCTURAL FAILURES OR MULTIPLE SYSTEMS/SSME FAILURES HAVE OCCURRED. IN SUCH INSTANCES, ACTION WILL BE TAKEN TO PROVIDE THE HIGHEST PROBABILITY OF A SAFE RETURN OF THE CREW AND ORBITER. THESE CASES WILL USUALLY RESULT IN ONE OR MORE OF THE FOLLOWING:

- A. CREW BAILOUT/ORBITER DITCH DUE TO THE LOSS OF MULTIPLE SSME'S IN A REGION WHERE NO ACCEPTABLE LANDING SITE IS AVAILABLE.
- B. AN ATTEMPT TO LAND AT AN RTLS, TAL, AOA, OR ACLS DUE TO STRUCTURAL OR MULTIPLE ORBITER SYSTEMS PROBLEMS WHICH NECESSITATE LANDING AT THE EARLIEST POSSIBLE TIME.
- C. AN ATTEMPT TO LAND AT AN RTLS, TAL, AOA, ELS, OR ACLS DUE TO MULTIPLE SSME FAILURES OR SINGLE SSME FAILURES COUPLED WITH OTHER ORBITER FAILURES (SUCH AS THE LOSS OF AN OMS ENGINE) WHICH RESULT IN SEVERE ASCENT PERFORMANCE LOSS. CONTINGENCY OR INTACT ABORT PROCEDURES (DEPENDING ON THE PARTICULAR FAILURES AND THE TIME OF EXECUTION) WILL BE PERFORMED AS REQUIRED PER THE ASCENT CHECKLIST AND ASSOCIATED CUE CARDS FOR THE FAILURES DESCRIBED ABOVE, BUT IN ANY CASE, THE OPERATIONS WILL BE CONSIDERED "CONTINGENCY" IN NATURE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-57

CONTINGENCY ASCENTS/ABORTS (CONTINUED)

NOTE: CONTINGENCY ABORTS DUE TO TOTAL SSME THRUST LOSS IN A "BLACK ZONE" OF THE FLIGHT PROFILE, SO DESIGNATED DUE TO THE CHANCES OF SURVIVABILITY, WILL RESULT IN VIOLATION OF VEHICLE Q-BAR, G-LOADING, AND/OR THERMAL LIMITS. LOSS OF TWO SSME'S PRIOR TO EARLIEST SINGLE ENGINE DITCH AVOIDANCE CAPABILITY (REF. RULE {A4-56}, PERFORMANCE BOUNDARIES) MAY RESULT IN VEHICLE LOSS OF CONTROL OR ET RUPTURE DUE TO LOW ALTITUDE TRAJECTORY AND THERMAL CONDITIONS. MANUAL FLIGHT PROCEDURES WILL BE USED IN THESE CASES TO ATTEMPT TO SEPARATE FROM THE ET FOR SUBSEQUENT BAILOUT PRIOR TO ANY LOSS OF CONTROL.

This rule addresses the general conditions and actions that result in contingency ascent/abort cases. These cases involve structural type failures such as the loss of cabin pressure integrity, propellant tank leaks, etc.; or multiple orbiter systems failures such as the loss of both Freon loops, the loss of both water loops, etc.; or the loss of multiple SSME's or single SSME, in conjunction with other orbiter failures such as the loss of an OMS engine. The execution of a contingency ascent/abort may or may not result in the use of intact abort procedures or a landing at an RTLS, TAL, or AOA site. While this type of abort would use these sites when possible, landing at an augmented contingency landing site (ACLS) or an ELS may be required. If none of these are available, then a crew bailout may be necessary. While some scenarios will allow an intact abort to be completed after a second SSME failure, these are still considered a contingency abort from a programmatic standpoint.

Crew procedures for flying contingency aborts are contained in the ascent checklist but are only used if intact abort procedures will not suffice for a given situation. In general, contingency abort procedures are not certified/verified to the level of intact abort procedures. Certain regions of the ascent trajectory profile (black zones) may not be survivable if a contingency abort has to be executed due to multiple SSME failures since violations of orbiter or ET constraints on Q-bar, G-level, and heating will occur. Earliest ditch avoidance capability refers to the first time that loss of two SSME's will still allow flight to continue under converged guidance and, at the same time, will not cause the subsequent trajectory to droop below 265,000 feet. This is the altitude below which loss of control may occur or the ET may rupture due to overheating. In these regions, should a contingency abort be required, manual special procedures may be used in an attempt to achieve ET separation and at least a subsequent bailout capability.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule. ©[081497-6307]

FLIGHT RULES

A2-58

ABORT LIGHT

A. ABORT REQUEST COMMANDS ARE TRANSMITTED FROM MCC, VIA PUSHBUTTONS LOCATED ON THE FD, FDO, AND EASTERN RANGE 45th SPACE WING FCO CONSOLES, WHICH ILLUMINATE THE ABORT REQUEST LIGHT ON THE COMMANDER'S PANEL. THE ABORT COMMAND WILL BE TRANSMITTED AT THE SAME TIME THAT THE ABORT REQUEST IS VOICED TO THE CREW OVER A/G TO INDICATE ONE OF THE FOLLOWING ABORT MODES OR ACTIONS IS REQUIRED: @[081497-6307]

1. RTLS
2. TAL
3. ATO
4. AOA
5. CONTINGENCY ABORT
6. MANUAL MECO (SECOND STAGE ONLY) @[081497-6307]

AFTER THE ABORT REQUEST IS RECEIVED AND EXECUTED BY THE CREW, THE ABORT LIGHT WILL BE TURNED OFF VIA GROUND COMMAND.

B. ABORT REQUEST CUES - THE GROUND WILL BASE ABORT REQUEST TRANSMISSIONS ON AT LEAST TWO INDEPENDENT CUES (E.G., TELEMETRY DATA, CREW VOICE REPORTS, FDO PERFORMANCE INDICATIONS, ACTUAL OR IMMINENT RANGE SAFETY LIMIT LINE VIOLATIONS). LIKewise, TWO CUES ARE REQUIRED FOR THE CREW TO TAKE THE NECESSARY ACTION TO ABORT THE FLIGHT (E.G., PHYSIOLOGICAL CUES, ILLUMINATED ABORT LIGHT, VOICE REPORT OVER A/G, COCKPIT INDICATIONS). THIS RULE ASSUMES NO FAILURES WHICH MAY MASK SECONDARY INDICATIONS OF ABORT REQUIREMENT. @[081497-6307]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-58

ABORT LIGHT (CONTINUED)

C. CREW ACTION:

1. FIRST STAGE - EXECUTE ANY AVAILABLE ABORT MODE (NOTE - AT PRESENT, NO FIRST STAGE ABORT EXISTS).
2. SECOND STAGE - EXECUTE RECOMMENDED ABORT MODE (RTLIS, TAL, ATO, CONTINGENCY, MANUAL MECO)
3. POST-MECO - AOA, TAL, DOWNRANGE ABORT/CONTINGENCY

This rule documents the conditions under which the abort light command will be issued, the cue requirements for requesting or initiating an abort, and the actions to be taken during each ascent phase. Assuming no other known failures are present which may mask malfunction indications, two independent cues are required before an abort will be requested or initiated in order to provide at least one confirming indication that an abort is required.

If an abort is necessary, the abort light command will be issued for all ascent abort modes. It was agreed that the abort command would be sent at the time that the abort request is passed to the crew as opposed to the time at which the abort is initiated. In most cases, these events are concurrent; however, in the RTLIS/TAL overlap region it is usually desirable to delay abort initiation until close to the last RTLIS boundary. The abort light will be reset (turned off) via ground command so that it may be used again if necessary to request a subsequent AOA and also to remove the bright light source in the case of night launches. As part of the 1996 ET Range Safety System removal effort, the Eastern Range/45th Space Wing Flight Control Officer (FCO) was provided with two redundant abort light switches in the event a range safety limit line is violated. Note that in most cases, however, MCC/flight crew action will already have taken place before FCO activation of the light is required. ©[081497-6307]

Paragraph C serves to delineate the abort options available for each ascent flight phase. ©[081497-6307]

FLIGHT RULES

A2-59

BFS ENGAGE CRITERIA

A. LOSS OF REDUNDANT SET (REF. RULE {A7-1A}, PASS DPS FAILURE).

Loss of the redundant set will result in a loss of vehicle control. Control may be regained by engaging the BFS.

B. LOSS OF CONTROL:

1. LOSS OF PASS CAPABILITY TO CONTROL THE VEHICLE DUE TO GPC/MDM/LRU FAILURES (BFS MUST RECOVER CRITICAL CAPABILITY).

Combinations of GPC/MDM/LRU failures may cause the flight control system to use bad system inputs resulting in loss of vehicle control. The BFS should only be engaged if it will pick up at least one IMU, control over two FCS channels, and satisfy the LRU constraints stated in Rule {A8-56}, BFS LRU REQUIREMENTS.

2. LOSS OF CONTROL DUE TO DIVERGENT TRAJECTORY. AFTER MET 1 MINUTE 30 SECONDS, CONTROL STICK STEERING (CSS) MAY BE ATTEMPTED BEFORE BFS ENGAGE.

During first stage, loss of control may occur very quickly due to the control authority of the SRB's. Early in the STS program it was determined that the crew could not manually control the vehicle during first stage load relief, which occurs during the high Q-bar region, even though CSS is available in PASS. Therefore, prior to high Q-bar, the crew should engage the BFS to regain lost system capability which may recover vehicle control. After MET 1 minute 30 seconds, CSS control is an option the crew has available to regain vehicle control. If CSS does not recover vehicle control, then engaging BFS is the last option available since it will place the vehicle control under different software commands. (Note: only AUTO flight control mode is available in the BFS during powered flight, MM 102 and 103). The FCS downmoding (AUTO to CSS or even BFS engage) is an onboard call. Rule {A8-54}, FIRST STAGE LOSS OF CONTROL DEFINITION, defines the vehicle rates and attitude errors for loss of control.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-59

BFS ENGAGE CRITERIA (CONTINUED)

C. ROLL MANEUVER NOT INITIATED AS SCHEDULED.

Since the onboard displays are inadequate for the crew to manually execute the roll/pitch profile through the critical high Q phase with the PASS, the BFS must be engaged if the roll maneuver is not initiated at the planned I-loaded value of relative velocity (ref. Rule {A4-58A}, AUTO GUIDANCE NO-GO). The BFS has an auto capability during powered flight.

D. PRE-MECO, FOR SET SPLITS SUBJECT TO THE CRITERIA LISTED IN RULE {A7-9A}, REDUNDANT SET SPLIT.

PASS GPC set splits are considered to be a low probability failure mode and are also complex to deal with in the short amount of time available or in the presence of other failures. In many instances, BFS engage is the quickest and simplest approach to avoiding catastrophic results (e.g., when they result in multiple command path failures to SSME's near MECO). Circumstances where PASS reconfiguration is preferred over BFS engage are detailed in Rule {A7-9A}, REDUNDANT SET SPLIT, which also contains the procedures required in those cases.

Rule {A7-9}, REDUNDANT SET SPLIT, references this rule.

A2-60

NAVIGATION UPDATE CRITERIA

WHEN AN INDEPENDENT NAVIGATION SOURCE IS AVAILABLE, NAVIGATION UPDATES WILL BE INITIATED TO PROVIDE ACCEPTABLE MECO CONDITIONS AND MAINTAIN THE HIGHEST ASCENT PRIORITY MODE AVAILABLE. IF NAVIGATION UPDATES CANNOT BE PERFORMED, MECO WILL BE COMMANDED MANUALLY (REF. RULE {A4-60}, MANUAL SHUTDOWN CRITERIA). ©[121296-4177D]

Orbiter navigation velocity errors not corrected until post-MECO cause an almost one for one OMS penalty during OMS-1. This penalty may cause downmoding to a lower ascent priority mode because of OMS propellant budget limitations. To avoid sacrifice of mission objectives, error limits are established for execution of pre-MECO navigation updates (ref. Rule {A4-57A}, NAVIGATION UPDATES). If a navigation update cannot be performed due to the unavailability of an independent navigation source, loss of command capability, or insufficient time prior to MECO, then the manual shutdown criteria (ref. Rule {A4-60}, MANUAL SHUTDOWN CRITERIA) will be used to ensure an acceptable cutoff. ©[121296-4177D]

FLIGHT RULES

A2-61

Q-BAR/G-CONTROL

- A. A FAILURE OF ALL THREE ENGINES TO THROTTLE DOWN FOR Q-BAR CONTROL IN FIRST STAGE OR G-CONTROL IN SECOND STAGE IS CAUSE FOR MANUAL THROTTLE TO OBSERVE THE RESPECTIVE Q-BAR AND G LIMITS. FAILURE OF A SINGLE ENGINE TO THROTTLE IN THE SAME REGIONS REQUIRES NO ACTION. FAILURE OF TWO ENGINES TO THROTTLE IN SECOND STAGE IS CAUSE TO MANUALLY SHUT DOWN ONE OF THE NONTHROTTLING ENGINES.

The ascent profile is designed to constrain the maximum Q-bar and g's to their respective limits. During the thrust bucket, the throttles are reduced to ensure that the maximum dispersed Q-bar will not exceed the structural specification limit (approximately 820 psf). Should all three of the SSME's fail to throttle down, manual throttledown is required to avoid structural damage.

The g-control region of second stage adjusts the throttles to ensure that no more than approximately 3g will be experienced. This limit was selected to protect vehicle and payload structure. Therefore, should none of the SSME's throttle down at initiation of the g-control region, the crew will manually throttle to maintain approximately 3g.

For failure of a single SSME to throttle down in either the thrust bucket or in the g-control regions, no action will be required by the crew to manually throttle. Analysis conducted in 1996 (reference Shuttle Loads and Structural Dynamics Panel Minutes for August 31, 1998) showed that there will be an approximately 4 percent exceedance of the wing certified limit load during maximum Q-bar should a throttle be stuck high before the thrust bucket. This stuck throttle condition is not a design requirement and has been documented with a FMEA/CIL in accordance with NSTS 07700, Volume X requirements. The risk due to the increased loads is acceptable because a safety factor greater than one is maintained. During the g-control region, the healthy SSME's will throttle lower than normal and the maximum g's will be approximately 3.5. This is in violation of NSTS 07700, Volume X. To cover this case, a waiver was approved to accept a one-time high-G exceedance of up to 3.6 g's. Should this occur, post-flight analysis and inspection of the orbiter will be required. ©[041097-4910A] ©[111298-6788]

Failure of two engines to throttle down when the g-control region is reached will definitely lead to a violation of the 3g limit (in excess of 4g). The good engine will only throttle down to the minimum percent (approximately 67 percent). Therefore, one of the appropriate nonthrottling engines will be shut down to allow the remaining good engine to control g's with the other stuck engine.

Refer to the Ascent Flight Techniques meeting #53 minutes, RI/Downey memo 92MA1056, and Shuttle Loads and Structural Dynamics Panel Minutes for August 31, 1998, for further background. ©[041097-4910A] ©[111298-6788]

Rule {A2-64}, MANUAL THROTTLE CRITERIA, references this rule.

FLIGHT RULES

A2-62

ET FOOTPRINT CRITERIA

DESIGN MECO CONDITIONS AND ABORT MODE BOUNDARIES MUST PROVIDE AN ET IMPACT POINT (IP) FOOTPRINT, INCLUDING 3-SIGMA DISPERSIONS, WHICH SATISFIES THE FOLLOWING CONSTRAINTS:

- A. NOMINAL MECO TARGET: THE ET IP FOOTPRINT IS MAINTAINED AT A MINIMUM OF 200 NM FROM ALL FOREIGN LAND MASSES (EXCEPT THE FRENCH-HELD POLYNESIAN ISLANDS, WHERE THE MINIMUM CLEARANCE MAY BE REDUCED TO 60 NM WHEN DICTATED BY MISSION OBJECTIVES) AND 25 NM FROM THE PERMANENT ICE SHELF. ALSO, THE ET IP FOOTPRINT MUST BE MAINTAINED AT LEAST 25 NM FROM U.S. ISLANDS. @[092195-1777A] @[111699-7066]
- B. TAL MECO TARGETS: THE ET IP FOOTPRINT IS MAINTAINED A MINIMUM OF 25 NM OFF ALL FOREIGN LAND MASSES.
- C. RTLS MECO TARGETS: THE ET IP FOOTPRINT IS MAINTAINED A MINIMUM OF 25 NM FROM ANY LAND MASSES.
- D. EARLIEST SINGLE SSME OUT "PRESS" TRAJECTORIES (PRESS-TO-MECO AND PRESS-TO-ATO): THE ET IP FOOTPRINT WILL BE MAINTAINED OFF CRITICAL LAND MASSES. CRITICAL LAND MASSES INCLUDE:
 1. FOR DIRECT INSERTION 28.5-DEGREE INCLINATIONS: AFRICAN MAINLAND AND MADAGASCAR
 2. FOR DIRECT INSERTION 39-DEGREE INCLINATIONS: AFRICAN MAINLAND
 3. FOR DIRECT INSERTION 51.6-DEGREE INCLINATIONS: AFRICAN MAINLAND AND THE MIDDLE EAST @[092195-1777A]
 4. FOR DIRECT INSERTION 57-DEGREE INCLINATIONS: EUROPEAN AND ASIAN MAINLANDS
 5. ALL OTHER INCLINATIONS AND INSERTION TYPES WILL BE ANALYZED ON A MISSION-SPECIFIC BASIS. @[092195-1777A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-62

ET FOOTPRINT CRITERIA (CONTINUED)

E. ET FOOTPRINT CONSTRAINTS WILL NOT APPLY TO THE FOLLOWING CASES:

1. MULTIPLE SSME-OUT CASES
2. SINGLE SSME-OUT CASES COUPLED WITH ANY OF THE FOLLOWING:
 - a. ANY LOSS OF OMS DUMP CAPABILITY (PROPELLANT OR ENGINE)
 - b. ANY AFT RCS PROPELLANT LEAK/FAILURES
 - c. ANY OTHER SSME(S) STUCK IN THE THROTTLE BUCKET

The premission-defined MECO targets and design underspeed MECO conditions are selected such that they will not violate Eastern Range (ER) guidelines on ET IP or State Department requirements. These guidelines specify that a 3-sigma dispersion footprint be used for application of the ET IP limitation criteria.

Nominal MECO target: The nominal MECO targets must meet the strictest constraints on the ET IP footprint. The 200 nm limit from any foreign land mass must be satisfied through the ascent flight design process. This limit will preclude infringement of the territorial boundaries of all foreign land masses, ensuring no property or human damage occurs from ET debris. The SSP has received State Department approval to reduce the limit for the French-held Polynesian Islands to 60 nm (reference NSTS 07700 Vol X Section 3.2.1.1.17.2, ET Disposal). This ET disposal relief allows the use of DI to 122 nm MECO targets for ISS missions. The lower MECO target increases rendezvous phasing capability and significantly improves the possibility of an early rendezvous. Although the minimum is 60 nm, the ET footprint clearance will only be reduced from 200 nm as required to meet mission objectives. The 25 nm limit applies to the permanent ice shelf which, although not very populated, must be avoided for environmental protection. A lateral clearance of 25 nm is used to protect U.S. islands; the potential for high density of shipping vessels and other small craft in these waters makes this margin prudent for a planned ET disposal. This limit was previously 45 nm prior to the incorporation of OI-21 flight software, which eliminated worst-case guided MECO lateral dispersions caused by a side engine out late in the nominal trajectory. The 45 nm ensured a 25 nm clearance for these cases; however, the extra margin is no longer required. @[092195-1777A] @[111699-7066]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-62

ET FOOTPRINT CRITERIA (CONTINUED)

TAL and RTLS MECO targets: Once an abort or failure has occurred, the ET IP constraints are less strict. The TAL and RTLS restrictions on the ET IP footprint ensure that no land mass impact damage occurs, although with little additional margin.

“PRESS” trajectories: The earliest PRESS, single SSME-out, trajectories (earliest capability to continue the ascent to an orbital condition: AOA, ATO, or nominal mission altitude) must protect only critical land masses from ET IP debris. For these cases, no margin is added to the 3-sigma footprint beyond the critical land mass boundaries. Critical land masses are determined through JSC, ER, and State Department agreements considering the political relations with the U.S. and population density. The 1990 ACTA Incorporated 28.5-degree inclination hazards analysis shows casualty expectation orders of magnitude for Madagascar of 10-2. For this reason, Madagascar is considered a critical land mass. An abort will be recommended if the ET IP footprint violates the PRESS trajectory limitations.

Additionally, if the ET footprint signifies a risk to the eastern U.S. coastline, real-time action will be taken to correct the trajectory (ref. Rule {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS).

When multiple performance-related failures occur, as noted above in paragraph E, ET IP constraints will no longer be protected due to substantial risks to the flightcrew and vehicle. With the exception of the OMS engine failure, SSME stuck in the throttle bucket, and multiple SSME-out cases, the remaining cases are the result of a vehicle structural failure (extent unknown).

It is more hazardous to perform a TAL abort (in order to protect ET IP) without some knowledge of the control capability losses due to this failure. By pressing to orbit, there is a greater chance of assessing the damage and determining any new crew procedures, if required. Multiple SSME-out cases are considered to be contingency cases, and for that reason the ET constraints are no longer protected. An OMS engine failure is typically detected after an OMS dump (ATO abort) because ET IP protection has already been initiated. Here, a TAL abort is considered hazardous as a TAL abort would require a second abort declaration and the initiation of a second (contingency) dump which would necessitate manual procedures. These cases are considered in-flight contingencies, outside the program recognized failure cases.

Rules {A4-1}, PERFORMANCE ANALYSES; {A4-55A}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS; and {A4-56E}, PERFORMANCE BOUNDARIES, reference this rule.

FLIGHT RULES

A2-63

ASCENT STRING REASSIGNMENT

- A. PRE-MECO, RESTRINGING WILL BE PERFORMED TO REGAIN SSME THROTTLE COMMAND CAPABILITY NECESSARY TO AVOID AN RTLS/TAL/CONTINGENCY ABORT, SUBJECT TO THE FOLLOWING:
1. IF THE BFS IS NOT AVAILABLE, RESTRINGING WILL NOT BE PERFORMED TO AVOID AN RTLS OR TAL ABORT PROVIDED A RESTRING IS NOT REQUIRED TO SUPPORT THE ABORT.
 2. RESTRINGING WILL BE PERFORMED TO AVOID A CONTINGENCY ABORT INDEPENDENT OF THE BFS STATUS.

NOTE: THE LAST TIME A RESTRING CAN BE COMPLETED TO REGAIN UPHILL CAPABILITY WILL BE DETERMINED IN REAL TIME.

The SSME's are throttled down for maximum dynamic pressure control in first stage. If an SSME experiences a command path failure while in the thrust bucket, the ARD will be used to evaluate the effect of the stuck throttle on vehicle performance. On performance critical missions, an RTLS or TAL may be required even though the remaining two SSME's have nominal performance; a contingency abort may be required when a separate SSME has failed or is operating with off-nominal performance. Therefore, restringing will be performed to regain SSME throttle command capability if doing so will regain uphill capability or avoid an RTLS, TAL, or contingency abort. The BFS is normally required to protect against the low probability occurrence that the restring action may result in loss of the PASS set. If the BFS is not available and a restring is required to support the abort (pre- or post-ET SEP), no advantage exists with aborting RTLS/TAL instead of restringing to regain throttle capability. For these cases, restringing is acceptable to regain throttle command capability and avoid the abort independent of the BFS status.

The last time a restring can be completed to regain uphill capability will be determined by the FDO. This time will change as a function of the winds of the day, SRB performance, SSME performance, and SSME throttle setting of the nonthrottling engine. Therefore, this time will be determined by the ARD in real time.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-63

ASCENT STRING REASSIGNMENT (CONTINUED)

B. POST-MECO:

1. PRE-ET SEPARATION: RESTRING WILL ONLY BE PERFORMED IF REQUIRED TO REGAIN THE APPROPRIATE NUMBER OF RCS JETS REQUIRED FOR RTLS ET SEPARATION OR NOM/TAL ET SEPARATION.

ET separation cannot be performed without sufficient RCS jet control authority. RTLS ET separation is especially critical because of the increased number of RCS jets required for mated coast and ET separation. Additionally, for either RTLS or TAL, delaying ET separation is not an option. For nominal conditions, ET separation can be delayed allowing more time to configure for the restrung.

2. POST-ET SEPARATION:

- a. RESTRING WILL NOT BE PERFORMED PRIOR TO ACHIEVING A SAFE ORBIT EXCEPT FOR THE FOLLOWING:

- (1) RESTRING TO MAINTAIN SINGLE-FAULT TOLERANCE.

- (2) RESTRING TO REGAIN INSIGHT FOR AN UNRELATED CRITICAL SYSTEM FAILURE WHERE THE FAILED STRING MASKS THE SYSTEM PROBLEM ANALYSIS.

- (3) IF UNDERSPEED CONDITIONS EXIST SUCH THAT AN OMS-1 BURN IS REQUIRED AT MECO PLUS 2 MINUTES, RESTRING WILL NOT BE PERFORMED PRIOR TO OMS-1 UNLESS REQUIRED TO MAINTAIN BOTH OMS ENGINES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-63

ASCENT STRING REASSIGNMENT (CONTINUED)

The desire is to rely upon system fault tolerance capability (BFS is counted as a level of redundancy) during the uphill phases of the mission when a safe orbit has not yet been established and thereby reduce the risks that may be associated with restringing (possible GPC failure, set split, etc.). Additionally, because the timeline is leading into a quiescent orbit phase (versus a more dynamic entry phase), greater emphasis is placed on the existing systems capability, as long as fault tolerance exists, rather than restringing to regain full capability.

For off-nominal MECO conditions where the OMS-1 TIG is required at MECO plus 2 minutes, restring will not be attempted in order to focus attention on the critical OMS-1 burn and preclude restring error from jeopardizing OMS-1 execution. The exception to this rule is when less than two OMS engines are available. Because of the large underspeed both OMS engines are required in order to overcome large drag effects and achieve the desired targets. Downmoding to the RCS four +X jets may not be an option because of the magnitude of the required delta V and the low thrust/long burn time requirements associated with the RCS.

- b. RESTRING WILL BE PERFORMED AT THE NORMAL OPS TRANSITION TIME FOR AOA OR TAL.

The OPS transition software is designed to perform restrings and is a certified capability.

- c. RESTRINGING WILL NOT BE PERFORMED WITHOUT PRIOR MCC COORDINATION.

The MCC is prime for determining when restringing is required as a result of multiple failures and the resulting GPC/string assignments required to satisfy critical capability and systems fault tolerance as identified in the preceding rules. The MCC is prime for determining the acceptability of restringing based upon the failure signature and conditions and for determining an acceptable data bus reassignment configuration. As a minimum, voice description of the failure and identification of the proposed bus reassignment must be coordinated with the MCC prior to performing any restring.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-63

ASCENT STRING REASSIGNMENT (CONTINUED)

- D. RESTRINGING GPC/STRING COMBINATIONS WILL BE SELECTED WHICH MOVE THE LEAST NUMBER OF STRINGS.

The greater the number of strings moved during a restringing attempt, the more complicated the restringing process. With this in mind, "good" strings should not be taken from "good" GPC's unless there is no other method of regaining critical capability.

- E. RESTRINGING WILL BE PERFORMED TO REGAIN CRITICAL CAPABILITY INDEPENDENT OF THE BFS STATUS. FOR CASES WHERE RESTRINGING IS ACCEPTABLE TO REGAIN FAULT TOLERANCE (REF. PARAGRAPH B.2.a.(1)), AN ENGAGEABLE BFS MUST BE AVAILABLE.

The BFS is normally required when restringing is performed as a precaution against the low probability occurrence that the restringing action may result in loss of the PASS set. However, when the vehicle has sustained failures such that less than critical capability remains (a capability which must be maintained or a loss of crew/vehicle will result), restringing will be performed to regain the needed capability independent of the BFS status in order to maintain the flying status of the orbiter.

If the BFS is not available and less than critical capability remains, restringing is allowed to recover the PASS capability to control the orbiter. If the BFS is available and conditions are such that either a BFS engage or a dynamic restringing will recover the critical capability, restringing will be attempted if time permits completion of the restringing while still maintaining the BFS engage option.

Rules {A2-5}, PORT MODING/RESTRINGING GUIDELINES; {A2-69}, REGAIN RCS JETS FOR RTLS ET SEPARATION; {A7-9}, REDUNDANT SET SPLIT; {A7-102C}.4, PASS DATA BUS ASSIGNMENT CRITERIA; {A7-52}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES; and {A8-55}, ET SEPARATION RCS REQUIREMENTS reference this rule.

A2-64

MANUAL THROTTLE CRITERIA

MANUAL THROTTLE CONTROL WILL BE PERFORMED WHEN REQUIRED TO PROTECT SYSTEMS LIMITS, GUIDANCE SOFTWARE PERFORMANCE, OR MISSION CAPABILITY. REFERENCE RULES {A2-61}, Q-BAR/G-CONTROL; {A4-59}, MANUAL THROTTLE SELECTION; {A5-112}, MANUAL THROTTLEDOWN FOR LO2 NPSP PROTECTION AT SHUTDOWN; {A5-152D}.1, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]; AND {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP, FOR SPECIFIC CASES INVOLVING MANUAL THROTTLE. @[090894-1676A] @[041097-4910A] @[ED]

Normally, all SSME throttling action will be commanded by the flight software. However, manual throttling can relieve certain failure conditions, some potentially catastrophic, which are not protected by software; examples include low SSME NPSP, an unstable guidance solution, or any generic failure of the software throttling logic itself. In addition, manual throttle can be used to maximize performance in propellant-critical TAL cases as well as to avoid a TAL or RTLS abort when design underspeed is limited by NPSP. In these scenarios, the use of manual throttle control is preferred to the alternatives. The referenced rules spell out the background and criteria for manual throttle usage in each case.

FLIGHT RULES

A2-65

OMS-1 DELAYED TARGET CRITERIA

THE OMS-1 BURN WILL UTILIZE DELAYED TARGET FOR:

- A. MAIN PROPULSION SYSTEM (MPS) PROPELLANT DISCONNECT VALVE FAILED OPEN.
- B. ANY OMS PROPELLANT FAIL/LEAK OR OMS HE TANK FAIL.
- C. TWO OMS ENGINES FAILED.

NOTE: UNDERSPEED MECO CONDITIONS MAY REQUIRE USE OF ON-TIME (MECO + 2) OMS-1 TARGETS.

Delayed targets are designed for nominal or small underspeed MECO conditions only. Larger underspeeds (mission-dependent) may require on-time targets to remain within orbiter delta V capability.

For OMS propellant or helium tank leaks/failures, significant delta V capability will be lost. Also, loss of two OMS engines implies that all the delta V maneuvers will be accomplished with the RCS 4 +X thrusters. Performing delta V maneuvers with the RCS requires a significant amount of additional propellant to compensate for the reduced engine efficiency of the RCS jets as compared to the OMS engines. For these cases, a delayed ATO OMS-1 burn is performed to minimize delta V requirements for insertion and deorbit and allow time for a thorough assessment of the delta V capability remaining.

FLIGHT RULES

A2-66

APU SHUTDOWN DELAY CRITERIA

IF ORBIT CAPABILITY IS QUESTIONABLE, THE APU'S WILL REMAIN "ON" WITH THE HYDRAULIC PUMPS DEPRESSURIZED UNTIL THE DECISION IS MADE TO CONTINUE TO ORBIT. [ED]

A2-67

ARD UPDATE CRITERIA

FOR SSME FAILURE CONDITIONS CAUSING PERFORMANCE DISPERSIONS, ADJUSTMENTS WILL BE MADE TO MIXTURE RATIO, POWER LEVEL, SPECIFIC IMPULSE, AND/OR FLIGHT PERFORMANCE RESERVE VALUES IN THE MCC ABORT REGION DETERMINATOR (ARD) PROGRAM.

Rule {A4-54}, ABORT MODE RESPONSIBILITY, states that the MCC is prime for abort mode determination. Pre-MECO, the primary tool used to fulfill this responsibility is the ARD processor, which resides in the SDPC computer. Its predictions of abort capability are contingent upon accurate modeling of SSME performance parameters and usable ET propellant remaining. Certain SSME failure conditions such as Pc sensor shifts, valve drift following lockup, etc., can cause the actual SSME performance to vary considerably from that assumed by the ARD; therefore, capability is provided to manually update the applicable performance data in real time. SSME parameters are updated per recommendation from the MCC Booster officer, while FPR adjustments are made by the Flight Dynamics team based on the predicted LOX or LH₂ unusable quantity at MECO. Such adjustments are necessary to preserve protection at the 2-sigma level when propellants are being consumed at a non-nominal mixture ratio.

FLIGHT RULES

A2-68

ET PHOTOGRAPHY

THE MANEUVERS FOR ET PHOTOGRAPHY WILL BE CANCELED FOR THE FOLLOWING REASONS:

- A. OMS OR RCS PROPELLANT OR HELIUM SYSTEMS LEAKS OR TANK FAILURES.
- B. KNOWN LOSS OF AN OMS ENGINE.
- C. LOSS OF MULTIPLE PRIMARY RCS JETS.
- D. KNOWN LOSS OF VERNIER RCS ATTITUDE CONTROL WHICH WOULD RESULT IN A PROPELLANT-CRITICAL MISSION.
- E. MECO UNDERSPEED > 26 FPS.
- F. ATO PRE-MECO OMS DUMP HAS BEEN EXECUTED.
- G. ET IN DARKNESS AT PHOTOGRAPHY TIME (EACH METHOD EVALUATED SEPARATELY).

There are two methods of photographing the ET. Method 1 utilizes automatic cameras in the ET umbilical wells of the orbiter and requires a +X translation immediately following the -Z separation burn. The +X maneuver requires about 120 pounds of RCS propellant. Method 2 utilizes crew handheld cameras and requires an orbiter pitch maneuver following the MPS dump. Method 2 is only effective on direct insertion flights since the photographs are at too great a distance for any detail following an OMS-1 burn. Method 2 requires about 70 pounds of aft RCS and 30 pounds of forward RCS propellant.

Significant failures in the OMS and RCS systems (propellant or helium leaks or tank failures or OMS engine failure or MECO underspeeds requiring an OMS-1 on a direct insertion flight or the dumping of propellant) results in a loss of delta-V capability and the ET photography propellant may be needed to accomplish flight-critical maneuvers (e.g., OMS-1, deorbit) or for entry control.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-68

ET PHOTOGRAPHY (CONTINUED)

The loss of multiple primary RCS jets requires conservatism in the use of the remaining jets since they are required for on-orbit and entry control.

Loss of the vernier RCS attitude control capability due to MDM or electrical bus failure can result in significant mission impact depending on the mission. For those missions where loss of VRCS results in the loss of high-priority objectives, the ET photograph should be canceled to maximize high-priority objectives.

Consideration of lighting at ET photography time is not a constraint for launch. ET photography typically is scheduled on all flights where at least part of the launch window allows sunlight for the photos. Photos of the ET in darkness are not useful. If lighting changes during the launch window, ET photography can be planned and trained for but will be canceled if sunlight will not be present at the same time photos are to be taken. Each of the two methods will be evaluated on its own lighting conditions.

If the ET separation will be in darkness, the +X translation should not be executed because this translation increases the distance between the orbiter and the ET for photos using method. ©[072398-6530]

Three-sigma navigation errors can result in MECO underspeeds of up to 26 fps. Greater underspeeds indicate significant performance anomalies requiring care in the expenditure of propellant. Therefore, any maneuver associated with ET photography (translations or rotations) should be deleted for underspeeds greater than 26 fps. ©[072398-6530]

FLIGHT RULES

A2-69

REGAIN RCS JETS FOR RTLS ET SEPARATION

DURING RTLS, FOR THE LOSS OF MORE THAN ONE RCS JET USED FOR MATED COAST RATE DAMPING, ET SEPARATION, OR ATTITUDE CONTROL THROUGH THE ALPHA RECOVERY PHASE, RECOVERY WILL BE ATTEMPTED IF THE FAILURE IS DUE TO DPS FAILURES OR LOSS OF RCS RM. RESTRINGING WILL BE PERFORMED POST-MECO/PRE-ET SEP PER RULE {A2-63}, ASCENT STRING REASSIGNMENT. ALL OTHER ACTIONS WILL BE ACCOMPLISHED ASAP (PREFERABLY PRE-MECO).

Recent aerodynamic studies show that early RCS jet aerodynamic models were incomplete with respect to jet failure effects for RTLS ET separation. With worst case aero assumptions and generic mass properties, a successful RTLS ET separation can be accomplished with little more than 1-sigma aero variations, and in that case large attitude errors will be incurred. It is nearly certain that the crew would engage the BFS if large attitude errors occurred in a dynamic time frame.

While either dynamic restringing or the use of RCS jets without redundancy management automatic deselection is subject to certain risks, the probabilities have been judged to be much less likely than the 1-sigma aero variations that are described above. Additionally, BFS engage at ET separation with strings down in the PASS has been documented by several BFS DR's that lead to catastrophic failure.

Therefore, the lowest risk option when multiple RCS jets are lost prior to ET separation on an RTLS is to perform the actions required to regain (or prevent loss of) the jets required for attitude control in the dynamic phases. The jets involved are the down, part of the up, and all of the left and right firing jets (loss of +X, -X, and +Z forward jets is no impact). Actions would include: reselecting jets that have been erroneously deselected for loss of instrumentation (oxidizer or fuel injector temperature, chamber pressure, manifold valved discrettes); or inhibiting RM from deselection in the future; or flight-critical string port mode; or dynamic restring. All actions except restring would be performed ASAP. Restring would be performed immediately post-MECO/pre-ET sep as described in Rule {A2-63B}.1, ASCENT STRING REASSIGNMENT. Rule {A8-55}, ET SEPARATION RCS REQUIREMENTS, should be understood to protect only 1-sigma aero variations for RTLS abort ET separation conditions. This rule defines what action will be taken operationally to improve protection for aero variations.

Only appropriate actions will be taken, e.g., restring is only to be used in the cases where it will restore the jets (GPC failure, GPC port failure).

There are other situations (i.e., MDM total failure, RJD half-box failure, manifold leaks, etc.) that cannot be solved by any of these options. Reference Rules {A2-63}, ASCENT STRING REASSIGNMENT, and {A8-55}, ET SEPARATION RCS REQUIREMENTS.

FLIGHT RULES**A2-70****DELAYED TRANSATLANTIC LANDING (TAL) ABORT**

IN THE WINDOW BETWEEN TWO-ENGINE TAL PLUS 10 SECONDS AND PRESS-TO-ABORT TO ORBIT (ATO) FOR 51.6 DEGREE INCLINATION MISSIONS, THE SELECTION OF THE TAL ABORT MAY BE DELAYED. THIS DELAY WILL MAXIMIZE EAST COAST ABORT LANDING (ECAL) ABORT COVERAGE WHILE PRESERVING INTACT TAL ABORT MARGIN. THE FOLLOWING GROUND RULES SHALL APPLY TO THE EXECUTION OF A DELAYED TAL ABORT: ©[092602-5667A]

- A. PRIOR TO ABORTING TAL, A MANUAL OMS DUMP WILL BE INITIATED THROUGH A CREW ITEM ENTRY.
- B. THE TAL ABORT SHALL BE SELECTED NO LATER THAN THE 3-SIGMA MAIN PROPULSION SYSTEM (MPS) FLIGHT PERFORMANCE RESERVE (FPR) PERFORMANCE BOUNDARY OR THE SINGLE-ENGINE OPS 3 BOUNDARY (REF. RULE {A4-56G}, PERFORMANCE BOUNDARIES), WHICHEVER COMES FIRST.
- C. DELAYING THE SELECTION OF THE TAL ABORT SHALL NOT APPLY FOR THE FOLLOWING SCENARIOS:
 1. LOSS OF COMMUNICATION
 2. SIGNIFICANT UNCERTAINTY EXISTS IN THE 3-SIGMA MPS FPR PERFORMANCE BOUNDARY.

In accordance with feasibility studies and risk trade assessments brought to the Ascent/Entry Flight Techniques Panel and the Space Shuttle Program Office, delayed TAL shall be implemented on all ISS missions starting with STS-110. The delayed TAL trajectory results in a groundtrack that is closer to the Eastern coast of the United States than if the TAL abort had not been delayed. The benefits of a delayed TAL trajectory include increased ECAL landing opportunities and improved bailout survival/recovery probabilities while maintaining intact TAL performance margins to no less than a 3-sigma confidence level. These benefits come at the expense of delayed single-engine performance boundaries and an extended Space Shuttle Main Engine (SSME) run time that vary as a function of the TAL delay time.

An ITEM 9 OMS propellant dump will be initiated prior to the TAL abort to improve intact TAL performance margins during the TAL delay period. The ECAL trajectory will also benefit from an early ITEM 9 OMS propellant dump because of an overall reduction in orbiter weight that should improve safety margins with respect to External Tank (ET) separation dynamics and overall orbiter load factors.
©[092602-5667A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-70**DELAYED TRANSATLANTIC LANDING (TAL) ABORT
(CONTINUED)**

The TAL abort shall be initiated at the earlier of the 3-sigma MPS FPR performance boundary for the prime TAL site or the single-engine OPS 3 performance boundary. It is expected for early engine-out cases close to the two-engine TAL performance boundary that TAL aborts will be initiated based on the 3-sigma MPS FPR performance boundary. Later engine-out cases and cases that implement an early ITEM 9 OMS propellant dump are likely to initiate TAL aborts based on the single-engine OPS-3 boundary. ©[092602-5667A]

As discussed with the Flight Director Office and the Space Shuttle Program Office, TAL delay will not be implemented during loss of communication situations, since the crew may not be aware of ground-determined performance boundaries used to terminate the TAL delay. More specifically, if there is no comm at the time of the SSME failure, the crew will follow the normal no-comm mode boundaries and abort as required. For all other cases, if comm is subsequently lost, then the crew will abort TAL at the no comm Vi per the MCC Delayed TAL abort call. Also, TAL delay will not be implemented for any scenario that results in a significant uncertainty in the real-time determination of the 3-sigma MPS FPR performance boundary in the ground Abort Region Determination (ARD) processor. In this instance, where significant uncertainty exists, it is conservative to abort TAL prior to the 3-sigma MPS FPR boundary to ensure adequate performance margin in support of the intact TAL trajectory. ©[092602-5667A]

A2-71 THROUGH A2-100 RULES ARE RESERVED

FLIGHT RULES

ORBIT

A2-101

VEHICLE SYSTEMS REDUNDANCY DEFINITIONS

- A. TWO-FAULT TOLERANT (FAIL OPERATIONAL/FAIL SAFE) - THE CONDITION OF AN ORBITER SYSTEM WHERE IT IS FULLY CAPABLE OF PERFORMING ITS CRITICAL FUNCTIONS WITH THE ABILITY TO SUSTAIN ANY TWO FAILURES (WITHIN THE SYSTEM) AND STILL HAVE THE CAPABILITY TO SAFELY DEORBIT AND LAND THE ORBITER.
@[101796-4561A]
- B. ONE-FAULT TOLERANT (FAIL SAFE) - THE CONDITION OF AN ORBITER SYSTEM WHERE IT IS FULLY CAPABLE OF PERFORMING ITS CRITICAL FUNCTIONS WITH THE ABILITY TO SUSTAIN ANY ONE FAILURE AND STILL HAVE THE CAPABILITY TO SAFELY DEORBIT AND LAND THE ORBITER.
- C. ZERO-FAULT TOLERANT (FAIL CRITICAL) - THE CONDITION OF AN ORBITER SYSTEM WHERE THE SYSTEM IS FULLY CAPABLE OF PERFORMING ITS CRITICAL FUNCTIONS BUT IS UNABLE TO SUSTAIN ONE OR MORE ADDITIONAL FAILURES AND STILL HAVE THE CAPABILITY TO SAFELY DEORBIT AND LAND THE ORBITER.
- D. UNFLYABLE - A SYSTEM CONDITION WHERE THE ORBITER IS INCAPABLE OF PERFORMING A SUCCESSFUL ENTRY AND LANDING. @[101796-4561A]

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS

THE FOLLOWING CRITERIA WILL APPLY TO PREMISSION AND REAL-TIME MISSION DURATION DECISIONS:

- A. NOMINAL EOM LANDING WILL OCCUR NO EARLIER THAN THE BEGINNING OF THE FIFTH DAY OF FLIGHT (APPROXIMATELY 96 HOURS). @[101796-4561A]

To aid in postmission orbiter turnaround planning in support of the number of shuttle flights possible in a year, it was necessary to define the constraints for a nominal mission. For a nominal mission, the minimum duration is designed to ensure a high probability of having a healthy crew for entry and landing, such that an EOM landing would not be attempted or planned prior to FD5. This provides a reasonable amount of exposure of the crew to zero-g for SAS conditioning.

- B. THE FLIGHT WILL NORMALLY CONTINUE TO NOMINAL END OF MISSION (NEOM) FOR THE FIRST FAILURE WHICH IMPACTS AN ENTRY-CRITICAL SYSTEM. IF THE SYSTEM IS NO LONGER FAIL-SAFE, A THOROUGH TECHNICAL REVIEW OF THE FAILURE MODE AND REMAINING SYSTEMS CAPABILITY WILL BE CONDUCTED TO DETERMINE WHETHER NEOM IS APPROPRIATE. @[101796-4561A]

IF THIS ASSESSMENT DETERMINES THAT A GENERIC FAILURE OR GENERIC GROUND PROCESSING PROBLEM HAS OCCURRED AND MAY AFFECT THE REMAINING SYSTEMS, TERMINATE THE FLIGHT PLS.

A single failure in any system which leaves that system with single-fault tolerance is an acceptable configuration to continue to NEOM. For single failures that result in less than fail-safe redundancy, a real-time assessment of the failure mode, remaining systems' capability, health, history, and redundancy will be completed to exonerate generic failures, common ground processing errors, etc. The APU/hydraulic system is not fail safe after the loss of one system since the orbiter is not certified for single APU operations. After the first failure, the IMU and FCS are fail safe with the exception of certain "smart failures" to occur during a certain timeframe during entry. For the IMU, FCS channel, or associated MDM, the risk will be re-assessed based on the latest run-time and failure history.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-102****MISSION DURATION REQUIREMENTS (CONTINUED)**

A risk assessment of the IMU, FCS, APU/hydraulic system, and MDM was completed by the AEFTP in 1996 (reference AEFTP #131 and 6/96 AEFTP splinter meeting). This assessment was quantitative for those items which have a sufficient statistical failure database, but relied on engineering judgment for other items. This assessment concluded that the relative risk of remaining on-orbit to NEOM rather than returning MDF for the first failure in these systems is less than the launch risks and orbital debris risks. This risk is acceptable as long as the remaining systems are good and generic problems are exonerated.

The following should be considered when making a flight determination decision: crew and vehicle health, vehicle mass properties, weather, trajectory, and landing site.

Reference Rule {A2-1001}, ORBITER SYSTEMS GO/NO-GO, for the number of failures in each system which result in early mission termination. Reference Rules {A2-207}, LANDING SITE SELECTION; {A10-21A}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS; and {A10-23A}, APU ENTRY START TIME. ©[101796-4561A] ©[ED]

C. FOR A SECOND FAILURE AFFECTING ANY ENTRY-CRITICAL SYSTEM
©[101796-4561A]

1. TERMINATE THE FLIGHT NEXT PLS IF THE AFFECTED SYSTEM HAS LOST ALL FAULT TOLERANCE OR IF THE FAILURE IS CONSIDERED TO BE GENERIC.
2. CONTINUE THE FLIGHT TO MDF IF THE ORBITER IS ONLY SINGLE-FAULT TOLERANT IN ORDER TO ACCOMPLISH DEPLOYMENT OF A PRIMARY PAYLOAD AND TO ENSURE CREW ADAPTATION, BOTH OF WHICH REDUCES THE OVERALL RISK TO THE CREW AND ORBITER.

NOTE: AN MDF WILL LAST APPROXIMATELY 72 HOURS AND LANDING WILL OCCUR AT THE PLS PRIOR TO THE END OF THE FLIGHT DAY 4.

Multiple failures in an entry critical system, even though it remains single-fault tolerant, may be indicative of a generic failure; Exposure to additional failures should be minimized by early termination of the mission.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

D. MDF GENERIC PAYLOAD RULES

1. THE DEORBIT OPPORTUNITY WILL NOT BE DELAYED FOR THE PURPOSE OF ACCOMPLISHING PAYLOAD OBJECTIVES.
2. FIRST PRIORITY WILL BE THE ACCOMPLISHMENT OF THE MINIMUM MISSION-SUCCESS OBJECTIVES OF THE PRIMARY PAYLOAD(S).
3. LOWER PRIORITY MISSION OBJECTIVES WILL BE CONSIDERED IN THE PRIORITY ORDER AS STATED FOR A NOMINAL MISSION.
@[101796-4561A]
4. SIGNIFICANT CONTINGENCY OPERATIONS, E.G., AN UNSCHEDULED EVA OR A CONTINGENCY RENDEZVOUS, WILL BE UNDERTAKEN ONLY IF ALL THE FOLLOWING ARE MET: @[101796-4561A]
 - a. IT IS NEEDED TO ACCOMPLISH A MINIMUM MISSION-SUCCESS OBJECTIVE FOR A PRIMARY PAYLOAD.
 - b. THE OPERATION WOULD NOT RESULT IN AN IMPACT TO THE MINIMUM MISSION SUCCESS OF ANOTHER PRIMARY PAYLOAD.
 - c. RULE {A13-101}, SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS, IS SATISFIED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

E. A NEXT PLS DEORBIT WILL BE EXECUTED AT THE EARLIEST PRACTICAL TIME TO A CONUS LANDING SITE FOR FAILURES WHICH PLACE THE ORBITER SYSTEM AT THE ZERO-FAULT TOLERANT LEVEL OR RESULT IN A CONDITION WHERE ONE MORE FAILURE CAUSES A SEVERE ORBITER CONFIGURATION MANAGEMENT CONDITION. CONUS LANDING SITE SELECTION SHALL PROVIDE FOR:

1. LANDING SITE PRIORITY (REF. RULE {A2-207}, LANDING SITE SELECTION)
 - a. PLS
 - b. SLS
 - c. ANY CONUS SITE
2. EOM LANDING CONSTRAINTS (CROSSRANGE, LIGHTING, WEATHER, AND BACKUP OPPORTUNITIES)
3. CREW SCHEDULE CONSTRAINTS
4. A NOMINAL DEORBIT PREPARATION TIMELINE IF POSSIBLE; OTHERWISE, A MINIMUM OF 3.5 HOURS DEORBIT PREPARATION
@[101796-4561A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-102

MISSION DURATION REQUIREMENTS (CONTINUED)

F. IF A FAILURE OCCURS THAT WOULD NORMALLY CAUSE AN MDF BUT THE TIME OF FAILURE IS PAST 72 HOURS FLIGHT DURATION, A LANDING WILL BE ACCOMPLISHED AT THE NEXT PLS OPPORTUNITY THAT PROVIDES ADEQUATE TIME FOR THE NORMAL EOM TIMELINE FOR VEHICLE STOWAGE AND ENTRY PREPARATION. @[101796-4561A]

Since a failure that would cause declaration of an MDF is a reason to shorten a normal flight, further operations of a payload/experiment are not sufficient reason to continue. The flight would be terminated at the next PLS that affords time to accomplish adequate stowage for entry and also allow the crew to have a sufficient sleep period.

G. FOR SOME FAILURE SITUATIONS AND/OR VIOLATION OF GO/NO-GO CRITERIA FOR FLIGHT CONTINUATION, IT IS SAFER TO REMAIN IN ORBIT INSTEAD OF ENTERING AT THE NEXT LANDING OPPORTUNITY. THAT IS, IF THE ADDITIONAL TIME CAN BE USED TO:

1. BETTER UNDERSTAND THE FAILURE AND ITS IMPLICATION ON ENTRY
2. VERIFY SYSTEMS CONFIGURATION PROCEDURES AND PERFORMANCE PRIOR TO ENTRY
3. PROVIDE ADEQUATE TIME FOR CREW REST THE NIGHT BEFORE ENTRY
4. PROVIDE THE OPPORTUNITY TO ACCOMPLISH ACTIVITIES THAT COULD ENHANCE ORBITER ENTRY/LANDING CONDITIONS @[101796-4561A]

Rules {A2-202}, EXTENSION DAY GUIDELINES; {A7-1001}, DPS GO/NO-GO MATRIX; and {A8-4B}, FAULT TOLERANT PHILOSOPHY reference this rule. @[ED]

FLIGHT RULES

A2-103

EXTENSION DAY REQUIREMENTS

A. ALL STS FLIGHTS ARE REQUIRED TO HAVE 2 EXTENSION DAYS. EXTENSION DAYS WILL BE UTILIZED AS FOLLOWS:

1. ONE OF THE 2 EXTENSION DAYS IS UTILIZED PRIMARILY FOR ACHIEVING ACCEPTABLE LANDING WEATHER CONDITIONS (REF. RULES {A2-6}, LANDING SITE WEATHER CRITERIA [HC]; {A4-107A}.3, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS; AND {A4-111}, RUNWAY ACCEPTABILITY CONDITIONS). @[111094-1622B]

An extension day must be allocated in orbiter resources to allow for improvement in weather conditions forecast at the PLS. A 1-day extension on orbit is preferred to preclude loss of postflight payload samples/data and to maintain full postlanding ground processing support at the PLS.

2. THE OTHER EXTENSION DAY (DEORBIT WAVE-OFF) IS UTILIZED FOR AN ORBITER SYSTEMS CONTINGENCY WAVE-OFF.

A second extension day must be allocated to allow for orbiter system problems which cause an unsafe or compromised configuration for entry. The 1-day wave-off (which includes a deorbit preparation) allows time to understand a problem or to arrive at the best entry configuration.

B. REAL-TIME CONSIDERATIONS TO EXTEND THE FLIGHT FOR ADDITIONAL PAYLOAD OPERATIONS MUST INCLUDE 2 EXTENSION DAY CAPABILITY.

The orbiter should not be exposed to unsafe/compromised entry conditions to further payload data return

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-103

EXTENSION DAY REQUIREMENTS (CONTINUED)

- C. IF ORBITER SYSTEMS CONFIGURATION MEETS EOM CRITERIA, THEN IN ORDER TO PROTECT FOR AN UNSCHEDULED EVA: @[090894-1670B]
1. PAYLOAD OR STS ARTICLES WHICH HAVE DEMONSTRATED STOW REDUNDANCY AND MUST BE MECHANICALLY SECURED FOR A SAFE ENTRY/LANDING WILL BE ALLOWED TO OPERATE UNSECURED UNTIL:
 - a. THE BEGINNING OF THE LAST NON-ENTRY CREW WORKSHIFT PRIOR TO ENTRY FOR CREW DUAL WORKSHIFT (24-HOUR CYCLE) FLIGHTS.
 - b. THE BEGINNING OF PRESLEEP ON THE SLEEP SHIFT PRIOR TO DEORBIT DAY FOR CREW SINGLE WORKSHIFT FLIGHTS (APPROXIMATELY TIG - 19 HOURS).
 2. ARTICLES WHICH HAVE NOT DEMONSTRATED STOW REDUNDANCY WILL BE STOWED AT LEAST 1 DAY EARLIER THAN THE TIMES DEFINED IN PARAGRAPH C.1 IN ORDER TO SUPPORT A LANDING ON THE NOMINAL EOM NO LATER THAN THE BEGINNING OF THE CREW WORKDAY PRIOR TO ENTRY.
 3. (FLIGHT SPECIFIC EXCEPTION) EXCEPTIONS TO THESE TIMELINES, IN ORDER TO ACHIEVE MANDATORY PAYLOAD MISSION OBJECTIVES, MUST BE JUSTIFIED IN THE FLIGHT SPECIFIC ANNEX. @[090894-1670B]

If the orbiter systems meet EOM criteria, it is an acceptable risk to allow a payload to operate late in flight which may require an unscheduled EVA to occur on nominal EOM day to safe that payload for entry. For this case, a landing would occur on the first extension day. If, however, a payload or STS article has had a failure in one of its redundant stow or jettison systems, then it must be mechanically secured on the morning of EOM-1 to allow for the potential of an unscheduled EVA on the end of that day to secure the article. A nominal deploy (release) of a drive mechanism which uses a different actuator/motors/motor windings to deploy and stow (or release/latch) does not verify the integrity of the drive mechanism's stow (latch) capability. Therefore, allowing operation of this type of system late in flight is not warranted.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-103****EXTENSION DAY REQUIREMENTS (CONTINUED)**

For dual-crew workshift flights, allowing a payload or STS article to operate unsecured until the beginning of the last non-entry team work shift (approximately deorbit TIG-12 hours). This usually allows for sufficient time to begin work on an unscheduled EOM day EVA, with entry occurring on the first extension day. The specific timeline invoked, however, should consider the number of articles to be secured, the time required for the EVA task(s), crew sleep shifting, and assignment of EVA/IVA crews. A 14.7 psi protocol is normally used, and the total EVA task time requires about 12 hours (for a 2-hour EVA, with equipment checks and post-EVA activities). ©[090894-1670B]

On single-crew workshift flights, EVA work to secure an unsafe payload or STS article must begin prior to the last sleep period. EVA would occur on nominal EOM with entry on the first extension day. A 10.2 psi cabin is usually established for 12 hours in support of approximately 9 hours of EVA related tasks (from equipment checks to post-EVA, including a 2-hour EVA). Delaying article stowage until the morning of entry and performing a 14.7 psi EVA may also be possible if required; but this timeline is not the preferred.

Reference Rule {A2-104A.9}, SYSTEMS REDUNDANCY REQUIREMENTS.

Rules {A10-301C}, ANTENNA STOW REQUIREMENT [CIL], and {A12-4}, RMS ACTIVITY TERMINATION, reference this rule. ©[090894-1670B] ©[090999-6930]

D. IF, AT THE BEGINNING OF THE CREW WORKDAY PRIOR TO ENTRY, THE FORECAST FOR THE WEATHER CRITERIA ELEMENTS IN RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC], VIOLATES THE LIMITS AT EOM PLUS 1 DAY FOR THE PRIME AND SECONDARY LANDING SITES, THEN ALL ARTICLES WHICH MUST BE MECHANICALLY SECURED FOR A SAFE ENTRY/LANDING, WILL BE SECURED FOR THE REMAINDER OF THE FLIGHT. ©[090894-1670B] ©[111094-1622B]

Any forecast for weather criteria that violates the limits given in Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC], for the landing on EOM plus 1 day at the primary and secondary landing sites makes a potential EVA on EOM unacceptable. Since the EOM plus 1 day deorbit opportunity is not expected to be available, this rule ensures that an EVA to secure mechanical devices does not preclude using the nominal deorbit opportunity, leaving the orbiter with only the one chance to deorbit on EOM plus 2 days. Securing mechanical devices early allows a nominal deorbit with a short contingency EVA on the nominal EOM minus 1 day to secure devices that cannot be made safe for entry using nominal procedures.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-103

EXTENSION DAY REQUIREMENTS (CONTINUED)

- E. THE KU-BAND DEPLOYED ASSEMBLY WILL BE STOWED, AND/OR THE MPM'S AND MRL'S WILL BE STOWED AND LATCHED, AS SOON AS PRACTICAL IF SYSTEMS FAILURES HAVE RESULTED IN LOSS OF STOW/LATCH REDUNDANCY. @[090894-1670B]
1. STOW/LATCH OPERATIONS MAY BE DELAYED IN ORDER TO COMPLETE MANDATORY MISSION OBJECTIVES (REF. RULE {A10-301A}, ANTENNA STOW REQUIREMENT [CIL], AND THE FLIGHT SPECIFIC ANNEX). @[090999-6930]
 2. ANY STOW/LATCH OPERATION DELAYS WILL PROTECT FOR AN EOM-1 DAY EVA.

The Ku-Band deployed assembly (antenna dish, gimbal motors, and deployed electronics), and/or the MPM's and MRL's (2 of 3), must be stowed/latched in order to close the Payload Bay Doors for entry. Without redundant stow/latch capability, this equipment is zero-fault tolerant to a jettison scenario. Therefore, if stow/latch redundancy is not available, these mechanisms should be secured as soon as possible in order to minimize the time of exposure to the next failure which would require a jettison.

The Ku-Band is essential in achieving high priority mission objectives during flights, such as for rendezvous operations or when payload data cannot be permanently stored on on-board media. Stowing the antenna immediately after stow redundancy has been lost would preclude downlinking this high priority payload data, and therefore, compromise mission success. Likewise, stowing/latching the MPM's/MRL's immediately after redundancy has been lost could also preclude mission success. For these flights, exceptions may be justified. However, because of the cost and difficulty in replacing these mechanisms, achieving even mandatory payload mission objectives does not warrant the risk of losing an antenna or RMS. Therefore, Ku-Band and MPM/MRL operations will be discontinued in time to protect for an EOM-1 day EVA. @[090894-1670B] @[090999-6930]

Reference Rules {A10-301A}, ANTENNA STOW REQUIREMENT [CIL]; {A12-72A}, MPM DEPLOY/STOW CONSTRAINTS; and {A12-73}, MRL CONSTRAINTS.

Rules {A6-303A}, OMS REDLINES [CIL]; and {A15-14C}, SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS, reference this rule. @[051194-1612A]

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS

A. SYSTEMS MANAGEMENT FOR MISSION DURATION

1. EVA WILL BE CONSIDERED AS A LEVEL OF REDUNDANCY FOR THE FOLLOWING ORBITER SYSTEMS FAILURES IN ORDER TO ACCOMPLISH:

- a. HIGH PRIORITY FLIGHT OBJECTIVES (AS DEFINED IN THE FLIGHT SPECIFIC ANNEX).

PAYLOAD DEPLOYMENT RETRIEVAL SYSTEM (PDRS) - END EFFECTOR (EE) RELEASE, MPM STOW, MRL LATCHES, SHOULDER BRACE RELEASE, AND RMS CRADLE (REF. RULE {A2-112C}, PDRS).

- b. MDF

PAYLOAD BAY DOOR (PLBD) - CLOSE DRIVE CAPABILITY DUE TO ELECTRICAL OR MECHANICAL FAILURE (REF. RULE {A10-209H}, PLBD RULE REFERENCE MATRIX). @[121296-3194B]

EVA capability is considered an acceptable backup to system redundancy for completion of high priority flight objectives in the following areas:

- a. *Crews are trained to EVA-release the end effector from a payload. This means that, if all capability to release a payload is lost except one, the activity will be continued relying on the EVA release, should the last remaining mode fail.*

EVA procedures also exist to overcome total electrical failure of the MPM's and MRL's and can back up system redundancy.

In all of the above cases, the orbiter is still fail safe as payload/RMS jettison capability is available should it be required before the EVA could be implemented to fix a problem.

- b. *EVA procedures and tools are available to protect against total failure of PLBD drive and can be used to back up system redundancy. An EVA for these tasks is protected against in all the consumable redlines. Reference Rule {A10-209H}, PLBD RULE REFERENCE MATRIX.*

@[121296-3194B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS (CONTINUED)

2. GPC REDUNDANCY REQUIREMENTS:

- a. CONTINUE TO END OF MISSION IF NO MORE THAN ONE GPC HAS FAILED. @[101096-4516]

This will allow a DPS configuration of at least one G2, one SM, a BFS, and one computer left to be configured as a redundant G2 or G3FD, depending on the flight requirements.

- b. MINIMUM DURATION FLIGHT CAN BE SUPPORTED IF NO MORE THAN TWO GPC'S HAVE FAILED. @[101096-4516]

The minimum GPC requirements to sustain orbit activities are a G2 GPC, an SM GPC, and a BFS GPC, i.e., three GPC's total. A subsequent GPC failure leaves only two GPC's, which would be used as a single PASS GPC and a BFS GPC for reentry. Because a BFS GPC is designed as a backup for a generic PASS software failure, a BFS GPC is always maintained as long as two good GPC's exist. The case of three remaining GPC's is considered a fail-safe case; i.e., with an additional failure, a PASS GPC is still available for vehicle control. Spare GPC usage (if manifested) is not considered for meeting requirements because of concerns about potential generic GPC failures that arise when two GPC's have failed. @[092195-1798] @[121296-3194B]

3. FOR FLIGHT-CRITICAL SYSTEM GENERIC FAILURES, TERMINATE THE FLIGHT AT THE NEXT PLS OPPORTUNITY.

If it is determined that there is a generic fault (i.e., two units fail with identical failure signatures) with a flight-critical system, then it is prudent to land at the next PLS opportunity in order to minimize exposure to subsequent failures.

4. OMS PROPELLANT IS NOT REQUIRED TO PROTECT ONE OMS-TO-RCS DOWNMODING IF BOTH OMS ENGINES ARE AVAILABLE. OMS PROPELLANT IS REQUIRED TO PROTECT DEORBIT TO OMS STEEP ENTRY TARGETS.

Protecting one OMS-to-RCS downmoding requires saving additional OMS propellant to compensate for the reduced engine efficiency of the RCS jets as compared to the OMS engines. Programmatic guidelines do not allow loading this additional propellant, so redlining this quantity may result in cancellation of planned on-orbit activities. With two good OMS engines, fail-safe redundancy for the deorbit burn is maintained without requiring RCS deorbit capability. Propellant required to deorbit to steep targets using the OMS engines will be protected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS (CONTINUED)

5. ELECTRICAL POWER REDUNDANCY:
 - a. THE FLIGHT WILL CONTINUE FOR A SINGLE FAILURE WHICH RESULTS IN LOSS OF ELECTRICAL POWER REDUNDANCY TO MULTIPLE ENTRY-CRITICAL LRU'S.
 - b. THE FLIGHT WILL BE TERMINATED NEXT PLS IF A SINGLE ELECTRICAL FAILURE IN CONJUNCTION WITH ANY OTHER EXISTING FAILURE WOULD RESULT IN AN UNFLYABLE CONDITION.
6. A NEXT PLS DEORBIT WILL BE EXECUTED FOR INSTRUMENTATION LOSSES WHICH PREVENT MONITORING OF CRITICALITY 1 FAILURES FOR WHICH THE PROGRAM RETENTION RATIONALE REQUIRES MONITORING.

The retention rationale for some criticality 1 failures is the ability to monitor that system and take action prior to a potentially catastrophic event. Therefore, loss of monitoring mandates termination of the flight at the next PLS because rationale for retention of a criticality 1 failure no longer exists.

7. ENTRY CONSUMABLES MUST BE PROTECTED AGAINST WORST CASE ENVIRONMENTAL AND AERODYNAMIC VARIATIONS.
8. ORBITER SYSTEMS TROUBLESHOOTING/IFM'S HAVE PRIORITY OVER PDRS AND PAYLOAD OPERATIONS IF CONFLICTS CANNOT BE AVOIDED (I.E., ACTIVITY SCHEDULING OR INTERRUPTION OF REQUIRED ORBITER SERVICES).

The prime objective on every flight is crew safety.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS (CONTINUED)

9. STOW REDUNDANCY DEMONSTRATION: @[090894-1670B]
- a. A PAYLOAD OR STS ARTICLE THAT HAS DEPLOYED NOMINALLY ON DUAL MOTORS, AND HAS SUSTAINED NO MECHANICAL, COMMAND, OR ELECTRICAL FAILURES WHICH WOULD PRECLUDE DUAL MOTOR STOW, WILL BE ASSUMED TO HAVE DEMONSTRATED STOW REDUNDANCY.
 - b. STOW REDUNDANCY WILL STILL BE ASSUMED TO HAVE BEEN DEMONSTRATED WHERE A PROCEDURAL WORKAROUND IS AVAILABLE FOR ELECTRICAL/COMMAND PATH FAILURES THAT WOULD NORMALLY PRECLUDE DUAL MOTOR STOW OPERATIONS.

A nominal deploy (release) of a drive mechanism which uses the same actuator/motors/motor windings to deploy and stow (or release/latch) will verify the integrity of that drive mechanism's capability to stow (latch). Although drive mechanisms typically use different switch contacts, motor control assembly (MCA) relays, and electrical/command paths for deploy and stow (release/latch) operations, these unlike components are thoroughly tested during ground turnaround. And due to the nature of mechanical equipment, performing a nominal stow using these stow path components does not necessarily guarantee dual motor operation during the following stow sequence. Therefore, stow redundancy can be sufficiently demonstrated by verifying a nominal deploy, without the requirement to actually perform a stow operation. Failed-on microswitches, or other failure scenarios, which may be overcome by an SSR, malfunction, or IFM procedure (EVA procedures not included), do not actually inhibit dual motor stow capability. Therefore, these type failures will not be cause for early stowage of the affected drive mechanism, or for additional demonstration of stow redundancy.

Rule {A2-103C}, EXTENSION DAY REQUIREMENTS, references this rule. @[090894-1670B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-104

SYSTEMS REDUNDANCY REQUIREMENTS (CONTINUED)

B. PAYLOAD OPERATIONS

ONCE THE DECISION HAS BEEN MADE FOR EARLY FLIGHT TERMINATION, PAYLOAD OPERATIONS MAY CONTINUE UNTIL DEORBIT MINUS 6 HOURS PROVIDED THAT THE OPERATIONS WOULD NOT JEOPARDIZE DEORBIT CAPABILITY. PAYLOAD OR SPACE SHUTTLE ARTICLES WHICH MUST BE MECHANICALLY SECURED FOR SAFE ENTRY/LANDING WILL BE SECURED PRIOR TO PRESLEEP ON DEORBIT MINUS 2 DAYS. IF STOW REDUNDANCY CAN BE DEMONSTRATED, OPERATIONS WILL BE ALLOWED TO CONTINUE UNTIL THE MORNING OF DEORBIT MINUS 1 DAY.

If a payload activity has no failure mode that could delay PLBD closing, there is no risk associated with allowing it to operate until deorbit minus 6 hours. If, however, the payload or space shuttle article must be mechanically or operationally secured prior to PLBD closure, then this operation should begin early enough to conduct an EVA (if required) without extending beyond the selected deorbit opportunity. This correlates to securing 2 days prior to deorbit which allows for an EVA on deorbit minus 1 day. If the potential of having to do an EVA has been significantly reduced (i.e., by demonstrating stow redundancy), then operation may continue until the morning of deorbit minus 1 day. Stowing in the morning will allow time for troubleshooting any unforeseen difficulties.

Rule {A9-4}, CAUTION AND WARNING (C&W), references this rule. ©[ED 1

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM)

A. DEFINITIONS:

1. SCHEDULED IN-FLIGHT MAINTENANCE (IFM) IS ACCOMPLISHED ON A PERIODIC (NOT NECESSARILY TIMELINED) BASIS TO KEEP EQUIPMENT OPERATIONAL AND EXTEND ITS LIFE. SCHEDULED IFM TASKS INCLUDE INSPECTION, CLEANING, AND REPLACING FILTERS AND CONSUMABLES. SPECIFICALLY EXCLUDED FROM THIS DEFINITION ARE REPAIR TYPE ACTIVITIES TO CORRECT OR WORK AROUND MALFUNCTIONS.

Examples of this type of maintenance are filter cleaning, LiOH canister replacement, and calibration of equipment.

2. UNSCHEDULED IFM IS UNDERTAKEN AS A RESULT OF ANOMALIES AND SPECIFICALLY INCLUDES TEST, MEASUREMENT, INSPECTION, AND REPAIR TYPE ACTIVITIES TO CORRECT OR WORK AROUND MALFUNCTIONS.

Definitions of categories of maintenance provide common terms for activities which may be constrained by flight rules. For example, scheduled maintenance is planned and approved preflight and usually accomplished without real-time consultation with the MCC-H. Unscheduled maintenance, which is conducted as a result of a hardware malfunction, is usually reviewed real time by the MCC-H whether or not it was preflight approved. This real-time review is conducted to determine orbiter/crew safety impacts.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

B. IMPLEMENTATION OF IFM

1. SCHEDULED IFM:

- a. IN GENERAL, SCHEDULED MAINTENANCE IS PERFORMED AS REQUIRED WITHOUT CONSULTING MCC. EXCEPTIONS TO THIS RULE MAY BE REQUIRED FOR EQUIPMENT WHICH CANNOT BE ISOLATED FROM THE ORBITER ELECTRICAL POWER SYSTEM, AIR REVITALIZATION SYSTEM, PRESSURE CONTROL SYSTEM, OR THERMAL SYSTEM. THOSE SCHEDULED IFM PROCEDURES WHICH REQUIRE MCC NOTIFICATION PRIOR TO IMPLEMENTATION WILL BE NOTED IN THE FLIGHT SPECIFIC FLIGHT RULE ANNEX.

Scheduled maintenance is usually considered a routine task. These procedures are reviewed preflight for impact on orbiter systems. In the interest of safety, some procedures may require MCC notification prior to implementation.

- b. SCHEDULED IFM PROCEDURES ON ORBITER HARDWARE WILL BE PERFORMED BY THE CDR, PLT, OR MISSION SPECIALISTS. PAYLOAD HARDWARE MAY BE MAINTAINED BY PAYLOAD SPECIALISTS.

CDR's, PLT's, and MS's undergo training specific to orbiter scheduled maintenance.

2. UNSCHEDULED IFM:

- a. UNSCHEDULED IFM PROCEDURES ON ORBITER HARDWARE WILL BE PERFORMED BY THE CDR, PLT, OR MISSION SPECIALISTS. REPAIR PROCEDURES ON PAYLOAD HARDWARE MAY BE PERFORMED BY PAYLOAD SPECIALISTS IF THE CDR/PLT OR MS IS COGNIZANT OF THIS ACTIVITY.

CDR's, PLT's, and MS's have an experience and training base to assess the overall impact of a repair procedure on hardware in general and the orbiter in particular.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

- b. UNSCHEDULED IFM PROCEDURES SHALL BE INITIATED ONLY WITH THE APPROVAL OF MCC-H. WHEN COMMUNICATION WITH THE MCC-H IS NOT POSSIBLE AND THE CDR DETERMINES THE SITUATION TO BE CRITICAL, REPAIR MAY BE PERFORMED TO ENSURE THE INTEGRITY OF THE ORBITER OR SAFETY OF THE CREW. SPECIFIC PAYLOAD REPAIR PROCEDURES MAY BE EXEMPTED FROM THIS RULE PREFLIGHT FOR EQUIPMENT ISOLATED FROM THE ORBITER ELECTRICAL POWER SYSTEM, AIR REVITALIZATION SYSTEM, PRESSURE CONTROL SYSTEM, OR THERMAL SYSTEM. THESE EXEMPTIONS WILL BE NOTED IN THE MISSION SPECIFIC FLIGHT RULES ANNEX.

Repair procedures are written preflight assuming particular hardware configurations, interrelationships, and sequences of hardware failures. In the interest of safety, the procedure is reviewed real time by the MCC-H to ensure that the assumptions under which it was written actually exist during on-orbit operations.

- c. UNSCHEDULED IFM PROCEDURES WILL BE PERFORMED ONLY IF ADEQUATE TECHNICAL DOCUMENTATION AND POSSIBLY REPRESENTATIVE HARDWARE ARE AVAILABLE. MCC-H WILL DETERMINE THE ADEQUACY OF THIS DOCUMENTATION/HARDWARE WHICH MAY INCLUDE, BUT IS NOT LIMITED TO, TECHNICAL DRAWINGS, FLIGHT LIKE HARDWARE, AND CLOSEOUT PHOTOS.

IFM procedures are always verified to the maximum extent possible. Past orbiter flight experience has shown that, when working to repair hardware, line drawings and specifications are not adequate to ensure that the final equipment closeout is known. On numerous occasions, preflight closeout photo documentation has revealed the presence of safety wire, ground straps, and other articles which could pose a hazard or cause permanent damage to the hardware. Closeout photos in the context of this rule include interior views of hardware taken during equipment fabrication/assembly as well as final module/pallet installation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

3. GENERAL:

- a. WHEN MULTIPLE IFM'S ARE REQUIRED, THE FOLLOWING PRIORITY WILL BE USED IN THEIR IMPLEMENTATION. MISSION SPECIFIC EXCEPTIONS WILL BE NOTED IN THE FLIGHT RULE ANNEX.

- (1) ORBITER SYSTEMS.
- (2) SPACELAB SYSTEMS (WHEN APPLICABLE).
- (3) EXPERIMENTS/PAYLOADS.

Self-explanatory.

- b. AN IFM WILL BE PERFORMED ASAP TO REGAIN THE REDUNDANCY AND/OR CAPABILITY NECESSARY TO SATISFY THE GO/NO-GO REQUIREMENTS TO CONTINUE PAST THE NEXT PLS OPPORTUNITY. AN IFM TO ESTABLISH ORBITER FAIL-SAFE CAPABILITY WILL HAVE PRIORITY OVER ALL FLIGHT ACTIVITIES AND WILL BE PERFORMED ASAP. FOR EXISTING VALIDATED IFM REPAIR PROCEDURES, IF TIME DOES NOT PERMIT COMPLETION PRIOR TO THE NEXT PLS OPPORTUNITY, A "GO" WILL BE GIVEN ASSUMING A SUCCESSFUL COMPLETION (FOR REAL-TIME DEVELOPED IFM'S, CONSIDERATION WILL BE GIVEN TO DECLARING A "GO" PRIOR TO COMPLETION).

@[011801-3851]

There is a high level of confidence in existing, validated IFM's. Therefore, the orbiter will remain on orbit, assuming the IFM will be successful, rather than terminate the mission for lack of time to complete the IFM. The confidence level may not be as great for real-time developed IFM's; therefore, the GO to stay on orbit is not automatic, but instead, depends on the level of confidence in the procedure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

- c. ON ENTRY DAY, PRIOR TO BEGINNING DEORBIT PREPARATION (DEORBIT TIG MINUS 4.0 HOURS), AN IFM WILL BE PERFORMED ONLY IF REQUIRED TO REGAIN THE REDUNDANCY AND/OR CAPABILITY NECESSARY TO SATISFY THE MINIMUM ENTRY REQUIREMENTS. AN IFM WILL NOT BE ATTEMPTED DURING DEORBIT PREPARATION EXCEPT FOR THE FOLLOWING SCENARIOS:
- (1) AN RHC OR DDU WILL BE REPLACED IF FAILURES IN THESE SYSTEMS RESULT IN THE LOSS OF TWO RHC CHANNELS PRIOR TO ENTERING OPS 3.
 - (2) ENTRY WILL BE DELAYED TO DO AVIONICS BAY FAN CHANGEOUT IF BOTH FANS HAVE FAILED IN AVIONICS BAYS 1 OR 2 AND A FAN CHANGEOUT MAY RECOVER COOLING IN THAT AVIONICS BAY. @[101096-4516]

IFM's require use of equipment and tools which are normally stowed. Their use affects the stowage timeline and other activities related to preparing the orbiter for entry. Rationale for the above exceptions is contained under the appropriate system in paragraph C.

- d. IFM PROCEDURES ON EXPERIMENTS WITH TOXIC HAZARDS - NO IFM PROCEDURES WILL BE INITIATED ON AN EXPERIMENT KNOWN TO REPRESENT A TOXIC HAZARD WITHOUT MCC-H CONCURRENCE. PROTECTIVE EQUIPMENT MAY BE REQUIRED (REF. RULE {A13-155}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE). PAYLOAD EQUIPMENT THAT REPRESENTS A TOXIC HAZARD WILL BE IDENTIFIED IN THE FLIGHT RULE ANNEX.

A real-time assessment of the possibility of repairing and the risk of exposing the crew to a toxic substance during the repair will be required. The IFM may require that the cleanup equipment specified in Rule {A13-155}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE, be used to minimize risk of crew exposure to toxic substance.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

C. SYSTEMS REPLACEMENT CRITERIA:

1. ANY FORWARD CRT WILL BE REPLACED WITH THE AFT CRT (N/A FOR MEDS VEHICLES). @[101096-4516] @[021397-4763] @[040899-2459B]

An IFM to replace any forward CRT with the aft CRT is required for entry to ensure at least two CRT's are available: One to monitor/control (item entry deselect/select) entry LRU's and PASS software, and the other to monitor/control orbiter systems via BFS software. CRT 3 satisfies the redundancy issues since it can be used by either the CDR or PLT. @[021397-4763]

2. ANY MDU CAN BE REPLACED WITH ANY OTHER MDU.

Because of the large number of MDU's (11), an IFM to replace a failed aft MDU with a forward MDU may aid the crew in critical aft station operations (RNDZ, dock/undock) without losing any capability in the forward cockpit. Because of the simple and low risk MDU IFM (45 minutes), the MDU can be reinstalled in the forward cockpit after the critical aft operations.

3. A KEYBOARD (1 OR 2) WILL BE REPLACED WITH THE AFT KEYBOARD.

The same rationale is used for the keyboard 1 or 2 IFM as for CRT's and also satisfies the requirement for fail-safe redundancy in entry-critical LRU's.

4. A SPECIFIC KEY ON (KEYBOARD 1 OR 2) WILL BE REPLACED WITH THE "ACK" OR "MSG RST" KEY FROM THE AFT KEYBOARD.

If a specific key in one of the forward keyboards is identified as failed, replacing that key with the ACK key from the aft keyboard can restore the keyboard to full operational status. Since the ACK key is only used to acknowledge fault messages by stopping them from flashing and turning off alarm tones, the aft keyboard may continue to be used even if the ACK key has been removed. As an alternative to the ACK key, the MSG RST key may be used. Forward keyboards are required for entry purposes, while no requirement exists for the aft keyboard. An IFM on a forward keyboard key will be done when required, while an IFM on an aft keyboard may be done.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

5. A DEU (1, 2, OR 3) WILL BE REPLACED WITH DEU 4.

IFM for DEU replacement rationale is the same as the CRT's except DEU 3, due to its location, is capable of being replaced whereas CRT 3 cannot. @[040899-2459B]

6. AN ADI (LEFT OR RIGHT) WILL BE REPLACED WITH THE AFT ADI (N/A FOR MEDS VEHICLES). @[101096-4516] @[040899-2459B]

An IFM to replace a failed ADI with the aft ADI is required for entry for the minimum required fail-safe capability and to allow the mission to continue past PLS. At least one ADI is required to ensure manual takeover capability is available high in the entry profile where the HUD is not available. In addition, the ADI is a prime pilot tool used to monitor the performance of the auto entry guidance to ascertain if a takeover is required.

7. AN RHC (LEFT OR RIGHT) WILL BE REPLACED WITH THE AFT RHC IF MORE THAN ONE CHANNEL IS FAILED ON THE SAME CONTROLLER. @[101096-4516]

Although the loss of two RHC channels does not violate minimum entry requirements (system is still fail-safe), an RHC will be changed out to increase redundancy anytime prior to OPS 3 transition due to its criticality in the CSS/takeover role for entry/landing.

8. THE FORWARD THC WILL BE REPLACED WITH THE AFT THC.

An IFM to replace the forward THC with the aft THC is required to ensure at least fail-safe redundancy is available for manual translational control for the deorbit burn.

9. A DDU (LEFT OR RIGHT) WILL BE REPLACED WITH AFT DDU.

An IFM to replace a failed DDU is required for entry to allow use of the ADI in non MEDS configured vehicles (ref. paragraph 6 for ADI entry criticality). This IFM may also be performed if necessary to regain RHC redundancy (ref. paragraph 7).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

10. THE LEFT OR RIGHT HUD WILL BE REPLACED WITH THE SPARE HUD. FOR FLIGHTS WHICH DO NOT CARRY A SPARE HUD, REPLACEMENT OF THE LEFT HUD WITH THE RIGHT HUD WILL BE PERFORMED, TIME PERMITTING, IF A NIGHT LANDING IS PLANNED. @[040899-2459B]

HUD replacement is considered highly desirable for entry in cases where visibility is restricted on the outer glide slope or for night landings. If a night landing is planned and no spare is available, the right HUD can be moved to the left side to provide the CDR with an operable HUD. The decision to perform the IFM will be based on consideration of the severity of the situation (e.g., weather, day or night, etc.). Reference: Memorandum CB-89-265.

11. AN OPS RECORDER (1 OR 2) WILL BE REPLACED WITH THE PAYLOAD RECORDER IF BOTH OPS RECORDERS HAVE FAILED. @[101096-4516] @[040899-2459B]

OPS recorder replacement is required only if both OPS recorders 1 and 2 have failed. The OPS recorder is required up to the deorbit burn to ascertain systems problems which occur during LOS.

12. THOSE CASES WHEN A FAILED PAYLOAD RECORDER WILL REQUIRE A PAYLOAD RECORDER REPLACEMENT WILL BE DEFINED IN THE FLIGHT SPECIFIC FLIGHT RULES ANNEX. @[101096-4516]

OPS recorder or PL recorder IFM criticality is addressed by the flight specific Annex rules. The payload or certain flight specific orbiter DTO's affect the criticality of entry related data requirements.

13. AN ACCU (1 OR 2) WILL BE REPLACED WITH BYPASS CONNECTOR J4.

An IFM to bypass a failed ACCU is required to ensure redundant voice links for entry and to determine whether next PLS must be declared. A failed IFM would be cause for next PLS with one ACCU down.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

14. TRANSPONDER (1 OR 2) BYPASS WILL BE CONSIDERED IF ONE FAILED. THE BYPASS WILL BE PERFORMED IF BOTH HAVE FAILED.

An IFM to recover S-band downlink telemetry is required if both transponders have failed. If one is failed, consider expenditure of crew time to perform the IFM to ensure redundancy.

15. IF BOTH AVIONICS FANS IN AV BAY 1 OR 2 HAVE FAILED, ENTRY WILL BE DELAYED TO REPLACE ONE FAN WITH A FAN FROM ANOTHER AV BAY. ©[040899-2459B]

AV bay fan replacement is done to recover cooling for two GPC's which provide redundancy for entry.

16. THE PF1/PF2 MDM'S WILL BE SWAPPED ONLY IF REQUIRED TO CLOSE PLBD'S. PLBD MOTOR OPERATION UTILIZING THE IFM PIN KIT WILL BE USED IN LIEU OF SWAPPING PL MDM'S IF, AFTER THE MDM'S ARE SWAPPED, THE PLBD MOTOR IFM WOULD STILL BE REQUIRED TO CLOSE AND/OR LATCH THE DOORS.

©[101096-4516] ©[040899-2459B]

Due to the potential for connector pin damage during demate/mate operations, replacement or swapping of PL MDM's is only considered for PLBD closure. No consideration is made to swap PL MDM's for mission success reasons. The PLBD motor operation IFM is a collection of pin kit procedures to recover PLBD motor functions lost as a result of a failed PL MDM, and the motor driven by the other PL MDM has hard failed. If swapping PL MDM's will not recover all the necessary functions to close and latch the doors, the pin kit procedures will be used to regain the lost functions in lieu of swapping the MDM's.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-105

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

17. FOR FLIGHT CRITICAL MDM'S - FF4 WILL BE SWAPPED WITH FF1, FF2, OR FF3 AFTER POWER CYCLING AND PORT MODING FAILS TO CLEAR A NON-GPC CAUSED "I/O ERROR FFX" OR TOTAL OUTPUT CARD FAILURE AND IT RESULTS IN THE LOSS OF: @[101096-4516] @[040899-2459B]
- a. A SECOND IMU.
 - b. A SECOND ACCELEROMETER ASSEMBLY (AA) (AA4 MUST BE FAILED).

Where previous LRU failures would cause a loss of at least fail-safe redundancy in an entry critical system, it is considered viable to replace FF1, FF2, or FF3 with FF4. The operation would be accomplished to recover an IMU for redundancy in onboard navigation for entry. The same is true for an AA to regain redundancy for entry control.

Rules {A7-5C}, PASS GPC BCE FAILURE MANAGEMENT; {A7-109D}, IN-FLIGHT MAINTENANCE (IFM); and {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION; reference this rule.

FLIGHT RULES

A2-106

PBD OPERATIONS [CIL]

LAUNCH DAY LANDING PLBD OPS:

- A. IF A LANDING IS REQUIRED AND SUPPLY/WASTE WATER WILL SUPPORT FES OPERATIONS UNTIL ENTRY, NO ATTEMPT WILL BE MADE TO OPEN ONE OR BOTH OF THE PLBD'S. @[020196-1804A]

For launch day landings at the first available PLS, the supply and waste water tanks are loaded such that there is sufficient water for FES operations; therefore, there is no requirement to incur the risks associated with opening the PLBD's, thus eliminating an increase in the crew workload during this timeframe.

- B. IF A LANDING IS REQUIRED AFTER PREDICTED EXHAUSTION OF SUPPLY AND WASTE WATER FOR THE FES, THE PLBD'S MAY BE OPENED.

For launch day landings after the first PLS opportunity, insufficient supply/waste water may have been loaded to support FES operations to entry. If the first PLS opportunity is NO-GO or likely to be NO-GO, then PLBD opening will be required. This situation may result in having to open the PLBD without close redundancy.

- C. FOR PROBLEMS PROHIBITING NECESSARY HEAT REJECTION, THE PLBD'S MAY BE OPENED (TIME PERMITTING) WITHOUT REGARD TO CLOSE-MOTOR REDUNDANCY, FES WATER SUPPLY AVAILABILITY, OR MET OF LANDING. @[020196-1804A]

For cases where there are cooling problems and opening the PLBD's is required to alleviate heating of entry-critical equipment, the PLBD's should be opened to provide the increased cooling capability. This may be necessary even though redundant door closure does not exist and/or the timeline/crew workload would be increased.

FLIGHT RULES

A2-107

EVA GUIDELINES

A. EVA WILL NORMALLY BE PERFORMED BY TWO EVA CREWMEMBERS;
HOWEVER, ONE MAN EVA MAY BE PERFORMED IN THESE CIRCUMSTANCES:

1. CONTINGENCY EVA.

Two crewmembers are always required for EVA to ensure that, if one EVA crewmember should experience trouble, the other is available to provide assistance. For contingency EVA, this rule is waived since the safety of the orbiter is involved and the risk of a one man EVA is therefore acceptable.

2. SCHEDULED EVA - A SCHEDULED EVA MAY BE PERFORMED BY A
SINGLE CREWMEMBER IF:

a. A SINGLE CREWMEMBER CAN EXECUTE THE TASK(S) ASSIGNED.

b. THE SECOND CREWMEMBER IS ABLE TO GO TO VACUUM AND
REMAIN ON THE SERVICE AND COOLING UMBILICAL (SCU) FOR
POSSIBLE RESCUE.

c. THE SCHEDULED EVA TASK(S) MUST BE CAPABLE OF BEING
TERMINATED AT ANY POINT AND LEAVE THE PLB IN AN ENTRY
COMPATIBLE CONFIGURATION.

3. UNSCHEDULED EVA - AN UNSCHEDULED EVA TO MEET HIGH
PRIORITY MISSION OBJECTIVES OR TO PREVENT JETTISON OF A
PAYLOAD MAY BE ACCOMPLISHED BY A SINGLE CREWMEMBER IF THE
FOLLOWING CRITERIA ARE MET:

a. A SINGLE CREWMEMBER CAN EXECUTE THE TASK(S) ASSIGNED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-107

EVA GUIDELINES (CONTINUED)

- b. THE SECOND CREWMEMBER MUST BE ABLE TO GO TO VACUUM AND REMAIN ON SERVICE AND COOLING UMBILICAL (SCU) FOR POSSIBLE RESCUE.
 - c. THE UNSCHEDULED EVA TASK(S) MUST BE CAPABLE OF BEING TERMINATED AT ANY POINT AND LEAVE THE PLB IN AN ENTRY COMPATIBLE CONFIGURATION.
4. AN EVA WILL BE DEFINED IN THE FLIGHT SPECIFIC ANNEX AS BEING CAPABLE OF BEING ACCOMPLISHED BY A SINGLE CREWMEMBER.
- B. IF CONTINGENCY EVA SUCCESSFULLY RESTORES PLBD'S, LATCHES, ETC., TO NORMAL OPERATION (E.G., FOREIGN OBJECT REMOVED), THE EVA WILL BE TERMINATED AND THE FLIGHT COMPLETED AS PLANNED.

If a contingency EVA is successful in restoring complete orbiter capability, there is no added risk to remaining on orbit and accomplishing the full mission duration.

- C. FOR EVA, DENITROGENATION WILL BE ACCOMPLISHED IN ACCORDANCE WITH AEROMED RULE {A13-103}, EVA PREBREATHE PROTOCOL.

Self-explanatory.

- D. EVA/ORBITER ATTITUDE, AND ATTITUDE CONTROL CONSTRAINTS:
- 1. DURING SIDE-TO-SUN ATTITUDE, THE SUN SIDE FORWARD RADIATOR PANEL WILL BE STOWED.
 - 2. DURING TOP SUN ATTITUDE, CREWMEMBERS WILL AVOID THE AREA WITHIN 15 FEET ABOVE DEPLOYED RADIATORS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-107

EVA GUIDELINES (CONTINUED)

For a side-to-Sun attitude during the EVA, the forward radiators must be stowed to preclude exposing a crewmember to the focusing effect of the Sun shining through the gap between the door and radiator. Short term exposure could produce thermal gradients which could overload the EMU capability to control the thermal environment, and longer term exposure could cause suit degradation. The same type of focusing effects are experienced at approximately 15 feet above the radiator when the vehicle is in a top Sun attitude and are potentially more severe.

E. MINIMUM COMMUNICATIONS REQUIREMENTS FOR SCHEDULED EVA:

IN ORDER TO COMMIT TO OR CONTINUE A SCHEDULED EVA, EACH EVA CREWMEMBER MUST HAVE TWO-WAY COMMUNICATIONS WITH THE ORBITER EITHER DIRECTLY OR VIA THE OTHER EVA CREWMEMBER.

It is difficult to be totally aware of the condition of an EVA crewmember by visual inspection. Minimum communication is required to ensure crew status and safety throughout the EVA period.

F. EVA WILL BE TERMINATED FOR MALFUNCTIONS WHICH RESULT IN SECONDARY OXYGEN PACK (SOP) O₂ FLOW.

Malfunctions which result in SOP flow indicate no other source of oxygen can supply total requirements for continued operation of the suit/EMU. Regardless of whether or not the primary life support system (PLSS) is functioning properly, SOP flow depletes the EVA crewmember's backup source of oxygen and is therefore cause to terminate the EVA. ©[021199-6747B]

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT

A. REDLINES WILL BE MANAGED TO ASSURE THAT THE FOLLOWING RESERVES ARE PROTECTED:

In order to achieve acceptable consumables margins (cryo, water, or OMS/RCS propellant, N₂, LiOH, etc.) required to continue on-orbit flight operations, flight activities requiring the limited consumable may be reduced/deleted. The capabilities that must be protected along with the potential activities that are candidates for deletion are identified. ©[092800-7247A]

1. DEORBIT CAPABILITY - OMS/RCS PROPELLANTS WILL NORMALLY BE MANAGED TO PROVIDE THE CAPABILITY TO DEORBIT TO STEEP TARGETS. HOWEVER, SHALLOWING TARGETS IS ALLOWED TO PROTECT ITEMS 2 THROUGH 8 BELOW.

NOTE: OMS PROPELLANT RESERVED TO PROTECT FUTURE EXTENSION DAYS (PARAGRAPHS 9 AND 11 BELOW) MAY BE COMMITTED TO PROVIDE STEEP DEORBIT TARGET CAPABILITY FOR A CURRENT OPPORTUNITY. ©[051194-1612A]

Deorbit capability is protected to allow safe return of the orbiter. This rule addresses consumables limitations and not deorbit methods. Other rules identify actions required for the loss of one OMS, etc.

2. EOM DEORBIT PREPARATION.

Consumables required to successfully perform the nominal EOM deorbit preparation are protected.

3. POST-DEORBIT AND ENTRY USAGE (EXCEPT PTI'S).

Consumables required to support orbiter operations from deorbit burn cutoff through landing are protected. PTI's are not considered as mandatory and, if scheduled, appear as a tradable item in the Flight Rules Annex propellant priority table. ©[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT (CONTINUED)

4. CONTINGENCY RESERVES (SYSTEM MALFUNCTION OR FLIGHT CONTINGENCY).

Consumables are reserved to protect against certain anomalies in order to guarantee system capabilities. For example, OMS/RCS propellant is redlined to account for attitude dispersions during the deorbit burn associated with an OMS engine failure.

5. X/Y CG BALLAST - RESERVES CONSUMABLES TO MAINTAIN THE ORBITER CG WITHIN ESTABLISHED LIMITS.

Self-explanatory.

6. DISPERSION ALLOWANCE (PERFORMANCE VARIATION).

Self-explanatory.

7. MEASUREMENT ERROR.

Self-explanatory.

8. TRAPPED RESIDUALS.

Self-explanatory.

9. DEORBIT WAVE-OFF EXTENSION DAY - INCLUDES CONSUMABLES RESERVED TO BACK OUT OF THE DEORBIT BURN CONFIGURATION, MAINTAIN ATTITUDE CONTROL FOR ANOTHER DAY ON ORBIT UTILIZING PRIMARY JETS (ONE IMU ALIGNMENT, -ZLV -XVV OR THERMAL PROTECT ATTITUDE, IF REQUIRED), PLUS ALLOW STANDARD DEORBIT PREPARATION ACTIVITIES. ©[051194-1612A]
©[092800-7247A]

Deorbit wave-off extension day: Consumables required to support a deorbit backout, one day of orbit stay time on primary jets, plus an additional deorbit preparation are protected. This wave-off extension day is reserved for orbiter contingencies per Rule {A2-103}, EXTENSION DAY REQUIREMENTS. See also Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, for thermal conditioning attitude profiles if required. Note that primary jets are protected for this extension day since many of the failures which require a deorbit wave-off extension day also fail the vernier jets. ©[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT (CONTINUED)

10. POSTLANDING REQUIREMENTS.

Self-explanatory.

11. WEATHER WAVE-OFF EXTENSION DAY - RESERVES CONSUMABLES FOR ONE DAY OF ORBITER MAINTENANCE ACTIVITIES WITH NORMAL SYSTEMS CONFIGURATION. THIS INCLUDES CONSUMABLES RESERVED TO DELAY ONE ORBIT IN THE DEORBIT BURN CONFIGURATION, BACK OUT OF THE DEORBIT BURN CONFIGURATION, MAINTAIN ATTITUDE CONTROL FOR ANOTHER DAY ON ORBIT UTILIZING VERNIER JETS (ONE IMU ALIGNMENT, -ZLV -XVV OR THERMAL PROTECT ATTITUDE, IF REQUIRED, FOLLOWED BY A NOMINAL (VERNIER) DEORBIT PREPARATION. THE WEATHER WAVE-OFF EXTENSION DAY MAY BE GIVEN UP FOR CRITICAL ACTIVITIES (REF. PARAGRAPH C). @[051194-1612A] @[092800-7247A]

Weather wave-off extension day: Consumables required to support a one-orbit delay in the deorbit burn configuration followed by one day wave-off for adverse weather conditions are protected. Vernier jets are assumed to be available since the weather extension day presumes a normal (non-contingency) systems configuration per Rule {A2-103}, EXTENSION DAY REQUIREMENTS. See also Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, for thermal conditioning attitude profiles, if required.

- B. VIOLATION OF THE RESERVES IDENTIFIED IN PARAGRAPH A WILL BE CAUSE TO SCHEDULE ENTRY AT THE NEXT PLS OPPORTUNITY (EXCEPT FOR LOSS OF THE WEATHER WAVE-OFF EXTENSION DAY CAPABILITY).
- C. FOR CONSUMABLES CONTINGENCIES, FLIGHT ACTIVITIES IN ORDER OF PRIORITY (HIGHEST FIRST) ARE AS FOLLOWS:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT (CONTINUED)

PRIORITY	FLIGHT ACTIVITY	
1.	TARGET 45 DEGREES TO 90 DEGREES PREBANK.	
2.	TARGET 0 DEGREES TO 45 DEGREES PREBANK.	
3.	SHORTEN MISSION TO LESS THAN MDF.	[1]
4.	RAISE ORBIT TO MINIMUM ALTITUDE REQUIRED TO ALLOW CRITICAL ON-ORBIT/PAYLOAD ACTIVITIES.	[2]
5.	WEATHER WAVE-OFF EXTENSION DAY.	[3]
6.	FLIGHT SPECIFIC ACTIVITIES (MDF PLUS TWO EXTENSION DAYS REMAIN HIGHER PRIORITY THAN FLIGHT SPECIFIC ACTIVITIES).	[4]

NOTE: EXCEPT FOR THE WEATHER WAVE-OFF EXTENSION DAY, CONSUMABLES RESERVED IN PARAGRAPH A HAVE HIGHER PRIORITY THAN THE ABOVE TABLE. @[092800-7247A]

NOTES:

[1] SHORTEN IN INCREMENTS OF NEXT DAILY PLS OPPORTUNITIES.

[2] REFERENCE FLIGHT RULES ANNEX FOR MINIMUM ALTITUDE AND PAYLOAD/MISSION PRIORITIES.

[3] ASSUMES ONE REV IN THE DEORBIT BURN CONFIGURATION FOLLOWED BY A VERNIER EXTENSION DAY IN -ZLV -XVV OR THERMAL PROTECT ATTITUDE, IF REQUIRED, FOLLOWED BY A NOMINAL (VERNIER) DEORBIT PREP.

[4] MISSION SPECIFIC CONSUMABLES PRIORITIES ARE DOCUMENTED IN THE FLIGHT RULES ANNEX. @[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT (CONTINUED)

When insufficient consumables are available to complete planned mission activities, the priority table is used to determine the remaining capability by deleting items from the bottom and moving upwards. A discussion of each priority follows:

- Priority 1. *Target 45 to 90 degrees prebank: Committing to a prebank greater than 45 degrees introduces considerable impact to the orbiter as a result of the increased thermal environment. Consequently, prebank greater than 45 degrees will only be utilized to protect the minimum requirements established as a higher priority than the priority table.*
- Priority 2. *Target 0 to 45 degrees prebank: Flight Techniques concluded that the minimal propellant gained as a result of committing to a prebank for the deorbit burn did not warrant the increased procedural/crew task complexity associated with the prebank (reference Entry Techniques minutes DA8-86-59).*
- Priority 3. *Shorten mission to less than MDF: All activities will be deleted to protect MDF requirements.*
- Priority 4. *Raise orbit to minimum altitude required to allow critical on-orbit/payload activities: The weather wave-off extension day capability may be deleted in order to accomplish critical on-orbit and/or payload activities which provide a direct orbiter benefit for deorbit and entry, or to accomplish a vital agency goal. One specific example of this would be the requirement to rendezvous with ISS and install/transfer a payload, thereby improving orbiter entry weight, required deorbit consumables, entry c.g., and flight control margins, etc. Similar rationale applies for a deployable payload with a minimum deployment altitude. However, the weather wave-off extension day may not be deleted merely to provide an incremental increase in payload science or mission duration. ©[092800-7247A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-108

CONSUMABLES MANAGEMENT (CONTINUED)

- Priority 5. *Weather wave-off extension day: The weather wave-off extension day provides the capability to delay the deorbit burn for one orbit in the deorbit burn configuration and then wave off for another 24 hours if weather, etc., make landing on the planned day unacceptable. Consumables budgeted for the weather wave-off extension assume VRCS control and minimum orbiter maintenance activities (IMU align, etc.). Combined with the deorbit wave-off extension capability (the latter reserved at a higher level than this table), the weather wave-off extension day provides a total capability of four deorbit attempts with three deorbit preparations. It is the intent to maintain the weather wave-off extension capability at a high priority to account for unforeseen weather problems (due to the unpredictability of the weather and forecasting uncertainty).*
- Priority 6. *Flight-specific activities: All flight specific activities are prioritized in the Flight Rules Annex. The priority of each activity considering specific flight objectives is established prelaunch. Implementation of the Flight Rule Annex propellant priority table must be completed before deleting high priority activities identified in this table.*

A2-109

PREFERRED ATTITUDE FOR WATER DUMPS

A. TO MINIMIZE RECONTACT POTENTIAL OF HIGH VELOCITY WATER PARTICLES WITH THE ORBITER OR PAYLOADS, SPECIFIC DUMP ATTITUDES ARE PREFERRED DURING SUPPLY/WASTE WATER DUMPS. THE REQUIRED ATTITUDE DEPENDS ON THE ORBITER POSITION RELATIVE TO THE PAYLOAD. THAT POSITION IS DEFINED AS BEING IN ONE OF FOUR REGIONS IN THE PAYLOAD CENTERED LVLH FRAME DEPICTED IN THE FOLLOWING DIAGRAM.

FIGURE A2-109-I - PREFERRED ATTITUDE FOR WATER DUMPS

REGION	DUMP ATTITUDE	RESTRICTIONS
A	+YVV (RETROGRADE DUMP)	THE ORBITER RELATIVE APOGEE MUST BE BELOW THE BOUNDARY OF REGION A. THE ORBITER MUST REMAIN WITHIN REGION A FOR THE DURATION OF THE DUMP.
B	+YVV (RETROGRADE DUMP)	THE ORBITER MUST BE IN A STATIONKEEPING OR SLOW SEPARATION SITUATION AND REMAIN WITHIN REGION B FOR THE DURATION OF THE DUMP.
C	+Y 40 DEG OUT OF PLANE FROM VV (BIASED RETROGRADE DUMP)	THE ORBITER MUST BE IN A STATIONKEEPING OR SLOW SEPARATION SITUATION AND REMAIN WITHIN REGION C FOR THE DURATION OF THE DUMP.
D	-Y 20 DEG OUT OF PLANE FROM VV (BIASED RETROGRADE DUMP)	THE ORBITER RELATIVE PERIGEE MUST BE ABOVE THE BOUNDARY OF REGION D. THE ORBITER MUST REMAIN WITHIN REGION D FOR THE DURATION OF THE DUMP.
ORBITER ALONE	+YVV (RETROGRADE DUMP)	INCLUDES PAYLOAD ATTACHED CASE.

PREFERRED ATTITUDE FOR WATER DUMPS (CONTINUED)

- B. THE FOLLOWING GUIDELINES ARE TO BE USED FOR THE CASE OF INTERSECTING ORBITS WHICH DO NOT SATISFY REGIONS A, B, C, OR D ABOVE.
1. IF THE ORBITS INTERSECT WITH THE ORBITER BEHIND THE PAYLOAD AND THE ORBITER IS MOVING AWAY FROM THE PAYLOAD OR CLOSING AT LESS THAN 50 NM/REV, THEN THE DUMP ATTITUDE WILL BE -Y, 20 DEG OUT OF PLANE FROM +VV (BIASED POSIGRADE).
 2. IF THE ORBITS INTERSECT WITH THE ORBITER AHEAD OF THE PAYLOAD AND THE ORBITER IS MOVING AWAY FROM THE PAYLOAD OR CLOSING AT LESS THAN 50 NM/REV, THEN THE DUMP ATTITUDE WILL BE -Y, 20 DEG OUT-OF-PLANE FROM -VV (BIASED RETROGRADE).
 3. DUMPS FOR CASES 1 AND 2 SHOULD BE COMPLETED AT LEAST TWO ORBITS BEFORE THE POINT OF CLOSEST APPROACH.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-109

PREFERRED ATTITUDE FOR WATER DUMPS (CONTINUED)

- C. GENERIC ATTITUDE RECOMMENDATIONS CANNOT BE MADE FOR ORBITAL GEOMETRIES WHICH DO NOT MEET THE CONDITIONS LISTED ABOVE.

These recommendations were approved at the On-Orbit Flight Techniques Panel #120. The major ground rules and assumptions are listed below:

- a. *Particle ejection velocity is assumed to be between 30 and 100 ft/sec. Measurements from an STS-29 supply dump video show particle velocities of 30-75 ft/sec. It is also known that waste dump rates are typically 3.3 lb/min, compared to 2.5 lb/min for supply dumps. Since each dump uses the same nozzle, the maximum velocity for a waste dump is assumed to increase in proportion to the flowrate. Thus, the maximum velocity is $3.3/2.5 \times 75 = 100$ ft/sec.*
- b. *The distribution of particle ejection angles is such that 95 percent of the particles are ejected within a 10 degree half-cone angle of the orbiter -Y axis. An additional 10 degree half-cone angle is protected in these recommendations.*
- c. *The boundaries protect a 1 nm radius sphere of position uncertainty for both the orbiter and payload.*
- d. *All particles are assumed to experience more atmospheric drag than either the orbiter or the payload.*

Retrograde dumps preclude particle recontact because differential drag aids in moving particles downward and forward.

Posigrade dumps may result in an eventual return of particles due to differential drag. Some particles may travel to the vicinity of the payload on the first orbit. The intensity of recontact is minimized by the following effects which act to disperse the particle cloud:

- a. *Differential drag among particles of different sizes.*
- b. *Out-of-plane velocity of particles minimizes time in plane.*
- c. *Particles sublimate over time.*

B. IF THE ABOVE SEQUENCE IS NOT FOLLOWED, FLIGHT-SPECIFIC ANALYSIS IS REQUIRED. FLIGHT-SPECIFIC ANALYSIS OF NOMINAL DEORBIT PREP PLUS WAVEOFF ATTITUDES WILL EVALUATE THE FOLLOWING SEQUENCES:

1. NOMINAL:

```

|- IMU -|- XSI -|- COMM -|- DEORBIT -|- EI -| @[072398-6645]
                PLBD      EOM
                CLOSE     TIG
    
```

2. NOMINAL + 1 REV:

```

|- IMU -|- XSI -|- COMM -|- COMM -|- DEORBIT -|- EI -|
@[072398-6645]
                PLBD      EOM      EOM+1 REV
                CLOSE     TIG      TIG
    
```

3. NOMINAL + 2 REVS:

```

|- IMU -|- XSI -|- COMM -|- COMM -|- COMM -|- DEORBIT -|- EI -|
@[072398-6645]
                PLBD      EOM      EOM+1 REV  EOM+2 REVS
                CLOSE     TIG      TIG          TIG
    
```

WORST-CASE EI BONDLINE LIMITS (FROM ALL POSSIBLE DEORBIT OPPORTUNITIES) WILL BE USED.

DETAILS REGARDING THE USE OF COMPUTER ANALYSIS TO EVALUATE DEORBIT ATTITUDE SEQUENCES ARE PROVIDED IN FLIGHT RULES {A18-401}, THERMAL PROTECTION SYSTEM (TPS) BONDLINE TEMPERATURES, AND {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL].

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-110 STRUCTURES THERMAL CONDITIONING (CONTINUED)

C. THE FOLLOWING GUIDELINES FOR PRE-ENTRY THERMAL CONDITIONING SHOULD BE USED FOR INITIAL PREFLIGHT PLANNING PURPOSES:

BETA ANGLE AT START OF THERMAL <u>CONDITIONING</u>	<u>10 HOURS OF:</u>	<u>FOLLOWED BY:</u>
0 TO ? 60 DEGREES	-ZLV, PTC OR ?XLV, ±ZVV	NORMAL DEORBIT ATL SEQUENCE AS DEFINED IN PARAGRAPH A
 > ? 60 DEGREES	 PTC	 NORMAL DEORBIT ATL SEQUENCE AS DEFINED IN PARAGRAPH A

@[050495-1768A]

FLIGHT-SPECIFIC ANALYSIS OF THE ON-ORBIT TIMELINE WILL DETERMINE WHETHER SPECIAL THERMAL CONDITIONING IS NEEDED PRIOR TO DEORBIT PREP. IF FLIGHT-SPECIFIC THERMAL CONDITIONING IS REQUIRED, IT WILL BE DOCUMENTED IN THE FLIGHT RULES ANNEX. @[050495-1768A]

Depending on the flight-specific attitude timeline, it is possible that the deorbit prep attitude sequence described in paragraph a will not satisfy all orbiter or payload thermal constraints. This is especially true for high beta or attitude intensive missions. Attitudes during the last sleep and postsleep period are typically -ZLV, unless payload desires drive otherwise. If analysis of an attitude timeline predicts violations, then attitudes prior to deorbit prep may need to be modified to improve the predicted temperatures. Typical conditioning attitudes could be a specific LVLH orientation, solar inertial attitude, PTC, etc. The durations and orientations of these conditioning attitudes will be worked on a flight-specific basis, and the plan will be documented in the flight-specific annex.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-110

STRUCTURES THERMAL CONDITIONING (CONTINUED)

- D. DEORBIT BURN WILL NOT BE DELAYED IF A TPS BONDLINE TEMPERATURE IS ABOVE ITS FLIGHT-SPECIFIC LIMIT, PROVIDED ALL OF THE FOLLOWING ARE MET:
1. NO TPS BONDLINE VIOLATIONS WERE PREDICTED FOR THE PLANNED DEORBIT SEQUENCE.
 2. RADIATOR COLD SOAK AND COMM ATTITUDES IN DEORBIT PREP HAVE BEEN CHOSEN TO MINIMIZE SOLAR EXPOSURE ON THE TPS BONDLINES. (THE COMM ATTITUDE MAY BE BIASED FROM TAIL-SUN AS SPECIFIED IN PARAGRAPH A TO MAINTAIN TDRS COMM.)
@[050495-1768A]
 3. IF, IN DEORBIT PREP, OFF-NOMINAL ATTITUDES AND/OR TIMES ARE REQUIRED DUE TO FAILURES OR OTHER UNEXPECTED SITUATIONS, THE PLANNED ATTITUDE TIMELINE IS RESUMED AS SOON AS CONDITIONS ALLOW. @[050495-1768A]
 4. THE FLIGHT SPECIFIC EXCEEDENCE IS NO GREATER THAN 5 DEG OR HAS BEEN APPROVED BY THE MER.

Flight-specific limits on bondline temperatures at entry interface (EI) are defined in each flight-specific annex. These limits must be met when the attitude timeline is analyzed and bondline temperatures are predicted at EI. However, if a temperature is actually above its limit prior to the deorbit burn, the burn is not waved off, because reasonable actions are taken ahead of time to attempt to preclude violations. Any surprise violations should be very small, possibly even due to instrumentation error (which is not protected).

The flight-specific bondline limits protect orbiter thermal/structural certification envelopes (with 1.4 factor of safety (FOS) during "design entry" mechanical loading). The bondline temperature upper limits are in place to protect a gradient temperature. Since the method of gradient protection is generic, and the limits protect for design cases plus 1.4 FOS, it is considered less risk to proceed with a small violation than to wave off deorbit burn. On STS-55, a 3-degree violation of V09T1012 occurred at entry interface. More detailed assessment by Engineering indicated that in this case there was actually approximately 20 degrees margin at TAEM and touchdown (the points really being protected).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-110**STRUCTURES THERMAL CONDITIONING (CONTINUED)**

A cold attitude(s) will be used for radiator coldsoak and “comm attitude,” to reduce bondline temperatures to the extent possible during deorbit prep. It is typically difficult, however, to satisfy the bondline limits, even when cold attitudes are chosen such as tail-sun or nose-sun. If bondline solar exposure is already minimized, there would be little or no corrective action available so nothing is gained by delaying the deorbit burn. STEP will be the primary tool used by the MCC to analyze the nominal attitude timeline. Any predicted violations (which include STEP accuracy biases) will be resolved either (1) by changing attitudes, including those prior to deorbit prep if necessary, or (2) by comparing STEP predictions to previous flight data in similar beta angles and attitudes, or to other thermal models, and “outvoting” the STEP prediction. The rationale for Rule {A18-401}, THERMAL PROTECTION SYSTEM (TPS) BONDLINE TEMPERATURES, provides more information on STEP analysis and biases.

Instrumentation error is not protected for the bondline temperature sensors. Instrumentation error is not considered in the structural analyses which are used to generate the EI limit models, nor are any other uncertainties. When analyzing structural stress, it is generally not known whether a positive or negative error causes worse structural gradients, so only “actual” temperatures are used. Analysis of all possible uncertainty combinations would require prohibitively large numbers of simulations. Also, inclusion of instrumentation error would cause frequent limit exceedences.

If real-time deviations from the planned attitude timeline are required (for reasons such as single star tracker IMU aligns, missed stars, time taken to troubleshoot a failure, etc.), they will take priority and will not be rushed or canceled in favor of bondline thermal limits. However, the orbiter will return to the planned cold attitude as soon as the situation allows, and deorbit burn will proceed as planned.
©[050495-1768A]

A small limit exceedence of up to 5 degrees is acceptable to the technical community without further discussion. Exceedences greater than 5 degrees should be understood or accepted given whether it could realistically be brought back into tolerance by further activity prior to deorbit. ©[050495-1768A]

Documentation: Ascent/Entry Flight Techniques #111, 3/25/94; Orbiter CCB 6/14/94, 8/9/94; Engineering Judgment. ©[050495-1768A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-110

STRUCTURES THERMAL CONDITIONING (CONTINUED)

- E. ADEQUATE THERMAL CONDITIONING IS PROVIDED FOR EMERGENCY ABORTS FROM ORBIT BY MAINTAINING NORMAL THERMAL LIMITS AND BY ENSURING THAT THE PROJECTED MISSION PROFILE OF BENDING EFFECT TEMPERATURE (BET) REMAINS LESS THAN 200 DEG F. THERE ARE NO BONDLINE TEMPERATURE CONSTRAINTS FOR EMERGENCY DEORBIT.

Maintaining BET < 200 deg F ensures that PLBD closing can be accomplished for anytime deorbit opportunities. Typical bondline temperature constraints for EI protect for a 1.4 factor of safety above design structural loads. Since typical entry loads are well below design loads, it is not necessary to protect the 1.4 factor of safety over design entry loads in the event of an emergency deorbit.

DOCUMENTATION: SODB, pg 3.4.1.1-5, and NASA JSC Memo ES2-93-096.

Rule {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL], references this rule.

Reference Rule {A10-206}, PLBD CLOSE GO/NO-GO, for BET definition and constraints.

FLIGHT RULES

A2-111

DPS COMMAND CRITERIA

- A. GPC MEMORY WRITE PROCEDURES CAN BE USED IN FLIGHT TO MODIFY DATA AND CODE IN BOTH THE PASS AND BFS.

The Orbiter Avionics Software Board (OASCB) has authorized the use of GPC memory write procedures to modify data or code in PASS or BFS. This is allowed to restore orbiter capabilities lost because of real-time orbiter hardware problems or to correct software problems that do not require a recompilation of the software.

- B. THE USE OF GPC MEMORY WRITE PROCEDURES ARE SUBJECT TO THE GUIDELINES DEFINED BY RULE {A7-16}, GPC MEMORY WRITE CRITERIA [CIL].

All GPC memory procedures must adhere to rigorous verification prior to their use to ensure crew and vehicle safety. Reference Rule {A7-16}, GPC MEMORY WRITE CRITERIA [CIL], for such guidelines, as well as the different types of GPC memory write procedures.

- C. DEU EQUIVALENT COMMANDING DURING CREW SLEEP WILL NOT BE PERFORMED UNTIL ALL OF THE FOLLOWING REQUIREMENTS HAVE BEEN MET: @[072795-1775A]
1. CONFIRMED PERIOD OF AOS AND GOOD COMM BOTH BEFORE AND AFTER SCHEDULED COMPLETION OF THE DEU EQUIVALENT COMMAND LOAD.

A valid downlist is required for the MCC to be able to verify DEU equivalent command execution. In addition, an active downlist is required from the destination GPC or major function for the ground command processing software to verify the uplink and automatically send the buffer execute command. A period of good comm is required so that the crew can be contacted in the event of an off nominal situation. During maneuvers, there may be brief periods of LOS or bad comm while the vehicle changes attitudes. These brief periods are acceptable, as long as the resultant attitude is confirmed to have good comm.

2. THE MCC MUST BE ABLE TO VERIFY ALL DEU EQUIVALENT LOADS VIA METHODS OTHER THAN SCRATCHPAD LINE RESPONSE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-111

DPS COMMAND CRITERIA (CONTINUED)

Due to the timing differences between the downlist cycle and when the GPC polls the DEU, the possibility exists such that all uplinked commands may not be seen on the downlisted scratchpad line. Since there is a requirement for ground confirmation of all DEU loads, there must be an alternate way to verify the uplink through end item telemetry feedback's. @[072795-1775A]

3. DEU EQUIVALENT LOADS SHOULD AVOID CONTAINING ITEM SERIES WHICH MUST BE UPLINKED AT A SPECIFIC TIME OR WITHIN A SPECIFIC TIME INTERVAL. @[072795-1775A]

Due to the dynamic nature of commanding and the requirement for good comm and AOS to allow the MCC to properly verify the execution of each DEU equivalent load, there may be times when the ground cannot uplink a required load at a specific time. Therefore, the MCC should not be constrained by specific time requirements for DEU equivalent loads. There may be occasions where this cannot be avoided, but time specific loads need to be closely analyzed for any risks associated with delaying their uplink.

4. IF A SERIES OF DEU EQUIVALENT LOADS ARE PLANNED, THE IMPACT OF NOT COMPLETING ALL UPLINKS MUST BE EVALUATED. FUTURE MANEUVER LOADS, CREW ALERT SPC'S, AND/OR CREW BAILOUT ATTITUDES MUST BE USED AS REQUIRED TO PROVIDE AN APPROPRIATE LEVEL OF PROTECTION FOR UNEXPECTED LOSS OF COMMUNICATION.

Due to the dynamic nature of commanding and the requirement for good comm and AOS to allow the MCC to properly verify the execution of each DEU equivalent load, there may be times when the ground cannot uplink a required load at a specific time. Because of this, there exists the potential to be in a specific orbiter configuration longer than originally intended. The MCC must have evaluated all associated risks (e.g., comm, thermal, payload constraints, etc.) with these situations and analyzed the cost/benefit tradeoff before proceeding with the uplink of the first load.

Based on the complexity of the desired DEU equivalent load(s) there may or may not be a desire to use a crew alert SPC to wake the crew at some time in the future in case an off nominal situation were to occur. The SPC would be set to time out far enough in advance to allow the MCC to clear it once they were able to verify the correct orbiter configuration after the DEU equivalent execution was complete. The crew should be notified prior to sleep of any potential bailout attitudes in the event they are awakened by an SPC and cannot establish communications with the MCC.

5. DPS DEU EQUIVALENT COMMANDING ARE SATISFIED PER RULE {A7-108}, DEU EQUIVALENT CRITERIA. @[072795-1775A]

FLIGHT RULES

A2-112

PDRS

- A. NORMAL PDRS OPERATIONS WILL CEASE AND THE RMS WILL BE CRADLED IF BACKUP PLUS ONE OTHER SINGLE JOINT MODE IS NOT AVAILABLE TO DRIVE EACH JOINT.

Reference Rule {A12-1}, EVA FOR RMS OPERATION, for rationale.

- B. ANY ORBITER FAILURE THAT REQUIRES A NEXT PLS DEORBIT OPPORTUNITY IS CAUSE TO TERMINATE RMS ACTIVITIES IMMEDIATELY.

In the event of a next PLS situation, the orbiter must be configured for entry as soon as possible, which requires that the RMS be cradled, latched, and stowed prior to PLBD closing. If critical operations are being performed, such as berthing a payload, the situation may allow for those operations to be completed depending on the time available prior to deorbit.

- C. EVA IS CONSIDERED A BACKUP CAPABILITY FOR THE FOLLOWING RMS FUNCTIONS FOR THE ACCOMPLISHMENT OF HIGH PRIORITY OBJECTIVES AS DEFINED IN THE FLIGHT SPECIFIC ANNEX:

1. END EFFECTOR RELEASE.
2. MPM STOW/DEPLOY.
3. MRL LATCHES.
4. SHOULDER BRACE RELEASE.
5. RMS CRADLE.

EVA techniques exist to accomplish the above activities. For high priority objectives, it may be acceptable to continue with the redundant method of accomplishing these operations requiring an EVA. Operating under these conditions is still safe since the arm can be jettisoned if an EVA cannot be performed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-112

PDRS (CONTINUED)

- D. NORMALLY DURING CREW SLEEP PERIODS OF NON-RMS OPERATIONS, THE RMS WILL BE CRADLED AND LATCHED AND THE SYSTEM LEFT IN THE TEMPERATURE MONITOR MODE.

This is the safest configuration should an emergency entry be required and protects against RMS or MRL failures. There is no system constraint against leaving the arm out other than as noted in paragraph E.

- E. CONSIDERATION WILL BE GIVEN TO PARKING THE RMS DURING CREW SLEEP PERIODS IF A PAYLOAD CANNOT BE BERTHED AND DEORBIT IS NOT PLANNED WITHIN 24 HOURS.

In the event of a PRLA failure or some other failure which prevents berthing the payload, the RMS/payload may be positioned and left with the brakes on during crew sleep. Various factors must be considered in order to accept this including payload inertias which have an important effect on DAP stability. In addition, when large payloads are attached to the arm with the brakes on, PRCS control jet firings can result in large arm movements which are not annunciated as failures. MCC must be able to monitor joint movement during the sleep period.

- F. PRIOR TO RMS AND/OR PAYLOAD JETTISON, AN EVA MAY BE PERFORMED TO AID PAYLOAD BERTHING, ARM CRADLE, AND/OR STOWAGE OF THE RMS WHEN ALL OTHER ATTEMPTS HAVE FAILED.

EVA techniques are available for RMS cradle and latch as well as the MPM. In addition, EVA techniques may be possible for releasing, berthing, and latching of the payload in the event of a failed RMS. In essence, this rule gives authority to attempt any method to berth the payload and/or cradle the arm prior to payload and/or arm jettison.

- G. ONCE THE MPM'S ARE DEPLOYED, PROVIDING THERE IS DUAL-MOTOR STOW CAPABILITY, THE MPM'S MAY BE LEFT DEPLOYED UNTIL THE RMS MISSION OPERATIONS ARE COMPLETED.

Reference Rule {A12-142}, EE CAPTURE/RIGIDIZE, for rationale.

Rule {A2-104}, SYSTEMS REDUNDANCY REQUIREMENTS, references this rule.

FLIGHT RULES

A2-113

OMS/RCS DOWNMODING CRITERIA

- A. OMS/RCS DOWNMODING IS DEFINED AS THE CHANGING OF THE OMS/RCS ENGINE CONFIGURATION(S) SO AS TO ALLOW CONTINUATION OF A DELTA V MANEUVER:
1. DUAL REDUNDANCY DOWNMODE (TRIPLE DOWNMODE) PROTECTION IS DEFINED AS THE CAPABILITY TO CHANGE THE BURN CONFIGURATION FROM THE OMS ENGINES TO ONE OMS ENGINE AND FURTHER DOWNMODE TO RCS WHILE STILL RETAINING THE ABILITY TO COMPLETE THE PLANNED MANEUVER.
 2. SINGLE REDUNDANCY DOWNMODE IS DEFINED AS TWO OMS, ENGINES DOWNMODE TO ONE OMS ENGINE, ONE OMS ENGINE DOWNMODE TO RCS, OR RCS RM DOWNMODE TO MAINTAIN TWO $\pm X$ JETS.
- B. DOWNMODING FROM TWO OMS ENGINES TO ONE OMS ENGINE IN RESPONSE TO AN ENGINE FAILURE IS ALLOWED UTILIZING OMS CROSSFEED AS REQUIRED.
- C. FOR ONE OMS ENGINE MANEUVER DOWNMODING TO RCS, THE BURN CAN BE CONTINUED USING OMS PROPELLANT (ON-ORBIT ONLY IF RCS WAS INTERCONNECTED DURING THE OMS BURN) OR RCS PROPELLANT TO RCS JETS AS LONG AS DEORBIT PROPELLANT REQUIREMENTS ARE PROTECTED.

Due to lifetime concerns, single OMS engine burns will be planned when possible in order to increase OMS engine lifetime. Additionally, because a sufficiently large TIG slip capability exists during the orbit-critical burns, utilizing the RCS to provide a downmode capability is reasonable as long as sufficient RCS margin is available to perform the minimum required separation delta V. Declaring the RCS as a viable downmode option decreases the number of times two OMS engines will be scheduled for on-orbit-critical burns (i.e., increases lifetime).

Only the minimum separation delta V is obtained by the RCS to complete the burn (subsequent to an OMS engine failure). Minimum propellant resources are expended to satisfy safety criteria while optimizing remaining propellant (OMS and RCS) available to protect RCS steep deorbit requirements.

On-orbit, downmoding from two $\pm X$ jets to a different set of two $\pm X$ jets by RCS RM is allowable for crew safety-critical burns since the downmode provides the same single failure protection as the OMS/OMS and OMS/RCS downmodes.

FLIGHT RULES

A2-114

OMS/RCS MANEUVER CRITICALITY

- A. DELTA V MANEUVERS CRITICAL FOR CREW SAFETY WILL BE TARGETED SUBJECT TO THE FOLLOWING GUIDELINES:
1. OMS-1, OMS-2, AND DEORBIT BURNS WILL BE PERFORMED USING TWO OMS ENGINES UTILIZING DUAL OR SINGLE-DOWNMODE CAPABILITY (AS AVAILABLE) IF REQUIRED TO MEET DELTA V REQUIREMENTS.
 2. SPACECRAFT SEPARATION BURNS WILL BE PLANNED SUCH THAT A SINGLE-DOWNMODE CAPABILITY (OMS OR RCS) EXISTS TO MEET MINIMUM DELTA V REQUIREMENTS.
- B. FLIGHT SUCCESS DELTA V MANEUVERS ARE DEFINED AS THOSE MANEUVERS ESSENTIAL TO FLIGHT SUCCESS WHICH CANNOT BE POSTPONED BEYOND THE SPECIFIED TIG SLIP. A SINGLE DOWNMODE ACTION WILL BE ACCOMPLISHED IF REQUIRED TO COMPLETE A FLIGHT SUCCESS DELTA V MANEUVER IF A PROPELLANT SYSTEM FAILURE DOES NOT EXIST, AND PROPELLANT IS AVAILABLE TO COVER RCS STEEP DEORBIT DELTA V REQUIREMENTS. @[121296-4213]
- C. NONCRITICAL DELTA V MANEUVERS ARE DEFINED AS ALL THOSE MANEUVERS WHICH DO NOT FALL IN THE CATEGORIES DEFINED IN PARAGRAPHS A AND B. DOWNMODING TO COMPLETE A NONCRITICAL BURN IS NOT ALLOWED.

For all maneuvers critical for crew safety, engine downmode capability is required to maintain fail-safe engine redundancy during the burn. Single OMS engine burns with downmode capability to the RCS +X jets are preferable to dual OMS engine burns, minimizing OMS engine starts, and increasing OMS engine lifetime. Sufficiently large delta V maneuvers such as OMS-1, OMS-2, and the deorbit burn will be performed using two OMS engines in order to avoid any OMS valve reconfiguration during a nominal burn (i.e., crossfeeding halfway through the burn so that OMS propellant remains balanced) and to reduce the amount of OMS propellant required for the burn if the downmode option is utilized.

@[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-114

OMS/RCS MANEUVER CRITICALITY (CONTINUED)

For spacecraft separation burns, downmoding will be performed only to satisfy the minimum delta V requirement necessary to avoid any orbiter damage from the spacecraft PKM firing. Following an OMS engine failure, propellant redlines must be redefined to protect RCS steep deorbit capability and propellant may not be available to complete the separation maneuver to the nominal delta V requirement.

Downmoding will be performed on flight success delta V maneuvers only for OMS engine failures providing preburn analysis shows that sufficient propellant is available to protect RCS steep deorbit delta V requirements. For a propellant system failure or an engine failure and insufficient propellant remaining to protect RCS steep deorbit capability, the burn must be terminated and deorbit will be attempted at the next PLS opportunity. The Flight Rules Annex may redefine the deorbit propellant requirement to allow RCS deorbit to 45-degree prebank targets.

Downmoding will not be performed on noncritical burns so that propellant redlines can be redefined prior to committing propellant to a delta V maneuver unnecessarily.

FLIGHT RULES

A2-115

ENGINE SELECTION CRITERIA

ENGINE SELECTION WILL BE BASED UPON OMS/RCS DOWNMODING CRITERIA, MANEUVER CRITICALITY, AND THE SPECIFIC DELTA V REQUIREMENTS FOR THE MANEUVER:

- A. DELTA V < 6 FPS - PERFORM MANEUVER WITH RCS. DOWNMODING PROTECTION IS PROVIDED BY JET REDUNDANCY.
- B. DELTA V >6 FPS - PREFERENCE WILL BE GIVEN TO SELECTING A SINGLE OMS ENGINE CONFIGURATION VERSUS TWO OMS ENGINES, SUBJECT TO MANEUVER CRITICALITY AND PROCEDURAL COMPLEXITY CONCERNS, IN ORDER TO ACCOMMODATE ENGINE LIFETIME CONSIDERATIONS. RCS MAY BE USED IF APPLICABLE.

For large delta V maneuvers (> 6 fps) OMS engines are selected over RCS jets in order to reduce propellant consumption and minimize burn residuals. RCS jets are used for smaller delta V maneuvers (< 6 fps) to avoid unnecessary OMS engine starts when propellant savings will be negligible. Also, for small OMS burns (< 6 seconds) guidance runs open-loop so postburn residuals may be large. If following these guidelines creates unnecessary procedural complexity (e.g., burns planned originally using the RCS system must be switched real time to OMS burns), it is acceptable to use RCS jets for delta V maneuvers of greater than 6 fps provided the additional propellant necessary is available.

Rule {A2-121E}.3, RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT, references this rule.

FLIGHT RULES

A2-116

RENDEZVOUS (RNDZ)/PROXIMITY OPERATIONS (PROX OPS)
DEFINITIONS

- A. RNDZ OPS ARE DEFINED TO INCLUDE ALL ORBITER RNDZ MANEUVERS AND ASSOCIATED RNDZ ACTIVITIES TERMINATING WITH THE INITIATION OF PROX OPS.
- B. PROX OPS BEGIN AT THE COMPLETION OF RNDZ OPS WHEN THE ORBITER RANGE TO THE TARGET IS <1000 FEET AND THE LVLH RELATIVE VELOCITY IS <1 FPS IN EACH AXIS.

RNDZ OPS utilize closed loop guidance, navigation, and control to achieve a desired relative state. PROX OPS is a post-RNDZ activity where different techniques used to “control” the orbiter trajectory than those used during RNDZ OPS. These techniques rely on crew visual observations and piloting techniques to achieve a desired relative state. These definitions are provided for reference.

FLIGHT RULES

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT

FAILURE TO MAINTAIN THE FOLLOWING CAPABILITIES WILL PRECLUDE APPROACH CLOSER THAN 250 FEET FROM A TARGET. IF THE FOLLOWING CAPABILITY IS NOT MAINTAINED WHILE OPERATING WITHIN 250 FEET OF A TARGET, A MANEUVER TO 250 FEET WILL BE PERFORMED UNTIL THE LOST CAPABILITY CAN BE REGAINED: @[021199-6798A]

- A. ROTATION AND TRANSLATION CAPABILITY IN EACH AXIS. MINIMUM JET REQUIREMENTS FOR TRANSLATION ARE AS FOLLOWS:
1. +X - ONE AFT-FIRING JET IN EACH AFT POD [1] @[081497-6283A]
 2. -X - ONE FORWARD-FIRING JET
 3. ±Y - ONE FORWARD YAW JET PER SIDE, ONE FORWARD DOWN JET PER SIDE, AND ONE AFT YAW JET PER SIDE [3][4]
 4. -Z - ONE DOWN-FIRING JET IN THE FORWARD MODULE AND EACH AFT POD [3][4]
 5. NORMAL +Z - ONE UP-FIRING JET IN THE FORWARD MODULE AND EACH AFT POD
 6. LOW +Z - TWO FORWARD-FIRING JETS AND ONE AFT-FIRING JET PER POD [2]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

NOTES:

- [1] IF THE ORBITER IS UNDER ACTIVE ATTITUDE CONTROL, ONLY ONE JET TOTAL IS REQUIRED, BUT PROPELLANT CONSUMPTION WILL BE GREATER DUE TO RESULTANT CROSS-COUPLING.
- [2] LOW +Z IS DESIRABLE BUT NOT NORMALLY REQUIRED LOW Z ATTITUDE CONTROL IS UNAFFECTED BY LOSS OF THESE JETS.
- [3] DAP LOGIC WILL INHIBIT Y TRANSLATIONS IF BOTH FORWARD SIDE-FIRING OR DOWN-FIRING JETS ON EITHER SIDE ARE NOT AVAILABLE. ©[081497-6283A]
- [4] FOR DOCKING MISSIONS, POST CONTACT THRUST (PCT) REQUIRES ONE FORWARD DOWN-FIRING JET PER SIDE AND ONE DOWN-FIRING JET IN EACH AFT POD (FOUR JETS TOTAL). THESE JET REQUIREMENTS ARE SATISFIED AS LONG AS ±Y AND -Z TRANSLATION CAPABILITIES EXIST. ©[021199-6798A] ©[ED]

If the above capabilities are not maintained outside of 250 feet while approaching a target, proximity operations inside 250 feet will be postponed until reconfiguration regains the lost capability. A minimum range of 250 feet is used because the ISS approach corridor begins at 250 feet, and it would not be prudent to approach within the corridor without full control capability. For other rendezvous targets, this minimum range is somewhat arbitrary, and 250 feet is used for consistency across all rendezvous flights. ©[021199-6798A]

Proximity operations within 250 feet of a target vehicle requires complete rotation and translation capability. Rotation is required for attitude control while maneuvering the orbiter to the target vehicle and can be achieved with either VRCS or PRCS. Translation (PRCS only) is required to properly achieve a relative position to the target vehicle. Satisfying the minimum jet requirements for translation listed above also ensures that full PRCS attitude control is available for both Low Z and Norm Z modes (rotational control requires a subset of the jets used for translation). Failure to maintain full capability could jeopardize crew safety, loads margins, and mission success. The number of jets required for each group is specified.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

Low Z capability is desirable for some target vehicles in order to minimize plume impingement on the target vehicle from the up-firing PRCS jets during attitude hold or +Z translations. ©[081497-6283A]

Low Z is defined in terms of two capabilities:

- a. *Translation: Simultaneous plus and minus X jets will fire in response to a +Z THC command.*
- b. *Attitude control: The DAP will not command any up-firing jets (TAIL-ONLY option for pitch control selected on SPEC 20 is overridden by Low Z, resulting in forward down-firing jets being commanded for pitch-up control). Therefore, one forward down-firing jet on each side and one down-firing jet in each aft pod is required to maintain pitch and roll control (yaw requirements are unchanged). The Low Z mode will be deselected and the DAP will mode to FREE if the IMU ATT DG flag is set BAD.*

Docking missions require Post Contact Thrusting (PCT) for successful capture. PCT capability is ensured as long as the minimum jet requirements for translation listed above are satisfied. ©[021199-6798A]

B. AFT CONTROLLERS REQUIRE AS A MINIMUM ONE CONTACT/CHANNEL PER AXIS (EXCEPT FOR -Z THC WHICH REQUIRES TWO CONTACTS).

The aft RHC is required to have one channel per axis in order to retain complete rotation capability. The loss of the forward RHC is not a constraint due to the difficulty in performing proximity operations from the forward station. The aft THC is required to have at least one contact per axis per direction (i.e., +X, -X, +Y, -Y, +Z, -Z) in order to retain complete translation capability using normal procedures. It is possible in some cases to perform THC operations from the forward station, but exclusive use of the forward station should not be planned.

Reference rationale for paragraph C.2 for the -Z THC.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

C. Z TRANSLATION MUST BE ONE-FAULT TOLERANT. THIS REQUIRES AS A MINIMUM:

1. PLUS Z TRANSLATION

- a. SUFFICIENT JETS TO MAINTAIN +Z TRANSLATION FOR THE LOSS OF ANY SINGLE JET OR MANIFOLD. EITHER NORMAL +Z OR LOW +Z ARE ACCEPTABLE FOR BRAKING AND SEPARATION MANEUVERS.
- b. TWO +Z TRANSLATION CONTACTS. ONE CONTACT IN EACH THC IS REQUIRED IF ONLY TWO CONTACTS REMAINING.

2. MINUS Z TRANSLATION

TWO -Z TRANSLATION CONTACTS FOR ANY THC WHICH IS POWERED ON. ONLY ONE CONTACT IS REQUIRED IF THE OTHER AVAILABLE CONTACT IS FAILED OFF.

+Z translation capability must be retained at all times in order to be able to back away from the target vehicle should failures cause the loss of critical system redundancy. Backing away to 200 feet gives the crew time to reconfigure their systems, if possible, to allow for safe continuation of PROX OPS. Continuing PROX OPS without one-fault tolerance in the +Z translation direction is a risk to the safety of the crew/vehicle should subsequent failures cause the loss of vehicle control in close proximity. One +Z contact is required in each THC to maintain one-fault tolerance, since neither a single contact in one THC nor two contacts on a single THC provide any fault tolerance. If two contacts were on one THC and none on the other, the crew would have insufficient time to resolve and correct a dilemma (should one of the two fail low) thereby providing no-fault tolerance. It is understood in the two-contact case that a fail high of the remaining contact on either THC would result in jets firing to achieve a +Z translation which would cause plume impingement on the payload.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

A fail "on" of the last remaining -Z translation contact in a powered THC will drive the orbiter toward the target with six PRCS jets. Commanding either THC in the +Z direction would cancel the +Z THC output but would not provide the intended backaway since a plus and minus command in the same axis would be algebraically summed to zero resulting in no selected output. Should a failed-on contact occur while prime selected, the flight controller power for the affected THC must be powered off to eliminate the erroneous THC command and allow the crew the capability to command a backaway maneuver along the +Z axis using the other THC. Since there may not be time to accomplish this while in proximity to a target, two contacts for a powered THC are required to be fail-safe (i.e., failure of one contact at the two-level results in a dilemma and therefore no erroneous commanding of jets).

For a fail-off of one of the two remaining contacts there is no single failure which would result in translation toward the target. For this case operating with only one good contact is allowed and the flight controller power can remain on and the sense switch in the preferred position. If one of the last two remaining contacts fails high, however, the next failure (fail-on or comm fault of good contact) will result in translation toward the target. For this case either the flight controller must be powered off or the sense switch placed in a different position to avoid the next failure in the orbiter -Z direction.

It should be noted that for the aft THC different contacts would be involved depending upon which sense is selected and taking into account the fact that, due to a fit problem, the aft THC is installed 90 degrees clockwise. For example, if the -Z sense is selected, the +X THC axis (-Z orbiter translation axis, +X on crew display) must have at least two contacts to be fail safe. If the -X sense is selected, the -Y THC axis (-Z orbiter translation axis, -Y on crew display) must have at least two contacts. For the forward THC, the -Z THC axis must be redundant. If the DAP is in translation NORM, failure of the last -Z contact will command six PRCS jets ON until either the flight controller power is turned off or until either THC is deflected (and held out of detent) in the +Z direction. If the DAP is in translation PULSE, six PRCS jets will fire to achieve the translation rate increment loaded on the DAP CONFIG display. Deflection and release of either THC in the +Z direction will result in another pulse in the -Z direction (toward the target). Subsequent cycling of either THC in the +Z direction will result in more pulses toward the target.

A2-117

RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

- D. TWO IMU'S. (CONSIDERATION WILL BE GIVEN TO CONTINUING NOMINAL V-BAR OPERATIONS WITH ONE IMU.)

Two IMU's are required to commit to TI. Since TI is the first burn which targets for an intercept trajectory, the orbiter systems should be healthy enough to support the requirements of the rendezvous.

Post TI to V-bar arrival (PROX OPS), two IMU's are required to ensure a safe post-breakout trajectory. The RNDZ breakout sequence was not designed to cover trajectory dispersions due to failed IMU accelerometers. The velocity output at the two-level is the average of the two remaining IMU's. If one of the two IMU's has bad velocity output, the state vector will be corrupted. It would be very difficult to quickly determine the damage done to the state vector should one IMU fail. RNDZ sensors may not correct the vector quickly enough to ensure an adequate breakout trajectory.

The RNDZ breakout also uses IMU attitude to correctly perform the breakout. If the IMU attitudes are incorrect, the breakout may not be executed in the proper direction.

Plus or minus R-bar approaches will not be considered on less than two IMU's because of the separation dynamics. For an R-bar approach, the separation sequence requires two burns, the first to ensure no immediate recontact and a second posigrade burn to ensure no long-term recontact concern. The second separation burn requires an IMU to provide the posigrade reference.

PROX OPS imposes similar requirements as the TI to V-bar phase, in that a correct reference is required to correctly perform the breakout. Thus, two IMU's are required to ensure a safe breakout.

One exception to the two-IMU requirement is nominal PROX OPS on the V-bar. The breakout for this situation is a posigrade burn executed manually, and not relying on the IMU's to provide a thrust direction. It is assumed that IMU drift would not take the orbiter far enough out of attitude to degrade the breakout maneuver and the crew can use the Earth horizon as a reference check that the IMU's are good.

Loss of two IMU's is cause to invoke next PLS. This should be the reason for terminating PROX OPS, not that the loss of the last IMU will result in loss of vehicle control. Manual control will still exist with the loss of all IMU's. Loss of IMU reference will mode the DAP to MAN; PULSE in rotation and translation. Low Z will also be automatically deselected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-117 RNDZ/PROX OPS GNC SYSTEMS MANAGEMENT (CONTINUED)

- E. STRINGING SUCH THAT FOR THE LOSS OF ONE GPC THE FOLLOWING FUNCTIONS ARE MAINTAINED:
1. EITHER LOW +Z OR NORMAL +Z TRANSLATION CAPABILITY
 2. IMU REFERENCE (IF TWO IMU'S AVAILABLE)

It is important to remember to string such that a GPC failure can be sustained without loss of +Z translation capability (Low +Z or Normal +Z) for backaway operations or IMU reference.

Two GNC GPC's are required for operations within 200 feet. This requirement is stated in DPS Rule {A2-120}, RNDZ/PROX OPS DPS SYSTEMS MANAGEMENT. While this DPS rule is standalone, the GNC reasons to maintain two GNC GPC's are to retain fail-safe redundancy in the hand controllers and jets.

A2-118 RNDZ/PROX OPS COMMUNICATION SYSTEMS MANAGEMENT

- A. THE KU-BAND SYSTEM WILL BE USED IN RADAR MODE DURING RNDZ/PROX OPS, BUT MAY BE USED IN COMMUNICATIONS MODE DURING PERIODS WHEN RADAR DATA IS NOT REQUIRED. @[061396-1961]

The Ku-band system can be switched between radar and communications mode as necessary.

- B. WHILE IN RADAR MODE, IF THE AZIMUTH ANGLE EXCEEDS 30 DEGREES FROM THE ORBITER -Z AXIS, THE KU WILL BE PLACED IN AUTO TRACK. WHILE IN THIS NO-SEARCH ZONE, A MANUAL SEARCH SHOULD ONLY BE INITIATED UPON MCC GO. @[061396-1961]

Radar scans should not be initiated for beta gimbal angles greater than ± 38 degrees (reference SODB, Communications and Tracking Subsystems - Constraints and Limitations page 3.4.5.2-6). An azimuth angle of 30 degrees satisfies this beta gimbal limit, and is independent of the elevation angle. While in this "No Search Zone," a manual search can be initiated upon evaluation by the MCC of the actual beta gimbal angles.

Reference {A11-16}, KU-BAND MANAGEMENT. @[061396-1961]

FLIGHT RULES

A2-119

RNDZ/PROX OPS SENSOR REQUIREMENTS @[091098-6707B]

- A. DATA FROM THE KU RADAR, -Z/-Y STAR TRACKER, OR COAS (IN ORDER OF PRIORITY FROM HIGHEST TO LOWEST) MUST BE INCORPORATED INTO THE ONBOARD NAVIGATION FILTER DURING DAY OF RENDEZVOUS OPERATIONS BETWEEN NC AND MANUAL TAKEOVER.

The intent of this rule is two fold. First, it identifies that Ku, Star Tracker, and COAS systems are required for rendezvous operations at a higher priority than other users (Comm, IMU align, etc.). Second, it identifies that rendezvous may not be possible within the pre-mission defined limits of the propellant budget without the incorporation of data from one of these systems into the onboard navigation system. Continuation of the rendezvous without having incorporated this data will likely lead to reaching the breakout criteria specified in Rule {A2-126}, RNDZ/PROX OPS BREAKOUT. Rendezvous may be possible without these sensors given a wide margin of error in the propellant budget.

Rendezvous maneuvers prior to the actual day of rendezvous do not require onboard navigation sensors and are targeted strictly off ground-based solutions.

PRIOR TO TI, THE RNDZ MAY BE DELAYED IF REGAINING A HIGHER PRIORITY SENSOR IS POSSIBLE.

Regaining a higher priority sensor will result in a more accurate onboard navigation filter state which will, in turn, result in a higher probability of a successful rendezvous and a more propellant-efficient manual phase. Rendezvous delays up through and including Ti can be achieved with aft propellant usage only and hence may be worthwhile if doing so allows for the recovery of a more accurate rendezvous sensor, resulting in the savings of forward propellant during the manual phase. Rendezvous Delay is described in Rule {A2-125}, RNDZ OPS DELAY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-119

RNDZ/PROX OPS SENSOR REQUIREMENTS (CONTINUED)

- B. THE KU SYSTEM, IF AVAILABLE, WILL BE CONFIGURED FOR RADAR OPERATIONS DURING MANUAL PHASE UNTIL THE CDR DEEMS THAT IT IS NOT REQUIRED TO SUPPORT PILOTING OPERATIONS GIVEN THE AVAILABILITY OF OTHER RANGING SENSORS (HHL OR TCS). AT THIS TIME, THE KU SYSTEM MAY BE CONFIGURED FOR COMM.

The Ku radar system is the prime range/range rate sensor during the manual phase until reliable HHL or TCS data becomes available. @[091098-6707B]

- C. COAS NAVIGATION CONSTRAINTS @[031500-7178A]

1. THE -Z COAS MUST BE CALIBRATED PRIOR TO EXECUTING COAS NAV.

COAS mounting errors are significant enough (typically 0.5 deg) to result in unacceptable navigation performance if COAS marks are taken with an uncalibrated COAS. The calibration is no longer valid if the cabin pressure changes significantly, such as a depress from 14.7 to 10.2 psi.

2. VERNIER ATTITUDE CONTROL IS REQUIRED TO PERFORM COAS NAV.

PRI jets provide coarser control than VERN's. The coarse control degrades the performance of COAS nav due to one or more of the following factors: 1) fewer marks can be taken in the limited time available, 2) less accurate marks can be taken, and 3) larger trajectory perturbations due to increased cross coupling of rotation into translation. In addition, PRI control can use significantly more propellant. Given the degraded performance and the potential use, more propellant analysis has shown that it is better to continue the rendezvous without performing COAS nav.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-119

RNDZ/PROX OPS SENSOR REQUIREMENTS (CONTINUED)

3. UNLESS THE CREW IS TOLD TO PROCEED WITH COAS NAV ALMOST IMMEDIATELY AFTER COMPLETING THE TI BURN, IT IS NOT AVAILABLE AS A SENSOR DOWNMODE OPTION.

The act of taking COAS NAV marks perturbs the trajectory. To overcome this effect, the COAS NAV pass must be long enough to ensure that an adequate number of marks are taken to converge the onboard nav state. Rather than attempting to determine through analysis the latest time that COAS NAV could be started, an operationally acceptable limit was defined and all analysis was performed using this limit. To be consistent with the analysis, the first COAS NAV mark must be taken no later than $T_i + 10$ minutes. Because there are several events that must happen between T_i and taking the first COAS mark, such as completing the T_i burn, OMS gimbal check, maneuver to -Z axis target track, ground uplink of COAS NAV covariance matrix, and step 1 of the COAS NAV procedure, the crew must be instructed to perform COAS NAV almost immediately after T_i . ©[031500-7178A]

4. IF COAS NAVIGATION IS EXECUTED, DO NOT EXECUTE MC1 OR THE OUT-OF-PLANE NULL. ©[031500-7178A]

There is not enough time between T_i and MC1 to take enough COAS marks to generate a converged nav state in support of MC1. Analysis indicates it is better to forego MC1 and take COAS nav through that time to get a good, converged nav state to support the MC2 burn.

COAS nav is not accurate enough to support execution of an out-of-plane null burn. The Y and Ydot on SPEC 33 will be quite dynamic from one COAS mark to the next and it is best to delay any out-of-plane control until the manual phase where more accurate sensors and visual observation can be used to null the out-of-plane motion.

Constraints 1, 2, 3, and 4 were presented to and approved by Orbit Flight Techniques Panel #175 on July 9, 1999. ©[031500-7178A]

FLIGHT RULES

A2-120

RNDZ/PROX OPS DPS SYSTEMS MANAGEMENT

- A. THREE GNC GPC'S ARE PREFERRED FOR RNDZ/PROX OPS. TWO GNC GPC'S ARE REQUIRED AT TI AND WITHIN 250 FEET OF THE TARGET VEHICLE: ©[021199-6798A]

Three GNC GPC's are preferred for rendezvous/prox ops to simplify recovery procedures if a GNC GPC fails during the period when rendezvous nav is enabled. If a GNC GPC fails, a restricting to the remaining two GPC's recovers all LRU redundancy, still meets rendezvous GPC requirements, and does not affect rendezvous nav functions as long as the target set is not changed.

TI is the starting point for requiring redundant GNC GPC's because this is the first burn which puts the orbiter on an intercept course with the target. This means that continuous control of the orbiter is required to preclude a collision with the target. Single fault-tolerance for control of braking and separation maneuvers is required, and redundant GNC GPC's meet this requirement. Prior to TI, the orbiter is not on an intercept course and momentary loss of control is not critical; therefore, single fault-tolerance is not required.

1. FOR LOSS OF ONE GNC GPC OUT OF A TWO GNC GPC REDUNDANT SET WHEN FURTHER THAN 250 FEET FROM TARGET, RECONFIGURATION TO A TWO-GNC REDUNDANT SET WILL BE DELAYED TO THE NEXT OPERATIONALLY CONVENIENT POINT.

The crew is very busy flying the manual phase of rendezvous operations. Reconfiguration would interfere (and may promote errors) with the manual task and, therefore, will be delayed to the next convenient point as long as the orbiter-to-target distance is greater than 250 feet.

2. LOSS OF ONE GNC GPC OUT OF A TWO GNC GPC REDUNDANT SET DURING PROX OPS WITHIN 250 FEET WILL RESULT IN A BACKOUT MANEUVER AWAY FROM THE TARGET OUT TO A DISTANCE OF 250 FEET UNTIL RECONFIGURATION TO A TWO-GNC REDUNDANT SET IS COMPLETED.

The fail-safe status afforded by two GNC GPC's is required for close proximity of the orbiter to other objects. Loss of one of the two GNC GPC'S within 250 feet is reason to terminate PROX OPS and back away from the target due to the possibility of vehicle contact with the target on the next failure (no longer fail-safe). A distance of at least 250 feet provides a safety margin before attempting to reconfigure.

©[021199-6798A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-120

RNDZ/PROX OPS DPS SYSTEMS MANAGEMENT (CONTINUED)

3. FOR LOSS OF ONE GNC GPC OUT OF A THREE GNC GPC REDUNDANT SET DURING PROX OPS, RESTRING TO REMAINING TWO GNC GPC'S WHEN POSSIBLE.

When starting with a three GNC GPC set, loss of a single GPC is not critical. A simple restring can be performed to regain the lost string(s) without disruption of rendezvous nav operations. With the standard stringing configuration for three GPC's (ref. Rule {A7-102C}.2.b, PASS DATA BUS ASSIGNMENT CRITERIA) loss of a single GPC does not require immediate action.

- B. IN A TWO GNC GPC SET CONFIGURATION FOR GNC OR SM GPC FAILURES, THE FREEZE-DRY GPC (G2FD) MAY BE RECONFIGURED AS GNC OR SM. IF G3 ARCHIVE HAS BEEN LOST AND A G3FD GPC HAS BEEN CONFIGURED, THE G3FD MAY BE GIVEN UP IF TWO G3 SOURCES (MMU 1, MMU 2) ARE AVAILABLE.

Recovery of a redundant GNC GPC is done to provide fail-safe vehicle control during rendezvous or PROX OPS. Recovery of an SM function is done to provide rendezvous radar antenna initialization, insight into or control of payloads, and GPC control for PDRS usage. The G2FD GPC may be given up without regard to the number of available sources of entry software because of G3 archive capability as long as there are two other sources of PASS G3 software. Two sources are considered to be an adequate level of redundancy for obtaining G3 software.

Reference Rule {A7-201C}, DPS REDUNDANCY REQUIREMENTS.

- C. IN A THREE GNC GPC SET CONFIGURATION FOR AN SM GPC FAILURE, ONE OF THE GNC GPC'S MAY BE RECONFIGURED AS AN SM GPC.

Since only two GNC GPC's are required for providing a fail-safe capability during the critical maneuvers of RNDZ/Prox Ops, it is allowable to give up one of the three GNC GPC's to recover the SM function.

FLIGHT RULES

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT

A. RNDZ/PROX OPS ACTIVITIES WILL BE TERMINATED AND A BREAKOUT MANEUVER WILL BE PERFORMED WHEN PROPELLANT AVAILABLE DECREASES TO THE TOTAL OF:

1. DEORBIT REDLINES:

- a. OMS DEORBIT REDLINE (REF. RULE {A6-303A}, OMS REDLINES [CIL]).
- b. FRCS DEORBIT REDLINE (REF. RULE {A6-304A}, FORWARD RCS REDLINES).
- c. ARCS ENTRY REDLINE (REF. RULE {A6-305}, AFT RCS REDLINES).

OMS and RCS deorbit redlines must be protected in order to continue any on-orbit operations. Violation of these redlines is cause to enter at the next PLS opportunity. Note that per Rule {A2-108}, CONSUMABLES MANAGEMENT, the weather wave-off extension day may be deleted in favor of critical on-orbit/payload activities. ©[092800-7247A]

2. PROPELLANT REQUIRED FOR ORBITER MAINTENANCE (ATTITUDE CONTROL -ZLV -XVV OR THERMAL PROTECT ATTITUDE IF REQUIRED, 1 DEGREE VRCS, ONE IMU ALIGN/DAY) FOR 1 DAY.
©[051194-1612A]

Following either a successful or aborted rendezvous, propellant must be available for attitude control until the next PLS deorbit opportunity (which could be up to 24 hours away).

3. RNDZ/PROX OPS BREAKOUT/SEPARATION MANEUVER.

If it is necessary to abort a rendezvous attempt when in close proximity to the target, a breakout maneuver is required in order to establish a safe separation rate from the target. The exact nature of the breakout maneuver is dependent upon the relative position to the target, but the maneuver usually entails several RCS translations. Also, for a successful rendezvous, a separation maneuver (e.g., ISS Joint Expedited Undock and Sep) may be required to safely separate from the target prior to deorbit. Thus, the worst case breakout propellant requirements will be covered in the terminate quantities.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT (CONTINUED)

4. HIGHER PRIORITY ACTIVITIES (REF. RULE {A2-108}, CONSUMABLES MANAGEMENT).

Propellant must be available to complete all post-rendezvous activities of higher priority than the rendezvous in order to continue with the rendezvous. Activities are listed in order of priority in Rule {A2-108}, CONSUMABLES MANAGEMENT. ©[092800-7247A]

5. PROPELLANT REQUIRED TO COVER RETURN OF THE PAYLOAD INCLUDING: ©[092800-7247A]

- a. X OR Y CG BALLAST (IF REQUIRED).

For payloads planned on being berthed in the payload bay, either for repair and redeploy or for return to Earth, OMS or RCS propellant may be required as ballast in order to maintain the orbiter CG within the acceptable envelope as outlined in Flight Rule {A4-153}, CG PLANNING.

- b. THERMAL PROTECT ATTITUDE AS REQUIRED.

Certain payloads may have thermal constraints which would necessitate maintaining the orbiter in attitudes and/or deadbands that require more than the nominal -ZLV 1 degree deadband propellant allocation. This item also applies to any payload planned on being berthed in the payload bay either temporarily or for return. ©[051194-1612A]

- c. INCREASED DEORBIT VEHICLE WEIGHT (INCLUDES WEIGHT OF PAYLOAD).

OMS propellant required for deorbit will be calculated using the vehicle weight with the payload on board unless the payload is incapable of being returned to earth (in which case the separation maneuver must be protected in paragraph 3 above). This guarantees enough propellant to deorbit safely with the payload onboard. This propellant requirement, if applicable, may be mutually exclusive with the rndz/prox ops breakout maneuver, so only the greater of the two must be protected. ©[092800-7247A]

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT
(CONTINUED)

- B. IF EITHER FORWARD OR AFT QUANTITIES DECREASE TO THE RNDZ/PROX OPS TERMINATION QUANTITIES, THEN IT IS ACCEPTABLE TO ADJUST REDLINES BY THE USE OF NOSE-ONLY OR TAIL-ONLY PRCS CONTROL FOR ACTIVITIES (INCLUDING NON-RENDEZVOUS ACTIVITIES) NOMINALLY PLANNED FOR NOSE/TAIL CONTROL.

Certain activities budgeted using nose/tail control may be switched to tail-only control if the aft propellant is available. These activities include the deorbit wave-off extension day included in the OMS/RCS deorbit redlines, deorbit preparation, and one day of attitude control. Nose-only pitch/yaw control may also be utilized when aft propellant is critical. The breakout maneuver may not be adjusted.
@[051194-1612A]

- C. TO CONTINUE RNDZ OPS, PROPELLANT MUST BE AVAILABLE TO COVER THE "GO FOR TI" AS DEFINED IN PARAGRAPH I AND THE MCC PREDICTED REQUIREMENTS FOR THE REMAINING MANEUVERS UP TO TI.

In order to continue a rendezvous, propellant must be available to ensure a reasonable chance of completion. When it is clear that adequate propellant is not available to complete a "best day" rendezvous, RNDZ OPS should be terminated and propellant can be made available for lower priority activities which would have been canceled in order to complete the rendezvous. The "GO for TI" requirements represent the minimum amount of propellant required to complete a rendezvous from TI through target retrieval. Propellant required to complete all of the required phasing maneuvers up to TI is also covered here, based upon maneuver delta V's as calculated by the Flight Dynamics Officer. Because the "Continue RNDZ Ops" quantities are based on minimum propellant requirements from TI through grapple, rendezvous maneuvers may continue to be performed with only a minimal chance of a successful rendezvous.

- D. RENDEZVOUS WILL NOT BE ATTEMPTED IF THE FRCS IS NOT AVAILABLE. @[092800-7247A]

FRCS propellant is necessary in order to maintain attitude in close proximity to the target (stationkeep). The FRCS is also required to perform a safe breakout maneuver. Without the FRCS it is not safe to remain in close proximity to the target. Additionally, terminal phase requires frequent small multi-axis translations which are not practical without the FRCS.

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT (CONTINUED)

- E. THE FOLLOWING GUIDELINES WILL BE USED WHEN EXECUTING RENDEZVOUS BURNS UP TO AND INCLUDING TI:
1. IF TOTAL DELTA V IS LESS THAN 4 FPS, BURN WILL BE PERFORMED MULTI-AXIS.
 2. IF TOTAL DELTA V IS BETWEEN 4 AND 6 FPS, A MANEUVER TO BURN ATTITUDE MAY BE PERFORMED AND THE BURN ACCOMPLISHED USING AFT RCS +X JETS.
 3. IF TOTAL DELTA V IS GREATER THAN 6 FPS, THE BURN MAY BE ACCOMPLISHED USING OMS ENGINE(S). OMS ENGINE GUIDELINES ARE ESTABLISHED PER FLIGHT RULE {A2-115B}, ENGINE SELECTION CRITERIA. (AFT RCS +X MAY BE USED IF MARGINS EXIST.)

The above guidelines for rendezvous burn execution have been established to ensure optimum use of OMS and RCS propellant. These guidelines are incorporated in the Rendezvous Flight Data File to assist the crew in burn execution and can be overridden by the MCC depending upon OMS/RCS propellant margins/system problems.

- a. Because the crew has no way to determining the forward RCS contribution to the rendezvous burn, the 4 fps criteria (equates to 2 fps forward RCS usage) was established to determine if a maneuver to burn attitude is required.*
- b. With rendezvous burns between 4 and 6 fps the attitude maneuver will be performed and the burn accomplished using aft RCS +X jets. This is performed to increase fwd RCS propellant availability. The OMS engines are not used because guidance is locked out if the OMS burns are 6 seconds or less (6-second countdown is used).*
- c. OMS engine(s) will be used if delta V requirements are greater than 6 fps (per Flight Rule {A2-115B}, ENGINE SELECTION CRITERIA, guidelines). Aft RCS +X jets may be used straight feed or interconnected if propellant margins exist.*

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT (CONTINUED)

- F. IF RENDEZVOUS MANEUVERS, UP TO AND INCLUDING TI, ARE TARGETED TO USE MORE THAN 2 FPS (50 LB) FROM THE FORWARD RCS, A MANEUVER TO BURN ATTITUDE MAY BE PERFORMED SO THAT THE BURN WILL BE ACCOMPLISHED USING OMS OR AFT RCS PROPELLANT.

During rendezvous/PROX OPS mission profiles, the forward RCS system is usually propellant-critical with the aft RCS and OMS systems having sufficient margins. It is usually desirable to save as much forward RCS propellant as possible to maximize the chances for mission success (rendezvous completion) without altering the planned mission profile (deletion of mission events). Rendezvous burns that require more than 2 fps (50 lb) from the forward RCS will normally incorporate a maneuver to burn attitude. Burn targets will be computed by onboard software, and the burn performed using aft RCS or OMS propellants to minimize forward RCS use. (Maneuvering to and from the burn attitude takes approximately 6 lb (VRCS) and 17 lb (PRCS).) Since attitude maneuvers can disturb the orbiter state vector, which is critical during rendezvous profiles, the decision to maneuver will be a tradeoff between disturbing the orbiter state and saving forward RCS. If forward RCS mission completion redline margins allow a multi-axis burn, a maneuver to burn attitude may not be required. The 2 fps (50 lb) constraint was selected to provide a compromise between increasing forward RCS propellant availability and avoiding excess maneuvering. ©[092800-7247A]

- G. NOSE/TAIL PRIMARY JET CONTROL WILL BE SELECTED POST-NCC BURN FOR THE LOSS OF VERNIER JET CONTROL CAPABILITY.

Nose/tail control is required post-NCC in order to maintain coupled jet firings for rotational attitude control. With nose-only or tail-only rotational attitude control, translation is induced which may significantly impact predicted TI and midcourse corrections.

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT
(CONTINUED)

- H. TO BE GO FOR TI DELAY, PROPELLANT MUST BE AVAILABLE TO COVER THE TOTAL OF:
1. TERMINATION QUANTITIES AS DEFINED IN PARAGRAPH A.
 2. ORBITER MAINTENANCE FOR THE DELAY PERIOD (USUALLY ONE OR TWO ORBITS).
 3. MCC PREDICTED TI-DELAY PLUS NEW TI USAGE.
 4. MEAN USAGE FROM POST-TI TO R-BAR, OR AS SPECIFIED IN THE FLIGHT RULE ANNEX. @[021199-6706B] @[092800-7247A]
 5. MEAN USAGE FROM R-BAR TO GRAPPLE/DOCK, IF SCHEDULED, OR AS SPECIFIED IN THE FLIGHT RULE ANNEX.

Delaying TI may be desired when time is required to better understand an orbiter problem. From a propellant standpoint, delaying TI is only acceptable when the delay does not significantly impact the chance of a successful rendezvous. For this reason, mean propellant usages are covered in this rule from post-TI through grapple as opposed to the minimum usages covered in the "GO for TI" call. Additional propellant is also required to perform a maneuver (usually at the nominal TI opportunity) to maintain a safe distance from the target for the period of the delay and to perform a subsequent TI burn. If insufficient propellant exists to be GO for TI delay, then either a breakout maneuver must be performed or the reason to delay TI must be waived. It is not acceptable to reduce the TI delay requirement by going to minimum usages for terminal phase and PROX OPS. The Flight Rules Annex is referenced in order to identify the details of the manual phase profile.

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT
(CONTINUED)

- I. TO BE GO FOR TI, PROPELLANT MUST BE AVAILABLE TO COVER THE TOTAL OF
1. TERMINATION QUANTITIES AS DEFINED IN PARAGRAPH A.
 2. USAGE FOR MCC PREDICTED TI.
 3. MEAN MINUS 3 SIGMA USAGE POST-TI TO R-BAR ARRIVAL.
@[021199-6706B] @[092800-7247A]
 4. MEAN MINUS 3 SIGMA USAGE FROM R-BAR ARRIVAL THROUGH GRAPPLE/DOCK. @[021199-6706B] @[092800-7247A]

The "GO for TI" propellant requirements are based upon the minimum amount of propellant required to complete a rendezvous prior to the TI burn. Mean minus 3 sigma protection based on Monte Carlo analysis provides a slim chance at being able to complete the rendezvous. If any chance exists that the rendezvous can be successfully completed, TI will be performed and the rendezvous will be continued until the terminate quantities are violated or violation of the terminate quantities becomes imminent in accordance with this rule and paragraph A. @[092800-7247A]

- J. POST-TI, IF THE NEXT PLANNED MANEUVER VIOLATES THE TERMINATION QUANTITIES AS DEFINED IN PARAGRAPH A, THE RENDEZVOUS WILL BE TERMINATED.

When it is obvious that termination quantities will be violated before completion of the rendezvous, there is no reason to continue the rendezvous.

- K. FOR DEPLOY/RELEASE MISSIONS TO BE GO FOR FREE FLYER RELEASE/RETRIEVE, PROPELLANT MUST BE AVAILABLE TO COVER THE TOTAL OF:
1. TERMINATION QUANTITIES AS DEFINED IN PARAGRAPH A.
 2. ORBITER MAINTENANCE FOR THE PLANNED DURATION OF FREE FLIGHT.
 3. MCC PREDICTED DELTA V FOR PAYLOAD SEPARATION AND REQUIREMENTS FOR THE REMAINING MANEUVERS THROUGH TI.
 4. AT LEAST MEAN USAGE POST-TI TO R-BAR (UP TO MEAN + 3 SIGMA USAGE PER FLIGHT RULES ANNEX).
 5. AT LEAST MEAN USAGE FROM THE R-BAR THROUGH GRAPPLE (UP TO MEAN + 3 SIGMA USAGE PER FLIGHT RULES ANNEX).

Before releasing a retrievable free flyer (e.g., SPARTAN), propellant must be available to ensure a reasonable likelihood of the return of the free flyer. As such, at least mean usage will be covered for all rendezvous maneuvers and PROX OPS activities. The Flight Rules Annex may redefine this requirement to require enough propellant to complete a rendezvous with up to 3-sigma usage. ©[021199-6706B]

- L. DURING A FAILED GRAPPLE/DOCKING ATTEMPT, TO PROTECT A RE-RENDEZVOUS CAPABILITY ON A SUBSEQUENT FLIGHT DAY, PROPELLANT MUST BE AVAILABLE TO COVER THE TOTAL OF: ©[021199-6706B]

The quantities indicated below are intended to provide guidelines for use after a failure to grapple/dock or during a grapple/docking attempt that is not proceeding smoothly. These quantities are required to entertain the option of a re-rendezvous on a subsequent day. These numbers can be used to generate a "re-rendezvous bingo" quantity at which grapple/dock activities should be terminated for that day and a separation burn performed. Once the separation burn is performed and the re-rendezvous sequence is underway, propellant minimums to complete the re-rendezvous are outlined in Paragraph I of this rule.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT
(CONTINUED)

If propellant quantities are below the re-rendezvous bingos, then re-rendezvous is most likely not possible and the ongoing attempts to grapple/dock should continue until a successful grapple/docking is achieved or the terminate quantities as indicated in Paragraph A of this rule are reached.

1. TERMINATION QUANTITIES AS DEFINED IN PARAGRAPH A.

Propellant must be protected to break out from the subsequent rendezvous, to provide a safe deorbit, and allow for the completion of higher priority mission activities.

2. MCC PREDICTED USAGE TO TERMINATE CURRENT GRAPPLE/DOCK ACTIVITIES AND SEPARATE.

Predicted usage to terminate the ongoing grapple/dock activities is based on a real-time assessment of these activities. For example, if a flyaround alignment is underway in an attempt to grapple a rotating free-flyer, propellant to arrest the orbiter's rotation rate, maneuver to the separation burn attitude, and separate must be protected. The separation burn will consist of the appropriate breakout per Rule {A2-126C}, RNDZ/PROX OPS BREAKOUT.

3. MCC PREDICTED DELTA V FOR THE RE-RENDEZVOUS MANEUVERS THROUGH TI.

Mean re-rendezvous propellant costs are included in the flight specific rendezvous propellant budget (Rndz-03 Flight Design product). ©[021199-6706B] ©[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-121

RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT (CONTINUED)

4. AT LEAST MEAN USAGE POST-TI THROUGH GRAPPLE/DOCK. BASED ON A REAL-TIME ASSESSMENT OF GRAPPLE/DOCKING ACTIVITIES, UP TO MEAN + 3 SIGMA USAGE MAY BE PROTECTED. ©[021199-6706B]

At least mean usage is protected for all rendezvous maneuvers and prox ops activities to ensure a reasonable chance of being able to re-rendezvous. Protecting only minimum usage post-Ti through grapple/docking is not recommended as it would significantly reduce the probability of being able to re-rendezvous before reaching the propellant terminate quantities while only reducing the propellant requirements by approximately 200 lb (1/3 fwd and 2/3 aft). In fact, depending on propellant availability and a real-time assessment of the ongoing grapple/dock activities, it may be prudent to protect more than mean propellant (up to 3 sigma) for all re-rendezvous maneuvers and prox ops activities. For example, if the ongoing grapple/docking activities have little chance for success due to the nature of the problem, then separating with 3 sigma protection will maximize prop availability for the subsequent grapple/docking attempt after troubleshooting steps have been performed. However, if a successful grapple/docking is imminent, then continuing below 3 sigma protection may allow the grapple/docking to be completed without assuming the risk of a re-rendezvous attempt. Protecting 3 sigma usage post-Ti through grapple/dock increases the propellant minimums by approximately 200 lb over mean usage (1/3 fwd and 2/3 aft). Post-Ti through grapple/dock prop costs (mean and sigmas) are included in the flight specific rendezvous propellant budget (Rndz-03 Flight Design product). ©[092800-7247A]

5. CONTINGENCY PROX OPS PROPELLANT AS APPROPRIATE GIVEN THE NATURE OF THE FAILURE.

Depending on the nature of the difficulty that led to the failure to grapple/dock, additional propellant should be protected for prox ops contingencies during the subsequent grapple/docking attempt (i.e. orbiter/target flyaround alignment, extended stationkeeping, etc.). Propellant requirements for contingency prox ops activities are included in the flight specific rendezvous propellant budget (Rndz-03 Flight Design product).

6. ORBITER ATTITUDE MAINTENANCE FOR THE PLANNED DURATION OF FREE FLIGHT THROUGH GRAPPLE/DOCK.

Propellant for orbiter attitude maintenance during the re-rendezvous sequence must be protected.
©[021199-6706B]

FLIGHT RULES

A2-122

RENDEZVOUS MANEUVERS

- A. THE GROUND WILL COMPUTE TARGETS FOR ALL MANEUVERS UP TO AND INCLUDING TI. ADDITIONALLY, THE GROUND WILL PROVIDE THE INITIAL ORBIT TARGETING BASETIME (TI TIG) USED FOR NCC, TI, AND MC1 MANEUVERS.
- B. THE ORBITER WILL COMPUTE TARGETS FOR NCC AND SUBSEQUENT MANEUVERS. THE ORBITER WILL REDEFINE THE ORBIT TARGETING BASETIME (MC2 TIG) FOR THE MC2, MC3, AND MC4 MANEUVERS.

NOTE: FLIGHT SPECIFIC MANEUVER DEFINITIONS AND TARGETING CRITERIA ARE SPECIFIED IN THE FLIGHT RULE ANNEX (THE ANNEX FLIGHT RULE, ORBITAL MANEUVER CRITICALITY). ©[ED]

Because of its relative navigation capability (ST, COAS, and RR), the orbiter is considered prime for all maneuvers from NCC to intercept. Typical criteria for TIG selection and maneuver targeting are given in the table. It should be emphasized that these data are flight-specific I-loads to orbit targeting (SPEC 34).

For pre-NCC maneuvers, the ground is the only system capable of targeting rendezvous maneuvers; due to software, orbit targeting (SPEC 34) can only target two-impulse maneuvers. The rendezvous maneuver sequence is designed to allow orbit targeting to compute NCC and subsequent maneuvers because the orbiter relative navigation systems can provide the most accurate states for the orbiter and target. For NCC and TI, the ground will provide an independently targeted solution for comparison with the orbiter solution. The solution will be selected per Rule {A2-123}, RENDEZVOUS MANEUVER SOLUTION SELECTION CRITERIA.

The NCC, TI, and MC1 maneuvers are scheduled relative to the initial basetime (TI TIG), which is usually a few minutes prior to orbital noon. This time is provided by the ground because the orbiter does not have the capability to compute it. For MC2, MC3, and MC4, the orbiter will redefine the basetime (MC2 TIG) automatically with orbit targeting. MC2 must be targeted at least once for this to occur.

FLIGHT RULES

A2-123

RENDEZVOUS MANEUVER SOLUTION SELECTION CRITERIA

- A. GROUND SOLUTIONS WILL BE EXECUTED FOR ALL MANEUVERS UP TO NCC.

Reference Rule {A2-122}, RENDEZVOUS MANEUVERS, for rationale.

- B. THE SOLUTIONS FOR THE NCC AND TI MANEUVERS WILL BE SELECTED ACCORDING TO THE FOLLOWING PRIORITIES:

1. ONBOARD FILTER SOLUTION IF, FOR THE PRESENT SENSOR IN ACQUISITION (RR, ST), 40 NAVIGATION MARKS HAVE BEEN ACCEPTED WITH A STATE VECTOR POSITION UPDATE LESS THAN 0.5K FEET FOR THE LAST FOUR MARKS. IF COAS, THIS CRITERION DOES NOT APPLY (REF. PARAGRAPH B.2).

The onboard filtered solution, with sufficient relative navigation data incorporated, consists of the most accurate and current relative state information and, therefore, should be considered the best solution. Sufficient navigation data is indicated by premission analysis to be greater than 40 marks in the current sensor pass and position updates of less than 0.5k feet for the last four measurement cycles. This is not the definition of the absolute best solution, but it ensures that the onboard solution will be more accurate than ground solution. Four consecutive marks with state vector position errors less than 0.5k feet was added to this criterion to eliminate transient effects and to ensure stability in the filtered state.

Obtaining and incorporating 40 COAS navigation marks are unrealistic, time-consuming, manual tasks. Statistical studies show that, after the first few COAS marks, updates to the filtered state are random and do not significantly contribute to the knowledge of the relative state. Therefore, since the COAS can never meet these criteria for sufficient navigation data, proceeding to paragraph B.2 forces a comparison with the ground solution.

2. ONBOARD FILTERED SOLUTION IF IT AGREES WITH THE GROUND SOLUTION.

NOTE: MANEUVER SOLUTIONS ARE DEFINED TO BE IN AGREEMENT IF, FOR EACH AXIS, THE DELTA V DIFFERS BY NO MORE THAN THE PREMISSION ONBOARD MINUS GROUND 3 SIGMA COMPARISONS LIMITS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-123

RENDEZVOUS MANEUVER SOLUTION SELECTION CRITERIA (CONTINUED)

3. ONBOARD PROPAGATED SOLUTION IF IT AGREES WITH THE GROUND SOLUTION.

NOTE: MANEUVER SOLUTIONS ARE DEFINED TO BE IN AGREEMENT IF, FOR EACH AXIS, THE DELTA V DIFFERS BY NO MORE THAN THE PERMISSION ONBOARD MINUS GROUND 3 SIGMA COMPARISONS LIMITS.

The onboard filtered and propagated solutions will be better than the ground solution because they will have been computed on at least the ground initialization state vector plus any IMU-sensed delta velocities. These solutions may contain additional improvements:

- a. *The filtered solution, even without sufficient relative navigation data as defined in paragraph B.1, will be as good or better than the propagated or ground solutions because it may have some relative navigation data incorporated in it.*
- b. *The propagated solution will be as good as or better than the ground solution because it may have been computed on a filtered state vector containing relative navigation data from a previous sensor pass that has been saved via a filter to propagator transfer.*

4. GROUND SOLUTION.

Agreement with the ground solution serves as a gross quality check for the onboard solution and, therefore, only needs to fall within the 3-sigma comparison limits.

The ground solution would be performed as a last resort.

- C. ONBOARD SOLUTIONS WILL BE EXECUTED FOR POST-TI MIDCOURSE MANEUVERS.

The ground has no capability to improve the relative state information between the orbiter and target for the midcourse correction maneuver computations. This is due to ground tracking uncertainties and the relatively close proximity of the two vehicles. Hence, the orbiter solution for these maneuvers will always be selected.

Rule {A2-122}, RENDEZVOUS MANEUVERS, references this rule.

FLIGHT RULES

A2-124**RENDEZVOUS MANEUVER EXECUTION**

- A. ALL MANEUVERS COMPONENTS WILL BE TRIMMED TO VGO < 0.2 FPS IN ALL AXES.

Based on flight experience, the required trim, < 0.2 fps, is the best trim accuracy achievable by the crew on a consistent basis. This accuracy is required during rendezvous to keep deviations from premission and real-time planned profiles to a minimum.

- B. MIDCOURSE MANEUVERS, MC1, MC2, AND MC3, AS WELL AS THE OUT-OF-PLANE NULL WILL ALWAYS BE EXECUTED. @[021199-6732]

Midcourse maneuvers are designed to correct the orbiter intercept trajectory based on the most current relative state information. Even with no additional relative state sensor data, these maneuvers correct for trim errors from previous burns and attitude maneuver effects that are sensed via the accelerometers. Additionally, executing MC1 reduces the probability of experiencing targeting alarms and/or significant TIG slips at MC2 as a result of these dispersion effects. Executing MC2 with its elevation angle constraint reduces dispersions at the manual phase take-over point. The radar fail correction burn "rule of thumb" used in the radar fail procedures at MC3 + 2 min is most valid when the MC3 burn is executed, resulting in a more benign manual phase and slightly lower prop usage (ref. Orbit Flight Techniques #166 on June 26, 1998). The out-of-plane null is performed when the orbiter is at the out-of-plane node which is the optimum point to null out-of-plane motion.

This rule is a result of the implementation of the ORBT Rendezvous Profile baselined during Orbit FTP #161, February 14, 1997.

- C. MC4 WILL NOT BE PERFORMED IN RADAR FAILED CASES.

The radar fail procedures have the CDR begin manual piloting immediately after MC3, so MC4 should not be performed in this case. The onboard navigation state is not accurate enough to support a targeted intercept of the R-bar when the radar is failed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-124

RENDEZVOUS MANEUVER EXECUTION

IN THE EVENT THAT RADAR DATA BECOMES AVAILABLE POST-MC2, THE DATA MAY BE INCORPORATED INTO THE NAV FILTER BUT WILL NOT BE USED FOR ORBITER POINTING OR TARGETING. RADAR FAILED PROCEDURES WILL CONTINUE TO BE PERFORMED UNLESS MCC DEEMS THAT THE ONBOARD RELATIVE STATE IS SUFFICIENTLY CONVERGED AND THAT THE TRAJECTORY WOULD BENEFIT FROM A TARGETED MC4 BURN.
@[021199-6732]

In the event that a previously failed (or unavailable) radar system becomes available after MC2, then radar failed procedures will continue to be executed including the MC3 + 2 minute radar failed correction burn based on target position in the -Z COAS. Since the radar failed correction burn is dependent on orbiter pointing (i.e., position of target in -Z COAS), the radar data may be incorporated into the FLTR vector only if the PROP vector has been selected as the UPP source on RelNav (SPEC 33) so as not to impact the target track attitude. At this point, the radar failed procedures are at least as good as executing MC3 and MC4 off an onboard relative state that may not be completely converged. The ground has the authority to return the crew to nominal MC3 and MC4 targeting making use of the new radar sensor data if it can be shown in real time that the onboard relative state is sufficiently converged and the trajectory would benefit from targeted burns. In general, targeted burns will benefit trajectories that are short of the targeted MC4 point while radar failed procedures are better suited for long trajectories. @[021199-6732]

This rule is a result of the implementation of the ORBT Rendezvous Profile baselined during Orbit FTP #161, February 14, 1997.

D. LAMBERT GUIDANCE BURNS MUST BE COMPLETED BY T1 TIG + 90 SECONDS. @[121296-4112A] @[021199-6732]

1. IF THE START OF A BURN IS DELAYED SUCH THAT IT CANNOT BE COMPLETED BY T1 TIG + 90 SECONDS, THE BURN WILL BE RETARGETED PRIOR TO STARTING THE BURN.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-124

RENDEZVOUS MANEUVER EXECUTION

2. IF A BURN IN PROGRESS IS NOT COMPLETE (I.E., VGO'S STILL > 0.2 FPS) BY T1 TIG + 90 SECONDS, THC INPUTS WILL BE STOPPED AND THE BURN WILL BE RETARGETED PRIOR TO COMPLETION.

Due to limitations in the onboard guidance software, Lambert guided burns should be completed within 90 seconds of the T1 TIG. This constraint is necessary because errors in the Lambert guidance solution increase as the time between T1 TIG and burn completion increases. At T1 TIG + 90 seconds, the worst case errors can be slightly larger than trim errors (0.2 fps) and can grow rapidly after that.

@[121296-4112A]

Flight history shows that rendezvous burns are usually complete 30 to 40 seconds after burn start. With rare exceptions, a burn started soon after TIG should be easily completed by T1 TIG + 90 seconds. If the start is delayed to the point its completion by T1 TIG + 90 seconds is in doubt, the burn should be retargeted prior to execution. When retargeted, the onboard software automatically computes a new T1 TIG equal to "current time + 1 minute." The burn must now be completed by the new T1 TIG + 90 seconds. In the unlikely event that a burn was started on time but not completed at T1 TIG + 90 seconds, THC inputs should be terminated and the burn retargeted prior to completion.

Because T1 TIG can be easily reset to a future time by simply retargeting the burn, this rule places no constraint on the total time a burn can slip past the planned TIG. The total slip capability is determined by the MCC on a burn by burn basis and is usually constrained by: 1) excess propellant usage; 2) Lambert targeting/guidance constraints that are not addressed in this rule, such as 180 degree transfers; or 3) links to ground targeted maneuvers such as the link between Ti and Ti delay. Other unique constraints are also possible.

Error in the burn solution arises from the fact that Lambert Cyclic Guidance (LCG) models the effects of gravitational oblateness (J2) in a fashion inconsistent with Lambert Targeting. This inconsistency and its effects on guidance performance are thoroughly documented in the references listed below. Reference Rockwell Transmittal Form # 660-NAV-710-96-037, "Lambert Cyclic Guidance Error Analysis," J.L.Goodman, 13 May 1996; and Rockwell Transmittal Form # D250-300-24, "STS-69 SPARTAN NCC Burn Guidance Performance," J.L.Goodman, 27 Sept 1995. @[121296-4112A]

FLIGHT RULES

A2-125

RNDZ OPS DELAY

- A. FOR DELAYS PRIOR TO TI, IF CONVENIENT, THE NOMINAL MANEUVERS WILL BE ADJUSTED TO SLOW PHASING SO THAT THE ORBITER ARRIVES AT THE TI POINT AT THE DESIRED DELAY TIME. OTHERWISE, THE NOMINAL RENDEZVOUS PLAN WILL BE EXECUTED UNTIL TI WHERE A DELAY WILL BE DONE.

The most efficient way, from a propellant standpoint, to delay a rendezvous is to slow the catch-up rate such that the orbiter will rendezvous with the target at the desired time, in an integral number of orbits. Desirable lighting conditions will be maintained since there is an integral number of orbits. This can be done at any preplanned phasing maneuver (NC), typically with no propellant penalty, or an additional maneuver can be inserted into the rendezvous profile. Mission activities and propellant budgets will determine which option to use.

In order to efficiently perform a phasing adjustment, an apogee point must be available prior to TI where the perigee can be raised and the catchup rates slowed. Any point other than apogee will necessitate a larger burn and fuel consumption. Communication availability and time to adjust the maneuver must also be considered. If any problems in these areas arise, it is no longer convenient to adjust phasing, and a TI delay should therefore be executed.

- B. FOR SHORT TI DELAYS (ONE OR TWO ORBITS), MANEUVERS WILL BE EXECUTED TO RETURN TO THE TI POINT WITH THE DESIRED LIGHTING CONDITIONS. FOR LONG TI DELAYS (GREATER THAN TWO ORBITS), MANEUVERS WILL BE EXECUTED TO GUARANTEE A SAFE OPENING RATE OF AT LEAST 1 NM PER ORBIT.

TI is the last convenient point to delay the rendezvous. This delay may be desirable to recover lost capability prior to committing to intercept. For short delays, the ground will compute a phasing maneuver to return to the TI position based on the most current onboard relative state. Desirable lighting conditions will be maintained since there is an integral number of orbits between the original and new TI maneuvers.

A long delay requires an opening rate to eliminate the need for the crew to continuously monitor the target. Long delays usually involve at least one crew sleep cycle. In this case, if propellant is available, the delay maneuver is targeted to a point in the following morning equivalent to where the original final phasing maneuver was executed. This range minimizes the possibility of awakening the crew to execute a trajectory control maneuver; shorter ranges may require interruption of crew sleep. In this manner, the second rendezvous trajectory will be similar to the original trajectory.

There is a propellant penalty for executing a TI delay. The magnitude of this penalty is dependent on the specific mission profile and delay scenario.

Rule {A2-119}, RNDZ/PROX OPS SENSOR REQUIREMENTS, references this rule. ©[091098-6707B]

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT

- A. PRIOR TO TI, A GROUND-COMPUTED BREAKOUT MANEUVER WILL BE EXECUTED, IF NECESSARY, TO GUARANTEE A SAFE MISS DISTANCE BETWEEN THE ORBITER AND TARGET.

Prior to Ti, dispersions and the lack of a standard rendezvous profile prevent designing a "canned" breakout maneuver. The ground will compute a maneuver, if required, to ensure the orbiter avoids the target by a safe distance. Possibly not executing a preplanned rendezvous maneuver will provide an acceptable miss distance.

- B. BETWEEN TI AND STABLE AT 500 FEET ON THE +RBAR, THE BREAKOUT MANEUVER WILL BE A 3-FPS RETROGRADE MULTI-AXIS MANEUVER. INITIATION OF THIS MANEUVER WILL BE AS FOLLOWS: @[091098-6705A] @[040899-6799C]

A single 3-fps retrograde breakout maneuver is required between Ti and the point of stability at 500 feet on the +Rbar to ensure safe relative motion. Prior to visual acquisition of the target and commencement of the manual phase, this maneuver provides an orbiter CG to target CG miss distance of at least 500 feet (to allow for vehicle dimensions) based on Monte Carlo analysis. The 3-sigma dispersion ellipse will maintain at least a 500-foot miss distance if the breakout is initiated due to failure to acquire the target per the sub-parts below.

After visual acquisition of the target, the pilot is allowed to continue the rendezvous to the manual takeover point and begin to affect the relative motion of the orbiter with respect to the target via manual piloting techniques. This breakout should still provide safe relative motion all the way to Rbar arrival assuming the manual phase has been flown in a nominal manner (i.e., the braking gates have been followed and the target has been maintained within the COAS). However, after the manual phase has commenced, it is the responsibility of the CDR to ensure that the breakout is adequate and positive clearance with the target exists. Assuming a nominally flown manual phase, this maneuver provides an orbiter CG to target CG miss distance of approximately 370 ft if executed at the minimum 500 ft range. This satisfies the "rule of halves" groundrule and constraint for separations which, for this case, would require at least a 250 ft miss distance. @[040899-6799C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-126****RNDZ/PROX OPS BREAKOUT (CONTINUED)**

A maneuver to burn attitude is prohibited because of the delay in initiating the maneuver and the loss of target acquisition while still on an intercept trajectory. Since this retrograde breakout maneuver can occur anytime from T_i through R_{bar} arrival and the orbiter is in a -Z target track attitude, propellant to cover the breakout maneuver for the range of orbiter attitudes during the terminal phase must be protected. Worst case prop usage for this breakout maneuver is 80 lb fwd (at R_{bar} arrival) and 40 lb aft (45 deg below V_{bar}). Prop requirements for the maneuver are independent of the Low Z transition range since the breakout maneuver will be a pure -X burn when the orbiter is in the Low Z regime.

@[091098-6705A]

1. FOR INSUFFICIENT PROPELLANT OR ORBITER CONTINGENCIES REQUIRING BREAKOUT, THE BREAKOUT CAN BE INITIATED ANYTIME POST-TI. IF POSSIBLE, THE BREAKOUT SHOULD BE INITIATED BETWEEN MC1 AND MC2.

Since relative perigee occurs between MC1 and MC2, the effects of the retrograde maneuver will be maximized.

@[091098-6705A]

2. IF NO TARGET SENSOR DATA (RR, ST, COAS) HAS BEEN INCORPORATED INTO NAV AND UTILIZED FOR BURN EXECUTION DURING THE RENDEZVOUS, THE BREAKOUT MANEUVER MUST BE EXECUTED WITH TIG NO LATER THAN MC2+20 MINUTES UNLESS THE TARGET IS ACQUIRED VISUALLY OR WITH THE RADAR.

@[091098-6705A]

With no target sensor data, the actual relative position between the orbiter and the target is not known with sufficient accuracy to warrant completion of the rendezvous. The breakout maneuver may be delayed to a point no later than MC2+20 minutes to allow the maximum time for crew visual acquisition of the target while maintaining the 3 sigma miss distance of 500 ft.

Note that this breakout point will be operationally implemented 2 minutes earlier than defined in this rule to provide enough time for the crew to execute the Rendezvous Breakout procedure such that TIG occurs at MC2+20 min per this rule.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

3. IF GOOD TARGET SENSOR DATA (RR, ST, COAS) HAS BEEN INCORPORATED INTO NAV AND UTILIZED FOR BURN EXECUTION DURING THE RENDEZVOUS, THE BREAKOUT MANEUVER MUST BE EXECUTED WITH TIG NO LATER THAN MC2+24 MINUTES UNLESS THE TARGET IS ACQUIRED VISUALLY OR WITH THE RADAR.

With good target sensor data, trajectory dispersions are reduced, and as a result, the breakout maneuver may be delayed beyond MC2+20 min (per paragraph 2) to a point no later than MC2+24 minutes while still providing an acceptable miss distance. "Good" sensor data means that at least one full star tracker pass has occurred prior to MC2 resulting in small state vector updates. The quality of the sensor pass will be evaluated in real time by the MCC, and the go to delay the breakout point from MC2+20 min to MC2+24 min will be per ground call. Note that the MC2+20 min point will always occur in orbital daylight, so this extra 4 minutes is not particularly valuable (it is very unlikely that the target would be visually acquired at MC2+24 min but not visually acquired at MC2+20 min). Time from MC2 is used as a reference since the MC2 TIG is variable.

Note that this breakout point will be operationally implemented 2 minutes earlier than defined in this rule to provide enough time for the crew to execute the Rendezvous Breakout procedure such that TIG occurs at MC2+24 min per this rule. ©[091098-6705A]

4. IF THE TARGET IS ACQUIRED VISUALLY OR WITH THE RADAR PER PARAGRAPHS 2 OR 3 ABOVE AND IT IS MORE THAN 30 DEG FROM THE ORBITER -Z AXIS, THE BREAKOUT MANEUVER SHOULD BE EXECUTED. IF MISSION DURATION DOES NOT ALLOW FOR THE POSSIBILITY OF RERENDEZVOUS, THEN THE MANUAL APPROACH MAY CONTINUE ON A BEST EFFORT BASIS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

Even if the crew visually acquires the target, certain off-nominal cases, particularly no sensor cases, can lead to trajectory dispersions that are unrecoverable via manual piloting techniques, or the manual recovery will expend more prop than a breakout and rendezvous. Target displacement from the orbiter -Z axis is a key indicator to the dispersed nature of the trajectory and hence the flyability of the approach. Target displacement of 30 deg or more is significantly greater than that seen in the 3-sigma radar fail trajectories used in the generation of the rendezvous propellant budget, and it would not be prudent to continue with the rendezvous in this case if a rendezvous capability exists. Rendezvous on another day provides the opportunity to troubleshoot the sensor/systems problems that led to the failure of the first rendezvous or to adjust rendezvous timing and procedures to maximize ground navigation effectiveness in an effort to increase the probability of a successful rendezvous. If mission duration cannot accommodate a rendezvous, the approach may continue on a best effort basis with a high probability that the rendezvous cannot be completed due to exceedance of propellant bingo constraints.

This rule is a result of the implementation of the ORBT Rendezvous Profile baselined during Orbit FTP #161, February 14, 1997. ©[091098-6705A]

C. THE SHUTTLE NOSE IN-PLANE BREAKOUT MAY BE EXECUTED WHEN THE SHUTTLE STATE SATISFIES THE FOLLOWING CONDITIONS: ©[040899-6799C]

SHUTTLE IS WITHIN 500 FT (CG TO CG) OF THE TARGET VEHICLE.

SHUTTLE X AND Z BODY AXES ARE IN THE ORBITAL PLANE OF THE TARGET VEHICLE.

THE TARGET VEHICLE IS IN A STABLE POSITION ON THE SHUTTLE -Z AXIS. ©[040899-6799C]

THE IN-PLANE BREAKOUT MANEUVER SEQUENCE WILL BE AS FOLLOWS: ©[040899-6799C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

1. IF WITHIN 75 FT INTERFACE TO INTERFACE, THE SHUTTLE CREW WILL NULL THE CLOSING RATE, THEN BACK OUT BY INITIATING AND MAINTAINING AT LEAST 0.1 FT/SEC OPENING RATE WHILE MAINTAINING THE TARGET VEHICLE POSITIONED NEAR THE SHUTTLE -Z BODY AXIS.

For ranges inside 75 ft, a backout must be initiated to provide adequate clearance to complete the breakout sequence. For ISS flights, this would involve performing a Corridor Backout.

2. WHEN RANGE IS GREATER THAN 75 FT INTERFACE TO INTERFACE, PERFORM AT LEAST A 1.5 FPS BURN IN THE "CLOCKWISE" DIRECTION (+X ORBITER BODY BURN IF OMICRON IS 0, -X ORBITER BODY BURN IF OMICRON IS 180 DEGREES). FOLLOWING THE BURN, MODE TO INERTIAL HOLD.

This X burn results in the orbiter opening from the target vehicle. Moding the DAP to INRTL results in an orbiter attitude profile that, when coupled with the relative motion, maintains the target vehicle near the orbiter -Z body axis. This relative orientation minimizes plume loads on the target when the DAP is in Low Z mode. The 1.5 fps burn was sized to ensure that the orbiter is at least 1000 ft from the target after 22 min at which time Low Z is deselected and the maneuver to attitude for the next burn commences. Since this breakout exposes the target vehicle to possible direct PRCS firings just outside of 1000 ft, it is not adequate for target vehicles that require Low Z protection outside 1000 ft.

3. AT 30 MINUTES AFTER THE $\pm X$ BURN, PERFORM A 3 FPS OUT-OF-PLANE AND 3.5 FPS POSIGRADE/RETROGRADE BURN USING THE +X RCS JETS. AT 22 MINUTES AFTER THE $\pm X$ BURN, DESELECT LOW Z AND INITIATE THE MANEUVER TO BURN ATTITUDE.

This final burn needs to be performed 30 minutes after the $\pm X$ burn to provide a safe trajectory. The size of this burn (4.6 ft/sec RSS) was designed to provide a safe trajectory for all initial conditions that satisfy the conditions of applicability for this breakout. The breakout also allows for the selection of either a posigrade or retrograde component to provide flexibility for subsequent mission objectives. The burn combines the out-of-plane and posigrade/retrograde components and is performed as a +X burn with a maneuver to attitude in order to save propellant. Time is allotted to allow a worst case 180 deg maneuver to attitude at 0.5 deg/sec. @[040899-6799C]

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

- D. THE RBAR BREAKOUT MAY BE EXECUTED WHEN THE SHUTTLE STATE SATISFIES THE FOLLOWING CONDITIONS: @[040899-6799C]

SHUTTLE IS WITHIN 500 FT (CG TO CG) OF THE TARGET VEHICLE.

SHUTTLE X AND Z BODY AXES ARE IN THE ORBITAL PLANE OF THE TARGET VEHICLE.

THE SHUTTLE IS POSITIONED ON THE ±RBAR WITH THE TARGET VEHICLE IN A STABLE POSITION ON THE SHUTTLE -Z BODY AXIS.

THE RBAR BREAKOUT MANEUVER SEQUENCE WILL BE AS FOLLOWS:

1. IF WITHIN 75 FT INTERFACE TO INTERFACE, THE SHUTTLE CREW WILL NULL THE CLOSING RATE, THEN BACK OUT BY INITIATING AND MAINTAINING AT LEAST 0.1 FT/SEC OPENING RATE WHILE MAINTAINING THE TARGET VEHICLE POSITIONED NEAR THE SHUTTLE -Z BODY AXIS.

For ranges inside 75 ft, a backout must be initiated to provide adequate clearance to complete the breakout sequence. For ISS flights, this would involve performing a Corridor Backout.

2. WHEN RANGE GREATER THAN 75 FT INTERFACE TO INTERFACE, PERFORM A 3 FPS +X OR -X TRANSLATION.

This +X or -X burn results in either retrograde or posigrade motion relative to the target vehicle. The direction of the burn should be selected based on subsequent mission objectives. The burn will result in the orbiter phasing away from the target vehicle at approximately 8 nm/rev. @[040899-6799C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

E. THE VBAR BREAKOUT MAY BE EXECUTED WHEN THE SHUTTLE STATE SATISFIES THE FOLLOWING CONDITIONS: @[040899-6799C]

SHUTTLE IS WITHIN 500 FT (CG TO CG) OF THE TARGET VEHICLE.

SHUTTLE X AND Z BODY AXES ARE IN THE ORBITAL PLANE OF THE TARGET VEHICLE.

THE SHUTTLE IS LOCATED ON THE ±VBAR WITH THE TARGET VEHICLE IN A STABLE POSITION ON THE SHUTTLE -Z BODY AXIS.

THE VBAR BREAKOUT MANEUVER SEQUENCE WILL BE AS FOLLOWS:

1. IF WITHIN 75 FT INTERFACE TO INTERFACE, THE SHUTTLE CREW WILL NULL THE CLOSING RATE, THEN BACK OUT BY INITIATING AND MAINTAINING AT LEAST 0.1 FT/SEC OPENING RATE WHILE MAINTAINING THE TARGET VEHICLE POSITIONED NEAR THE SHUTTLE -Z BODY AXIS.

For ranges inside 75 ft, a backout must be initiated to provide adequate clearance to complete the breakout sequence. For ISS flights, this would involve performing a Corridor Backout.

2. WHEN RANGE GREATER THAN 75 FT INTERFACE TO INTERFACE, MODE TO INERTIAL HOLD AND PERFORM A 1 FPS RADIAL BURN WITH THE +X OR -X JETS. IF THE SHUTTLE IS ON THE +VBAR, PERFORM THE BURN RADIAL UP. IF THE SHUTTLE IS ON THE -VBAR, PERFORM THE BURN RADIAL DOWN.

This +X or -X burn results in a trajectory that lofts the orbiter above (for +Vbar) or below (for -Vbar) the target. Moding the DAP to INRTL results in an orbiter attitude profile that, when coupled with the relative motion, maintains the target vehicle near the orbiter -Z body axis in order to protect the target vehicle from jet plume loads during the subsequent burn.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

3. AT 22 MINUTES AFTER THE RADIAL BURN, PERFORM A 3 FPS +X OR -X TRANSLATION.

This +X or -X burn results in either retrograde or posigrade motion relative to the target vehicle. The direction of the burn should be selected based on subsequent mission objectives. The burn will result in the orbiter phasing away from the target vehicle at approximately 8 nm/rev. ©[040899-6799C]

- F. THE FLYAROUND BREAKOUT MAY BE EXECUTED WHEN THE SHUTTLE STATE SATISFIES THE FOLLOWING CONDITIONS:

SHUTTLE IS WITHIN 500 FT (CG TO CG) OF THE TARGET VEHICLE.

SHUTTLE X AND Z BODY AXES ARE IN THE ORBITAL PLANE OF THE TARGET VEHICLE.

THE SHUTTLE IS PITCHING AT A CONSTANT RATE LESS THAN 0.2 DEG/SEC WITH THE TARGET VEHICLE IN A STABLE POSITION ON THE SHUTTLE -Z AXIS.

THE FLYAROUND BREAKOUT MANEUVER SEQUENCE WILL BE AS FOLLOWS:

1. CONTINUE FLYAROUND PROCEDURE TO NEXT RBAR CROSSING.
2. PERFORM A 3 FPS +X OR -X PRCS TRANSLATION.

The simplest and most expedient way to break out from a flyaround is to continue the flyaround to the next Rbar crossing and perform a single +X or -X burn, resulting in either retrograde or posigrade motion relative to the target vehicle. The direction of the burn should be selected based on subsequent mission objectives. If it is desirable to minimize the use of forward propellant when performing the breakout, then performing the Shuttle Nose In-Plane Breakout (paragraph C) may be better depending on the orientation of the orbiter during the flyaround and the desired breakout direction.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

G. IF A BREAKOUT IS DESIRED ASAP AND THE SHUTTLE STATE DOES NOT SATISFY THE CONSTRAINTS OF PARAGRAPHS C THROUGH F, THEN PERFORM THE FOLLOWING 1-2-3 BREAKOUT (AKA SEP MANEUVER, ORB OPS CHECKLIST):

1. MANUALLY ROTATE THE ORBITER SUCH THAT THE TARGET IS VISIBLE THROUGH THE OVERHEAD WINDOW.

The target must be positioned near the orbiter -Z axis so that the crew can acquire it with either the KU radar or the HHL and null any closing rate with orbiter +Z translations. @[040899-6799C]

2. NULL ANY CLOSING RATE AND ESTABLISH A 1 FPS OPENING RATE IN NORM Z. THIS BURN MAY BE PERFORMED IN LOW Z (ON MCC CALL, IF PROP AVAILABLE) IN ORDER TO PROVIDE PLUME PROTECTION TO THE TARGET VEHICLE. @[040899-6799C]

This 1 fps opening rate ensures short term relative motion will not result in a collision with the target vehicle. Although use of Low Z for this burn provides plume protection to the target vehicle, the prop requirements are so high that it should only be performed in Low Z if MCC deems that prop is available to support it.

3. 22 MIN AFTER THE 1 FPS OPENING BURN, PERFORM A 2 FPS MULTI-AXIS OUT-OF-PLANE BURN IN NORM Z. IN TIME CRITICAL SITUATIONS, THIS BURN CAN BE PERFORMED 2 MIN AFTER THE OPENING BURN.

Since this 2 fps out-of-plane burn is performed multi-axis, it is possible that a significant component of the burn will be directed at the target vehicle. Waiting 22 minutes to perform this burn maximizes the out-of-plane separation of the orbiter from the target as a result of the initial opening burn, thus minimizing plume impingement on the target vehicle. In time critical situations, however, this out-of-plane burn can be performed almost immediately after the initial opening burn with the possibility of significantly pluming the target vehicle. Use of Norm Z is required to avoid the excessive cross-coupling resulting from performing a multi-axis burn in Low Z.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-126

RNDZ/PROX OPS BREAKOUT (CONTINUED)

4. 15 MIN AFTER THE OUT-OF-PLANE BURN, PERFORM A 3 FPS POSIGRADE BURN IN NORM Z.

Coasting 15 min after execution of the 2 fps out-of-plane burn results in the orbiter moving approximately 1500 ft out-of-plane, well outside the Low Z range for most target vehicles. Burning posigrade will then allow the orbiter to phase behind the target to set up for a subsequent rendezvous, if desired. Three fps ensures that the resultant posigrade component after the completion of the 1-2-3 burn sequence is at least 2 fps, which provides a safe separation rate of approximately 5 nm/rev. ©[040899-6799C]

THIS BREAKOUT IS NOT PROTECTED IN THE RNDZ/PROX OPS TERMINATE QUANTITY. ©[040899-6799C]

Plume impingement analysis does not protect for breakout scenarios. However, all the above prox ops breakout sequences have been designed to use "common sense" piloting techniques to minimize plume impingement on the target vehicle and provide safe relative motion. The breakouts outlined in paragraphs C through F are optimized to cover the nominal operating regimes of the orbiter while in proximity operations. If outside these normal regimes, then the breakout procedure described in paragraph G (ref. SEP MANEUVER, Orbit Ops Checklist) will provide safe relative motion for any initial condition at the cost of more propellant and possible plume impingement of the target vehicle. Propellant for this breakout will not be protected given the extremely low probability of requiring such a breakout (ref. Flight Rule {A2-121}, RNDZ/PROX OPS PROPULSION SYSTEMS MANAGEMENT). Furthermore, it is typically more propellant efficient to fly the orbiter to a state that satisfies the constraints of one of the paragraphs C through F, then execute the applicable breakout. The above breakouts were approved at a Splinter Generic Orbit Flight Techniques meeting held on March 26, 1999. ©[040899-6799C]

FLIGHT RULES

A2-127

RENDEZVOUS GUIDANCE

- A. THE ONBOARD ORBITER AND TARGET NAVIGATION STATES WILL BE INITIALIZED BY GROUND UPLINK PRIOR TO INITIATION OF RNDZ NAVIGATION.

An onboard software restriction prohibits enabling rendezvous navigation if the timetag of the target state vector is older than 15 hours. The target state vector timetag I-load is zero; therefore, without a ground uplink of the target state vector, rendezvous navigation cannot be enabled.

It is also desirable for both the ground and the onboard to have the most accurate orbiter and target state vectors available, hence the most accurate relative state vector to initialize rendezvous navigation for the first navigation sensor tracking interval. This allows the filter to rapidly determine the "true" state and prevents undesirable transients caused by large updates.

- B. THE PROPAGATED STATE VECTOR WILL BE SELECTED FOR USER PARAMETER PROCESSING (UPP) STATE VECTOR UNTIL THE BEGINNING OF THE FIRST RELATIVE TRACKING INTERVAL. THE FILTER STATE VECTOR WILL BE SELECTED:
1. IF 10 ST MEASUREMENTS HAVE BEEN ACCEPTED WITH THE LAST STATE VECTOR POSITION UPDATE <1.0K FEET, OR,
 2. IF 10 RR MEASUREMENTS HAVE BEEN ACCEPTED WITH THE LAST STATE VECTOR POSITION UPDATE <0.3K FEET, OR,
 3. IF 3 COAS MEASUREMENTS HAVE BEEN ACCEPTED.

Accepting 10 ST or RR measurements prior to selecting the filtered state vector for the UPP prevents filtered vector transients from reaching the UPP. This delay also allows the crew time to take appropriate action to prevent the use of a filtered state which may have incorporated bad measurements. Since COAS processing takes longer, only three marks are taken prior to selecting the filtered state vector.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-127

RENDEZVOUS GUIDANCE (CONTINUED)

- C. FOR ALL TRACKING INTERVALS, MEASUREMENT INCORPORATION WILL BE INHIBITED PRIOR TO SENSOR ACQUISITION.

Inhibiting data prior to sensor acquisition prevents marks from being immediately incorporated. This allows the crew time to assess the quality of the sensor data prior to its incorporation into the filtered state vector.

- D. ST MEASUREMENTS WILL NOT BE INCORPORATED INTO THE FILTERED STATE UNTIL PROPER TARGET LOCK IS VERIFIED. IF AFTER FOUR CONSECUTIVE MEASUREMENT CYCLES (31 SECONDS), THE RESIDUAL VALUES CHANGE <0.05 DEGREE PER CYCLE AND THE RATIO VALUES ARE <1.0 , THEN THE AUTO/INHIBIT/FORCE OPTION FOR ANGLES WILL BE SELECTED TO AUTO.

In target track attitude hold, the target should remain essentially stationary in the ST field of view; a star will have an angular rate of 0.5 degree per cycle. If the residuals are continuously changing by more than 0.05 degree per cycle, the object being tracked is most likely a star. Monitoring four consecutive measurement cycles (31 seconds) allows the data quality to be assessed and ensures that the ST has not locked onto a false target.

- E. RR MEASUREMENTS WILL BE INCORPORATED INTO THE FILTERED STATE AS FOLLOWS. IF AFTER FOUR CONSECUTIVE MEASUREMENT CYCLES (31 SECONDS) THE RESIDUAL VALUES ARE STABLE AND THE RATIO VALUES ARE <1.0 THEN THE AUTO/INHIBIT/FORCE OPTION WILL BE SELECTED TO AUTO. RADAR DATA WILL NOT BE INCORPORATED INTO NAVIGATION AT RANGES GREATER THAN 135K FEET.

Four consecutive measurement cycles (31 seconds) allow transients to settle and the crew to assess the quality of the data. Stable measurements are an indirect indication that the radar sensor is locked onto the target with the main lobe instead of a side lobe. Ratios <1.0 indicate that the measurements, if accepted by selecting AUTO, will not be rejected by the navigation filter. At ranges greater than 135k feet, the radar range becomes biased due to eclipsing of the return signal.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-127

RENDEZVOUS GUIDANCE (CONTINUED)

F. WHENEVER EITHER RR ANGLE EXCEEDS 30 DEGREES FROM THE -Z AXIS, RADAR ANGLE MEASUREMENTS WILL BE INHIBITED.

Angle data is considered valid only within a 30-degree half-cone of the -Z axis.

G. THE FOLLOWING PRIORITIZED ACTIONS WILL BE TAKEN IF SUCCESSIVE SENSOR MEASUREMENTS ARE REJECTED BY RESIDUAL EDITING (RATIO VALUES >1.0) AT THE START OF A TRACKING INTERVAL:

1. BREAK LOCK AND REACQUIRE TARGET (ST ONLY).

If residual editing continuously occurs, most likely the ST has either locked onto a star, has a malfunction, or very large relative state errors are present. To prevent bad measurements from being incorporated into the filtered state vector, breaking lock and reacquiring the target is the desirable first step since it does not update anything in the relative navigation state.

2. REINITIALIZE COVARIANCE.

If the covariance matrix has been reduced (e.g., measurement incorporation, wrong covariance uplinked), reinitializing the covariance will expand it and allow larger updates to be incorporated into the filtered state. Incorporating these larger updates should correct the relative state vector which will stop the residual editing.

3. FORCE UP TO THREE MEASUREMENTS.

If covariance reinitialization is not sufficient to prevent residual editing, data can be forced into the filtered state. Three consecutive measurements should correct the relative state vector sufficiently to stop the residual editing. If measurements continue to be edited, a generic problem may exist; and forcing more measurements, most likely, will not improve the situation.

4. FILTER RESTART (PROPAGATOR TO FILTER TRANSFER).

A filter restart eliminates all data incorporated into the filtered state vector since the last filtered to propagated state vector transfer. This is a last resort procedure to correct the rendezvous navigation relative state.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-127

RENDEZVOUS GUIDANCE (CONTINUED)

- H. FOR ALL BUT THE INITIAL TRACKING INTERVAL, A FILTERED TO PROPAGATED STATE VECTOR TRANSFER WILL BE PERFORMED AFTER SUCCESSFUL SENSOR LOCK-ON TO THE TARGET BUT PRIOR TO DATA INCORPORATION.

A filtered to propagated state vector transfer is done to maintain a good backup state vector (propagated) for restart purposes in the event that the filtered state vector subsequently incorporates bad sensor data. Sensor lock-on is an independent means of evaluating the filtered state vector prior to executing the transfer. A transfer is not required prior to the first sensor pass because the filtered state vector and the propagated state vector are identical at that time.

- I. IF FILTER MINUS PROPAGATOR CHANGES BY MORE THAN 40K FEET WITHIN AN ST PASS, THEN ALL OF THE FOLLOWING WILL BE DONE:
1. SELECT PROPAGATED STATE VECTOR FOR UPP.
 2. INHIBIT ANGLES.
 3. FILTER RESTART (PROPAGATED TO FILTERED STATE VECTOR).
 4. BREAK TRACK AND USE NOMINAL PROCEDURES TO REACQUIRE.

If filtered minus propagated state changes by more than 40k feet during a single ST pass, the ST data is considered bad and has corrupted the filtered state. These actions will recover rendezvous navigation to a point equivalent to the beginning of the ST tracking interval.

FLIGHT RULES

A2-128

EMCC/TMCC ACTIVATION

IN THE EVENT THAT THE EMERGENCY MISSION CONTROL CENTER (EMCC) OR TEMPORARY MISSION CONTROL CENTER (TMCC) MUST BE ACTIVATED, THE FLIGHTCREW WILL BEGIN ORDERLY TERMINATION OF ANY PAYLOAD-RELATED OR HAZARDOUS ACTIVITY. WHEN THE ACTIVITY HAS BEEN TERMINATED, THE ORBITER WILL BE MANEUVERED TO +XVV, -ZLV AND REMAIN IN THIS ATTITUDE UNTIL FURTHER INSTRUCTIONS FROM THE EMCC/TMCC. FLIGHT SPECIFIC EXCEPTIONS AND CRITERIA FOR ORDERLY TERMINATION MAY BE IDENTIFIED IN THE FLIGHT SPECIFIC ANNEX.

When the EMCC or TMCC is required to be utilized, a major portion of the real-time telemetry monitoring, flight planning, and data analysis capability provided by the MCC is not available. In addition, the capability to provide payload data to the POCC/payload customer may be lost. With the loss of these MCC capabilities, the ground cannot provide adequate support to safely execute a nominal flight plan and must use the reduced facilities provided by the EMCC/TMCC to monitor orbiter systems. The selected attitude is thermally benign and restrictions on attitude maneuvers significantly reduces the support required for ground monitoring.

FLIGHT RULES

A2-129

ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS

THE ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS ARE SUMMARIZED BELOW. PAYLOAD DATA SHALL BE GIVEN UP IF REQUIRED TO SATISFY THE ORBITER HIGH DATA RATE REQUIREMENT. IF HIGH DATA RATE CANNOT BE ACHIEVED DUE TO SYSTEMS PROBLEMS, THE LISTED ACTIVITIES MAY STILL BE ACCOMPLISHED.

ORBITER OPERATION	HIGH DATA RATE REQUIREMENT [1]

FLIGHT RULES

A2-129

ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS
(CONTINUED)

NOTES:

- [1] HIGH DATA RATE MAY BE REQUIRED ANYTIME FOR FAILURE ANALYSIS OR TROUBLESHOOTING.
- [2] MUST HAVE HIGH DATA RATE PERIODICALLY TO CHECK TEMPERATURES. ONCE PER ORBIT IS TYPICALLY THE MAXIMUM REQUIREMENT. ACTUAL FREQUENCY DEPENDS ON THE ATTITUDES BEING FLOWN AND THE BETA ANGLE.

EECOM - All orbiter TPS measurements lost except V09T1524A cabin upper skin center line. Data is used to determine flight rule impacts for:

Payload bay door closing vehicle gradients (Rule {A10-206A}, PLBD CLOSE GO/NO-GO).

Entry prep maximum temperatures (Rule {A18-401A}.b, THERMAL PROTECTION SYSTEM (TPS) BONDLINE TEMPERATURE). [ED]

Anytime minimum temperatures for glassy transition of RTV (Rule {A18-451A}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL]).

FDO/RNDZ - Rendezvous loses data required to verify proper configuration. Prime NAV and sensor evaluation job can still be performed. This applies to PROX OPS only if a universal pointing fly-around is being performed. Rendezvous data lost:

Universal pointing - body vector, target ID, MNVR attitude, attitude error.

DAP configuration - attitude and rate deadbands, translational pulse size, discrete MNVR rate.

Guidance mode - Lambert or external delta V, TV roll.

Star tracker status - Shuttle position, track indications, star present.

Navigation - Uplink timetags associated with onboard vectors.

RMS - Virtually all RMS data lost in SM low data rate. This includes all data required to analyze failures.

EVA - Data is highly desirable for biomed.

All requirements were reviewed at Orbit Flight Techniques #106.

FLIGHT RULES

A2-130

PAYLOAD OBJECTIVES VS. PAYLOAD DAMAGE POLICY

- A. THE HARDWARE FOR ANY PAYLOAD WILL NOT BE JETTISONED SOLELY TO ACCOMPLISH MISSION SUCCESS OBJECTIVES FOR ANOTHER PAYLOAD.
- B. CONSIDERATION WILL BE GIVEN TO ALLOWING HARDWARE DAMAGE TO A PAYLOAD TO OCCUR IF THIS ALLOWS ACCOMPLISHING MANDATORY MISSION SUCCESS OBJECTIVES OF ANOTHER PAYLOAD AS LONG AS SUCH DAMAGE DOES NOT PRESENT AN ORBITER OR CREW SAFETY CONCERN.

A payload can be reflown if its mission success objectives cannot be met, but this is a significant expense to the program. It may be worth the impact of repairing damage to one payload as opposed to reflaying a payload which will not meet its objectives. Such an option should be considered. Each case must be looked at individually to determine if hardware damage is an appropriate tradeoff. The jettisoning of hardware has such severe implications to the agency as a whole that it is judged not appropriate for any mission-success objective gain.

FLIGHT RULES

A2-131

ATTITUDE RESTRICTIONS FOR ORBITAL DEBRIS

- A. TIME IN THE FOLLOWING ATTITUDES WILL BE MINIMIZED IN PREFLIGHT PLANNING AND IN REAL TIME:
1. -ZVV (PAYLOAD BAY FORWARD).
 2. +XVV, +ZLV OR ±YLV (NOSE FORWARD, PAYLOAD BAY UP OR OUT OF PLANE).
- B. -ZLV WILL BE THE NORMAL ORBITER ATTITUDE UNLESS PAYLOAD OR ORBITER REQUIREMENTS DICTATE OTHERWISE. TIME IN +XVV WILL BE MINIMIZED.

FOR THE PURPOSE OF THIS RULE, THE ORBITER WILL BE CONSIDERED TO BE IN ONE OF THE ABOVE ATTITUDES IF THE -Z(X) AXIS IS CLOSER TO ONE OF THE REFERENCED LVLH AXES (+V, +R, ±H) THAN TO ANY OTHER.

IF MORE THAN 48 HOURS CUMULATIVE TIME IN THESE ATTITUDES IS PLANNED, FLIGHT-SPECIFIC EXCEPTIONS WILL BE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX.

Both the Rockwell orbital debris study and the JSC Space and Life Sciences studies looked at various shuttle attitudes and assessed the risk of catastrophic damage due to orbital debris and micrometeoroids. The JSC study also assessed the probable window replacements and radiator repairs required from various attitudes. Data was presented to Orbit Flight Techniques Panel meeting number 131 on August 14, 1992. Numbers are for a 160 nm orbit. This rule addresses relative risk of different attitudes and not absolute risk.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-131

ATTITUDE RESTRICTIONS FOR ORBITAL DEBRIS (CONTINUED)

There are two fundamental reasons to restrict attitudes. One is the risk of catastrophic damage from debris; the other is not a catastrophic risk, but will much more likely cause damage that will result in turnaround impacts and increased costs. The major turnaround drivers are the windows and the radiators.

The -ZVV attitude, regardless of the yaw about the Z axis, is the worst attitude from a catastrophic damage perspective. The risk was between three and five times greater in -ZVV than the best attitude which is -ZLV, -XVV (bay down, tail forward). The -ZVV attitudes were noticeably more risky than other attitudes in both studies. Other attitudes fall in between the two, but the uncertainty in the studies was judged great enough to not put any restrictions on other attitudes than -ZVV with regard to critical damage from orbital debris.

The radiator damage is 16 times worse in -ZVV than in -ZLV. Window damage is also worse in -ZVV (20 times worse) with +XVV (nose forward) being a close second. The +XVV attitude is relatively safe from catastrophic damage.

Time in attitude is an important factor. The longer the time in the attitude, the greater the risk. Forty-eight hours was chosen somewhat arbitrarily. Forty-eight hours results in an expectation of less than 0.5 window replacements and 15 radiator dings. Some flights will have objectives that justify the increased risk of these attitudes. These must be documented as exceptions in the flight-specific annex.

Time in the listed attitudes will be minimized in real time, but it is impractical to compute and police the 48-hour number or any other number in real time.

Many attitudes will not be purely in one of the directions spelled out above. Thus the orbiter -Z (and X for part B) axis will be considered to be pointed in the direction of the LVLH axis that it is closest to.

FLIGHT RULES

A2-132

THERMAL CONDITIONING FOR FLIGHT DAY 1 LANDING

IN THE EVENT THAT A FD1 LANDING IS REQUIRED, PRE-ENTRY THERMAL CONDITIONING WILL BE ON A "BEST-EFFORT" BASIS, CONSISTENT WITH OTHER ATTITUDE REQUIREMENTS. FLIGHT-SPECIFIC END-OF-MISSION BONDLINE LIMITS SHOULD BE MET IF POSSIBLE. THE FOLLOWING GENERIC GUIDELINES SHOULD BE USED FOR THE PERIOD BETWEEN OMS-2 AND D/O BURN (BRIEF EXCURSIONS FOR IMU ALIGN, ETC. ARE ACCEPTABLE):

ATTITUDE GUIDELINES *		
	$0 < \beta < 60$	$60 < \beta < 90$

FLIGHT RULES

A2-132

THERMAL CONDITIONING FOR FLIGHT DAY 1 LANDING (CONTINUED)

For a launch day deorbit, time may not be available to meet all thermal constraints, due to other constraints such as landing opportunity, burn attitudes, IMU alignment and verification, and communications. Within these other constraints, attitudes will be chosen to meet thermal constraints, such as tail-sun for bondlines or biased starboard-sun for OMS Ox Hi Point Bleedline QD and aft-firing RCS thrusters. @[092195-1787B]

* TABLE NOTES:

ORBIT AND THEN" REFERS TO THE TIME FROM NOMINAL PLBD OPENING ATTITUDE (1:12) UNTIL MANEUVER TO DEORBIT IMU ATTITUDE (OR DEORBIT COMM ATTITUDE FOR REV 3).

TIMES IN PARENTHESES SHOW THE ATTITUDE DURATIONS WHICH WERE ASSUMED AND ANALYZED. THESE TIMES ALSO REFLECT THE DESIRED DURATIONS. IF MORE (LESS) ATTITUDE TIME IS AVAILABLE BETWEEN THE ACTUAL OMS-2 AND DEORBIT COMM ATTITUDES, THE 'ORBIT' ATTITUDE MAY BE LENGTHENED (SHORTENED). IF TWO ATTITUDES ARE SHOWN, I.E., 'ORBIT' AND 'THEN', THE DURATIONS MAY BE ADJUSTED PROPORTIONALLY.

ORB RATE DEFINITION: ORBITER WILL ROTATE ABOUT A SUN POINTING VECTOR OF P=180, Y=40 OR 45 AT ORBIT RATE, KEEPING THE ORBITER BOTTOM TOWARD SPACE DURING ROTATION (I.E., EQUIVALENT TO OMICRON 90 FOR POSITIVE BETA AND OMICRON 270 FOR NEGATIVE BETA AT NOON).

-ZLV AND ORB RATE ATTITUDES REQUIRE GNC OPS 2 SOFTWARE. IF GNC OPS 2 IS NOT AVAILABLE, "THERMALLY SIMILAR" SOLAR INERTIAL ATTITUDES WILL BE SELECTED.

DOCUMENTATION: CCB February 28, 1995, May 16, 1995, SODB Volume V. @[092195-1787B]

FLIGHT RULES

A2-133**POCC THROUGHPUT COMMAND RATES**

THE GENERIC COMMAND SERVER (GCS) WILL BE CONFIGURED TO ALLOW ONLY ONE POCC THROUGHPUT COMMAND PER SECOND TO BE OUTPUT INTO THE ORBITER UPLINK DATA STREAM. @[121197-6398] @[062702-5513]

The Network Signal Processor (NSP) interface with the Flight Software (FSW) Systems Management (SM) command application may require as much as 960 msec to completely process a single uplinked payload throughput command (PTC) without error. The POCC INPUT RATE CONTROL adjusts the rate at which commands will be accepted into the GCS. By setting this control to one command per second, first word/last word (FW/LW) rejects of commands by the SM GPC caused by too rapid payload commanding can be eliminated. Any setting of this control above one command per second, even if the commands are routed to the same vehicle address, will allow the potential for onboard rejects of commands to exist. See Section 6.2.2.5 of the Space Shuttle Computer Program Development Specifications (CPDS) - SS Downlist/Uplink Software Requirements (SS-P-0002-140). @[062702-5513]

Rejection of commands, for whatever reason, requires analysis of the command system to ensure that it remains intact with no failures. By eliminating this source of command rejects, resources can be more efficiently used. Limitation of payloads to one PTC per second should not present a significant impact if command timelines are planned appropriately. @[121197-6398]

FLIGHT RULES

A2-134

ON-ORBIT CRYO MARGIN BUYBACKS

THE FOLLOWING CRYO MARGIN BUYBACKS CAN BE USED AS SPECIFIED BELOW TO EXTEND MISSION DURATION IF REQUIRED, INCREASE THE NUMBER OF DEORBIT OPPORTUNITIES, INCREASE THE AVAILABLE POWER FOR HIGH PRIORITY MISSION OBJECTIVES, OR IN OTHER SITUATIONS WHICH INCREASE THE OVERALL SAFETY AND SUCCESS OF THE MISSION. @[052401-4386A]

This rule uses the Group C Powerdown as a starting point for the listed items and assumes that the shuttle is already at a Group B Powerdown level. Some items in the Group C Powerdown have already been unpowered per the Group B Powerdown. Those items were not listed in this rule. The estimated savings is listed next to each item. Paragraphs A through D are not necessarily listed in priority order although paragraphs A and B are considered minimal impact and will be considered first. Specific priorities will depend on flight specific trades.

- A. THE CIRC PUMP THERMAL CONTROL LIMITS MAY BE LOWERED TO REDUCE DUTY CYCLES AND RUN TIME AS LONG AS THE SODB AND FLIGHT RULE LIMITS ARE PROTECTED. CRYO SAVINGS MAY BE BUDGETED PREFLIGHT.

SODB and flight limits for the Hydraulic system will be maintained. Circ pumps can be cycled manually to protect CIRC PUMP INLET TEMP and BODY TEMP > 20 deg (SODB and Flight Rule limit to preclude potential Circ pump cold start). Reference SODB paragraph 3.4.2.4-1c and Rule {A10-74A}.6, HYDRAULIC CIRCULATION PUMP OPERATION [CIL].

- B. THE FOLLOWING ITEMS MAY BE UNPOWERED REAL TIME AND INCLUDED IN THE PREFLIGHT BUDGET:

The following items are not necessarily in priority order since the priority will depend on mission activities but are all minimal impact.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-134****ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)**

1. KU-BAND SYSTEM TO STANDBY WHEN NOT IN USE 160 WATTS

Ku-band system will be commanded to Standby when antenna is in blockage or during a ZOE. While in Standby, the transponder is still transmitting but the power amplifier is not amplifying the signal. The Ku-band draws 370 watts when on but not radiating, and only 210 watts while in Standby, resulting in a 160-watt reduction.

2. MIDDECK LIGHTS (3) 16 WATTS EACH

The Group B Powerdown includes all but three middeck lights. These lights may be powered off at the crew's discretion, but this results in small savings. @[052401-4386A]

3. MDU'S 3 @ 66 WATTS EACH

IDP 55 WATTS

MDU's will be cycled on only when required; at all other times, they will remain off. Remaining IDP can also be turned off if all MDU's are off. @[052401-4386A]

4. S-BAND PL (PSP & PI) 130 WATTS

PDI 25 WATTS

The PSP, PI, and PDI may be required for orbiter, ISS, or payload telemetry and command interface. The PI is typically unpowered for ISS and non-deployable payloads. The PDI will remain off when there are no payload data telemetry processing requirements. With the PDI off, PCMMU element bypass checks will be masked on several SM GPC tables because these tables will be bypassed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-134****ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)**

5. S-BAND FM 81 WATTS

The S-band FM system is typically only powered on for about 10 minutes each orbit and only if Ku-band is unavailable (for ops recorder dumps).

6. STAR TRACKERS 18 WATTS EACH

Star trackers can be powered off with no impact if the tracker is blocked or pointed at Earth. For example, the -Z star tracker is predicted to be blocked when docked to ISS. Star trackers that have a clear field of view can be powered off with minimal impact but would need to be powered on as required for IMU alignments (approximately 10 minutes every 48 hours depending on alignment and star availability). There is a potential tradeoff between orbiter propellant and cryo if stars of opportunity are missed while the star trackers are powered off, requiring a maneuver to attitude for IMU align. However, this can be mitigated since the Pointing Officer can predict when stars of opportunity are expected such that the tracker(s) can be powered on at the appropriate time.

- C. THE FOLLOWING ITEMS MAY BE UNPOWERED REAL TIME BUT WILL GENERALLY NOT BE INCLUDED IN THE PREFLIGHT BUDGET:

The following items have more substantial impacts to operations, are not necessarily listed in priority order, and will not generally be included in the preflight budget.

1. FES CONTROLLER PRI , SEC 120 WATTS MAX (ACTIVE)
4 WATTS (STANDBY)

FES operations will be based on projected Evap Out temperatures. Thermal analysis would be required to assess the FES requirements and impacts. FES will only be turned off after thermal analysis verifies that the FES is not required. ©[052401-4386A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-134****ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)**

2. TOPPING EVAP NOZ, DUCT HTRS 700 W MAX (100% DUTY CYCLE)
255 W (FES IN STANDBY)

If the FES is not required, the nozzle and duct heaters may be powered off. Thermal analysis would be required to assess the FES requirements and impacts. The FES heaters would need to be powered on approximately 1 hour prior to requiring the FES for duct warm-up. @[052401-4386A]

3. RADIATOR DEPLOY

Radiator deploy can be considered to minimize FES usage, resulting in the savings in paragraphs 1 and 2 for the periods where rad deploy eliminates the need for the FES. Thermal analysis would be required to assess the FES requirements and radiator deploy impacts.

4. OPS RECORDER 56 WATTS (RECORD MODE)
17 WATTS (STANDBY MODE)

One Ops Recorder can be powered off if the other Ops Recorder is in RECORD continuously. Since the second Ops Recorder is generally in Standby, this would result in approximately 17 watts savings. However, with only one recorder operating, onboard recording would not be available during Ops Recorder dumps.

5. RMS D&C 92 WATTS
RMS HEATERS 627 WATTS MAX (~125 W AVG)

The Port RMS D&C panel and heaters may be powered off as long as the Port RMS heaters are cycled on for approximately 30 minutes when a low temperature message (PDRS PORT TEMP) is annunciated. Heaters will be managed for crew sleep periods to ensure the crew is not awakened by alarms/heater action. All panel A7 D&C lights will be unpowered when the D&C circuit breaker is open. The 125-watt average power for the heaters is based on a 20-percent duty cycle.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-134****ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)**

6. OCAC 50 WATTS

The OCAC is a crew preference item, which provides white noise for crew sleep, reduces dust and debris particles in the air, and reduces avionics filter cleaning. The OCAC may also be used for air mixing within the orbiter or between the orbiter and ISS. ©[052401-4386A]

7. PF MDM 50 WATTS

A PF MDM can be powered off but will result in some loss of commanding and data. PF2 will result in loss of commanding to CCTV, Ops Recorder 2, PSP 2, and commanding through antenna electronics #2. PF1 will result in loss of Ku commanding, Ops Recorder 1, PSP 1, and commanding through antenna electronics #1. If MDM PF1 or 2 is powered off for cryo savings, it will be cycled on to regain commanding and data as required. ©[052401-4386A]

8. STOW KU-BAND EARLY OR DEPLOY LATE 460 WATTS

Although the hardware community is uncomfortable with an additional in-flight power cycle of the Ku-band system, it is acceptable from a hardware perspective to stow the Ku-band early or deploy it late for cryo savings. Prior to Ku-band activation and after deactivation, downlink video and the primary method of OCA capability (KFX) are lost. Furthermore, two-way voice, command, and telemetry redundancies are lost as well as high rate payload telemetry. Reducing Ku-band system use may also require additional recorder dumps and the scheduling of S-band FM ground sites. Stowing the Ku-band early is generally preferred over deploying late since the SSME data is downlinked using the Ku-band system and any problems with the Ku-band system will be identified earlier. However, flight specific requirements could reverse this priority. Depending on mission requirements, changing the nominal Ku-band deploy and stow times may have minimal or significant impacts and may or may not be an acceptable option.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-134

ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)

9. S-BAND PM TO STANDBY (KU-BAND ON) 310 WATTS (S-BAND PM)

Although this is an option that can be considered by the flight control team, it is an undesirable option since it results in the loss of S-band downlink voice and data (uplink still available). If S-band is in Standby and the Ku-band is unavailable, data will be recorded onboard but not available real time. This will result in requirement for additional recorder dumps, the scheduling of FM ground sites, and additional INCO backroom personnel. Furthermore, the S-band PM system is used to obtain TDRS tracking data on the orbiter for state vector maintenance. TRDS tracking may be required for certain mission activities (Post Insertion, Rndz/Docking, etc.). Without TDRS tracking, C-band sites will have to be scheduled if required for onboard state vector update.

10. COMBINATION OF KU-BAND AND S-BAND TO STANDBY ~250 WATTS

This is also an option that can be considered by the flight control team but is undesirable since it places a high workload on the INCO position. INCO would manage the comm system manually such that while one system is being used, the other system would be in Standby mode. Although this config would maintain the current level of communications coverage and provide some cryo savings, there would be a significant operational effort required to effectively operate in this configuration. Additional manning (INCO) would be required for this operation. This type of operation may increase the likelihood of loss of communication due to human error. @[052401-4386A]

- D. THE FOLLOWING ITEMS MAY ONLY BE UNPOWERED REAL TIME OR INCLUDED IN THE PREFLIGHT BUDGET WITH PROGRAMMATIC/MMT CONCURRENCE : @[052401-4386A]

The following items are additional orbiter powerdowns included in the Priority Powerdown Group C that have more substantial impacts to hardware or ops. These items will be unpowered only with concurrence from the Program:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-134****ON-ORBIT CRYO MARGIN BUYBACKS (CONTINUED)**

1. KU-BAND SYSTEM OFF

460 WATTS

Powering off the Ku-band has operational impacts and potential hardware issues. When the Ku-band system is powered off, downlink video and the primary method of OCA capability (KFX) are lost. Furthermore, two-way voice, command, and telemetry redundancies are lost as well as high rate payload telemetry. Powering off the Ku-band system may also require additional recorder dumps and the scheduling of S-band FM ground sites. The engineering community is concerned that powering off the Ku-band system will increase the likelihood of a gimbal failure, preventing the Ku-band deployed assembly from being stowed. To address these concerns, if the Ku-band is considered as a cryo saving measure, the priority will be to first simply stow the Ku-band radar early or deploy it late, eliminating an additional in-flight power cycle. However, if additional cryo savings are still required, and the Program concurs with an additional power cycle of the Ku-band, the gimbals will be locked prior to powering the Ku system off. If an EVA is available to lock the gimbals, this may also be acceptable risk mitigation to protect against a Ku jettison scenario.

2. MDM'S FF2, FF4, FA4

50 WATTS EACH

When the MDM's are powered off, the corresponding jets are unavailable for use, but more importantly, there is no direct insight into jet leaks using orbiter instrumentation. Although it is expected that there will be other means of detecting a jet leak (crew visual observation or indirect insight via chamber pressure data), the Program deems this an undesirable option. If this option is utilized, the MDM's would be cycled on as required to periodically snapshot PROP RCS data. These MDM's would also be powered on for rendezvous operations, FCS checkout, RCS Hot Fire, and other periods where RCS insight is desirable. When the MDM's are required, they will be powered on at least 15 minutes prior to the desired activity. Note that MDM FF2 is required for single-string MAGR (GPS) data interface and would also be powered on when data is required. ©[052401-4386A]

FLIGHT RULES

A2-135

**COMMANDER (CDR) AND PILOT (PLT) PARTICIPATING AS
TEST SUBJECTS**

THE CDR AND PLT MAY PARTICIPATE AS TEST SUBJECTS ON A VOLUNTEER BASIS AND AS NEGOTIATED PREFLIGHT. THE CDR MAY NOT PARTICIPATE AS A TEST SUBJECT IN ANY EXPERIMENT OF A PROVOCATIVE OR DISORIENTING NATURE. THE CDR AND PLT MAY NOT SIMULTANEOUSLY PARTICIPATE IN ANY EXPERIMENT THAT IS PHYSICALLY RESTRAINING.
@[111501-4962A]

The CDR may not participate in any experiment which might compromise the CDR's ability to command and fly the orbiter. Either the CDR or PLT must always be available to handle emergencies or other actions. @[111501-4962A]

A2-136 THROUGH A2-200 RULES ARE RESERVED

FLIGHT RULES

DEORBIT

A2-201

DEORBIT GUIDELINES

- A. LOSS OF ALL REDUNDANCY IN DEORBIT METHODS WILL BE CAUSE TO DEORBIT AT THE NEXT PLS OPPORTUNITY
1. LOSS OF ONE OMS ENGINE AND ONE RCS +X JET
 2. LOSS OF TWO OMS ENGINES
 3. INSUFFICIENT PROPELLANT TO SUPPORT TWO METHODS OF STEEP DEORBIT

When all redundancy in deorbit methods has been lost, the orbiter is fail-critical with respect to deorbit capability. Deorbit must be performed at the next opportunity to avoid prolonged exposure to the failure of the remaining deorbit method.

Three deorbit methods are considered in assessing the ability to remain on orbit: the left OMS engine, the right OMS engine, and the four +X RCS jets. The availability of a deorbit method is based upon two criteria: the health of the hardware and the availability of sufficient propellant to satisfy the deorbit delta V requirements through the respective engine(s).

While a three +X RCS deorbit is possible, the increased burn arc and the imbalance in thrust (creating a yawing moment which must be countered by the RCS yaw jets) make the deorbit propellant requirement prohibitively large.

- B. IF INSUFFICIENT PROPELLANT EXISTS TO PROVIDE TWO METHODS OF STEEP DEORBIT CAPABILITY, MISSION DURATION MAY BE EXTENDED BEYOND THE NEXT PLS IF THE DEORBIT DELTA V CAPABILITY CAN BE IMPROVED AS A RESULT OF THE FOLLOWING (WHILE PROVIDING AT LEAST TWO METHODS OF DEORBIT):
1. PAYLOAD DEPLOY.
 2. DECREASE IN DEORBIT DELTA V REQUIREMENTS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-201

DEORBIT GUIDELINES (CONTINUED)

NOTE: IF PAYLOAD DEPLOY IS CONSIDERED AS AN OPTION TO IMPROVE THE OVERALL DELTA V CAPABILITY, SUFFICIENT PROPELLANT MUST BE AVAILABLE TO PROTECT TWO METHODS OF DEORBIT ASSUMING THE PAYLOAD IS NOT DEPLOYED IN ORDER TO PASS THE NEXT PLS OPPORTUNITY.

Consideration should be given to remaining on orbit if two methods (steep or shallow) of deorbit capability will be available and improved deorbit capability guaranteed at the next day PLS and activities beneficial to orbiter safety can be achieved.

The gain in delta V more than makes up the additional propellant cost for an additional 24 hours on orbit plus deploy operations and the minimum separation required for each payload. The net gain in delta V for all deploys is positive thereby adding additional capability for deorbit. The heavier the payload, the greater the increase in delta V.

For an ATO or elliptical orbit, the deorbit delta V may decrease with on-orbit stay time. For some ATO's, the shallow deorbit delta V on day 1 is greater than the steep deorbit delta V on day 2. For this case, staying on orbit 24 hours may gain steep deorbit delta V capability eliminating any risk due to a shallow entry.

C. IF OMS PROPELLANT IS NOT AVAILABLE TO ACCOMPLISH OMS DEORBIT TO STEEP TARGETS, TWO STAGE DEORBIT BURNS ARE ACCEPTABLE TO MAINTAIN DEORBIT STEEP CAPABILITY WHEN SUFFICIENT PROPELLANT IS AVAILABLE (IN ACCORDANCE WITH RCS JET REDUNDANCY REQUIREMENTS AS SPECIFIED IN RULE {A6-355}, OMS PROPELLANT DEFICIENCY FOR DEORBIT).

If propellant is not available in the OMS to complete a steep deorbit burn, a perigee adjust burn may be planned using the forward or aft RCS, reducing the OMS propellant requirement for deorbit. Reserving propellant for a two-stage deorbit is only acceptable when sufficient RCS jet redundancy exists as stated in Rule {A6-355}, OMS PROPELLANT DEFICIENCY FOR DEORBIT.

Rules {A6-51}, OMS FAILURE MANAGEMENT [CIL]; and {A6-107}, OMS ENGINE FAILURE MANAGEMENT, reference this rule.

FLIGHT RULES

A2-202

EXTENSION DAY GUIDELINES

- A. IF MANDATORY LANDING AIDS, GROUND TRACKING, COMMAND, VOICE, OR TELEMETRY EQUIPMENT AT THE PLS (REF. SEC. 3, GROUND INSTRUMENTATION REQUIREMENTS) ARE NOT AVAILABLE OR IF WEATHER CONDITIONS AT THE PLS ARE OBSERVED AND/OR FORECAST TO BE UNACCEPTABLE FOR LANDING, A WAVE-OFF OF 24 HOURS OR MORE MAY BE PERFORMED TO ACHIEVE A LANDING AT THE PRIMARY LANDING SITE IF ALL OF THE FOLLOWING CONDITIONS ARE MET:
1. THE ORBITER EXCEEDS MDF SYSTEMS CONFIGURATION STATUS.
 2. CONSUMABLES PROVIDE FOR AT LEAST A 48-HOUR MISSION EXTENSION (WAVE-OFF 24 HOURS TO THE NEXT PLS OPPORTUNITY WITH AN ADDITIONAL 24 HOURS MORE FLIGHT DURATION TO ALLOW RECOVERY FROM ANY ORBITER SYSTEM FAILURES).
 3. THE WEATHER FORECASTS INDICATE THERE IS A HIGH PROBABILITY THAT THE WEATHER AT THE PRIMARY LANDING SITE (WHILE MAINTAINING REASONABLE OPTIONS AT THE SECONDARY LANDING SITE) WILL BE ACCEPTABLE ON A LANDING OPPORTUNITY PRIOR TO 24 HOURS BEFORE THE EXPIRATION OF CONSUMABLES.
 4. ORBITAL ALTITUDE ALLOWS AT LEAST A 48-HOUR MISSION EXTENSION.
 5. ANY MANDATORY EQUIPMENT OUTAGE HAS AN ETRO THAT WILL SUPPORT A PLS LANDING PRIOR TO 24 HOURS BEFORE EXPIRATION OF CONSUMABLES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-202

EXTENSION DAY GUIDELINES (CONTINUED)

- B. IF THE EXTENSION DAY GUIDELINES ABOVE CANNOT BE MET AND THE PLS IS NOT AVAILABLE, THEN AN SLS LANDING WILL BE IMPLEMENTED.

It is desirable to land at the primary landing site if possible. Mission extension is acceptable to accomplish this goal. If the PLS weather is unacceptable, either observed at the decision time or forecast for landing time (ref. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC], and Rule {A4-156}, HAC SELECTION CRITERIA), then consideration will be given to a mission extension to achieve a PLS landing. Similarly, for an outage of mandatory equipment supporting a landing at the PLS (ref. rules in Section 3, GROUND INSTRUMENTATION REQUIREMENTS).

It is programmatically desirable to land at the primary landing site. Diversion to alternate sites results in significant additional postflight work and may involve some risk to orbiter or payload hardware reusability. If the orbiter system status and consumables will support continued flight, then continuing to attempt landings at the PLS is preferable to early diversion to an SLS. However, when orbiter systems status is such that an MDF or PLS is required (systems redundancy is compromised) or if consumables cannot support an additional 48-hour flight extension, then the risk incurred by continuing the flight outweighs the programmatic advantages of a landing at the primary site. The consumables and orbital altitude must support the 24-hour extension to the next PLS opportunity and an additional 24-hour mission lifetime if an orbiter systems problem occurs late in the preparations for deorbit that requires a day to fix.

Reference Rule {A2-102}, MISSION DURATION REQUIREMENTS.

Rules {A4-156}, HAC SELECTION CRITERIA, and, {A2-207} LANDING SITE SELECTION, reference this rule.

FLIGHT RULES

A2-203

DEORBIT DELAY GUIDELINES

- A. DELAY A MAXIMUM OF ONE ORBIT TO UNDERSTAND, VERIFY, RECONFIGURE, OR (WHERE A REASONABLE PROBABILITY EXISTS) TO FIX A PROBLEM ASSOCIATED WITH A BASIC GROUND OR VEHICLE CAPABILITY, INCLUDING ADDITIONAL FAULT TOLERANCE.
- B. CONSIDERATION WILL BE GIVEN TO EXTENDING 1 DAY TO REGAIN REDUNDANCY IN AN ENTRY-CRITICAL SYSTEM PROVIDED FAIL-SAFE REDUNDANCY EXISTS IN ALL OTHER SYSTEMS CRITICAL TO ENTRY/LANDING.
- C. ON ENTRY DAY, DELAY A MAXIMUM OF 1 DAY TO PROVIDE A SINGLE-FAULT TOLERANT PASS SYSTEM, A BFS, ACCEPTABLE NAVIGATION, PLBD CLOSURE, OR MANDATORY GROUND CAPABILITY.
- D. AN INTERNAL OMS, RCS, OR APU LEAK RESULTING IN THE VIOLATION OF MINIMUM THERMAL OPERATING CONSTRAINTS RESULTING FROM THE LOSS OF THE POD OR APU IS CAUSE FOR A DEORBIT DELAY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-203

DEORBIT DELAY GUIDELINES (CONTINUED)

- E. FOR A SINGLE GPC FAILURE PRIOR TO DEORBIT PREPARATION OR FOR MULTIPLE GPC FAILURES PRIOR TO TIG, UNLESS OTHER FACTORS DICTATE DEORBIT ON THE SCHEDULED DAY, ENTRY WILL BE DELAYED UP TO 24 HOURS TO ALLOW FOR RECOVERY, ANALYSIS, AND POSSIBLE IFM TO INSTALL THE CARRY-ON SPARE GPC (IF MANIFESTED). FOR A SINGLE GPC FAILURE DURING DEORBIT PREPARATION, ENTRY MAY BE DELAYED ONE ORBIT TO ALLOW FOR GPC RECOVERY. @[092195-1798]

It is desired to have all GPC's for use during entry. Some GPC failures may be recovered by an IPL, but such a transient GPC may fail again and therefore use of a transient GPC shall be avoided if possible. It is also undesirable to assign two flight-critical strings to a single GPC which would be required if entering with only three PASS GPC's. During the deorbit preparations, however, backing out of the deorbit preparation requires systems reconfiguration which entails inherent risks of its own. At that point, it is better to use a transient GPC or continue without it if it cannot be recovered. The failure of two or more GPC's is a more serious case that implies a significant loss of redundancy; therefore, entry will be delayed a day to allow for the best attempt at GPC recovery which could include a changeout of one of the failed GPC's if a spare is manifested. @[092195-1798]

Rule {A7-17B}, GPC MEMORY DUMP CRITERIA, references this rule. @[092195-1798]

- F. A CONFIRMED OMS LEAK MAY DELAY DEORBIT.
- G. THE FLIGHT WILL NOT BE EXTENDED PAST THE NEXT PLS OPPORTUNITY UNLESS ORBITAL LIFETIME CAN BE GUARANTEED THROUGH THE LAST PLS OPPORTUNITY OF THE FOLLOWING DAY. A REAL-TIME DETERMINATION OF THE MINIMUM 24-HOUR PERIGEE WILL BE MADE FOR OFF-NOMINAL ORBITS.

The 24-hour minimum orbital lifetime is required to ensure crew and vehicle safety if extending past the next PLS opportunity. As perigee approaches the entry interface altitude, the drag buildup significantly increases orbital decay and is thermally more severe on the vehicle. At these low altitudes, the MCC modeling of the orbit is also greatly deteriorated. Exposure to very low altitudes would eventually result in an uncontrolled reentry, which would likely result in loss of crew and vehicle.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-203

DEORBIT DELAY GUIDELINES (CONTINUED)

- H. FOR PROPELLANT LEAKS THAT OCCUR AFTER LOS AND PRIOR TO THE DEORBIT BURN, THE FOLLOWING ACTIONS WILL APPLY:
1. OMS LEAK - A PERIGEE ADJUST MANEUVER WILL BE PERFORMED AT THE NOMINAL DEORBIT TIG.
 2. RCS LEAK - THE DEORBIT BURN WILL BE DELAYED TO ASSESS THE THERMAL ENVIRONMENT.

A perigee adjust is performed on an OMS leak in order to minimize the deorbit delta V. Since the thermal effects of an OMS or RCS leak cannot be predicted, the deorbit burn will be delayed to evaluate whether the pod thermal environment can support deorbit. A leak can result in OMS and RCS feedlines freezing, rendering both systems unusable for deorbit and entry.

- I. DEORBIT MAY BE DELAYED TO ACHIEVE A PLS LANDING IF THE WEATHER CONDITIONS ARE UNACCEPTABLE OR MANDATORY GROUND EQUIPMENT IS NOT AVAILABLE.

It is desirable to land at the primary landing site if possible. Mission extension is acceptable to accomplish this goal.

Rule {A7-17D}, GPC MEMORY DUMP CRITERIA, references this rule.

A2-204

MDF DEORBIT GUIDELINES

AN ENTRY PREPARATION TIMELINE WILL PROVIDE FOR ENTRY STOWAGE AND PREPARATION ON THE AFTERNOON OF ENTRY MINUS 1 DAY FOR THE FOLLOWING:

- A. MDF.
- B. A NEXT PLS IF REQUIRED DUE TO A CONDITION WHICH REQUIRES MDF, BUT AFTER MDF OBJECTIVES HAVE BEEN SATISFIED.

FLIGHT RULES

A2-205

EMERGENCY DEORBIT

A. EMERGENCY DEORBIT IS REQUIRED FOR:

1. LOSS OF TWO FREON LOOPS.

If both loops are lost, an abort from orbit is required because there is absolutely no cooling of the vehicle. The fuel cell stack temperature will reach the specification limit of 250 deg F within approximately 50 minutes. In addition, the electrolyte concentration will reach the 25 percent operational limit in approximately 75 minutes. At this point, continued operation of the fuel cells is questionable. This assumes a simultaneous purge of all three fuel cells and a 12.54 kWh (4.18 kWh/fuel cell) power level. Without the purge, the fuel cells will flood in approximately 18 minutes based on an 8.0 kWh (2.67 kWh/fuel cell) power level (ref. Rule {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]).

DOCUMENTATION: DUAL FREON LOOP FAILURE ENTRY ANALYSIS, Rockwell International IL # 388-301-79-018, July 21, 1981, and SODB table 3.4.4.1-1.

2. ANY OF THE FOLLOWING THAT WILL NOT SUPPORT A NEXT PLS:

- a. CABIN LEAK.

Cabin pressure integrity is lost when O₂ and N₂ consumables are not enough to maintain the cabin pressure at 14.7 psia to the next PLS opportunity while protecting the 165-minute hole-in-the-cabin contingency requirement. If a cabin leak is such that the consumables will not maintain the minimum metabolic pressure (8.0 psia) until the next PLS, the only option left is an emergency deorbit.

DOCUMENTATION: Engineering judgment.

- b. IMPENDING LOSS OF ALL O₂ (H₂) CRYO.

If the pressure cannot be maintained in at least one cryo tank and manifold, the fuel cells will eventually stop producing electrical power, no matter what the quantity is in the cryo tanks. Therefore, this condition warrants the selection of the earliest abort opportunity (ref. Rule [A9-261], IMPENDING LOSS OF ALL CRYO).

DOCUMENTATION: Engineering judgment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

- c. LEAKING PROPELLANT FROM THE REMAINING DEORBIT BURN SYSTEM.

Capability will be lost to successfully complete the deorbit burn.

- d. TWO ARCS PROPELLANT TANKS LEAKING, SAME PROPELLANT AND EITHER LEAK RATE SUPPORTS ENTRY TO A Q-BAR = 20 FOR A DAYLIGHT LANDING AT AN ELS (IF A NIGHT LANDING AND NO LANDING AIDS DELAY DEORBIT).

If the leak rate supports entry to a Q-bar = 20 for any ELS, perform an emergency deorbit to that site. This action would provide entry control until NO YAW JET selection. The risk of an ELS landing without landing aids at night is considered to be higher than proposed options of procedure/software changes to provide control from EI to Q-bar = 20. Therefore, for a night landing without landing aids, the deorbit will be delayed.

- e. IMPENDING LOSS OF ALL APU/HYDRAULIC SYSTEMS CAPABILITY. @[111699-7070B]

Loss of all APU/hydraulic systems capability will result in loss of aerosurface control required for entry (ref. Rule {A10-21A}.4, LOSS OF APU/HYDRAULIC SYSTEM (S) ACTIONS). @[111699-7070B]

- f. LOSS OF TWO WATER LOOPS.

Thermal analysis indicates that, if two water loops are lost, cabin conditions will become intolerable within 2 hours of the failure. Cabin temperatures approach 90 deg F and relative humidity reaches 100 percent. Avionics temperatures exceed their loss of cooling operate periods and must be powered down. The cabin conditions can be relieved by performing cabin depress/repress (DEP/REP) cycles. The 4-hour time to landing is based on a crew of seven with an N₂ quantity of 262 lb. Crew exposure to the extreme cabin conditions is the primary driver for terminating the flight. The DEP/REP cycles provide relief from the high heat and humidity by dumping the excessive heat and humidity overboard and replacing the air with cool, dry N₂ and O₂.

DOCUMENTATION: Lockheed Technical memorandum, G189A ECLSS ANALYSIS OF THE LOSS OF TWO WATER LOOPS AFO (TIG >2.5), to be published. Document no. LESC-24843.

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

B. IN THE EVENT AN EMERGENCY DEORBIT IS REQUIRED, ORBITER CONSUMABLES LIFETIME IS THE PRIMARY CONSIDERATION. WHEN CHOOSING BETWEEN VARIOUS ELS OPPORTUNITIES, BOTH OF THE FOLLOWING CRITERIA MUST BE SATISFIED, AS A MINIMUM:

@[120894-1744B]

1. ENTRY CROSSRANGE < UNDISPERSED CROSSRANGE LIMIT.
2. LANDING FACILITY REQUIREMENTS AS SPECIFIED IN RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA.

Consumables lifetime will limit the emergency landing site choices available. If no landing site is available within time limits, then a bailout is required.

The undispersed entry crossrange limit represents the total vehicle crossrange capability, assuming perfect onboard navigation, design winds and atmosphere, and nominal vehicle energy, control, and response. Landing sites outside this limit are not achievable on an average (zero sigma) day and; therefore, deorbiting to such a site is not much better than a bailout.

Minimum ground equipment, including night landing equipment, is specified in rule {A2-264}, EMERGENCY LANDING FACILITY CRITERIA.

C. WHEN ALL THE CRITERIA IN PARAGRAPH B ARE MET AND A CHOICE BETWEEN SITES CAN STILL BE MADE, THEN THE FOLLOWING PRIORITIES APPLY (NOTE: IF TIME PERMITS, CONSIDERATION WILL BE GIVEN TO ADDITIONAL CRITERIA AS SPECIFIED IN RULE {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS):

1. NASA CONUS:
 - a. EDW
 - b. KSC
 - c. NOR

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

NOTE: A NIGHT LANDING AT A NASA CONUS SITE EQUIPPED WITH NAV-LANDING AIDS AND XENON LIGHTS IS PREFERRED OVER A DAYLIGHT LANDING TO ANY OTHER SITE BELOW.

2. TAL SITES PRIOR TO RELEASE FROM LAUNCH SUPPORT @[120894-1744B]
3. DOD: @[120894-1744B]
 - a. HICKAM AFB, HAWAII
 - b. ANDERSEN AFB, GUAM
 - c. MORON, SPAIN (POST-RELEASE FROM TAL SUPPORT)
 - d. DIEGO GARCIA, CHAGOS ISLANDS
 - e. OTHER DOD, LISTED IN NSTS-07700, VOLUME X, BOOK 3
4. NON-DOD WITH UHF COMM AVAILABLE:
 - a. KING KHALID, SAUDI ARABIA
 - b. ZARAGOZA, SPAIN (POST-RELEASE FROM TAL SUPPORT)
 - c. OTHER NON-DOD WITH UHF, LISTED IN NSTS-07700, VOLUME X, BOOK 3
5. ALL OTHER NON-DOD (NO UHF):
 - a. BEN GUERIR, MOROCCO (POST-RELEASE FROM TAL SUPPORT)
 - b. BANJUL, THE GAMBIA (POST-RELEASE FROM TAL SUPPORT)
 - c. OTHER NON-DOD WITHOUT UHF, LISTED IN NSTS-07700, VOLUME X, BOOK 3

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

6. OTHER SITES NOT LISTED IN NSTS-07700, VOLUME X, BOOK 3

First priority for emergency deorbit landings are the NASA CONUS sites. The only time a night landing is preferred over daylight for emergency deorbit is when it can be made at a CONUS site equipped with operational nav aids, landing aids, and xenon lights. TAL sites are not staffed after release of launch support; however, for failures very early in the mission which require an emergency deorbit, any TAL site which is still available and staffed would be preferred over an ELS. Sites with permanent DOD presence are next since ELS augmentation for emergency deorbit use has been eliminated. Further priorities are based upon available landing site security, control, and communications. Ben Guerir and Banjul are ranked very low as they have no UHF support and minimal (at best) security and control after TAL launch support is gone. @[120894-1744B]

- D. EMERGENCY DEORBIT PROTECTION REQUIREMENTS: @[120894-1744B]

1. SYSTEMS AND PAYLOADS MUST BE CONFIGURED TO PROTECT EMERGENCY DEORBIT WITHIN 1 HR 55 MINUTES FOR ISS DOCKED AND ASSEMBLY OPERATIONS AND WITHIN 30 MINUTES FOR NON-ISS OPERATIONS. @[110900-3758B]
2. IF A CONFIGURATION OR ACTIVITY WILL RESULT IN EXCEEDING THE ALLOTTED TIME ABOVE, THE CONFIGURATION OR ACTIVITY WILL BE TERMINATED OR THE SAFING TIMELINE UPDATED BASED ON MMT CONCURRENCE OR FLIGHT SPECIFIC EXCEPTIONS DOCUMENTED IN THE FLIGHT RULES ANNEX.
3. IF EXTERNAL HARDWARE SAFING TIME EXCEEDS THE ACTUAL TIME AVAILABLE, HARDWARE MAY BE JETTISONED AS REQUIRED FOR CREW SAFETY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

4. EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

It is the policy of the SSP to protect the capability to perform an emergency deorbit. For unmated shuttle operations, the quickest time the crew can respond to an emergency situation and perform a deorbit burn is 30 minutes. To support this requirement, cabin payloads must be stowed and external payloads must be "safed" to allow payload bay door closure in less than 20 minutes. If the RMS is in use by the payload, only approximately 10 minutes will be available to safe the payload since approximately 10 minutes is required to configure the RMS in preparation for deorbit.

While docked to the ISS, the capability to perform an emergency deorbit within 30 minutes no longer exists. Therefore, the emergency deorbit protection timeline is extended for joint shuttle/ISS operations. The SSP has accepted the slight additional risk of extending the rapid safing duration to 1 hr 45 minutes for ISS to allow payload bay door closure approximately 10 minutes after separation, and deorbit 10 minutes later (minimum time between separation and deorbit burn is approximately 20 minutes). If the RMS is in use by an element or payload, only 1 hr 35 minutes will be available for the element on the RMS to perform safing functions required to clear the PLBD envelope since approximately 10 minutes is required to configure the RMS in preparation for deorbit. @[110900-3758B]

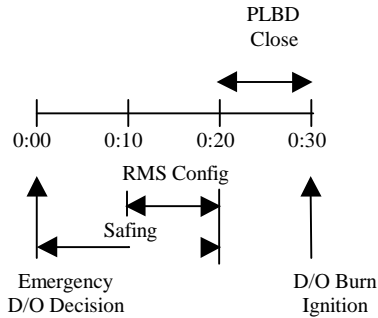

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

Non-ISS Timeline: @[110900-3758B]

ISS Timeline:

The single failure that drives the requirement to maintain an emergency deorbit capability is an orbital debris impact that results in the loss of cabin pressure integrity. The risk of a debris strike requiring a deorbit within 1 hr 55 minutes for a typical 10-day mission is approximately 1 in 10,000. @[022201-4123]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

This risk is mitigated by maintaining sufficient nitrogen reserves to protect the contingency 165-minute return capability, plus the nitrogen budgeted for the typical 2 days between undocking and nominal end of mission landing. For a typical station trajectory, the 165-minute nitrogen reserve would cover 1 hour 40 minutes prior to the burn, plus 1 hour 5 minutes from burn to landing. To stretch this by 15 minutes, and maintain nitrogen flowing through the 8 psi regulator until landing, requires an additional 12.5 lbm of nitrogen in reserve. This is approximately the amount that is budgeted for the 2 days of standard mission usage between nominal undocking and landing. Reference Rule {A17-202}, 8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY. @[022201-4123]

In addition to payload safing, systems must also be configured to support deorbit within the specified time in Paragraph D.1. (e.g., DAP, Ku-band antenna, radiators, APU/HYD, FES, IMU's, payload bay doors). The safing timeline for each flight phase is defined in the flight specific Flight Rules Annex, which defines the actions required during a rapid safing scenario and may include hardware jettison if required to meet the time requirement or a flight specific exception to this rule. If, during real-time operations, a failure or unplanned configuration or activity occurs requiring more safing time than allowed, the activity or configuration will be terminated or the additional risk incurred accepted by the MMT. @[110900-3758B]

If an event occurs which requires deorbit in less time than allocated per this flight rule or the flight specific Flight Rules Annex, every effort will be made, including hardware jettison if required, to maximize crew safety. @[110900-3758B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-205

EMERGENCY DEORBIT (CONTINUED)

E. EMERGENCY LANDING SITE NOTIFICATION: @[120894-1744B]

SHOULD AN EMERGENCY LANDING BE REQUIRED, NOTIFICATION WILL BE PROVIDED AS SOON AS POSSIBLE TO THE INTENDED LANDING SITE BY MCC/GROUND PERSONNEL THROUGH STATE DEPARTMENT-APPROVED CHANNELS. HOWEVER IN SOME CASES, IT MAY NOT BE POSSIBLE TO PROVIDE ADVANCED NOTIFICATION PRIOR TO THE DEORBIT/ATTEMPTED LANDING. WHEN SELECTING THE LANDING SITE, CONSIDERATION WILL BE GIVEN TO THOSE SITES THAT HAVE AN ORBITER COMPATIBLE UHF SYSTEM IN ORDER TO PROVIDE LANDING NOTIFICATION BY THE CREW DURING DESCENT IF POSSIBLE.

SHOULD NOTIFICATION OF THE SELECTED LANDING SITE NOT BE POSSIBLE, THE DECISION ON WHETHER TO ATTEMPT THE LANDING OR BAILOUT WILL BE THE RESPONSIBILITY OF THE CDR BASED ON LANDING SITE CONDITIONS AT THE TIME OF ARRIVAL WITH RESPECT TO WEATHER, AIRCRAFT TRAFFIC, RUNWAY CONDITIONS, ETC.

@[120894-1744B]

In order to reduce the risk to the orbiter crew and the general public/civilian population should an emergency landing be required, it is necessary that an intended landing site be notified of an attempted landing as soon as possible. This will allow the airspace and runways to be cleared as well as emergency equipment to be prepared. Notification may be via state department prearranged channels, NASA agreed to communication channels, or possibly via communication directly with the orbiter. As a last resort, a landing may be attempted at a site that has not been notified, with the final decision on whether to attempt the landing or bailout resting with the CDR based on conditions at the time of arrival.

Rules {A6-52}, RCS FAILURE MANAGEMENT; {A8-1001D}.9, GNC GO/NO-GO CRITERIA, and {A16-12A}, EMERGENCY POWERDOWN, reference this rule. @[110900-3758B]

FLIGHT RULES

A2-206

DEROTATION SPEED

- A. NOMINAL DEROTATION WILL BE TARGETED FOR 185 KEAS USING BEEP TRIM.
- B. IN THE EVENT OF A BEEP TRIM FAILURE, THE CDR WILL INITIATE MANUAL DEROTATION BY APPROXIMATELY 175 KEAS AND TARGET FOR A 1-2 DEG/SEC RATE.
- C. FOR A LEAKING/FLAT MAIN GEAR TIRE, BEEP TRIM DEROTATION MAY BE DELAYED TO NO SLOWER THAN 165 KEAS TO ACHIEVE A 10 KT DELTA FROM THE ACTUAL DRAG CHUTE DEPLOY VELOCITY. @[041097-4009E]

Nominal derotation is initiated by the crew using beep trim at 185 KEAS on both concrete and lakebed runways and for all vehicles. Based on a nominal 195 KEAS lightweight MLG touchdown, the drag chute is deployed immediately after touchdown. Flight data and testing at Ames (1/96 and 7/96) show that, to ensure disreef prior to NGTD, the chute should be deployed 10 knots prior to derotation. If the drag chute is deployed at 195 knots (post MGTD), the chute will be in the full-open configuration just prior to nose gear touchdown, thus reducing the slapdown loads. Faster touchdowns result in more time spent in the 2-pt attitude hold stance waiting for the velocity to decelerate to the nominal chute deploy/vehicle derotation cues. Although a nominal drag chute deploy and derotation sequence will usually result in a chute disreef prior to NGTD, dispersions in touchdown speed, chute deploy, and derotation velocities may result in chute disreef after NGTD. Derotation may therefore be delayed until 10 knots below the actual chute deploy velocity to ensure maximum load relief for a leaking/flat tire. The 165 KEAS minimum derotation velocity protects nose gear slap down loads, assuming no beep trim failures. (Reference AEFTP Splinter, October 8, 1996.) @[041097-4009E]

FLIGHT RULES

A2-207

LANDING SITE SELECTION

NORMAL LANDING SITE SELECTION WILL BE BASED ON THE FOLLOWING PRIORITIES. ALL REQUIREMENTS FOR ACCEPTABLE WEATHER, LIGHTING CONDITIONS, RUNWAY CONDITIONS, AND ENTRY CONSTRAINTS MUST BE SATISFIED FOR A SITE/RUNWAY TO BE USED. @[102402-5804C]

NOTE: REFERENCE THE FLIGHT-SPECIFIC FLIGHT RULE ANNEX FOR ANY EXCEPTIONS TO THE FOLLOWING LANDING SITE PRIORITIES DUE TO SPECIAL CIRCUMSTANCES/REQUIREMENTS.

A. RTLS/TAL PRIORITIES:

RTLS [1]	
INCLINATION < 39°	INCLINATION > 39°
KSC 15	KSC 33
KSC 33	KSC 15

NOTE:

[1] FOR INCLINATIONS OF EXACTLY 39 DEGREES, THERE IS NO DIFFERENCE IN DOWNMODE RANGING BETWEEN KSC 15/33. RUNWAY WILL BE CHOSEN BASED ON WEATHER, SURFACE WINDS, TOUCHDOWN/ROLLOUT MARGINS, ETC. @[020196-1802A]

TAL			
28.5	39	51.6	57
BEN GUERIR (BEN)	BEN GUERIR (BEN)	ZARAGOZA (ZZA)	ZARAGOZA (ZZA)
MORON (MRN)	MORON (MRN)	MORON (MRN)	MORON (MRN)
	ZARAGOZA (ZZA)	BEN GUERIR (BEN)	BEN GUERIR (BEN)

@[020196-1802A] @[102402-5804C]

RUNWAY SELECTION FOR RTLS OR TAL SHOULD BE IN PRIORITY ORDER OF GO RUNWAYS. HOWEVER, IF A RUNWAY APPROACHES FLIGHT RULE LIMITS OR OTHER CONDITIONS MAKE A RUNWAY LESS DESIRABLE (I.E., SUN GLARE, STA EVALUATION, ETC.), THEN CONSIDERATION MAY BE GIVEN TO SELECTING A LOWER PRIORITY RUNWAY. @[020196-1802A] @[102402-5804C]

Runway priorities for RTLS are based solely on energy downmode capability. For inclinations less than 39 degrees, GRTLS range-to-go analysis has shown that a larger range recovery capability exists for an OVHD KSC 15 downmode to STIN KSC 33 than OVHD KSC 33 downmode to STIN KSC 15.

TAL runway priorities were determined based on the site that provides the best single-engine coverage once a TAL abort has been selected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-207****LANDING SITE SELECTION (CONTINUED)**

B. AOA PRIORITIES @[102402-5804C]

NOTE: AOA PRIORITIES ARE MODIFIED BY INCLINATION. AT 28.5 AND 39 DEGREE INCLINATIONS, ALL AOA SITES ARE AVAILABLE FOR SELECTION. AT 57 DEGREES, ONLY NOR IS AVAILABLE, AND AT 51.6 DEGREES, NOR AND KSC ARE AVAILABLE. @[020196-1802A]

1. EDWARDS 22/04
2. KSC
3. NORTHRUP

Since AOA landings are typically heavyweight, the Edwards complex provides more margin in the event of landing/rollout or vehicle energy problems. For high inclination missions, Northrup may be the only AOA landing site available due to the large crossrange required to land at Edwards or KSC. (ref. Rule {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS). @[111094-1622B]

C. EOM PRIORITIES

1. KSC
2. EDWARDS 22/04
3. NORTHRUP

Due to the advantages in vehicle turnaround, the Space Shuttle Program has directed that nominal end of mission (EOM) landings utilize KSC as the first priority landing site.

After KSC, next in the EOM runway selection priority is Edwards, because of the availability of the concrete runway and because of the significant vehicle post landing and turnaround operations capabilities. NOR is generally last priority, because although it provides an excellent orbiter landing site (laser-leveled runways, crossing runways, significant runway lateral and longitudinal margin, all required landing aids and NAVAIDS for day and night, etc.), the ability to support the orbiter systems postlanding and for turnaround/ferry operations is much reduced as compared to KSC or Edwards, resulting in the potential for significant (several weeks) shuttle schedule/manifest impacts. @[102402-5804C]

Reference Rule {A4-109}, DEORBIT PRIORITY FOR EOM WEATHER.

Reference Rule {A2-202}, EXTENSION DAY GUIDELINES, for cases where the PLS is NO-GO.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

D. SYSTEMS FAILURE PRIORITIES [1][3][5][6] @[102402-5804C]

FOR SYSTEMS FAILURES THE LANDING SITE PRIORITY SHALL FOLLOW THE EOM PRIORITIES. CONSIDERATION WILL BE GIVEN TO THE FOLLOWING EXCEPTIONS:

SYSTEM FAILURES [1]	PRIORITY
1 OR 2 APU/HYD SYSTEMS	LANDING SITES WITHIN SINGLE APU WX PLACARDS [2]
2 IMU'S 2 NORM/LAT AA'S 2 RGA'S	EDW 22/04 NORTHROP KSC
2 ADTA'S	LANDING SITE WITH MOST FAVORABLE ATMOSPHERIC CONDITIONS [4]
2 FCS CHANNELS (SAME SURFACE)	NORTHROP EDW 22/04 KSC

@[102402-5804C]

NOTES:

[1] ALL FAILURES OCCUR PRIOR TO DEORBIT BURN.

[2] WX PLACARDS ARE AS FOLLOWS:

- A. CEILING - GREATER THAN OR EQUAL TO 10K FEET
- B. VISIBILITY - GREATER THAN OR EQUAL TO 7 STATUTE MILES
- C. CROSSWIND - LESS THAN OR EQUAL TO 10 KNOTS (PEAK)
- D. NO GREATER THAN LIGHT TURBULENCE
- E. ACCEPTABLE ROLLOUT MARGIN/BRAKE ENERGY ON HALF BRAKES WITHOUT NOSEWHEEL STEERING (DIFFERENTIAL BRAKING)

(REF. RULE {A10-23A}, APU ENTRY START TIME.) LANDING SITE PRIORITY SHALL MINIMIZE CROSSWINDS AND TURBULENCE.

[3] IF THE PRIMARY LANDING SITE IS NO-GO AND IF THE FORECAST CONDITIONS ARE PREDICTED TO IMPROVE, DEORBIT WILL BE DELAYED, IF PRACTICAL.

[4] UNFAVORABLE ATMOSPHERIC CONDITIONS ARE DEFINED AS UPPER LEVEL HAC WINDS IN EXCESS OF 80 KNOTS, HAC DYNAMICS THAT COULD AFFECT THE VEHICLES ENERGY STATE (I.E., ENERGY DUMP MANEUVERS), OR DENSITY ALTITUDE AFFECTS THAT BIAS THE INDICATED AIRSPEED. PRESENCE OF ANY OF THESE CONDITIONS INCREASES THE WORKLOAD ASSOCIATED WITH MANUALLY FLYING THETA LIMITS, COULD RESULT IN ADDITIONAL ENERGY LOSS, AND INCREASES THE POSSIBILITY OF LANDING FASTER OR SLOWER THAN THE TARGETED AIRSPEED. (REF. RULE {A8-111}, AIR DATA SYSTEM MANAGEMENT).

[5] LIGHTED RUNWAY REQUIRED AT NIGHT.

[6] REFERENCE RULE {A2-202}, EXTENSION DAY GUIDELINES, FOR WAVE-OFF CRITERIA. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

The NEOM landing site priority of KSC, EDW 22/04, NOR is driven by Space Shuttle Program directive, based on the cost in time and money for vehicle turn-around. Exceptions to this standard priority order will be reviewed on a case-by-case basis for orbiter systems failures. Factors in selecting the best landing site include, but are not limited to, weather conditions, runway lateral and rollout margins, and touch-down margins for flight control or navigation issues. KSC 15/33 is a 300 ft wide grooved concrete runway with 50 ft loadbearing paved shoulders and has a total length of 17,000 ft including the 1,000 ft underrun and 1,000 ft overrun. The KSC runway is surrounded by a non-loadbearing grassy area and a moat. EDW 22/04 is a 300 ft wide non-grooved concrete runway with 25 ft lakebed material shoulders that are not generally considered loadbearing. EDW 22/04 has a total length of 16,975 ft. The EDW 04 end has a 1,000 ft underrun and an 1,800 ft overrun with the possibility of rollout onto another 9,588 ft of prepared lakebed surface. The EDW 22 end has a 1,800 ft underrun and no overrun. NOR 17/35 and 05/23 are 300 ft wide leveled lakebed runways with 300 ft shoulders of the same hard mantle material. Each runway has a total length of 39,000 ft including a 12,000 ft underrun and 12,000 ft overrun. For all runways, the existence and location of obstructions in the shoulders should be discussed in situations where lateral margins are a factor in landing site selection. ©[102402-5804C]

The following cases have been addressed in the development of this rule (ref AEFTP #187):

1 or 2 APU HYD SYSTEMS: For loss of a single APU/hydraulic system, vehicle hydraulic capability is unimpaired. However, loss of a second APU, results in potential system losses (nosewheel steering, braking capability, control effectiveness at derotation, etc.) requiring more stringent weather placards to assure a safe landing. If two APU/hydraulic systems are lost, it is desirable to provide significant lateral and longitudinal margins while providing a surface that is hard enough to allow better control of derotation rate in order to limit nose gear touchdown loads. Concrete runways provide a lower coefficient of friction than lakebeds, including Northrup. A lower coefficient of friction reduces the pitch down moment and, thus, reduces hydraulic load. With only one APU remaining for flight control, an evaluation of appropriate weather conditions, including upper level and surface winds, is critical in the planned landing site selection criteria. Since the control degradation and systems losses would only be apparent with a single operating APU during approach and landing, derotation, and rollout, it is prudent to pick the best runway within the stated weather placards. The stability of the weather, and minimizing cross-winds and turbulence, are the key consideration if more than one landing site is within placards. ©[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

2 IMU's, 2 NORM/LAT AA's, 2 RGA's: The IMU's, AA's, and RGA's provide feedback to the orbiter flight control loops. Specifically, the IMU's are used to propagate the vehicle navigation state vector and provide attitude and attitude rate information to the flight control system. Lateral AA's provide feedback to the flight control system to improve stability during turn coordination and roll reversals, and are used to provide feedback during use of nose wheel steering (NWS) on the runway. Normal AA's are used to sense normal acceleration (N_z) during TAEM to prevent from overstressing the vehicle's structure by maintaining the pitch angle such that the vehicle stays below the N_z limits. The RGA's are used to stabilize the flight control system by providing high frequency rate information between IMU rate samples. The IMU's, AA's, and RGA's are used by the Aerojet DAP during the EI-5 through landing and rollout timeframe (MM304 and MM305). A critical failure in one of these systems could result in degraded vehicle control and/or significant energy loss during the entry profile. The intent of selecting Edwards 22/04 as the primary landing site is to provide the maximum number of contingency energy downmode options in the event the next LRU fails early in the entry profile and results in significant energy loss. Downmode options in the vicinity of Edwards 22/04 include Palmdale, China Lake, the Edwards lakebed, etc. If Edwards is not available, then Northrup provides the next best energy downmode capability because the Northrup landing site complex has multiple runways available, and it is collocated with several other contingency landing sites (i.e., Holloman, etc). If Edwards and Northrup are unavailable, then a KSC landing should be targeted since the probability of the next worst failure is low and it is the prime landing site with significant ground forces available. ©[102402-5804C]

2 ADTA's: The ADTA's are only used during TAEM, provide altitude data to navigation, and determine the Mach number and angle of attack (Alpha) for use by flight control. This limits the window of exposure for another ADTA problem to only the last portion of entry. Next worst failures could include a loss of all air data measurements (due to dilemma or a probe problem). Landing site selection with two ADTA's failed protects for landing without air data. Flying without air data requires use of manual flying techniques (i.e., theta limits). The level of difficulty associated with maintaining theta limits and survivability is significantly affected by the atmospheric conditions. As such, only the landing site with the most benign atmospheric conditions should be targeted. Unfavorable atmospheric conditions that could result in a loss of control, significant energy loss due to flying outside the HAC, or difficulty in maintaining theta limits include high upper level winds on the HAC (i.e., winds in excess of 80 knots) or other HAC dynamics such as an energy dump pull-up maneuver. Density altitude effects should also be considered when targeting a landing site, because the density altitude could bias the indicated airspeed and result in a landing that is considerably faster or slower than the targeted touchdown airspeed. This is due to the fact that the flight control system assumes a standard atmosphere as the default with no air data and that default may differ significantly from the actual atmospheric conditions of the day at the selected landing site. (Ref. rule {A8-111}, AIR DATA SYSTEM MANAGEMENT.) ©[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

2 FCS CHANNELS: *The FCS channels control the orbiter aerosurfaces during the later portion of entry once sufficient atmospheric density has built up to give those aerosurfaces effective control authority. This limits the window of exposure of a next worse failure (i.e., a 1-on-1 force fight, bad feedback going into flight control, etc.) to the later portion of entry. Such a failure could result in a control transient or persistent vehicle control problems that impact the vehicle's energy state. Most flights require a concrete runway landing (or equivalent runway hardness) due to the large mass moment at nose gear touchdown. Northrup provides the most flexibility of the available primary landing sites due to the availability of several runways of sufficient hardness. If Northrup is unavailable, then Edwards should be targeted because it provides the option to downmode to the large lakebed landing complex in the event that it is not possible to reach the concrete runway. The Edwards lakebed would only be used in a contingency. If Edwards and Northrup are unavailable, then a KSC landing should be targeted since the probability of the next worst failure occurring is low and KSC is the prime landing site with significant ground forces available. The landing site selection philosophy for FCS channels assumes that sufficient aft RCS margin is available to perform the entry with Wrap-DAP active. Use of Wrap-DAP provides yaw jet control authority to fight any drag that may be caused by degraded aerosurface movement above Mach 1 (i.e., performing an entry with no-yaw-jet selected does not limit window of exposure to TAEM because sufficient RCS jet control authority does not exist to fight a bad aerosurface).* ©[102402-5804C]

MLG TIRE PREDICTED TO BE BELOW THE MINIMUM ACCEPTABLE PRESSURE AT

TOUCHDOWN: *If a tire pressure is low, due to temperature or leakage, such that sufficient load-carrying capability of that tire may not exist (ref. rule {A10-142}, TIRE PRESSURE [CIL]), total loss of that tire may occur at derotation, when the highest tire loading is reached. Based on Northrup hardness data, Northrup is acceptable for blown tire cases. However, the coefficient of friction on the strut if both tires on a MLG fail is greater than at a concrete runway, indicating that the vehicle would be harder to control on the Northrup lakebed than at KSC or EDW 22/04. Runway prioritization, consequently, gives preference to concrete runways. Consideration should be given to minimizing crosswind during landing site selection to reduce loads on the remaining tires. Landing with the crosswind on the side of the vehicle with the flat tire will help reduce loads on the affected landing gear, reducing the risk of blowing the remaining tire. Loads on the NLG tires are low enough that if one tire is failed, the remaining tire is not likely to blow. Loss of one or both NLG tires is not considered a directional control problem, since the vehicle should be controllable with differential braking.*

NWS FAILED (ALL): *With the loss of NWS, differential braking remains as the only method of directional control. Sufficient braking system redundancy exists to accept the risk of landing at KSC or EDW vs. NOR. Consideration should be given to minimizing crosswind during landing site selection.* ©[102402-5804C]

FLIGHT RULES

A2-207

LANDING SITE SELECTION (CONTINUED)

E. PREDEORBIT LANDING SITE EVALUATION @[102402-5804C]

1. AFTER DEORBIT MINUS 2.5 HOURS, IF UNACCEPTABLE WEATHER CONDITIONS EXIST (OBSERVED OR FORECAST) OR ENTRY REQUIREMENTS CANNOT BE SATISFIED (TAEM, A/L, TOUCHDOWN, ROLLOUT, ETC.), THE AFFECTED LANDING SITE MAY BE ELIMINATED AS A PRIMARY OPTION.
2. AFTER DEORBIT MINUS 1.5 HOURS, ONLY A SINGLE LANDING SITE WILL CONTINUE TO BE EVALUATED. OTHER LANDING SITE OPTIONS MAY BE REEVALUATED IN THE EVENT OF A DEORBIT WAVE-OFF.

The above guidelines will allow the evaluation of multiple runways at multiple landing sites for multiple deorbit opportunities without significantly compromising the required evaluation of the actual runway where landing will occur. It is always prudent to eliminate landing site/runway options as they become unlikely to remain within limits. This is especially true after deorbit minus 2.5 hours, the standard time at which deorbit pads will be voiced to the crew. Up until deorbit minus 1.5 hours, sufficient time is available to evaluate multiple landing sites for the nominal deorbit as well as preliminary evaluation of landing sites on the next deorbit. Due to multiple wind sets, landing sites, runways, aimpoints, etc. being evaluated, a total team focus on the primary runway on the last orbit prior to deorbit is necessary.

Rules {A2-102}, MISSION DURATION REQUIREMENTS, and {A2-6}, LANDING SITE WEATHER CRITERIA [HC], reference this rule.

FLIGHT RULES

A2-208

ACES PRESSURE INTEGRITY CHECK @[012402-5089]

DEORBIT WILL NOT BE DELAYED FOR FAILURE OF ANY ADVANCED CREW ESCAPE SUIT (ACES) PRESSURE INTEGRITY CHECK.

ACES pressure integrity is not required for the present bailout scenario. In addition, beyond verifying the proper connections, there is little that the crew could do during flight to locate the source of a leak in an ACES or to repair it. @[012402-5089]

FLIGHT RULES

A2-209

LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY

- A. AN INFLIGHT EMERGENCY WILL BE DECLARED AND AN ATTEMPT WILL BE MADE TO PERFORM AN EMERGENCY LANDING IF A LANDING AT THE TARGETED SITE IS IMPOSSIBLE. @[120894-1744B]

NOTE: THE DETERIORATION OF WEATHER (WINDS, TURBULENCE, CEILING, PRECIPITATION, ETC.) AND/OR LANDING AND ROLLOUT MARGINS, WHICH RESULT IN FLIGHT RULE EXCEEDANCES POST-DEORBIT BURN, ARE NOT CAUSE TO REDESIGNATE FROM THE TARGETED SITE.

- B. LANDING WILL BE ATTEMPTED AT AN EMERGENCY LOCATION THAT MEETS THE FOLLOWING CRITERIA:

1. THE LANDING FIELD IS WITHIN THE ENERGY CAPABILITY OF THE ORBITER AS DEFINED IN RULE {A2-251}, BAILOUT.
2. THE LANDING FIELD FACILITIES SATISFY THE REQUIREMENTS DOCUMENTED IN RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA.

- C. TIME PERMITTING, WITH MULTIPLE SITES OF SIMILAR ENERGY CAPABILITY, SELECTION OF THE EMERGENCY LANDING FIELD WILL BE BASED ON THE FOLLOWING PRIORITY:

1. ANOTHER NASA AUGMENTED LANDING SITE
2. A DOD AIRFIELD WITH COMPATIBLE SHUTTLE UHF COMMUNICATIONS
3. A DOD AIRFIELD WITHOUT COMPATIBLE SHUTTLE UHF COMMUNICATIONS

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-209

LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY (CONTINUED)

4. A COMMERCIAL AIRFIELD WITH COMPATIBLE SHUTTLE UHF COMMUNICATIONS
5. A COMMERCIAL AIRFIELD WITHOUT COMPATIBLE SHUTTLE UHF COMMUNICATIONS

Should orbiter or facility problems be encountered which make landing at the designated NASA landing field impossible, the actions to be taken are identified in order of priority in an attempt to save the crew and orbiter (national resource), while at the same time minimizing public exposure to additional risk. During entry should the need arise, an "inflight emergency" (as declared by all aircraft if in trouble) will be declared. and a landing at an ELS will be attempted if energy is sufficient to reach the landing site (reference Rule {A2-251}, BAILOUT) and the facility meets the minimum requirements (reference Rule {A2-264}, EMERGENCY LANDING FACILITY CRITERIA). ©[120894-1744B]

Weather forecasts for shuttle landings are made by well-trained, experienced meteorologists with the best tools available and within 90 minutes of landing. At the A/E FTP #73, the results of a multimonth study of forecasting accuracy showed that these forecasts were extremely accurate and in the very small percentage of cases where a GO prediction turned into a NO-GO situation, the violations were minor and survivable. It is inconceivable that these forecasts would be in error by a degree that would entail greater risk by continuing to the landing site than would be incurred by diverting to an emergency field with its lack of facilities, navigation aids, trained personnel, and flightcrew familiarity.

Diverting from the targeted site will not be done just for deteriorating weather conditions which will violate weather flight rules or landing and rollout margin reductions. We will accept the nonoptimum conditions rather than divert to another site since it is believed that this option provides less risk to the orbiter and crew as well as the general public. ©[120894-1744B]

Should it be necessary to divert from the primary landing field, another NASA augmented landing field will be selected if available. Otherwise, site selection will be based on facility type (DOD vs commercial) and the availability of compatible shuttle UHF communications. The facility priority has been selected to minimize risk to the general public. ©[120894-1744B]

BAILOUT

- A. THE CDR IS RESPONSIBLE FOR BAILOUT ACTION.
- B. THE MCC WILL EVALUATE ALL POSSIBLE ENERGY MANAGEMENT ACTIONS PRIOR TO RECOMMENDING BAILOUT. @[120894-1744B]
- C. THE FOLLOWING DEFINITIONS APPLY TO THE BAILOUT REGIONS DEFINED BELOW:
1. MCC MAX RANGE LINE: THIS LINE IS GENERATED ON LANDING DAY AND BASED ON A STRAIGHT-IN APPROACH TO THE MINIMUM ENTRY POINT HAC, WITH MAXIMUM L/D STRETCH TECHNIQUES AND ACTUAL WINDS AND ATMOSPHERIC CONDITIONS.
 2. MCC RTLS MINIMUM ENERGY LINE: THIS LINE IS GENERIC FOR ALL FLIGHTS AND ASSUMES A FORWARD CG, MID-WEIGHT, HEAVYWEIGHT I-LOADS, COLD ATMOSPHERE, AND NO WINDS.
 3. MCC BAILOUT LINE: THIS LINE IS GENERIC FOR ALL FLIGHTS AND REPRESENTS A BEST-ON-BEST MAXIMUM CAPABILITY, BASED ON 3 SIGMA FAVORABLE WINDS, MAXIMUM HAC SHRINK, AND MAXIMUM ORBITER L/D.
- D. AN MCC BAILOUT RECOMMENDATION WILL BE MADE BASED ON THE FOLLOWING CRITERIA, USING THE BEST AVAILABLE SITE, RUNWAY, AND STATE VECTOR SOURCE, AND WITHOUT REGARD TO TOUCHDOWN, BRAKE ENERGY AND ROLLOUT MARGIN PLACARDS:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251

BAILOUT (CONTINUED)

1. GREEN: BAILOUT NOT REQUIRED (CALL ONLY REQUIRED IF TRANSITIONING FROM THE "YELLOW" REGION).
 - a. EOM LANDINGS: ORBITER ENERGY/WEIGHT ABOVE THE MAX RANGE LINE.
 - b. ALL OTHER LANDINGS: ORBITER ENERGY/WEIGHT ABOVE THE MCC RTLS MINIMUM ENERGY LINE. @[120894-1744B]
 2. YELLOW: BAILOUT IF DEEMED NECESSARY BY THE CDR; MCC CONTINUES TO MONITOR. @[120894-1744B]
 - a. EOM LANDINGS: ORBITER ENERGY/WEIGHT BELOW THE MAX RANGE LINE AND ABOVE THE MCC BAILOUT LINE.
 - b. ALL OTHER LANDINGS: ORBITER ENERGY/WEIGHT BELOW THE MCC RTLS MINIMUM ENERGY LINE AND ABOVE THE MCC BAILOUT LINE.
 3. RED: MCC RECOMMENDS BAILOUT.

ORBITER ENERGY/WEIGHT BELOW THE MCC BAILOUT LINE.
- E. IF POSSIBLE, BAILOUT WILL BE DECLARED NO LOWER THAN 50K FT ALTITUDE (70K FT FOR ECAL).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251 BAILOUT (CONTINUED)

- F. NORMALLY, ZERO DEGREES OF BANK WILL BE USED FOR BAILOUT GUIDANCE "FREEZE" CONDITIONS. HOWEVER, THE MCC MAY PROVIDE A DESIRED BANK ANGLE (UP TO 10 DEG) IF REQUIRED TO AVOID ORBITER IMPACT IN POPULATED AREAS.
- G. IF BAILOUT IS DECLARED FOR ECAL, A TURN SHALL BE EXECUTED TO A HEADING OF 120 DEG, UNLESS FDO DETERMINES IN REAL TIME A HEADING MORE FAVORABLE FOR SAR OPERATIONS (E.G., PARALLEL THE COAST, ETC.)

Reference Rule {A1-6}, SHUTTLE COMMANDER AUTHORITY, for CDR responsibilities.

The MCC has more accurate evaluation tools with which to determine energy capability and uses radar tracking data (when available) as the prime state vector source. All energy management and recovery procedures will be evaluated prior to any bailout recommendation being issued by the MCC. Three bailout zones, green, yellow, and red, have been identified for MCC bailout recommendation, based on areas delineated on FDO Energy/Weight versus Range-to-go displays.

The bailout green zone is defined as that area above the MCC maximum ranging capability line which is generated for EOM on landing day, based on a straight-in approach to the minimum entry point HAC, with maximum L/D stretch techniques and actual winds and atmospheric conditions. For all other cases, this flight and landing day-specific actual capability line does not exist, and the MCC RTLS minimum energy line will be used. This line is generic for all flights and assumes a forward CG, mid-weight, heavyweight I-loads, cold atmosphere, and no winds. These two lines generally lie very close together. In the green region, bailout is not required. A green zone call is not made unless the vehicle has recovered from the yellow zone below. @[120894-1744B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-251 BAILOUT (CONTINUED)

The bailout yellow zone is defined as that area below the MCC maximum ranging capability line, described above (again, when a max range line is not available, the generic MCC RTLS minimum energy line will be used), but above the MCC bailout line. The bailout line is generic for all flights and represents a best-on-best maximum capability, based on 3 sigma favorable winds, maximum HAC shrink, and maximum orbiter L/D. In this region, the a “bailout yellow zone” call will be made. Requests are likely to be made for runway/HAC redesignation, stretch techniques, and relaxation of NZ, surface wind, touchdown point, and rollout margin constraints to increase available runways. Below the maximum ranging capability line, there is less than a 50 percent chance of reaching the field. In this region, the MCC will only advise the crew of the energy situation and continue to monitor their progress in making up the energy shortfall. A final bailout decision is the CDR’s call. ©[120894-1744B]

The bailout red zone is defined as that area below the MCC bailout line described above. In this region, there is no chance of reaching the runway threshold and the MCC will recommend bailout. To provide adequate time for bailout operations, bailout will be declared at an altitude no lower than 50K ft, if possible. For ECAL trajectories, 70K ft is used to allow adequate time to execute a maximum turn of 180 deg prior to initiating bailout, thus ensuring bailout over water.

The MCC will recommend a bank angle in order to improve recovery effectiveness or to steer away from populated areas. Analysis has shown that a bank angle of greater than 10 deg can cause the vehicle to turn a full 360 deg of heading with impact occurring in the crew bailout landing area. If bailout is required during an ECAL, a turn to a standard heading of 120 deg will be made to avoid orbiter land impact and to provide search and rescue (SAR) forces with a consistent heading with which to begin rescue operations, unless the FDO can determine a more favorable heading based on knowledge of the positions and potential ranging capability of the SAR forces. ©[120894-1744B]

A2-252 GCA CRITERIA

IF THE TRAJECTORY DIVERGES AND APPROACHES ENERGY LIMITS POST-TRACKING, CSS WILL BE SELECTED AND GCA PERFORMED. AUTO GUIDANCE WILL BE RESELECTED WHEN ENERGY AND NAVIGATION ARE WITHIN LIMITS, THE GCA WILL ALSO BE TERMINATED WHEN THE CREW TAKES OVER AFTER VISUAL ACQUISITION OF THE RUNWAY. ©[120894-1663]

Generally, the entry trajectory can get into an off-nominal emergency situation by (1) incorporating erroneous navigation data into guidance and flight control, and (2) selecting an incorrect or invalid landing site. Performing GCA provides a possibility of making the runway.

FLIGHT RULES

A2-253

ENERGY MANAGEMENT

IF INSUFFICIENT OR EXCESS ENERGY EXISTS TO ACHIEVE THE TARGETED APPROACH TO THE SELECTED RUNWAY, THE FOLLOWING OPTIONS WILL BE EVALUATED FOR CORRECTION OF THE ENERGY ERROR.

- A. OVERHEAD/STRAIGHT-IN HAC RESELECTION
- B. NOMINAL/MINIMUM ENTRY POINT SELECTION
- C. RUNWAY REDESIGNATION - MAY RESULT IN VIOLATION OF TOUCHDOWN, BRAKING, AND/OR ROLLOUT MARGIN CONSTRAINTS
- D. GROUND CONTROLLED APPROACH (GCA)

Several options are available to correct a bad energy situation. These options include HAC reselection (overhead/straight-in), runway redesignation, final approach entry point downmoding (NEP/MEP), or GCA. No action will be recommended until data shows that the energy error is large enough that the prime selected runway/HAC cannot be achieved or will cause the vehicle to exceed H-dot or g-limits while following auto guidance.

Runway redesignation or HAC reselection are both very powerful methods of changing the required range-to-go (energy requirements). These two methods are preferred since valid guidance commands are available. Runway redesignation may be recommended over HAC reselection, based on the amount of energy correction required. The approach direction relative to the runway layout will define which is the most effective option for correcting the energy error (range error). Redesignation may result in selection of a runway which violates some of the touchdown, rollout, or brake energy constraints. Reaching the runway final approach within an acceptable energy corridor has priority over satisfying the touchdown and rollout constraints. All efforts will be made to redesignate to runways which satisfy the touchdown and rollout criteria.

Downmoding the final approach entry point (NEP to MEP) does provide valid guidance commands; however, the MEP selection greatly reduces the amount of time available for trajectory corrections on final approach. (NEP intercepts final approach at approximately 12K feet; MEP is at approximately 6K feet.) Once each of the above options has been evaluated and excessive energy error persists, a GCA will be required. The GCA may include HAC or runway reselection and will require action outside of the current guidance capability in order to correct the range error.

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT

- A. PRIOR TO MM 304, RESTRINGING WILL BE PERFORMED TO REGAIN FULL CAPABILITY FOLLOWING A GPC FAILURE.

The timeframe between post-deorbit burn and the transition to MM 304 is generally quiet from a computer point of view and crew workload. As such, the risk of restringing is considered to be low. Consequently, restringing will be performed to regain full capability for the dynamic phases of entry (MM 304/305).

- B. RESTRING GPC/STRING COMBINATIONS WILL BE SELECTED WHICH MOVE THE LEAST NUMBER OF STRINGS WHILE SATISFYING CRITICAL CAPABILITY OR ONE-FAULT TOLERANT REQUIREMENTS AS IDENTIFIED IN PARAGRAPH C.

The greater the number of strings moved during a restring attempt, the more complicated the restring process. With this in mind, "good" strings should not be taken from "good" GPC's unless there is no other method of satisfying the identified requirements in orbiter systems.

- C. DURING ENTRY/GRTLS (MM 304, 305, 602, AND 603), RESTRINGING WILL BE PERFORMED AS FOLLOWS (TIME PERMITTING) TO REGAIN THE FOLLOWING CRITICAL SYSTEMS CAPABILITY:

Certain systems capabilities are required to be maintained for safety considerations where the BFS cannot provide additional systems capability.

1. NOSE WHEEL STEERING (FOR RTLS/TAL/AOA (KSC) OR ANY SITE WITH KNOWN DIRECTION CONTROL PROBLEMS).

NWS is required to maintain lateral control during rollout at landing sites where the lateral runway environment is limited. BFS engage at touchdown to recover NWS is an option. However, it was determined to attempt restring during entry to regain NWS and accept risk of BFS engage as a result of the restring instead of nominally engaging the BFS for this case at NGTD. Reference Rule {A10-141A}, NOSE WHEEL STEERING (NWS), for NWS directional control requirements.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-254****ENTRY STRING REASSIGNMENT (CONTINUED)**

2. ASA COMMAND (MAINTAIN TWO ELEVON, RUDDER, AND SPEEDBRAKE; MAINTAIN ONE BODY FLAP).

Two elevon, rudder, and speedbrake FCS command channels (each of which have four command channels) are required since flying with only one FCS channel on an actuator is an uncertified flight control mode. Only one of three body flap command channels is required to maintain acceptable drive capability. Control may be available long enough to allow restring procedures to be completed to regain the required FCS channels rather than defaulting over to the BFS.

3. VENT DOORS:

- a. FORWARD/AFT VENT DOORS IF REQUIRED TO REGAIN THE CAPABILITY TO OPEN AT LEAST ONE SIDE OF THE FWD AND AFT COMPARTMENTS FOR SUFFICIENT VENTING.

Data presented at the Ascent/Entry Flight Techniques Panel (A/E FTP) #43 (August 1988) showed that adequate venting margins could be maintained if at least one side of the forward and aft compartments is opened by 70,000 feet altitude. Failures resulting in loss of open capability on both sides of the forward or aft compartments would result in structural failure and loss of crew/vehicle. Therefore, a critical bus reassignment prior to or at TAEM to regain the open capability on at least one side should be performed, when applicable.

- b. MIDBODY VENT DOORS: @[051194-1586A]

(1) FOR LOSS OF MORE THAN TWO MIDBODY VENT DOORS

OR

(2) FOR LOSS OF OPPOSING MIDBODY VENT DOORS

JSC Engineering presented a venting analysis of the modified vent door configuration (vents 4 and 7 deleted) at the A/E FTP #87 (February 1992). The data showed that positive structural margins exist for a nominal entry trajectory, even after two midbody vent doors have failed closed. This analysis was performed only for scenarios that could result from two electrical/avionics failures. Because opposite vent door failures (i.e., left/right 5) require more than two failures, they were not specifically analyzed, but to assure adequate venting, a restring should be performed. JSC Engineering also presented data which suggested that opposite forward and aft compartment vent doors are redundant to each other in providing adequate venting for a nominal entry. @[051194-1586A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-254

ENTRY STRING REASSIGNMENT (CONTINUED)

The A/E FTP #87 members concluded that a critical bus reassignment should only be performed after loss of more than two midbody vents has occurred for either vehicle configuration. Restringing for these cases provides the most prudent venting management plan, trading the effects of a potentially dispersed entry trajectory with the potential risks of a dynamic restrung of flight-critical buses.

4. MPS LH₂ MANIFOLD ENTRY PRESSURIZATION (FOR RTLS/TAL).
@[022802-5221]

There is insufficient time on RTLS and TAL entries to dump all hydrogen from the Main Propulsion System (MPS) LH₂ manifold. The pressurization of the LH₂ manifold with helium prevents air from being ingested into the manifold during entry. The loss of this helium pressurization will result in the creation of an explosive mixture in the LH₂ manifold as air is ingested and mixes with the hydrogen residuals. Although difficult to quantify, the hazard to the flight crew from an explosive mixture in the MPS LH₂ manifold represents an unnecessary risk. At the A/E FTP #168 (October 27, 2000), it was decided that the recovery technique for the loss of LH₂ manifold pressurization could be a switch throw, temporary port mode (to latch the LH₂ manifold pressurization commands), or restrung. In general, a switch throw will be attempted before a port mode, which will be attempted before a restrung; however, the recovery technique used will depend upon the specific flight phase and failure scenario present in the orbiter. @[022802-5221]

- D. RESTRINGING WILL NOT BE PERFORMED WITHOUT PRIOR MCC COORDINATION.

The MCC is prime for determining when restringing is required as a result of multiple failures and the resulting GPC/string assignments required to satisfy critical capability and systems fault tolerance as identified in the preceding rules. The MCC is prime for determining the acceptability of restringing based upon the failure signature and conditions and for determining an acceptable data bus reassignment configuration. As a minimum, voice description of the failure and identification of the proposed bus reassignment must be coordinated with the MCC prior to performing any restrung.

- E. FOR A SINGLE GPC FAILURE, RESTRINGING WILL NOT BE PERFORMED AFTER EI MINUS 5 MINUTES.

EI minus 5 minutes was selected as the last time for which restringing would be performed as a result of a single GPC failure in order to allow recovery time prior to EI to regain PASS capability should the restrung be unsuccessful.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-254****ENTRY STRING REASSIGNMENT (CONTINUED)**

F. RESTRINGING WILL NOT BE PERFORMED AFTER HAC INTERCEPT.

Crew workload increases after HAC acquisition as concentration is directed towards the immediate landing tasks. Restringing will not be performed during this timeframe so as not to divert crew attention away from the critical landing phase tasks. Although no fault tolerance exists, the exposure to the next failure is minimized since the time between HAC intercept and touchdown is relatively short.

G. RESTRINGING WILL BE PERFORMED TO REGAIN CRITICAL CAPABILITY INDEPENDENT OF THE BFS STATUS. FOR CASES WHERE RESTRINGING IS ACCEPTABLE TO REGAIN FAULT TOLERANCE (REF. PARAGRAPH A), AN ENGAGEABLE BFS MUST BE AVAILABLE.

The BFS is normally required when restringing is performed as a precaution against the low probability occurrence that the restring action may result in loss of the PASS set. However, when the vehicle has sustained failures such that less than critical capability remains (a capability which must be maintained or a loss of crew/vehicle will result), restringing will be performed to regain the needed capability independent of the BFS status in order to maintain the flying status of the orbiter.

If the BFS is not available and less than critical capability remains, restring is allowed to recover the PASS capability to control the orbiter. If the BFS is available and conditions are such that either a BFS engage or a dynamic restring will recover the critical capability, restring will be attempted if time permits completion of the restring while still maintaining the BFS engage option.

Rules {A2-5}, PORT MODING/RESTRINGING GUIDELINE; {A5-209}, ENTRY MPS HELIUM PURGING FOR CRITICAL VEHICLE POWER/COOLING; {A7-6}, DATA PATH FAILURE; {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA; {A7-105}, MDM PORT MODING; {A7-52}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES; and {A10-25}, APU HIGH SPEED SELECTION/SHIFT reference this rule. ©[022802-5221] ©[ED]

FLIGHT RULES

A2-255

CREW TAKEOVER

CREW TAKEOVER (DOWNMODING FROM AUTO TO CSS) PRIOR TO NOMINAL TAKEOVER ALTITUDE WILL BE PERFORMED FOR THE FOLLOWING REASONS ONLY (REF. RULE {A4-208}, ENTRY TAKEOVER RULES):

- A. TO AVOID LOSS OF CONTROL OF THE VEHICLE.
- B. TO PRESERVE THE TRAJECTORY WITHIN THE TARGETED RUNWAY LANDING CAPABILITY.

Whenever the crew must override the guidance limitations to maintain adequate energy capability for reaching the prime selected runway, the CSS mode must be selected. Whether under GCA control or manually flying with visual assistance, the crew must select CSS and bypass the onboard guidance commands.

- C. DELTA STATE UPDATES:
 - 1. ANY POSITION AND VELOCITY DELTA STATE.
 - 2. A POSITION-ONLY DELTA STATE BETWEEN M5 AND TAEM (M2.5 FOR EOM/AOA, M3.2 FOR RTLS).

CSS mode is required for all position/velocity delta states to avoid severe attitude transients once the onboard NAV is updated. For OPS 3 position-only delta states between M5 and TAEM, CSS must be selected to avoid strong attitude transients. MM 304 entry guidance will very aggressively attempt to remove energy errors by TAEM interface (M2.5). Above M5, the guidance has more time to correct energy errors. Therefore, position delta states above M5 should not cause severe transients. After the energy has converged close to nominal, the crew can reselect auto. GRTLS guidance is not as aggressive as OPS 3 guidance in removal of energy errors by TAEM interface (M3.2). ©[052401-4524A]

- D. GPS NAVIGATION UPDATES WHEN PERFORMED AS AN ALTERNATIVE TO DELTA STATE UPDATES.

Once GPS state vector accuracy has been confirmed with ground filter solutions, a GPS update is preferred over the delta state update process to correct onboard navigation errors that exceed flight rule limits. Metering logic, which limits the updates to the user parameter reset state, may be overridden prior to the GPS force procedure to expedite the time required to update the user parameter reset state. If metering is overridden, CSS mode is required for all GPS to NAV force operations to avoid severe attitude transients once the user parameter reset state is updated. ©[052401-4524A]

FLIGHT RULES

A2-256

EARLY POWERDOWN

EARLY POWERDOWNS ARE DEFINED AS REMOVAL OF POWER FROM THE ORBITER ELECTRICAL BUSES PRIOR TO EOM POWERDOWN. EARLY POWERDOWN WILL BE ACCOMPLISHED FOR ELS LANDINGS, FAILURE OF THE COOLING CART, ANY ORBITER MALFUNCTIONS THAT CONSTITUTE A SAFETY HAZARD (E.G., FUEL LEAK), OR THE THREAT OF SIGNIFICANT ORBITER EQUIPMENT DAMAGE. IN ALL CASES, THIS WILL BE WITHOUT REGARD TO THE INTEGRITY OF ANY RETURNED PAYLOAD.

A2-257

DEORBIT BURN TERMINATION

THE DEORBIT BURN WILL BE TERMINATED (PRIOR TO EXCEEDING A SAFE PERIGEE AS PROVIDED ON THE DEORBIT/ENTRY/LANDING (DEL) PAD FOR THE FOLLOWING FAILURES:

- A. OMS PROPELLANT TANK (ABOVE SINGLE TANK COMPLETION HP ON DEL PAD).
- B. PASS REDUNDANT SET FAIL OR RS SPLIT FOR WHICH RECOVERY HAS NOT BEEN ATTEMPTED.
- C. IMU DILEMMA.
- D. TWO MAIN BUSES.
- E. TWO OMS ENGINES (IF RCS DOWNMODE CAPABILITY DOES NOT EXIST).

The deorbit burn will be terminated for systems failures which preclude controllability or the ability to perform a safe entry. Loss of fault-tolerance will not be cause for terminating the deorbit burn.

For failure of both OMS engines, propellant may not be available to complete the deorbit burn with the RCS +X jets to the original targets. The deorbit burn must be terminated and retargeted to shallower targets. This retargeting will require a 24-hour deorbit delay.

A2-258

BFS ENGAGE

BFS WILL BE ENGAGED IN ENTRY FOR THE FOLLOWING:

- A. LOSS OF REDUNDANT SET.
- B. LOSS OF CONTROL.

Reference Rule {A7-1}, PASS DPS FAILURE. ©[071494-1636]

FLIGHT RULES

A2-259

CHASE AIRCRAFT OPERATIONS

- A. T-38 CHASE AIRCRAFT WILL BE UTILIZED ON AN "AS REQUIRED" BASIS.

T-38 chase aircraft can be used to provide photo documentation of orbiter condition and damage prior to touchdown and rollout, visual inspection for fluids, flames, gear door damage, etc., backup for altitude and airspeed, visual call to orbiter crew in case of wind screen obscurations, and downlink TV to NASA/PAO.

- B. T-38 CHASE RENDEZVOUS WILL BE DISCONTINUED IF:
1. VISUAL/RADAR CONTACT NOT ESTABLISHED WITHIN 1 MINUTE OF ORBITER RENDEZVOUS POINT AT 40K FEET MSL
 2. VISUAL CONTACT NOT ESTABLISHED WHEN WITHIN 4 NM AS REPORTED BY RADAR CONTROLLER DIRECTING THE INTERCEPT
 3. CHASE RENDEZVOUS NOT COMPLETE BY PREFLARE
 4. VISUAL CONTACT LOST AFTER RENDEZVOUS

The T-38 chase aircraft will break off from the rendezvous attempt when it is considered unsafe to continue. Attempting a join-up without visual contact could result in vehicle collision or create a situation that would cause the orbiter to maneuver to avoid impact. Chase aircraft procedures are found in Aircraft Operating Procedures, Volume 1, T-38A Aircraft.

- C. CHASE AIRCRAFT WILL MAINTAIN A MINIMUM LATERAL SEPARATION OF 200 FEET FROM THE ORBITER DURING THE AUTOLAND PORTION OF THE LANDING APPROACH.

The orbiter autoland flight path characteristics are unpredictable and may be abrupt. A 200-foot T-38 chase aircraft separation will allow the chase pilot adequate time to safely avoid unexpected orbiter maneuvers.

FLIGHT RULES

A2-260

ENTRY LOAD MINIMIZATION

IF IT IS REQUIRED TO MINIMIZE ENTRY LOADS, THE FOLLOWING STEPS WILL BE CONSIDERED:

- A. DELETE ENTRY TEST MANEUVERS.
- B. SELECT RUNWAY AND HAC TO MINIMIZE TAILWIND COMPONENT AT HAC INTERCEPT.
- C. SELECT AN SLS IF SIGNIFICANT WINDS AND/OR TURBULENCE CANNOT BE AVOIDED AT THE PLS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

a. AERO PTI DTO NO-GO:

The AERO PTI and Xwind DTO's will not be performed when navigation or flight control systems are fail critical. Maintaining single-fault tolerance for AUTO flight control, and allowing an acceptable crew workload are required for performing the DTO's. In addition to be GO for the Xwind DTO, single-fault tolerance is required for the CDR's displays and controls.

(1) APU/HYD

2 APU - If two APU/HYD systems are lost, the remaining system must supply all necessary loading to perform entry. PRL will limit the available hydraulic power in an optimum management scheme in order to prevent overloading the single remaining system. Data has shown that entry PTI's place a short duration high load on a hydraulic system. For this reason, aero PTI'S should not be performed in order to minimize stress on the single APU/HYD system.

(2) DISPLAYS

(a) ADI

AERO PTI DTO:

The ADI is required to monitor vehicle attitude and rates for crew takeover.

(b) CDR HUD

XWIND DTO:

The CDR relies on the HUD for critical landing data and cues. Flying is more difficult without this instrument, and landing in high crosswinds increases the level of difficulty. The CDR's HUD is not required if PAPI's and ball bar are available, since these landing aids provide guidance for the approach and glide slope.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(3) *CONTROLLERS*

(a) *RHC*

L RHC-ONE CHNL FAILED L RHC FAILED

XWIND DTO:

The left RHC is either zero-fault tolerant or failed. It is very desirable for the CDR to manually control the vehicle during approach and landing. For this reason, the PLT will not execute the DTO. If the PLT must fly (left RHC failed), then it is prudent to redesignate, if possible, to a runway with more nominal conditions.

TWO RHC CHNL'S FAILED EACH SIDE

AERO PTI DTO, XWIND DTO:

The next failure could cause vehicle control problems since the output from the remaining two channels is summed. The additional maneuvers associated with the DTO's increase the possibility of having vehicle control problems with the next failure. For these failures, at least one of the flight controller power switches should be turned OFF, and both when not being used (ref. Rule {A8-105}, CONTROLLERS).

(b) *RPTA*

TWO RPTA CHNL's FAILED ONE SIDE

XWIND DTO:

The RPTA channels are zero-fault tolerant and the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(4) GNC

(a) AA's

TWO LATERAL AA's FAILED

AERO PTI DTO:

The AA lateral feedback is used for turn coordination to reduce the effects of IMU errors. It is also used in the roll/yaw channel to help form the lateral (Ny) command. The next failure could cause bad vehicle control.

XWIND DTO:

The lateral AA feedback is zero-fault tolerant and the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

(b) TWO NORMAL AA's FAILED

AERO PTI DTO, AUTO MODE:

The NORM AA feedback is used by guidance to form the Nz command for flight control in MM 305. After two failures the system is zero-fault tolerant in AUTO. The crew is required to fly CSS in pitch in MM 305 (ref. Rule {A8-5}, ACCELEROMETER ASSEMBLIES (AA) FAULT TOLERANCE), and aero PTI's are automatically inhibited while in CSS.

(c) RGA's

AERO PTI DTO, XWIND DTO:

The system is zero-fault tolerant for feeding bad vehicle rate data to the flight control system. It is not prudent to perform the DTO's since the added maneuvers increase the risk for control problems with the next failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(d) IMU's

AERO PTI DTO, XWIND DTO:

After the second IMU failure or when one of the remaining two IMU's has a BITE, the system is fail critical. In either case, the next failure can cause navigation and flight control to use bad IMU data. The additional maneuvers associated with the DTO's increase the probability of vehicle control problems with the next failure.

(e) ADTA's

TWO ADTA's FAILED

XWIND DTO:

The system is zero-fault tolerant because the next failure requires the crew to fly theta limits. Manual flying is more difficult with no air data, and the higher crosswinds increase the piloting task.

ADTA NOT INCORPORATED

AERO PTI DTO, AUTO MODE:

If AD is not incorporated into G&C below M=2.5, aero PTI's are automatically inhibited. If below M=2.0 and AD is not incorporated into G&C, the crew is required to fly CSS in the pitch axis to control theta limits. Manual speedbrake is required below 5k feet (ref. Rule {A8-111}, GNC AIR DATA SYSTEMS MANAGEMENT [CIL]). Note that the XWIND DTO is NO-GO if it is known that AD will not be incorporated and it is still possible to redesignate.

(f) FCS CHNL's

AERO PTI DTO, XWIND DTO:

The system is zero-fault tolerant for being in an uncertified flight control mode. The additional maneuvers associated with the DTO's incur more risk with the next failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(g) *RIGHT DDU**XWIND DTO:*

The right DDU provides power for NWS. With two power supplies failed the DTO is NO-GO since NWS must be powered off (ref. Rule {A10-141E}, NOSE WHEEL STEERING (NWS)).

(h) *LOSS OF WOW/WONG**XWIND DTO:*

The crosswinds further complicate the piloting task for loss of WOW or WONG. Both WOW and WONG are required in order to enable NWS, activate AUTO load relief, and enter the rollout DAP mode at nose gear TD. A known loss of WOW or WONG requires the crew to manually set the WOW and WONG discrettes by pushing the SRB or ET Sep pushbutton after nose gear TD. Potential delays in enabling NWS and increased piloting task cause the DTO to be NO-GO.

As a result of OI-21 WOW modifications, the only two-failure scenarios of concern involve the loss of both WONG discrettes (MDM, BUS, or the discrettes themselves).

(5) *AFT RCS*

(a) *Once a leak is detected, the PTI's will be inhibited. This action prevents the PTI's from occurring while performing leak troubleshooting. The leak procedures isolate a leg of RCS jets at a time thus minimizing the amount of jets available for attitude control. Inhibiting the PTI's ensures that any off-nominal perturbations that could possibly occur during PTI execution will be prevented. If a nonisolatable leak is present or the NO-GO criteria is violated due to isolation of the leak (minimum RCS quantity, loss of jets), no further PTI's will be performed.*

(b) *Due to the loss of fail-safe redundancy for orbiter control, the PTI's will not be performed.*

(c) *RCS quantity checks are performed at different points during entry. The minimum quantity includes 3-sigma entry usage at the check and PTI usage to the next check. PTI's will be inhibited to protect 3-sigma entry redlines. ©[041196-1782A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(6) FWD RCS

- (a) *Loss of two FWD RCS yaw jets on the same side would result in unbalanced jet firings during PTI's. The entry command SOP software will prevent the PTI's from occurring as long as RCS RM has deselected the jets. If the FRCs yaw jets have become unavailable prior to entry, the PTI's will not be enabled* @[090894-1562].
- (b) *FWD RCS quantity checks are performed at different points during entry. The minimum quantity includes PTI usage to the next check and ensures positive propellant flow from the FWD RCS.*

Tank residual required to prevent screen breakdown

677 lb	<i>(FWD RCS tanks not designed for entry use)</i>
+ 84 lb	<i>Gauge error</i>
761 lb	<i>Total tank</i>
-307 lb	<i>Hardware trapped</i>
454 lb	<i>Minimum usable FWD RCS</i>
+PTI lb	<i>PTI usage</i>
XXX lb	<i>Total quantity check</i>

- (c) *Once a leak is detected, the PTI's will be inhibited. This action ensures that the PTI's will not occur during leak isolation. Leak troubleshooting consists of securing the entire system. If the leak is nonisolatable or the minimum FWD RCS quantity is violated or minimum jets violated, the PTI's will remain inhibited.*
- (d) *For the loss of RCS RM, the jets will be deselected and not utilized for the PTI's. Per Rule {A6-156}, RCS RM LOSS MANAGEMENT, jets with loss of RM will only be selected if required for attitude hold or to maintain fail-safe redundancy. Because of the risk of firing jets without RM and the low priority of FWD RCS PTI's, the jets will not be reselected to perform PTI's.*
- (e) *FWD RCS gaging is required to monitor the propellant quantity to ensure that minimum FWD RCS quantity will not be violated.*
- (f) *The FWD RCS bulk propellant temperature must be 70 deg F or greater at deorbit TIG. This is required to prevent ZOT's from occurring during PTI's. This is an MCC call since the crew has no insight into the parameter during OPS-3.* @[090894-1562]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(7) TRIM/RATES/CG @[041196-1782A]

TRIM(a) *AILERON TRIM* > ± 2.0 DEGREES @[041196-1782A]*AERO PTI DTO:*

The aileron trim saturation limit is 3.0 degrees. When the trim reaches 2.0 degrees, the PTI's should be inhibited to avoid possible control problems or high RCS usage. Based on SES analysis and previous flight data, 2.0 degrees is a comfortable margin for control, while not being too restrictive. @[041196-1872A]

(b) *ELEVON TRIM* > 3.0 DEGREES (FROM EXPECTED)*AERO PTI DTO:*

The elevon schedule has a 1-degree deadband. Performing PTI's with large elevon trim could increase the level of difficulty in trimming the vehicle. Three degrees off schedule is a sufficiently large elevon trim limit to permit aero maneuvers in any reasonable flight condition, yet provides adequate safety margins for control.

XWIND DTO:

This elevon trim condition indicates that the vehicle is in an off-nominal configuration which may lead to additional problems. It is prudent then to NO-GO the XWIND DTO and avoid complicating the situation during A/L and rollout.

(c) *VEHICLE RATES (PTI)**AERO PTI DTO:*

These limits are in the software and will automatically inhibit (terminate) any PTI in progress. The additional maneuvers associated with the PTI's could make it more difficult for the FCS to damp the rates and regain good control.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

(d) CG

AERO PTI DTO:

With the X or Y CG out of the nominal CG box, continuous firing of ARCS jets may be required to maintain attitude control. To ensure maximum control authority in an uncertified configuration, as well as to save propellant, PTI's will not be performed.
©[041196-1782A]

(8) DOWNMODE

FCS PROBLEM

AERO PTI DTO, AUTO MODE, XWIND DTO:

If the vehicle is experiencing problems with the FCS, due to multiple systems failures and/or unpredicted effects of the environment, then all flight control DTO's are NO-GO, and the crew should fly CSS, if required. The risks associated with performing the DTO's are too great while vehicle control is off-nominal.

(9) PLB

PLBD LATCHES - It is acceptable to perform an entry with any one latch gang (bulkhead or centerline) failed open. Entry loads should be minimized (per Rule {A10-203B}, PLBD CRITICAL LATCHES, and SODB 3.4.2.3). Aero PTI's will not be performed in order to ensure a nominal entry.

(10) DATA

According to the sponsor of the aero PTI DTO, the crew cannot evaluate the results from onboard indications. Either real-time or recorded telemetry is required. This is in agreement with the DTO requirements as documented in NSTS 16725, Flight Test and Supplementary Objectives Document.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

b. XWIND DTO NO-GO

(1) APU/HYD

1 APU and 2 APU

Loss of one APU/HYD system places the orbiter a single failure away from performing entry/rollout on a single system. Orbiter handling qualities have been demonstrated to be degraded when only a single APU/HYD system is operating. If only one APU/HYD system remains, conditions that could adversely affect the already degraded handling qualities should be avoided if possible. Therefore, if one or two APU/HYD systems are lost, the crosswind DTO should be NO-GO.

(2) LANDING/DECEL

(a) TIRE (LEAK)

For a confirmed main gear tire leak, a landing with a crosswind from the side of the affected tire is desirable. If a leak is confirmed in a main or nose gear tire, the load-carrying capability of that tire is reduced.

(b) BRAKE ISOL VLV

Loss of the ability to open one brake isolation valve puts the orbiter one failure away from having only 50 percent braking capability. Full braking capability is required for the crosswind DTO in order to ensure good control of the vehicle in high crosswind conditions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

- (c) <100 PERCENT BRAKES

Full braking capability is required for the crosswind DTO in order to ensure good control of the vehicle in high crosswind conditions.

- (d) NWS

NWS is the primary means of steering the vehicle during rollout. In a strong crosswind, differential braking may not be sufficient to maintain directional control.

- (3) XWIND

- (a) <10 KNOTS PEAK @[041097-4890A]

Winds less than 10 knots are not within the DTO limits and would not produce conditions appropriate for collecting the required DTO data.

- (b) >15 KNOTS PEAK

Crosswinds greater than 15 knots peak violate nominal crosswind limits.

- (c) >10 KNOTS GUST @[041097-4890A]

Crosswinds with gusts greater than 10 knots above the steady-state wind violate nominal limits.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-261

ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO
(CONTINUED)

c. DPS

In general, DPS failures that cause aero PTI DTO, auto mode, and crosswind DTO to be NO-GO are driven by various failures in the GNC, MMACS, and/or PROP systems.

GPC 1 (NOT RSTNG), GPC 2 (NOT RSTNG), FF1, FF2 - Crosswind DTO is NO-GO due to loss of a left RHC channel, and for vehicles without improved NWS, loss of GPC NWS.

GPC 3 (NOT RSTNG), FF3 - Crosswind DTO is NO-GO due to loss of a left RHC channel.

2 GPC (RSTNG) - Aero PTI DTO is NO-GO due to the inherent risk of another GPC failure which would cause GNC systems violations for the DTO.

2 GPC (NOT RSTNG), 2 FF - Aero PTI DTO, auto mode (<M2.5), and crosswind DTO are all NO-GO due to multiple GNC LRU failures.

2 FA - Aero PTI DTO and crosswind DTO are NO-GO due to multiple GNC LRU failures. The aero PTI DTO is also NO-GO due to two aft jets being down.

For additional technical information concerning the rationale for aero PTI DTO, auto mode, and crosswind DTO NO-GO requirements, refer to the rationale for the GNC, MMACS, and PROP systems. @[041097-4890A]

FLIGHT RULES

A2-262

LANDING DTO'S

- A. BRAKING OR NOSE WHEEL STEERING DTO TASKS MAY BE PERFORMED ON DAYLIGHT LANDINGS REGARDLESS OF THE WEIGHT/CG OR FLIGHT DURATION. @[111894-1690B]
- B. BRAKING DTO TASKS MAY BE PERFORMED ON NIGHT LANDINGS SO LONG AS THEY INVOLVE ONLY VARIATIONS IN BRAKING PROFILE OR DECELERATION LEVEL. NO DTO STEERING TASKS USING DIFFERENTIAL BRAKING WILL BE PERFORMED ON NIGHT LANDINGS. @[111894-1690B]
- C. NO DTO STEERING TASKS USING DIFFERENTIAL BRAKING OR NWS WILL BE PERFORMED ON NIGHT LANDINGS. @[111894-1690B]
- D. CROSSWIND LANDING DTO'S ABOVE 12 KNOTS PEAK WILL NOT BE PERFORMED ON NIGHT LANDINGS OR EXTENDED DURATION ORBITER (EDO) FLIGHTS. @[111894-1690B]

Braking or nose wheel steering testing is acceptable during daylight landings since vehicle weight and CG have minimal effects on the rollout piloting task, and visual cues are available to the crew to assess test inputs/results. Braking tests at night are acceptable if they only involve basic braking functions such as varying the deceleration levels or specific braking profile. Steering task DTO's involving either differential braking or nosewheel steering are not acceptable at night due to the loss of visual cues and runway shadowing effects which put the crew and orbiter at unnecessary additional risk. The crosswind limit for EDO or night flights has been set at 12 knots regardless of where you land. You may land with a crosswind between 8 and 12 knots and still meet the crosswind DTO requirements, but the peak wind will not be allowed to exceed 12 knots and approach the 15-knot normal crosswind DTO limit. @[ED]

- E. THE CROSSWIND DTO MAY RESULT IN EXCEPTIONS TO RULE {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES.

If the crosswind DTO is GO per Rule {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, the drag chute will be deployed after NGTD, as stated in the applicable Flight Rule Annex. @[041097-4890A]

- F. LANDING AND ROLLOUT DTO'S WILL NOT BE PERFORMED ON ABORTS (RTLS, TAL, AOA, FD1 PLS) UNLESS THEY ARE DATA GATHERING ONLY, INVOLVE NO CREW ACTIONS, AND POSE NO ADDITIONAL RISK TO THE CREW OR VEHICLE. HOWEVER, DATA FROM ANY ABORT LANDING MAY BE USED TO SATISFY PROGRAM DTO OBJECTIVES. @[100997-6294A]

Programmatic risk is high during an abort. Additional risk or crew distraction should not be incurred for the sake of engineering data that can more safely be obtained on another flight. However, some DTO's are data gathering only and are transparent to the crew; these are allowed. Some DTO's cannot be avoided (e.g., crosswind landings) during aborts and thus will be accomplished anyway. This rule means that off-nominal crew actions (such as delayed drag chute deploy for the crosswind DTO) will not be performed. @[100997-6294A]

FLIGHT RULES

A2-263

STA/WEATHER AIRCRAFT RUNWAY APPROACH OPERATIONS FOR SITES WITH ONLY ONE RUNWAY

A. PRELAUNCH (RTL/TAL)/PREDEORBIT (AOA/EOM)

STA AND/OR WEATHER AIRCRAFT APPROACHES TO PLANNED LANDING SITES WITH ONLY ONE RUNWAY (OPPOSITE END MAY OR MAY NOT BE AVAILABLE) MAY BE PERFORMED AS REQUIRED TO ASSESS NAVAID/VISIBILITY STATUS. ONCE THE FINAL GO FOR LAUNCH OR THE DEORBIT BURN HAS BEEN GIVEN, THESE OPERATIONS WILL BE TERMINATED UNLESS REQUIRED PER PARAGRAPH B.

B. POSTLAUNCH (RTL/TAL)/POSTDEORBIT BURN (AOA/EOM)

POSTLAUNCH OR POSTDEORBIT BURN, STA OR WEATHER AIRCRAFT APPROACHES TO THE SELECTED RUNWAY AT LANDING SITES WITH ONLY ONE RUNWAY (OPPOSITE END MAY OR MAY NOT BE AVAILABLE), WILL ONLY BE DONE IF CONDITIONS MAKE SUCH AN APPROACH NECESSARY. APPROACHES WILL BE MINIMIZED AND WILL BE PERFORMED TO REDUCE THE RISK OF RUNWAY LOSS DUE TO AIRCRAFT PROBLEMS ON APPROACH. TO REQUIRE AN APPROACH POSTLAUNCH OR POSTDEORBIT, A CHANGE OR CONCERN IN ONE OR MORE OF THE FOLLOWING AREAS MUST EXIST:

1. VISIBILITY.
2. NAVAID STATUS/CAPABILITY.

For the case where a landing facility has only one runway (availability of its alternate end does not matter), approaches to landing runways are still performed prelaunch or predeorbit burn to aid in assuring that landing flight rules are met with respect to navaid and visibility status. Such approaches are not considered a threat to landing prior to launch or the deorbit burn.

Once committed to a runway, approaches to that runway or its alternate end, should not be done unless necessary to confirm the ability to land on that runway. There is no reason to continue to shoot approaches to the selected runway if conditions have not changed since the commitment to use the runway. If changes are suspected, however, additional approaches may be performed. If required, they will be done such that risk of losing the runway due to approach aircraft problems will be minimized in order to preserve shuttle landing capability. Techniques to accomplish this include breaking off an approach early or runway flybys vice approaches.

FLIGHT RULES

A2-264

EMERGENCY LANDING FACILITY CRITERIA

THIS RULE DOCUMENTS THE MINIMUM ACCEPTABLE LANDING FACILITY REQUIREMENTS FOR COMMITMENT TO AN EMERGENCY LANDING VERSUS BAILOUT. IT APPLIES FOR ALL LANDINGS. @[120894-1744B]

- A. RUNWAY AT LEAST 7500 FT LONG AND 130 FT WIDE. @[110900-3733C]
- B. RUNWAY COORDINATES RESIDENT IN THE ONBOARD SOFTWARE OR AVAILABLE FOR UPLINK.
- C. OPERATIONAL TACAN OR DME WITHIN 50 NM OF THE SITE, AVAILABLE FOR INCORPORATION INTO THE NAV (MAY REQUIRE UPLINK).
- D. AIRSPACE AND RUNWAY CLEAR.
- E. CONFIRMATION OF FACILITY READINESS FOR ORBITER LANDING VIA MCC OR CREW VOICE CONTACT WITH THE AIRFIELD.
- F. ACCEPTABLE WEATHER FOR ORBITER EMERGENCY LANDING OPERATIONS (REFERENCE RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]).
- G. ACCEPTABLE LIGHTING FOR ORBITER EMERGENCY LANDING OPERATIONS. IF LANDING AT NIGHT WITHOUT XENONS, THE FOLLOWING MINIMUM REQUIREMENTS APPLY:
 - 1. OPERATIONAL RUNWAY EDGE LIGHTS
 - 2. ONE HUD OPERATIONAL

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-264

EMERGENCY LANDING FACILITY CRITERIA (CONTINUED)

Due to the inherent hazards of an orbiter landing, especially at a non-augmented facility, adequate site readiness must be ensured before a landing will be attempted. The runway to be used must be of sufficient length and width to accommodate a safe orbiter landing. The 130 ft value corresponds to the narrowest approved ELS runways in NSTS-07700, Volume X, Book 3. Although the effects of landing on 130 ft wide runways have not been evaluated directly, examination of data from the 2/00 Ames VMS study on minimum acceptable runway length indicates adequate performance should be expected. This study included crosswinds up to 15 kt on runways between 148 ft to 200 ft wide. The maximum lateral excursions seen in this study were less than that required to stay on a 130 ft wide runway. Rio Gallegos, Argentina, the only Program-approved Emergency Site < 148 ft wide, is considered acceptable given the significant gain in emergency deorbit capability it provides. However, until a minimum runway width study is performed, any new runways less than 148 ft being considered for SSP use should be evaluated on a case-by-case basis. The 7500 ft length is based on studies performed in the 2/00 NASA Ames VMS session that showed acceptable performance can be obtained if additional TD energy is removed from the system. ©[1109-3733C]

Prior to OI-30, a manual speedbrake technique can be used to stop the orbiter on a 7500 ft runway and assumes the following: short field speedbrake logic is selected; Auto speedbrake is used down to 3000 ft; the speedbrake is manually set to the Auto speedbrake retract command plus 20 percent at 3000 ft; limiting the maximum speedbrake setting to 75 percent; no speedbrake adjustment made at 500 ft; touchdown at 195 KEAS; at maingear touchdown deploy the chute, derotate, and set the speedbrake to 100 percent; use maximum braking at nosegear touchdown. OI-30 software changes will eliminate the need for the manual speedbrake procedure. Rule {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION, will define when the manual technique is to be employed. Minimum runway length for Space Shuttle purposes, as defined in Vol X, Book 3, considers usable underruns and overruns for runway length. Usable runway length is measured from the threshold (actual or displaced) to the end of the usable overrun. If no overrun is available, usable runway length is measured to the end of the usable runway. Refer to AEFTP #165 minutes for further details. The runway must be resident in the onboard software or available for uplink to allow guidance and navigation aids to be used. ©[110900-3733C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-264

EMERGENCY LANDING FACILITY CRITERIA (CONTINUED)

An operational TACAN or DME is required to provide sufficient onboard navigation accuracy. The coordinates must be resident in the onboard software or available for uplink to allow incorporation into the navigation state. Fifty miles distance from the TACAN to the field is based on Monte Carlo analysis of various TAL scenarios. Redundancy in the TACAN or its power supply is desirable but not required.
©[120894-1744B]

The airspace and the chosen runway must be clear. MCC or crew voice contact with the airfield is required to ensure that the facility is prepared for the landing. In order to reduce the risk to the orbiter, crew, and the general public/civilian population, it is necessary that an intended landing site be notified of an attempted landing as soon as possible. This will allow the airspace and runways to be cleared as well as emergency equipment prepared. Notification may be via state department prearranged channels, NASA agreed to communication channels, or via communication directly with the orbiter crew.
©[120894-1744B]

Acceptable weather for orbiter landing operations is required. These criteria are documented in rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC].

Restrictions are placed on night landings due to a significant loss of visual cues. As a minimum, runway edge lights and a HUD must be operational to assist in visually acquiring the runway and the outer glide slope (if MLS is not available) and to provide a visual reference during braking and rollout (regardless of MLS status).

Rules {A2-205}, EMERGENCY DEORBIT, and {A2-209}, LANDING SITE SELECTION FOR AN INFLIGHT EMERGENCY, reference this rule. ©[120894-1744B] ©[ED]

FLIGHT RULES

A2-265

SINGLE STRING GPS OPERATIONS @[072398-6586A] @[040899-6847]

- A. THE GPS A/I/F FLAGS WILL REMAIN IN INHIBIT FOR ANY CERTIFIED FLIGHT MODE (NOMINAL ASCENT, ATO, AOA, TAL, RTLS, ORBIT, AND NOMINAL ENTRY). GPS USE IN THE PASS AND/OR BFS IN OTHER THAN THE INHIBIT MODE MAY BE CONSIDERED FOR CONTINGENCY CASES WHERE ITS USE COULD PREVENT A CREW BAILOUT AND LOSS OF THE ORBITER. @[072398-6586A] @[040899-6847]

The PASS and BFS have been certified for flight only if the GPS to NAV and GPS to G&C auto/inhibit/force flags remain in the inhibit position. Testing has been performed to confirm the PASS and BFS continue to function with incorporation of GPS; however, full certification testing has not been completed. Performance testing of GPS data incorporated into the onboard navigation has not been completed. Potential contingency scenarios in which GPS may be used could include, but are not limited to, a contingency landing to a site with no ground TACAN or DME and no radar tracking support; a contingency landing to a site with no ground MLS and a low cloud ceiling and visibility; multiple onboard problems resulting in an unacceptable navigation state requiring a command or manual delta state update; multiple IMU problems resulting in a runaway navigation state which is not manageable with delta state updates. In OPS 1 and Major Mode (MM) 601, GPS is only available for incorporation in the BFS. Contingency use of GPS in OPS 1 and MM 601 in the BFS would require CSS in the PASS to fly out the BFS ADI digital errors, unless the commander deemed it necessary to engage in order to fly the vehicle. If possible, contingency use of GPS should be delayed until OPS 3 or MM 602/603. GPS state vector accuracies can be degraded during powered flight due to external tank blockage of GPS satellite signals. BFS navigation updates with GPS during powered flight would only be required to correct extreme errors which could result in unsafe MECO conditions. Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma), since the estimated position error increases rapidly with higher FOM values. The GPS DTO objectives expected to be performed on single string GPS missions may call for the GPS A/I/F function to be in a position other than inhibit. If so, the flight specific flight rules annex will document the exception to this rule and specify the conditions under which the DTO objectives will be performed. @[040899-6847] @[052401-4525]

- B. EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC FLIGHT RULES ANNEX. @[072398-6586A]

FLIGHT RULES

A2-266

SUBSONIC PILOT FLIGHT CONTROL

AT THE DISCRETION OF THE COMMANDER (CDR), THE PILOT (PLT) MAY FLY CONTROL STICK STEERING (CSS) FOR A SINGLE PERIOD (APPROXIMATELY 20 SECONDS) BELOW MACH 1.00 WITH THE FOLLOWING CONSTRAINTS:

@[082202-5636] @[ED]

- A. THE CDR WILL FLY THE ORBITER FROM 15 SECONDS PRIOR TO HAC INTERCEPT THROUGH THE INITIAL ROLL ONTO THE HAC.
- B. THE CDR WILL FLY FROM AN ALTITUDE AGL OF 20,000 FT THROUGH LANDING AND ROLLOUT.
- C. WHEN CSS IS ENGAGED, ONBOARD GUIDANCE COMMANDS WILL BE FOLLOWED.
- D. THE CDR WILL FLY (NO TRANSFER OF CONTROL) FOR THE FOLLOWING CASES:
 1. IF THE MCC RECOMMENDS "DELAYED CSS PREFERRED" PER RULE {A4-156}, HAC SELECTION CRITERIA.
 2. SYSTEMS OR NAVIGATION PROBLEMS THAT REQUIRE CSS, PER RULES {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO NO-GO, AND {A4-208}, ENTRY TAKEOVER RULES.
 3. VEHICLE ENERGY PROBLEMS REQUIRING A GROUND CONTROLLED APPROACH (GCA).
 4. ANY ABORT LANDING.
 5. BFS ENGAGED. @[082202-5636]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-266

SUBSONIC PILOT FLIGHT CONTROL (CONTINUED)

6. ANY GUIDANCE, NAVIGATION, OR FLIGHT CONTROL SYSTEM(S) FAILURE (E.G., CDR HUD) THAT INCREASES THE PROBABILITY OF A TRAJECTORY TRANSIENT RESULTING FROM THE TRANSFER OF CONTROL (MCC CALL). LOSS OF A SINGLE STRING OF REDUNDANCY IN ANY SYSTEM (E.G., ONE AA, ONE FCS CHANNEL, ONE RHC CHANNEL, ETC.) WITH NO OTHER FAILURES IS NOT CAUSE FOR PRECLUDING TRANSFER OF CONTROL. @[082202-5636]
7. IF THE MCC RECOMMENDS NO-GO FOR PLT FLYING BASED ON HAC DYNAMICS (E.G., HIGH TAIL WINDS AT HAC INTERCEPT).
- E. THE PLT IS THE BACKUP TO THE CDR FOR ANY FLIGHT PHASES REQUIRING CSS CONTROL. IF REQUIRED FOR VEHICLE SAFETY, THE CDR MAY TRANSFER CONTROL TO THE PLT AT ANY TIME.

Allowing the PLT to fly for a short period of time during entry enhances training and better prepares the pilot for future orbiter flying tasks. Regular in-flight exercise of transfer of vehicle control between the CDR and PLT during nominal approaches will better prepare crews for potential off nominal situations where an efficient transfer of control would be required to ensure vehicle and crew safety. The intent of this rule is to allow the PLT to fly for approximately 20 seconds during a single period, either prior to HAC intercept or once established on the HAC. During a normal entry, there is sufficient time below Mach 1.00 to allow the PLT to control the orbiter and still allow the CDR sufficient time to complete the more critical maneuvers, such as the initial roll onto the HAC and lining up on final. For periods prior to HAC intercept, control must be transferred back to the CDR no later than 15 seconds prior to HAC intercept to allow the CDR sufficient time to prepare for the time-critical maneuver to roll onto the HAC. The 15-second limit was chosen based on flight experience (STS-102, 100, 108, 109, and 110) and to make the best use of the onboard cues, primarily the HAC predictor (the HAC predictor begins flashing 20 seconds prior to HAC intercept and begins moving 10 seconds prior to HAC intercept). For periods after HAC intercept, or for straight-in approaches, control must be transferred back to the CDR prior to 20,000 feet altitude above ground level (AGL). For an overhead HAC approach this equates to approximately the 90-degrees to go point on the HAC. When CSS is engaged, onboard guidance will be followed, and no inputs will be made other than those required to fly to the glideslope and course centerline, or otherwise ensure a safe landing. @[082202-5636] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-266

SUBSONIC PILOT FLIGHT CONTROL (CONTINUED)

There are some cases in which it is not prudent to allow the PLT to have this training time, however. If the 6 degrees of freedom entry simulation as explained in Rule {A4-156}, HAC SELECTION CRITERIA, indicates that delaying CSS until a HAC turn angle of 180 degrees is preferred, the CDR should fly from CSS initiation through rollout. For these HAC cases, energy stops diverging at the 180-degree point and begins to slowly recover. Handing control of the vehicle between the CDR and PLT in this timeframe is not prudent, since the vehicle energy is already lower than typical and the time to correct any energy problems is diminished. Likewise a vehicle problem as outlined in Rules {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO NO-GO or {A4-208}, ENTRY TAKEOVER RULES, requires significant concentration on the flying task, and a handover of control is inappropriate. Systems failures that would invoke this rule are two AA failures, no or single air data, no yaw jet flight control mode, or a navigation system anomaly that affects the vehicle energy state (GCA). In the event of an abort, flight control handovers between CDR and PLT should be avoided due to the increased risk inherently associated with the abort, and to eliminate the possibility of introducing any handover dispersions to an already challenging abort landing. The transfer of control is assumed to have an insignificant impact on the vehicle trajectory and energy state, although arguably that impact is non-zero. That is, in most cases it is nearly impossible to transfer vehicle control without introducing some very small transient, which for the nominal case is acceptable. However, the transfer of control is not warranted for any guidance, navigation, or flight control system(s) problem(s) that could cause a transfer of control to result in more than an insignificant impact on the trajectory. Additionally, for certain HAC dynamics (e.g., high tail winds at HAC intercept), the flying task requires more setup time prior to HAC intercept, and more time-critical inputs before, during, and after HAC intercept. In these cases, vehicle energy state can be less forgiving for delayed piloting response (at HAC intercept, and for the first 180 deg of HAC) and transfer of vehicle control is not warranted. ©[082202-5636]

Flight crews are trained preflight to transfer control positively and verbally in a CRM environment. Any time that a situation occurs that detracts from the CDR's ability to fly the vehicle, it is acceptable for the CDR to hand control of the vehicle over to the PLT, regardless of the constraints imposed by this rule, if required to ensure a safe landing. NOTES:

- [1] CERTAIN RAPID ENTRY CONDITIONS COULD REQUIRE ENTRY PRIOR TO MCC AND LANDING SITE NOTIFICATION.
- [2] COMM/DATA LINES TO SUPPORT LISTED REQUIREMENTS ALSO MANDATORY.
- [3] 24 OF 64 DTE CHANNELS MANDATORY.
- [4] ASSUMES THREE UNRECOVERABLE GPC'S.
- [5] ACCEPT HIGHEST ABORT MODE AVAILABLE.
- [6] REFERENCE RULE {A5-108}, MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP. @ [ED]
- [7] SECOND STAGE ONLY (REF. RULES {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS.
- [8] REFERENCE RULE {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES). @ [ED]
- [9] TAL/AOA IS ACCEPTED TO PROTECT THE CONTINGENCY CG BOX. IF TAL/AOA DUMP MGMT WILL NOT RECOVER CG, CONTINUE UPHILL.
- [10] TO ALLOW TESTING JETS PRIOR TO ENTRY.
- [11] IF PRIOR TO OMS-1, PERFORM DELAYED ATO. FOR DIRECT INSERTION CUTOFF OMS-2 AT MINIMUM HP. FOR DELAYED ATO, THE RAISE ORBIT MANEUVER WILL NOMINALLY BE PLANNED FOR TTA = 2 (TIME TO APOGEE).
- [12] AFTER OMS-1. CUTOFF OMS-2 AT MINIMUM HP.
- [13] WHERE LEAK IN BOTH SIDES SAME PROPELLANT. IF LEAK RATE SUPPORTS (PROPELLANT ONLY) (IF RCS MUST SUPPORT TO A Q-BAR = 20).
- [14] AFTER DEORBIT TIG, TERMINATING BURN FOR THIS FAILURE REQUIRES DEORBIT 24 HOURS LATER.
- [15] SHALLOW ENTRY IF REQUIRED.
- [16] IF LEAK, PERFORM PERIGEE ADJUSTMENT AT PLANNED DEORBIT TIG IF LEAK RESULTS IN PROJECTED VIOLATION OF POD THERMAL CONSTRAINTS.
- [17] THIS HP ALLOWS DEORBIT OPPORTUNITY 24 HOURS LATER WITH WORST CASE ATT PROFILE (PTC).
- [18] DEORBIT DELAY ONLY REQUIRED IF RCS DOWNMODE CAPABILITY DOES NOT EXIST.
- [19] IF BOTH LEAKS IN SAME SIDE OR BOTH SIDES LEAKING BUT DIFFERENT PROPELLANT, PERFORM NOM.
- [20] IF UNABLE TO OBTAIN VIABLE GNC 3 OPERATION, ENTER ON BFS.
- [21] FAILURE PRECLUDES SINGLE FAULT TOLERANCE. DELAY TO VERIFY RM DECLARED FAILURES OR TO RESOLVE A DILEMMA CASE (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION; AND RULE {A8-8}, ENTRY SYSTEMS RM DILEMMA).
- [22] A ONE-ORBIT WAVE-OFF MAY OR MAY NOT ALLOW SUFFICIENT TIME TO REGAIN SINGLE-FAULT TOLERANCE. IN MANY CASES, DELAYING UP TO ONE DAY WILL BE NECESSARY IN ORDER TO ALLOW SYSTEM COMPENSATION/RECONFIGURATION (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION).
- [23] POST-MECO OMS-1/OMS-2, SHALLOW ENTRY IF REQUIRED.
- [24] IF NECESSARY TO RECONFIGURE TO REDUCED POWER LEVEL.
- [25] AFTER OMS-1, CHECKOUT OMS-2 WHEN MINIMUM HP. NEXT PLS DEORBIT WITH MIXED CROSSFEED IF REQUIRED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-301****CONTINGENCY ACTION SUMMARY (CONTINUED)**

- [26] GO TO ORBIT AND OPEN PLBD'S ASAP.
- [27] ATTITUDE ERROR (>3 DEGREES IN PITCH OR YAW OR >10 DEGREES IN ROLL) WITHOUT CONVERGING RATES OR RATES GREATER THAN 3 DEG/SEC WITHOUT CORRESPONDING ATTITUDE ERRORS (REF. RULE {A8-1}, FCS DOWNMODE).
- [28] IMMEDIATE POWERDOWN REQUIRED.
- [29] POWER DOWN TO SURVIVAL POWER LEVEL.
- [30] DELAY IF REQUIRED TO RECONFIGURE DPS TO TWO PASS AND ONE BFS OR ALLOW 3.5 HOURS OF GPC COOLDOWN TO REGAIN ALL GPC'S.
- [31] IF A 2-SIGMA CONFIDENCE LEVEL OF ACHIEVING AOA CAPABILITY EXISTS. (REF. RULE {A5-157}, ET LOW LEVEL CUTOFF SENSOR FAILED DRY).
- [32] POWER DOWN FOR SINGLE FC ENTRY.
- [33] RESERVED.
- [34] IF INSUFFICIENT DELTA V AVAILABLE TO ACHIEVE ATO, PERFORM AOA SHALLOW OMS-1,-2.
- [35] REFERENCE RULE {A8-2}, SSME THRUST VECTOR CONTROL (TVC) HARDOVER.
- [36] REFERENCE RULES {A11-52A AND B}, LOSS OF BOTH VOICE AND COMMAND.
- [37] WITH CABIN AT 14.7 PSIA AND BOTH 14.7 PSI REGULATORS CLOSED, DP/DT DECAY RATE > 0.15 PSI/MIN, RTLS OR TAL. IF ? 0.15 AND > 0.02 PSI/MIN PLS OR AOA (REF. RULE {A17-201}, CABIN PRESSURE INTEGRITY). @[ED]
- [38] OTHER OPTIONS AND PRIORITIES PER RULE {A4-109}, DEORBIT PRIORITY FOR EOM WEATHER.
- [39] LOSS OF BOTH CABIN FANS WILL REQUIRE IMMEDIATE POWERDOWN AND EXTENSIVE HARDWARE CYCLING TO OBTAIN ORBIT AND ENTRY.
- [40] LIMITING TIME OF ~18 MINUTES (BASED ON 2.76 KWH/FC FOR FC FLOOD WITHOUT PURGING).
- [41] ASSUMES PLBD NOT OPEN.
- [42] REF. RULE {A10-23A}, APU ENTRY START TIME.
- [43] DELAY DEORBIT TO DEplete A LEAKING H₂ TANK OF ANY SIZE. IF TANK CANNOT BE DEPLETED OR IF LEAK IS IN MANIFOLD, DELAY DEORBIT TO ALLOW PRESSURE BLOWDOWN TO REDUCE LEAK RATE TO <1 LB/HR. REFERENCE RULE {A9-260C}.1, CRYO SYSTEM LEAKS [CIL].
- [44] DELAYED ATO IF SUFFICIENT PROPELLANT AVAILABLE IN BLOWDOWN. FOR DELAYED ATO, THE RAISE ORBIT MANEUVER WILL NOMINALLY BE PLANNED FOR TTA = 2 (TIME TO APOGEE).
- [45] RESERVED
- [46] RTLS UNTIL NEGATIVE RETURN BECAUSE OF INABILITY TO CLOSE ET DOORS.
- [47] RESERVED
- [48] IF DEPLOYABLE PAYLOADS ARE ONBOARD, PERFORM NEXT PLS ENTRY AFTER ATTEMPTS HAVE BEEN MADE TO DEPLOY THE PAYLOADS. OTHERWISE ENTER FIRST DAY PLS (REF. RULES {A10-21A}.2, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS, AND {A10-122}, LOSS OF WSB(S) ACTIONS.
- [49] IF FREEZEUP SUSPECTED, REMAIN ON ORBIT TO ATTEMPT TO THAW OUT THE HI-LOAD EVAPORATOR.
- [50] THE SIMULTANEOUS CLOSE PROCEDURE IS AN OPTION FOR THE EXCESSIVE OVERLAP CASE (REF. RULE {A10-207}, PLBD OVERLAP).
- [51] SELECT ABORT MODE WITH SHORTEST RETURN TIME.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A2-301****CONTINGENCY ACTION SUMMARY (CONTINUED)**

- [52] IF BOTH LOOPS FAILED IN BYPASS OR MEDIUM FLOW.
- [53] AFTER DEORBIT TIG, TERMINATE BURN FOR FAILURE IF HP > SAFE HP. REQUIRES DEORBIT 24 HOURS LATER.
- [54] RATES > 5 DEG/SEC IN PITCH OR YAW. REFERENCE RULE {A8-54}, FIRST STAGE LOSS OF CONTROL DEFINITION. @[ED]
- [55] AT LEAST ONE CHANNEL REQUIRED EACH SIDE. REFERENCE RULE {A8-1001}, GNC GO/NO-GO CRITERIA.
- [56] IF ONE ORBIT DELAY NOT AVAILABLE, DELAY 1 DAY. FOR PROPELLANT LEAKS, IT MAY BE NECESSARY TO DELAY LONGER THAN ONE ORBIT IN ORDER TO ALLOW POD THERMAL ENVIRONMENT TO SUPPORT ENTRY.
- [57] IF TIG BETWEEN 45 AND 15 MINUTES AND ONE REV LATE DEORBIT IS AVAILABLE, REOPEN PLB DOORS AND WAVE OFF ONE REV. IF RADS ARE COLDSOAKED AND ONE REV LATE DEORBIT NOT AVAILABLE, UTILIZE THE COLDSOAK TO CONTINUE WITH PLANNED TIG. IF RADS ARE NOT COLDSOAKED AND ONE REV LATE IS NOT AVAILABLE, REOPEN PLB DOORS AND WAVE OFF 1 DAY. @[020196-1810A]
- [58] IF TOXIC COMBUSTION PRODUCTS CANNOT BE SATISFACTORILY REMOVED FROM THE CABIN ATMOSPHERE, THE CREW WILL REMAIN ON QDM/LES UNTIL ORBITER EGRESS. EOM IS BASED UPON AVAILABLE N₂ CONSUMABLES FOR MAINTAINING THE O₂ CONCENTRATION WITHIN ACCEPTABLE LIMITS. REF. RULE {A13-152C}, CABIN ATMOSPHERE CONTAMINATION AND {A17-254}, CABIN O₂ CONCENTRATION. @[070201-4726A]
ON ASCENT, FIRST DAY PLS WILL ONLY BE NECESSARY IF THE CABIN ATMOSPHERE CANNOT BE CLEANED UP. IF THE EXTENT OF THE DAMAGE TO EQUIPMENT AND WIRE BUNDLES IS UNKNOWN, EVEN IF THE ATMOSPHERE HAS BEEN CLEANED UP, A NEXT DAY PLS WILL BE PERFORMED TO MINIMIZE THE RISK OF THE OCCURRENCE OF AN ADDITIONAL FIRE OR ARC TRACKING. @[072795-1779] @[070201-4726A]
- [59] PROPELLANT LEAK ONLY.
- [60] ELS WILL PROBABLY BE REQUIRED IF THE NEXT PLS OR SLS IS GREATER THAN 8 HOURS. AS LONG AS CABIN ENVIRONMENT IS ACCEPTABLE, A PLS WILL BE TARGETED. @[020196-1810A]
- [61] CAUSES LOSS OF ONE MOTOR IN EACH OF TWO SEPARATE PLBD LATCH GANGS (REF. RULE {A10-209B}, PLBD RULE REFERENCE MATRIX). DC AND AC SUB-BUSES THAT CAUSE THIS FAILURE ARE:
MNA MPC1, MMC1, MMC3
MNB MPC2, MMC2, MMC4
MNC MPC3, MMC2, MMC4
AC1 MMC1, MMC3
AC2 MMC2, MMC4
AC3 MMC2, MMC4
- [62] ENTER FIRST DAY PLS UNLESS DELTA V IMPROVEMENT POSSIBLE.
- [63] PERFORM PERIGEE ADJUST BURN SEPARATION.
- [64] ORBIT 2 DEORBIT REQUIRED. (REF. RULE {A11-52}, LOSS OF BOTH VOICE AND COMMAND.)
- [65] RESULTS IN LOSS OF TWO FCS CHANNELS.
- [66] EXCEPT COMBINATION OF MDM'S FF4 AND ANY OTHER FF MDM. OTHERWISE, THE FAILURE OF ANY COMBINATION OF MDM'S FF1, FF2, OR FF3 WILL RESULT IN THE LOSS OF TWO IMU'S. MDM IFM MAY BE PERMITTED TO MEET IMU REQUIREMENT. REFERENCE RULE {A7-109}, IN-FLIGHT MAINTENANCE (IFM). @[090894-1684]
- [67] RESERVED
- [68] REFERENCE RULE {A9-158B}, AC POWER TRANSFER CABLE.
- [69] IF REQUIRED TO MAINTAIN TWO-FC ENTRY CAPABILITY.

FLIGHT RULES

A2-301

CONTINGENCY ACTION SUMMARY (CONTINUED)

- [70] FIRST DAY PLS FOR CONFIRMED, UNRECOVERABLE LOSS OF TWO AFT RCS PITCH JETS, SAME AXIS, SAME POD (N/A YAW JETS).
- [71] LOSS OF CNTL CA1 LOSES BFS ENGAGE CAPABILITY FOR GPC 3 AND 5. A DELAY WILL BE INVOKED TO SWITCH BFS MACHINES. REFERENCE RULE {A7-53B}, ON-ORBIT BFS MANAGEMENT GUIDELINES.
- [72] LOSS OF COMPLETE PRIMARY SYSTEM MAY HAVE RESULTED FROM FREEZING OF THE FC H2O RELIEF PANEL. THIS COULD ALSO CAUSE LOSS OF OVERBOARD RELIEF AND LEAVE ONLY THE ALTERNATE SYSTEM FOR FC H₂O REMOVAL. REFERENCE RULE {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA.
- [73] RESERVED
- [74] ENTER NEXT PLS IF A SINGLE ELECTRICAL FAILURE (AC BUS) COULD CAUSE THE LOSS OF AIR COOLING TO TWO AVIONICS BAYS.
- [75] DELAY TO VERIFY POWER, MDM, AND BITE RELATED FAILURES, AND TO ASSESS THE RISKS OF FLYING THETA LIMITS VS. INCORPORATING THE LAST ADTA (REF. RULE {A8-7}, ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION, AND RULE {A8-111B}, GNC AIR DATA SYSTEM MANAGEMENT [CIL]).
- [76] DELAY TO TARGET FOR REQUIRED RUNWAY (REF. RULE {A2-207}, LANDING SITE SELECTION).
- [77] A LANDING WILL BE REQUIRED WITHIN 4 HOURS OF THE FAILURE.
- [78] PLS REQUIRED IF AUTO/MANUAL PPO2 CONTROL CANNOT MAINTAIN AEROMED MINIMUM (REF. RULE {A13-53A}.1, MINIMUM PPO2 CONSTRAINTS) AND LESS THAN 30 PERCENT O₂ AT TOUCHDOWN. ELS REQUIRED IF 40 PERCENT O₂ IS EXPECTED TO BE EXCEEDED PRIOR TO NEXT PLS TOUCHDOWN.
- [79] ENTER NEXT PLS IF TIRE PRESSURE WILL BE £ 275 PSI MAIN, 260 PSI NOSE AT NEXT PLS LANDING OPPORTUNITY PLUS 2 DAYS.
- [80] RESERVED
- [81] RESERVED @[102402-5804C]
- [82] REFERENCE RULE {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.
- [83] FOR LOSS OF TWO MMU'S DURING ASCENT, CONSIDERATION WILL BE GIVEN TO PERFORMING THOSE MISSION OBJECTIVES THAT DO NOT REQUIRE MASS MEMORY RESIDENT FUNCTIONS (I.E., GNC 2, SM, SM ROLL-IN DISPLAYS, OR TELEMETRY/DECOM FORMAT LOADS).
- [84] REFERENCE RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS. IF FD 1 LANDING SITE IS GO, LAND FD 1. IF FD 1 LANDING SITE IS NO-GO, IF POSSIBLE, DELAY DEORBIT TO FD 2. @[121593-1590]
- [85] IF HIGH-SPEED C-BAND RADAR NOT SCHEDULED FOR ENTRY, DELAY AS REQUIRED TO SCHEDULE (REF. RULE {A3-1}, GROUND AND NETWORK DEFINITIONS), UNLESS GPS IS AVAILABLE AND FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). IF MLS FAILURE, DELAY ONLY IF MLS REQUIRED PER RULE {A3-202}, MLS. @[041196-1914] @[ED] @[092602-5640]
- [86] A TOTAL COMBINATION OF 2 TACAN/GPS LRU'S MUST BE LOST FOR THIS RULE TO APPLY GIVEN THAT THE REMAINING 2 LRU'S PROVIDE AT LEAST FAIL-SAFE CAPABILITY WITHOUT REGARD FOR TRACKING AVAILABILITY. @[092602-5640]

A2-302 THROUGH A2-310 RULES ARE RESERVED

FLIGHT RULES

SPACEHAB OPERATIONS MANAGEMENT

A2-311

SPACEHAB SAFETY DEFINITION AND MANAGEMENT

A. DEFINITIONS: @[102793 -1552]

1. **RAPID SAFING** - SECURING OF ANY PAYLOAD ELEMENT IN A TIME-CRITICAL MANNER AS DEFINED BY THE SPACE SHUTTLE PROGRAM FOR ABORTS AND CONTINGENCY RETURN OF THE ORBITER. @[111501-4981E]
2. **UNSAFE** - ONLY TWO INHIBITS CAN BE VERIFIED TO A CATASTROPHIC HAZARD.
3. **HAZARDOUS** - ONLY ONE INHIBIT CAN BE VERIFIED TO A CATASTROPHIC HAZARD.
4. **SAFE** - SHALL BE DEFINED AS ANY ONE OF THE FOLLOWING:
 - a. AT LEAST THREE INHIBITS REMAIN TO A CATASTROPHIC HAZARD, TWO OF WHICH MUST BE MONITORABLE.
 - b. RESTRAINT/SECURING OF ANY PAYLOAD ELEMENT CAPABLE OF PENETRATING A MODULE AS A RESULT OF ORBITER INDUCED ENTRY/LANDING LOADS.

Reference: NSTS 18798A, MA2-96-190, "CONTINGENCY RETURN AND RAPID SAFING," memo dated January 9, 1997. @[111501-4981E]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-311

SPACEHAB SAFETY DEFINITION AND MANAGEMENT
(CONTINUED)

B. GENERALIZED RESPONSES TO UNSAFE/HAZARDOUS CONDITIONS:

1. **RAPID SAFING** - FOR SPACEHAB, CONTINGENCY DEACTIVATION/EGRESS PROCEDURES ARE USED FOR OFF NOMINAL/EMERGENCY SITUATIONS REQUIRING AN EXPEDITED RESPONSE TO SECURE THE MODULE FOR A SAFE ENTRY AS DEFINED IN RULE {A2-329}, SPACEHAB DEACTIVATION/ENTRY PREP. @102793 -1552] @[111501-4981E] @[ED]
2. **UNSAFE** - NO IMMEDIATE ACTION IS REQUIRED. IF POSSIBLE, RESTORATION OF THE SAFE CONDITION WILL NORMALLY BE ATTEMPTED, BUT SUCH ACTION WILL NOT BE ALLOWED TO JEOPARDIZE MISSION SUCCESS.
3. **HAZARDOUS** - QUICK RESPONSE IS MANDATORY: TAKE POSITIVE ACTION TO RESTORE THE SYSTEM TO NO WORSE THAN AN UNSAFE CONDITION. IF UNSUCCESSFUL, TERMINATE THE EXPERIMENT AS SOON AS POSSIBLE (ASAP). @[111501-4981E]

FLIGHT RULES

A2-312

REAL-TIME SAFETY COORDINATION

- A. ANY SPACEHAB PAYLOAD FAILURE WHICH POSES AN IMMEDIATE THREAT TO ORBITER SYSTEMS OR CREW HEALTH (FOR EXAMPLE: BROKEN GLASS, TOXIC SPILLS, SMOKE/FIRE, ANIMAL WASTE, AND FREE WATER) WILL BE COORDINATED BY THE CREW DIRECTLY WITH HOUSTON FLIGHT THROUGH EECOM AND SURGEON, WITH ASSISTANCE FROM HOUSTON PAYLOADS/ACO. HOUSTON PAYLOADS/ACO WILL IMMEDIATELY NOTIFY THE PAYLOAD OPERATIONS CONTROL CENTER (POCC) AND WILL PROVIDE ANY ADDITIONAL COORDINATION WITH OTHER MCC FCT DISCIPLINES, IF NECESSARY. [060800-7124] [111501-4981E]

This approach allows the MCC FCT to prioritize, coordinate, and address the immediate health threat to the crew. All payload-specific questions will be relayed to the POCC. It is understood that the crew will work the appropriate onboard contingency procedures to reduce the immediate threat without talking to the ground first. Crew indication of an electrical short is fire/smoke (covered in paragraph A), popped circuit breaker (covered in paragraph B), or maintained increase in current (covered in paragraph B). For coordination of electrical problems/shorts, reference Rule {A9-355}, FUSE/CIRCUIT BREAKER MANAGEMENT. [111501-4981E] [ED]

- B. ANY PAYLOAD FAILURES, WHICH ORIGINATE FROM PAYLOAD HARDWARE AND DO NOT POSE AN IMMEDIATE THREAT TO ORBITER SYSTEMS OR CREW HEALTH AS DEFINED IN PARAGRAPH A, WILL BE COORDINATED BY THE CREW DIRECTLY WITH THE POCC. THE POCC WILL IMMEDIATELY NOTIFY HOUSTON PAYLOADS/ACO OF ANY SITUATION AFFECTING SAFETY (I.E., LOSS OF CONTAINMENT LEVEL, LOSS OF REDUNDANCY, POTENTIAL SHORT WITHIN PAYLOAD HARDWARE, ETC.). IF THE SITUATION IS NOT WITHIN THE SCOPE OF THE PERMISSION-DEFINED FLIGHT RULES AND PROCEDURES, NO ACTION (OTHER THAN REMOVAL OF THE HAZARD POTENTIAL) WILL BE TAKEN WITHOUT FULL AND PRIOR COORDINATION WITH THE MCC FCT. [111501-4981E]

Safety related payload failures which can be addressed directly between the crew and POCC are those which originate in payload equipment and which do not affect the atmosphere leading to an immediate threat to orbiter systems or crew health. These payload-originated failures must be specifically addressed in permission-defined flight rules and procedures. Although the MCC Flight Director is ultimately responsible for the safety of the orbiter/Spacehab and crew, it is recognized that the POCC has the expertise on and sufficient data/insight into the payload hardware. As soon as the POCC is cognizant of a payload safety situation; however, the MCC must be notified for further assessment of orbiter/Spacehab and crew impacts. The only action(s) which may be taken that is (are) not in the scope of the permission defined flight rules or procedures and without prior coordination with the MCC is (are) to eliminate the hazard cause(s) (i.e., remove power, etc.). For coordination of electrical problems/shorts, reference Rule {A9-355}, FUSE/CIRCUIT BREAKER MANAGEMENT. [060800-7124] [111501-4981E] [ED]

FLIGHT RULES

A2-313

GROUND COMMANDING

- A. ALL PAYLOAD COMMANDING WILL BE COORDINATED WITH HOUSTON FLIGHT THROUGH HOUSTON PAYLOADS/ACO. NOMINALLY, POCC COMMANDING WILL BE THROUGHPUT COMMANDS. TWO-STAGE COMMANDING, CONTINGENCY COMMANDING, AND KU-BAND 128 COMMAND LINK (RDM ONLY) WILL REQUIRE COORDINATION WITH INCO. @[060800-7125] @[111501-4981E]

HOUSTON FLIGHT is responsible for all commanding to the shuttle vehicle, and all commanding must be done with the cognizance of HOUSTON FLIGHT. The specific coordination tasks and configuration authority is usually delegated on Spacehab missions to the Instrumentation And Communications Officer, call sign HOUSTON INCO, HOUSTON PAYLOADS/ACO, and their support personnel. Payload commanding will be identified premission with POCC command windows reflected in the command timeline. Nominally, the Payload Operations Control Center (POCC) will only be enabled during these premission-defined windows. If off-nominal conditions arise real time which necessitate sending commands outside the premission-defined windows, coordination between the POCC and HOUSTON PAYLOADS/ACO will be required to discuss these changes to the Command Timeline during the Tracking and Data Relay Satellite (TDRS) pre-pass briefing and/or just prior to the command sequence. As a minimum, the need to use a premission scheduled command window will be identified to HOUSTON PAYLOADS/ACO during the TDRS pre-pass briefing.

The Ku-band 128-command link, in addition to PSP commanding, is used for Spacehab RDM experiment and experiment data system commanding. @[111501-4981E]

- B. IF COMMAND VOLUMES ARE SUCH THAT COMMAND COORDINATION IS A SIGNIFICANT DETRIMENT TO MISSION SUCCESS, CONSIDERATION WILL BE GIVEN TO SIMULTANEOUS (SIMO) POCC COMMANDING THROUGHOUT EACH TDRS PASS UNDER THE FOLLOWING CONDITIONS. SIMO COMMANDING MUST BE APPROVED BY HOUSTON FLIGHT.
1. THE COMMANDING PARTY IS RESPONSIBLE FOR DETECTING AND RETRANSMITTING ANY LOST COMMANDS.
 2. ALL POCC HAZARDOUS COMMANDING WILL BE COORDINATED WITH HOUSTON PAYLOADS/ACO PRIOR TO COMMAND INITIATION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-313

GROUND COMMANDING (CONTINUED)

3. LARGE COMMAND BLOCKS WILL BE COORDINATED.

SIMO commanding includes two or more POCC's enabled for commanding. The addition of the payload throughput buffer in the systems management (SM) GPC allows for continuous commanding by both the MCC and the POCC's; therefore, MCC and POCC commanding is not considered SIMO commanding. ©[060800-7125]

SIMO commanding is possible, with the risk of the ground system rejecting commands that have insufficient spacing. The ground system is set to allow a maximum of one command per second. If this rate is exceeded, then the ground system will reject the additional commands. This method of commanding is less desirable than a more structured method where ground system rejects are procedurally avoided. If the overhead of the coordination is judged to be a significant impact to payload operations and the overhead of retransmitting the commands is judged to be less, consideration will be given to SIMO commanding. Due to safety considerations, hazardous commands must always be coordinated. Since large blocks of commands require more command system time, more care must be used to avoid ground system rejects and loss of these types of commands; therefore, large command blocks will still require coordination. ©[060800-7125]

- C. IF TWO-STAGE POCC COMMANDING IS REQUIRED, POCC COMMANDING AND MCC COMMANDING TO THE SAME GENERAL PURPOSE COMPUTER (GPC) TWO-STAGE BUFFER WILL BE MANAGED SO THAT ONLY ONE IS COMMANDING AT A TIME. ©[111501-4981E]

A POCC may require two-stage commanding for critical commanding or troubleshooting command problems. To avoid two-stage buffer contention, POCC and MCC commanding will be coordinated. ©[060800-7125]

- D. FOR FAILURE OF THE SPACEHAB FAN IN USE OR FAILURE OF A WATER COOLING LOOP PUMP DURING ASCENT/ENTRY, CONTINGENCY COMMANDS WILL BE SENT TO SWAP FANS OR PUMPS ASAP POST MAIN ENGINE CUT OFF (MECO) OR DURING ENTRY PER RULES {A17-706}, SPACEHAB FAN CONFIGURATIONS OR {A18-553}, SPACEHAB SUBSYSTEM PUMP OPERATIONS.

Air circulation is required to maintain module airflow over the Spacehab fire/smoke detectors. Without switching fans following the loss of the fan in use, all fire/smoke detection capability is lost. The Spacehab water-cooling loop is required for achieving thermal control of the module environment. Without switching pumps following a pump failure, all module cooling is lost. Without smoke detection or adequate cooling, the module would need to be powered down. Powering the module down has the potential for a significant mission success impact. No on-board command capability exists in OPS 1 or OPS 3 (SM GPC not available), so reconfiguration during ascent/entry must be performed via ground commands. The water line heaters must be turned ON, to prevent freezing of the PLHX, if the PLBD's are open. ©[111501-4981E]

FLIGHT RULES

A2-314

SPACEHAB MINIMUM DURATION FLIGHT CRITERIA

FOR AN ORBITER FREON LOOP TO SPACEHAB WATER LOOP LEAK, THE SPACEHAB MODULE WILL BE PREPARED FOR ENTRY, EGRESSED, ISOLATED, AND A MINIMUM DURATION FLIGHT (MDF) WILL BE INSTITUTED. ©[111501-4981E]

Entry prep and egress of the Spacehab module are performed to configure the module for entry and to avoid the possibility of the crew being exposed to toxic Freon. Although the water loop is compatible with Freon 21, a relatively high pressure in the water loop (caused by Freon leaking into the water loop) increases the chances of the water loop developing a leak into the module and exposing the crew to Freon.

An MDF is called for a heat exchanger leak between dissimilar fluids because the possibility exists that a generic problem, such as corrosion, exists in the heat exchanger. This problem could eventually result in a total loss of the heat exchanger and orbiter due to the subsequent loss of two Freon loops. The risk of losing the heat exchanger does not warrant a next primary landing site (PLS) but does warrant an MDF. ©[111501-4981E]

A2-315

POWERING OFF AND REPOWERING SPACEHAB EQUIPMENT

A. SPACEHAB EQUIPMENT/COMPONENTS WILL BE POWERED OFF IF THEY HAVE FAILED AND HAVE ON/OFF CAPABILITY. REFERENCE FAILURE DEFINITIONS IN SECTION 9, SPACEHAB SUPPORT AND SPACEHAB ELECTRICAL POWER SUBSYSTEM (EPS) MANAGEMENT. ©[111501-4981E]

Failed equipment will be powered off to prevent possible intermittent operation and/or shorting. Powering off failed equipment also saves power. Equipment powered by the Emergency Bus cannot be powered off unless both the PL AUX and PL AFT B busses are powered off.

B. SPACEHAB EQUIPMENT NOT CONCERNED WITH SAFETY MAY BE OPERATED OUTSIDE THE QUALIFICATION LIMITS BASED ON CUSTOMER CALL.

Operation to the qualification limits may result in unpredictable operation and/or violation of lifetime limits. The Spacehab customer has chosen to allow for equipment operations (ops) outside of qualification limits based on preflight test experience.

C. REPOWERING SPACEHAB EQUIPMENT AFTER FAILURE OR AFTER EXCEEDING QUALIFICATION TEST LIMITS WILL BE ON MCC CALL ONLY.

The MCC has the ability to evaluate data on the equipment. Consideration must be given to possible damage to orbiter systems or further damage to the affected equipment if repowered. MCC may give consideration to an inflight maintenance (IFM) procedure, trend data, etc., after careful review.

FLIGHT RULES

A2-316

ORBITER-TO-SPACEHAB HATCH CONFIGURATION

- A. FOR THOSE OPERATIONS REQUIRING THE ORBITER INNER HATCH OR THE SPACEHAB HATCH TO BE CLOSED AND LATCHED, ALL CREWMEMBERS ARE REQUIRED TO REMAIN ON THE ORBITER SIDE OF THE CLOSED AND LATCHED HATCH. ©[111501-4981E]

There is no air exchange between the orbiter and the Spacehab module with the hatch(es) closed. In addition, conditions could occur, such as an airlock leak or hatch malfunction, which could trap a crewmember in the Spacehab module.

- B. THE SPACEHAB HATCH WILL REMAIN OPEN FOR NOMINAL OPERATIONS, UNLESS REQUIRED TO BE CLOSED FOR EXTRAVEHICULAR ACTIVITY (EVA) OPERATIONS OR DOCKING OPERATIONS.

Reference: Rule {A2-317}, EVA CONSTRAINTS.

- C. THE MODULE WILL BE CONFIGURED FOR A SAFE ENTRY AS REQUIRED BY PAYLOAD SAFETY PRIOR TO CLOSING THE HATCH.

The module is configured for safe entry (i.e., all penetration hazards restrained/stowed) in the event the module cannot be re-entered. ©[111501-4981E]

FLIGHT RULES

A2-317

EVA CONSTRAINTS

- A. PREBREATHING AT 10.2 PSI CAN BE DONE WITH THE SPACEHAB MODULE AT 14.7 PSI AND THE SPACEHAB HATCH CLOSED OR WITH THE SPACEHAB AT 10.2 PSI. THE STRATEGY WILL BE DETERMINED ON A MISSION SPECIFIC BASIS AND DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

The minimum design operating pressure for Spacehab components is 10 psia. Freon flow to the payload heat exchanger will be reduced in order to keep the orbiter cabin within temperature limits. This is accomplished by moving one of the orbiter's Freon flow proportioning valves (FPV's) from the nominal on-orbit payload heat exchanger position to the interchanger position. This will reduce the cooling capability in the Spacehab water loop.

Spacehab may be able to operate at the reduced pressure (and cooling level) of 10.2 psi if these conditions are compatible with experiment science and hardware requirements and if overall module thermal loads allow. The benefit of open hatch operations at 10.2 psi is increased crew access time to the module during prebreathe.

Assessment of 10.2 psi prebreathe strategy will be conducted on a flight specific basis. ©[111501-4981E]

- B. SPACEHAB LEAK DURING EVA ©[111501-4981E]

SCHEDULED/UNSCHEDULED EVA

1. IF A SPACEHAB CABIN LEAK OCCURS DURING AIRLOCK/TUNNEL ADAPTER DEPRESS WHICH IS NOT UNDERSTOOD OR WHICH IS PREDICTED TO REDUCE CABIN PRESSURE BELOW 10.2 POUNDS PER SQUARE INCH ABSOLUTE (PSIA) BEFORE NOMINAL EVA COMPLETION TIME, THE EVA/AIRLOCK DEPRESS WILL BE TERMINATED.
2. IF A SPACEHAB CABIN LEAK OCCURS DURING EVA, THE EVA WILL BE TERMINATED AND THE AIRLOCK/TUNNEL ADAPTER REPRESSURIZED BEFORE THE SPACEHAB IS PREDICTED TO REACH 10.2 PSIA.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-317 EVA CONSTRAINTS (CONTINUED)

CONTINGENCY EVA

3. IF THE EVA IS AN ORBITER CONTINGENCY EVA, IT WILL CONTINUE AND THE SPACEHAB WILL BE UNPOWERED EXCEPT FOR EMERGENCY POWER (AUX A AND AFT B) PRIOR TO REACHING 10 PSIA.

The Spacehab systems are certified to operate above a cabin pressure greater than or equal to 10 psia. For example, a leak rate of 7.3 lb/hr for 4 hours based on 14.7 equivalent will bring the cabin to 10 psia. PL AUX A and AFT MN B provide redundant power to Spacehab sensors. AFT MN B is the only source of power to the Spacehab water line heaters that protect the Spacehab water line from freezing. Additionally, smoke/fire detection sensors are powered by the emergency circuits.

- C. EXPERIMENT IMPACTS TO A 10.2 PSI PREBREATHE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

A2-318 ORBITAL MANEUVERING SYSTEM/REACTION CONTROL SYSTEM (OMS/RCS) CONSTRAINTS

ORBITAL MANEUVERING SYSTEM/REACTION CONTROL SYSTEM (OMS/RCS) CONSTRAINTS ARE EXPERIMENT COMPLEMENT DEPENDENT AND ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

A2-319 CONTAMINATION AND MICROGRAVITY CONSTRAINTS

ANY CONSTRAINTS SPACEHAB HAS ON WATER DUMPS, FES OPS, OMS/RCS LEAKS, ORBITER LEAKS, OR FUEL CELL PURGES WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

FLIGHT RULES

A2-320

COMMAND AND DATA SYSTEM CONSTRAINTS

- A. FOR A NONRECOVERABLE LOSS OF THE DATA MANAGEMENT UNIT (DMU), SPACEHAB ACTIVITIES WILL CONTINUE. HOWEVER, THE WATER LINE HEATERS WILL BE TURNED ON TO PREVENT FREEZING. @[111501-4981E]

Loss of the DMU results in loss of all Payload Data Interleaver (PDI) data to the Orbiter Display System, Payload General Support Computer (PGSC) downlink, and all subsystem control capabilities (except that which is routed through the orbiter multiplexer/demultiplexer (MDM)). All experiment data to the DMU would also be lost. However, safety critical monitoring and control is all routed through the PL MDM and Caution and Warning Electronics Assembly (CWEA). Water line heaters are turned on because a DMU failure results in loss of water pump monitoring capability.

- B. FOR LOSS OF THE MODULE SYSTEMS PGSC CAPABILITY, SPACEHAB OPERATIONS WILL CONTINUE.

The PGSC is used for backup monitoring only. Primary monitoring still exists at the Orbiter Display System, as well as through the Fault Detection and Annunciation (FDA) and CWEA systems. Ground monitoring via the PDI downlink is also still available.

- C. PDI DECOM LOSS IMPACTS WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

FLIGHT RULES

A2-321

SPACEHAB AIR-TO-GROUND (A/G) USAGE

- A. THE STANDARD ORBITER A/G CHANNEL (A/G 1) WILL BE USED FOR ANY DISCUSSIONS RELATED TO SPACEHAB SUBSYSTEMS. THE SSP CAPCOM WILL BE THE GROUND COMMUNICATOR. @[111501-4981E]

Since the module is integrated to the orbiter, it is necessary that any systems issues be discussed on A/G 1, which all Space Shuttle Program (SSP) flight control team members monitor. In addition, this strategy guarantees that emergency/time critical issues are discussed on the prime A/G loop.

- B. EITHER A/G 1 OR A/G 2 WILL BE USED FOR ANY DISCUSSIONS RELATED TO SPACEHAB EXPERIMENTS DEPENDING ON THE AMOUNT OF A/G USAGE. A SPACEHAB CREW INTERFACE COORDINATOR (CIC) WILL BE THE GROUND COMMUNICATOR.

Spacehab is responsible for all experiment procedures and the experiment flight data file. Therefore, the most efficient communication path is directly between the crew and the CIC. The CIC will be in the JSC POCC. The Flight Director will decide which A/G loop is the most appropriate to use. @[111501-4981E]

- C. ANY SAFETY-RELATED ISSUES, INCLUDING THOSE RELATED TO EXPERIMENTS, WILL BE CONDUCTED ON THE PRIME A/G LOOP (A/G 1). @[111501-4981E]

Self-explanatory.

- D. ROUTINE CONVERSATIONS DURING SPACEHAB EXPERIMENTS OPERATIONS BETWEEN THE CIC AND THE CREW ON A/G 1 OR A/G 2 WILL NORMALLY BE INITIATED BY CREW REQUEST. THE FOLLOWING RESTRAINTS SHALL APPLY TO CIC PROTOCOL AND A/G 1 OR A/G 2 USAGE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-321 **SPACEHAB AIR-TO-GROUND (A/G) USAGE (CONTINUED)**

1. THE VOICE PROTOCOL SHALL BE THE SAME AS THAT USED BY THE JSC CAPCOM.
2. THE SPACEHAB OPERATIONS DIRECTOR (SHOD) IS RESPONSIBLE FOR APPROVING ALL CALLS INITIATED FROM THE GROUND TO THE CREW.
3. DIRECT EXPERIMENTER CALLS TO THE CREW ON A/G 1 OR A/G 2 SHALL BE UPON CREW REQUEST ONLY.
4. THE CALL SIGN FOR THE SPACEHAB POCC SHALL BE "SPACEHAB POCC."
5. OCA S-BAND (MFX) OPERATIONS WILL TAKE PRECEDENCE OVER ROUTINE SPACEHAB A/G 2 USAGE.
6. EXCEPTIONS TO THIS RULE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

Past flight crew comments on overuse of A/G by payloads point out the need for more rigid control of the traffic and voice protocol. In addition, use of the OCA S-Band (OCA Ku-Band is nominal) adds complexity to the scheduled use of one of the A/G links. With the many users as well as the many experimenters on a Spacehab flight, careful definition of the A/G 1 or A/G 2 usage is required. This rule represents an agreed to baseline with the customer for Spacehab flights. ©[111501-4981E]©[111501-4981E] ©[111501-4976A]©[092701-4872]

A2-322 **SPACEHAB CAUTION AND WARNING ANNUNCIATION IN MODULE**

LOSS OF ALL CAUTION AND WARNING ANNUNCIATION CAPABILITY IN THE SPACEHAB MODULE IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES PROVIDED: ©[111501-4981E]

- A. ANNUNCIATION CAPABILITY EXISTS IN THE ORBITER AND,
- B. VOICE COMMUNICATION BETWEEN THE ORBITER AND SPACEHAB IS AVAILABLE.

All emergency safety parameters are redundantly monitored by the orbiter GPC and CWEA. In addition, both of these monitoring systems cause annunciating in both Spacehab and the orbiter. Loss of the Spacehab C&W annunciating capability is therefore only loss of redundancy. The orbiter crew would alert the Spacehab crew of any emergencies. ©[111501-4981E]

FLIGHT RULES

A2-323

COMMUNICATIONS CONSTRAINTS

LOSS OF VOICE COMMUNICATION BETWEEN THE ORBITER AND SPACEHAB CREWMEMBERS IS NOT CAUSE TO TERMINATE SPACEHAB OPERATIONS PROVIDED CAUTION AND WARNING ANNUNCIATION CAPABILITY STILL EXISTS IN SPACEHAB. @[111501-4981E]

Loss of voice communication does not present a hazard to the crew if caution and warning alarms are still available from the audio control system (ACS). Spacehab operations would be impacted, but may be continued in the best possible manner. Coordination can be carried out by voice calls down the tunnel or possibly by using the BPSMU or a wireless crew comm unit (WCCU) connected in the airlock.
@[111501-4981E]

A2-324

SPACEHAB IN-FLIGHT MAINTENANCE (IFM) PROCEDURES

A. IN SUPPORT OF ALL FLIGHTS RULE {A2-105}, IN-FLIGHT MAINTENANCE (IFM), ALL SPACEHAB UNSCHEDULED IFM PROCEDURES CONTAINED IN THE SPACEHAB OPERATIONS CHECKLIST (JSC-48089) AND SPACEHAB RDM MALFUNCTION PROCEDURES (JSC-48099) HAVE BEEN PERMISSION COORDINATED AND REQUIRE REAL-TIME MCC APPROVAL ONLY PRIOR TO IMPLEMENTATION, EXCEPT THOSE LISTED IN PARAGRAPH B. EXPERIMENT IFM'S ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4981E]

These IFM's have been reviewed preflight and identified as acceptable; however, because of their nature, implementation must be coordinated with the MCC.

B. THE FOLLOWING ARE LISTS OF SPACEHAB SCHEDULED IFM PROCEDURES IN THE SPACEHAB OPERATIONS CHECKLIST (JSC-48089) WHICH DO NOT REQUIRE REAL-TIME APPROVAL OR COORDINATION PRIOR TO IMPLEMENTATION.

1. FAN CLAMP REMOVAL (IFM-1.3)
2. FAN CLAMP REPLACEMENT (IFM-1.4)

C. ALL REAL-TIME DEVELOPED SPACEHAB/EXPERIMENT IFM PROCEDURES WILL BE COORDINATED AND APPROVED BY THE MCC.

Implementation of unplanned IFM's may require activities which, if not properly reviewed and coordinated, could result in an array of unsafe conditions. Therefore, unplanned IFM activity must be coordinated with MCC to ensure the safety of the orbiter, payloads, and crew. If no previous IFM work has been done, a minimum of 24 hours may be expected before an experiment IFM may be approved and uplinked. @[111501-4981E]

FLIGHT RULES

A2-325

IFM PROCEDURES ON EXPERIMENTS WITH TOXIC HAZARDS

NO IFM PROCEDURES WILL BE INITIATED BY THE CREW ON AN EXPERIMENT KNOWN TO REPRESENT A TOXIC HAZARD UNTIL CONCURRENCE FOR THE REPAIR PROCEDURE IS OBTAINED FROM THE MCC FLIGHT DIRECTOR. SPACEHAB EVACUATION AND/OR PROTECTIVE EQUIPMENT MAY BE REQUIRED (SEE RULE {A13-156}, SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE). ALL PAYLOAD EXPERIMENTS/SAMPLES CONTAINING HAZARDOUS MATERIALS ARE DEFINED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

A real-time assessment of the possibility of repairing an experiment and the risk of exposing the crew to a toxic substance during the repair will need to be made. The IFM may require that the cleanup equipment specified in Rule {A13-156}, SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE, be used to minimize risk of crew exposure to toxic substances. ©[111501-4981E]

FLIGHT RULES

A2-326

EQUIPMENT EXCHANGE BETWEEN ORBITER CABIN AND SPACEHAB MODULE

- A. ELECTRICAL EQUIPMENT OR EXPERIMENTS, SELF-POWERED OR FACILITY-POWERED, SHALL NOT BE TRANSFERRED BETWEEN THE ORBITER AND SPACEHAB UNLESS CERTIFIED FOR USE IN BOTH LOCATIONS. APPROVED EQUIPMENT WILL BE IDENTIFIED IN PARAGRAPH B. ©[111501-4981E]

Equipment may only be used in areas where it has been approved from an electromagnetic compatibility standpoint. In addition, power budgeting/planning can only be accomplished effectively if equipment movement strategy is coordinated preflight via this rule.

B. SPACEHAB SUBSYSTEM GENERIC EQUIPMENT

1. WIRELESS CREW COMMUNICATION SYSTEM (WCCS)
2. ORBITER COMM EQUIPMENT
3. VACUUM CLEANER AND ACCESSORIES (CABLE AND ATTACHMENT)
4. ORBITER CAMCORDER AND ACCESSORIES
5. PAYLOAD AND GENERAL SUPPORT COMPUTER (PGSC) AND ACCESSORIES
6. ORBITER CAMERA AND ACCESSORIES
7. ELECTRONIC STILL CAMERA (ESC)

EXCEPTIONS TO THIS RULE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4981E]

FLIGHT RULES

A2-327

SPACEHAB MODULE/TUNNEL SLEEP CONSTRAINTS

- A. NO CREWMEMBERS SHALL SLEEP IN THE SPACEHAB-TO-ORBITER TUNNEL.
 ©[111501-4981E]

In the event it was necessary to rapidly evacuate the module, a sleeping crewmember either tethered or in a sleeping bag would pose a hazard. In addition, the tunnel does not offer the same amount of protection for radiation that is provided by the module or orbiter cabin.

- B. CREWMEMBERS MAY SLEEP IN THE SPACEHAB MODULE IF:
1. SPACEHAB SYSTEM DATA IS BEING NOMINALLY TRANSMITTED TO THE ORBITER'S SM GPC AND TELEMETERED TO THE GROUND.
 2. THE CAUTION AND WARNING LINK BETWEEN THE ORBITER AND SPACEHAB IS OPERATIONAL.
 3. AT LEAST ONE SPACEHAB SMOKE SENSOR IS OPERATIONAL.
 4. THE AUDIO LINK BETWEEN THE ORBITER AND SPACEHAB IS OPERATIONAL.
 5. THE ARS FAN AND AT LEAST ONE ARS FAN DELTA PRESSURE SENSOR ARE OPERATIONAL IN ADDITION TO THE FOLLOWING:
 - a. (LDM ONLY) THE AFT MODULE FAN AND ITS ASSOCIATED DELTA PRESSURE SENSOR ARE OPERATIONAL.
 - b. (RDM ONLY) AT LEAST ONE HAB FAN ASSEMBLY (HFA) FAN AND ONE HFA FAN DELTA PRESSURE SENSOR ARE OPERATIONAL.

Nominal safety monitoring is via the SM GPC and the Caution and Warning Electronics Assembly (CWEA). Ground monitoring of safety parameters provides a further safety monitoring capability. The audio link to the Spacehab is desirable for communication in the case of a contingency commencing during sleep. The ARS fan and the ARS fan delta pressure sensor are required to verify that the ARS fan is operating, thus ensuring air exchange with the orbiter. In addition to the ARS fan and ARS fan delta pressure sensor, one HFA fan and one HFA fan delta pressure sensor in the RDM configuration are required for cooling, or the aft module fan and its associated delta pressure sensor in the LDM configuration are required to ensure adequate air flow through the aft module. Any one AC fan (Cabin or ARS) in the SM/LDM or one HFA fan in the RDM is adequate for smoke detection.

Reference: Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS, Boeing memo, 2C-SPACEHAB-01044, A90-SPACEHAB-97088, A90-SPACEHAB-2000192, MDC92W5610, and MDC95W5829.
 ©[111501-4981E]

FLIGHT RULES

A2-328

CREW LIMITATIONS IN THE SPACEHAB MODULE

- A. THE MAXIMUM NUMBER OF CREWMEMBERS PERMITTED IN THE MODULE MAY BE LIMITED BASED ON REAL-TIME EVALUATION OF O₂ AND CO₂ LEVELS, RELATIVE HUMIDITY, AND CABIN TEMPERATURE. ©[111501-4981E]

Spacehab SM/LDM is designed to reject 1400/1000 watts (respectively) of waste heat from surface air-cooled experiments with two crewmembers in the module. Spacehab RDM is designed to reject 2000 watts of waste heat from surface air-cooled experiments with three crewmembers in the module. Boeing/Spacehab analysis shows that each additional crewmember over the design value of two will decrease the available experiment air heat rejection accommodations by 115 watts minimum and 265 watts maximum (SM/LDM only). Each additional crewmember is expected to increase module dew point by about 1 deg F. Moisture is not a limiting factor for the Spacehab RDM since it has moisture removal capability. The RDM with the 53 cfm air exchange rate with the orbiter is designed to accommodate three crewmembers continuously. In the RDM, CO₂ generation may be the limiting factor for crew occupancy above its design limit. Increases in oxygen (O₂) consumption show no immediate concern for nominal operations in all module configurations.

- B. ORBITER CREWMEMBERS MAY ASSIST IN OPERATIONS IN THE SPACEHAB MODULE OR SERVE AS TEST SUBJECTS (SUBJECT TO ALL FLIGHTS RULE {A2-135}, COMMANDER (CDR) AND PILOT (PLT) PARTICIPATING AS TEST SUBJECTS) AS NEGOTIATED PREFLIGHT.

Preflight coordination will guarantee that the workloads of the orbiter crewmembers are acceptable and that All Flights Rule {A2-135} COMMANDER (CDR) AND PILOT (PLT) PARTICIPATING AS TEST SUBJECTS, is not violated. ©[111501-4981E]

FLIGHT RULES

A2-329

SPACEHAB DEACTIVATION/ENTRY PREP @[111501-4981E]

SPACEHAB DEACTIVATION WILL PROCEED BY ONE OF THE FOLLOWING METHODS DEPENDING ON CIRCUMSTANCES: @[111501-4982A]

- A. NOMINAL ENTRY PREP - SECURING OF THE SPACEHAB BY NOMINAL CHECKLIST PROCEDURES. THE NOMINAL ENTRY PREP WILL BE DONE FOR:
1. NOMINAL END-OF-MISSION
 2. ANY FAILURE THAT RESULTS IN A PRIMARY LANDING SITE (PLS) WITH DEORBIT TIME OF IGNITION (TIG) OCCURRING BEYOND 12 HOURS.

Nominal entry prep requires approximately 1-2 hours and is scheduled in the Flight Plan. A PLS TIG greater than 12 hours away will allow the crew to perform the desirable, nominal module entry prep.

The procedure will include equipment stowage, nominal deactivation of experiments, and an orderly reconfiguration to the Spacehab entry configuration.

- B. SPACEHAB 30-MINUTE CONTINGENCY DEACTIVATION - SECURING OF SPACEHAB AND EXPERIMENT HARDWARE IN MINIMUM TIME WITHOUT INCURRING DAMAGE TO SPACEHAB, AND WHEN POSSIBLE, EXPERIMENT EQUIPMENT. SPACEHAB 30-MINUTE CONTINGENCY DEACTIVATION PROCEDURES WILL BE DONE FOR:
1. ANY FAILURE THAT RESULTS IN A PLS WITH DEORBIT TIG OCCURRING BETWEEN 3.5 TO 12 HOURS.
 2. UNRECOVERABLE LOSS OF ALL SPACEHAB AIR CIRCULATION FANS.

Spacehab 30-minute contingency deactivation is intended to perform as much of the normal deactivation of the module as possible. It also provides a balance between deactivating the module in a shorter-than-nominal time and preserving equipment (and science, if possible). The procedure will include critical entry stowage, an abbreviated but orderly Spacehab shutdown, and safing of experiments, if time permits. @[111501-4982A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-329

SPACEHAB DEACTIVATION/ENTRY PREP (CONTINUED)

- C. SPACEHAB EMERGENCY DEACTIVATION - IMMEDIATE STOW OF ANY PENETRATORS, EGRESS, AND CLOSURE OF THE HATCH WITHOUT ANY OTHER ACTIVITIES WITHIN THE 3-MINUTE CONSTRAINT. IF CIRCUMSTANCES WARRANT, ALL POWER, EXCEPT PL AFT MN B, WILL BE REMOVED. SPACEHAB EMERGENCY DEACTIVATION PROCEDURES WILL BE DONE FOR: @[111501-4982A]
1. ORBITER PROBLEMS REQUIRING EMERGENCY DEORBIT
 2. AN ORBITER/MODULE LEAK (DEACTIVATION STEPS ONLY NEEDED IF LEAK CANNOT BE ISOLATED). IF THE LEAK IS ISOLATED TO THE SPACEHAB MODULE AFTER EGRESS, THE CREW MAY REOPEN THE SPACEHAB TO PERFORM ADDITIONAL DEACTIVATION/ENTRY PREP, IF CONSUMABLES PERMIT PER RULE {A17-751}, MODULE PRESSURE INTEGRITY.
 3. FOR SPACEHAB MODULE FIRE (DEACTIVATION STEPS ONLY NEEDED IF FIRE SUPPRESSION NOT SUCCESSFUL.)
 4. DISCHARGE OF ALL HALON SYSTEM BOTTLES (EGRESS STEPS ONLY)
 5. SPACEHAB MODULE LEVEL-4 TOXIC SPILL (EGRESS STEPS ONLY)

In emergency situations (i.e., fire, depress, or toxic spill), the crew must be able to safe and isolate the module within 3 minutes. Safe return of the crew is paramount in these cases. Only payload procedures required for safe entry (restraint of penetrators, crew module egress, and hatch closure) are allowed in these time critical situations. No attempt is made to prevent damage to the module or experiments, except stowing any penetrators. Reference NSTS 18798A, MA2-96-190, "CONTINGENCY RETURN AND RAPID SAFING," memo dated January 9, 1997. The Spacehab Emergency Deactivation procedure includes steps for egress and power removal. All main AC and DC power, except PL AFT MN B, which is required to power the Spacehab water line heaters, is removed for an emergency deactivation. In some cases, Spacehab emergency egress steps are integrated into the applicable orbiter procedures (i.e., cabin leak) and Payload powerdowns, when it is appropriate. @[111501-4982A]

FLIGHT RULES

A2-330

EXTENSION DAY GROUND RULES

A. POWER LEVELS @[111501-4981E]

THE SPACEHAB AND ITS EXPERIMENTS WILL BE POWERED DOWN TO THE GREATEST EXTENT POSSIBLE (SURVIVAL POWER CONFIGURATION) AS DEFINED IN RULE {A9-357}, SPACEHAB SURVIVAL POWER CONFIGURATION. @[ED]

The amount of consumables remaining at the nominal end of flight does not allow for operations of experiments without degrading the capability of the orbiter to remain in orbit. For those cases which require that additional power be provided to allow for preservation of experiment samples/data, the consumable must be allocated preflight and thus affect the mission duration.

B. CONSUMABLES

NO SPACEHAB EXPERIMENT ACTIVITIES WHICH REQUIRE ORBITER CONSUMABLES WILL NORMALLY BE PLANNED. FLIGHT-SPECIFIC OPTIONS ARE DEFINED IN THE FLIGHT SPECIFIC ANNEX.

Extension days would generally be required only for weather, orbiter, and/or landing site problems that would benefit from extra time before landing. To prevent further complications, the Spacehab/experiments should be maintained in a safe, deactivated state. This should not impact the Spacehab/experiments since all payload activities should have already been completed by the nominal end of mission. In addition, the crew must be available to perform necessary orbiter activities to ensure a safe return.

C. SPACEHAB CONSTRAINTS ON EXTENSION DAY ATTITUDE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

-ZLV attitude will normally provide a stable thermal environment for the orbiter and Spacehab module during an extension day and is accomplished with a minimum amount of propellant for attitude maintenance. With radiators deployed, the -ZLV attitude will provide sufficient orbiter heat rejection when flying with any beta angle. With radiators stowed, the -ZLV attitude may be acceptable, or a flight-specific attitude can be determined. If a cooler attitude is required, the orbiter can execute passive thermal control (PTC) which gives the advantage of providing a consistent thermal environment for the entire vehicle. @[111501-4981E]

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH AND TUNNEL

THE SPACEHAB HATCHWAY AND TUNNEL SHALL BE FREE AND CLEAR OF OBSTRUCTION TO ENSURE THAT THE CREW IS CAPABLE OF SAFING AND ISOLATING THE MODULE WITHIN 3 MINUTES FOR AN EMERGENCY.

©[111501-4984]

Every effort shall be made to preclude routing cables through the Spacehab hatch and tunnel. In emergency situations (i.e., fire, depress, or toxic spill), the crew must be able to secure penetrators and isolate the module within 3 minutes. The hatch closure itself takes approximately 1 minute, which leaves approximately 2 minutes to safe the module and clear the hatchway. Cables, in addition to anything that may pose interference with hatch closure, are considered "drag-throughs."

IN THE EVENT DRAG-THROUGH ROUTING CANNOT BE PRECLUDED, THE FOLLOWING CRITERIA SHALL APPLY:

- A. THE ABILITY TO SAFE AND ISOLATE THE MODULE WITHIN 3 MINUTES SHALL BE RETAINED.

The 3-minute constraint is paramount for the crew to have the ability to respond to any emergency situation (i.e., fire, depress, or toxic spill) and allow the hatch to be closed regardless of whether or not drag-throughs are present across the hatchway. Tests show it takes approximately 10 seconds to break each quick disconnect (QD) by a single crewmember.

- B. IF THE DRAG-THROUGH IS NOT UNDER THE CONTROL OF A CREWMEMBER, IT SHALL BE RESTRAINED TO AVOID CREW ENTANGLEMENT WHILE TRANSLATING THROUGH THE HATCH AND TUNNEL. IF A QUICK DISCONNECT RELATED TO THE DRAG-THROUGH HAS BEEN POSITIONED IN PROXIMITY TO THE HATCH, THE RESTRAINT SHALL NOT BE LOCATED BETWEEN THE DISCONNECT AND THE HATCH.

A drag-through that is under the control of a crewmember implies short-term use and will be taken back through the hatch as a crewmember exits when circumstances dictate hatch closure. A restraint between the hatch and the quick disconnect complicates the effort to clear the hatchway and close the hatch.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH AND TUNNEL (CONTINUED)

- C. DRAG-THROUGHS SHALL NOT IMPEDE CREW NAVIGATION THROUGH THE HATCHWAY. A TRANSLATION CORRIDOR, SUFFICIENT TO ALLOW A CREWMEMBER TO PASS THROUGH THE HATCH, SHALL BE MAINTAINED.

A 32-inch minimum diameter must be maintained through the Spacehab hatch. @[111501-4984]

- D. WHERE PRACTICAL, AND WITHIN DESIGN LIMITATIONS AND TIME CONSTRAINTS IMPOSED BY THE HARDWARE AND OPERATIONAL REQUIREMENTS, THE FOLLOWING CONSTRAINTS WILL BE IMPLEMENTED:
@[111501-4984]

1. ALL DRAG-THROUGHS ROUTED THROUGH THE SPACEHAB HATCH SHALL BE CONFIGURED WITHIN A SINGLE 90-DEGREE SECTION OF THE HATCH AS SHOWN BY THE FIGURE BELOW:

Drag-throughs should be routed within the 90-degree section of the Spacehab hatch to aid in the ability of the crew to quickly locate and remove hatch obstructions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A2-331

CONSTRAINTS ON CABLES THROUGH THE SPACEHAB HATCH
AND TUNNEL (CONTINUED)

2. DRAG-THROUGHS SHOULD BE ROUTED SUCH THAT A QUICK RELEASE CONNECTOR IS LOCATED WITHIN 2 FEET ON EITHER SIDE OF THE SPACEHAB HATCH. DISCONNECT FEATURES FOR ALL DRAG-THROUGHS ROUTED THROUGH THE HATCH SHOULD BE ON THE SAME SIDE OF THE HATCH.

The quick release connector features, and constraints on having all such connectors lie within 2 feet of the Spacehab hatch and on the same side of the hatch for all drag-throughs, allows quick location and removal (tests show at 10 seconds per quick release connector) of drag-through obstruction(s) to hatch closure. @[111501-4984]

3. DRAG-THROUGHS SHOULD BE LIMITED TO NO GREATER THAN FOUR DURING CREW AWAKE TIME AND, IF LEFT IN PLACE DURING THE CREW SLEEP PERIOD, THE NUMBER OF DRAG-THROUGHS ROUTED THROUGH THE SPACEHAB HATCH AND TUNNEL SHOULD BE REDUCED TO TWO. @[111501-4984]

An operational limit of two drag-throughs across the Spacehab hatch during the crew sleep period has a better chance of accommodating the 3-minute constraint on safing and isolating the module. Limiting the number of drag-throughs to a maximum of four drag-throughs, whether temporary or permanent, will minimize the risk in not being able to meet the 3-minute rapid safing constraint.

4. IF TIME ALLOWS, PRIOR TO DEMATING AN ELECTRICAL CONNECTION EXCEEDING 32 VOLTS UPSTREAM, POWER WILL BE REMOVED.
- E. THE BPSMU IS THE ONLY DRAG-THROUGH APPROVED GENERICALLY FOR USE IN SPACEHAB. ADDITIONAL DRAG-THROUGHS MAY BE APPROVED ON A MISSION SPECIFIC BASIS AND LISTED IN THE FLIGHT SPECIFIC ANNEX.

The BPSMU meets the requirements for drag-throughs in this rule and was the only drag-through identified at the time this rule was written. It can be used nominally for communication between the Spacehab and orbiter or Spacehab and ISS when the Spacehab ACS is not available or operational. @[111501-4984]@[111501-4981E] @[111501-4962A] @[111501-4982A]

FLIGHT RULES

A2-332

LOSS OF SM GPC DURING SPACEHAB ACTIVATION/ENTRY
PREP @[111501-4981E]

- A. LOSS OF THE SYSTEMS MANAGEMENT (SM) GPC PRIOR TO ARS FAN ACTIVATION WILL REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES UNTIL THE SM GPC IS RECOVERED OR THE ARS FAN IS POWERED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS COULD BE OPERATED IN THE SPACEHAB ASCENT CONFIGURATION. @[060800-7116A]

Nominal Spacehab ARS fan activation and subsystem reconfiguration are achieved via the SM GPC. The ARS fan provides the only means for conditioned air exchange with the orbiter. Therefore, Spacehab operations must be postponed until the ARS fan can be activated. When the Spacehab is powered for ascent, the water pump and several experiment utility outlets are powered in addition to the ARS fan or Cabin/HFA fan. In the SM and LDM configurations, the ARS fan is the preferred fan to operate during ascent. In the RDM configuration, one HFA fan is preferred over the ARS fan. Spacehab RDM is always powered for ascent. Reference Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS.

- B. LOSS OF THE SYSTEMS MANAGEMENT (SM) GPC AFTER SPACEHAB ACTIVATION AND BEFORE ENTRY PREP IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES. @[111094-1733]

Spacehab activities may continue because the module remains in a good configuration for operation. Nominal reconfiguration of Spacehab subsystems during entry prep cannot be achieved without the SM GPC. Consideration will be given to leaving Spacehab equipment configured on orbiter power for entry provided orbiter resources are available. @[111501-4981E]

FLIGHT RULES

A2-333

LOSS OF PAYLOAD MDM DURING SPACEHAB ACT/ENTRY PREP
@[111501-4981E]

A. PAYLOAD MDM FAILURE

LOSS OF PAYLOAD (PL) MDM PL1, PRIOR TO ARS FAN ACTIVATION, WILL REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES UNTIL THE MDM IS RECOVERED OR THE ARS FAN IS POWERED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS COULD BE OPERATED IN THE SPACEHAB ASCENT CONFIGURATION. @[060800-7117A]

Spacehab Activation and subsystem reconfiguration are achieved via the Payload MDM 1 (PL1) and otherwise cannot be nominally performed. The ARS fan is important because it provides the only means for conditioned air exchange with the orbiter. Spacehab operations must be postponed until the ARS fan can be activated. Hard failure of PL1 will result in the inability to activate Spacehab. All Flights Rule {A7-109F}, IN-FLIGHT MAINTENANCE (IFM), specifies that a PL MDM will only be swapped to regain PLBD close capability. When the Spacehab is powered for ascent, the water pump and several experiment utility outlets are powered in addition to the ARS fan or Cabin/HFA fan. In the SM and LDM configurations, the ARS fan is the preferred fan to operate during ascent. In the RDM configuration, one HFA fan is preferred over the ARS fan. Spacehab RDM is always powered for ascent. Reference Rule {A17-706}, SPACEHAB FAN CONFIGURATIONS.

B. LOSS OF PAYLOAD MDM PL2 DURING SPACEHAB ACTIVATION WILL NOT REQUIRE SUSPENSION OF SPACEHAB ACTIVITIES. @[111094-1734]

Spacehab activation does not require Payload MDM PL2. @[060800-7117A]

C. LOSS OF EITHER PAYLOAD MDM, PL1 OR PL2, AFTER ACTIVATION AND BEFORE ENTRY PREP IS NOT CAUSE TO TERMINATE SPACEHAB ACTIVITIES.

Caution and warning parameters, which are nominally redundantly monitored by the CWEA directly and via the PL1-GPC-PL2 string, are still monitored by the CWEA if either PL MDM fails. Significant command capability, including that used during the nominal deactivation process (ARS fan, cabin/HFA fan, and water pump reconfiguration for powered entry), is lost if PL1 is lost. However, some operations may still be conducted. Safety-related redundant command capability for fire suppression still exists (Standard Switch Panel and C3A5).

D. IF A CHOICE EXISTS BETWEEN PL1 AND PL2, SPACEHAB PREFERS PL1.

The majority of MDM discretetes are through PL1. The impact of losing PL1 is greater than the impact of losing PL2. @[111501-4981E]

FLIGHT RULES

A2-334

LOSS OF SM MAJOR FUNCTION

TEMPORARY LOSS OF SM MAJOR FUNCTION AFTER SPACEHAB ACTIVATION AND BEFORE SPACEHAB ENTRY PREP IS NOT A CONSTRAINT TO CONTINUING SPACEHAB OPERATIONS IF: ©[111501-4981E]

- A. THE SPACEHAB-TO-CWEA INTERFACE IS OPERATING NOMINALLY.
- B. THE FOLLOWING SAFETY SENSORS ROUTED TO THE CWEA ARE OPERATIONAL:
 - 1. FIRE/SMOKE DETECTOR A OR B
 - 2. ARS FAN DELTA P - SENSOR 2
 - 3. (RDM ONLY) HFA FAN DELTA P - SENSOR 2

If the SM interface is down, one of two redundant methods of monitoring safety-critical parameters is lost. Module operations may continue if the CWEA is still monitoring safety parameters and the sensors feeding the CWEA (at least one fire/smoke and the ARS fan) are nominal. Note that monitoring of Spacehab parameters is still available on the ground and via the PGSC in the module. Redundancy for partial pressure of oxygen (PPO₂) and total cabin pressure is provided by the orbiter sensors via hardware caution and warning.

Loss of SM also eliminates a significant amount of command capability; however, redundant methods are still available for fire suppression. ©[111501-4981E]

FLIGHT RULES

A2-335

**LOSS OF ORBITER MASTER TIMING UNIT (MTU)/PAYLOAD
TIMING BUFFER**

- A. LOSS OF THE MTU DURING SPACEHAB ACTIVATION OR DEACTIVATION IS NOT A CONSTRAINT TO CONTINUING SPACEHAB ACTIVITIES; HOWEVER, NOMINAL ACTIVATION/DEACTIVATION CANNOT BE PERFORMED. CONSIDERATION WILL BE GIVEN TO WHICH EXPERIMENTS CAN OPERATE IN THE SPACEHAB ASCENT/ENTRY CONFIGURATION. @[111501-4981E]

Loss of the MTU results in loss of a clock signal to the Payload Signal Processor (PSP), which causes loss of commanding to Spacehab. PSP commanding is required to perform a nominal Spacehab activation and deactivation. Operations may still be conducted in the ascent/entry configuration. If Spacehab is unpowered during ascent, operations may still be conducted using SSP and MDM commanding. @[111501-4981E]

- B. LOSS OF THE MTU AFTER SPACEHAB ACTIVATION AND BEFORE SPACEHAB DEACTIVATION IS NOT A CONSTRAINT TO CONTINUING SPACEHAB ACTIVITIES; HOWEVER, THE FOLLOWING IMPACTS OCCUR: @[111501-4981E]
1. LOSS OF PSP UPLINK COMMANDING IS DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

PSP commanding is lost when the MTU fails. All nominal uplink commanding to Spacehab subsystem equipment and to some experiments is through the PSP.

2. LOSS OF GREENWICH MEAN TIME (GMT) TIMETAG INFORMATION INSERTED BY THE DMU INTO THE PDI DATA STREAM.

The GMT timetag is inserted into the PDI data stream by the DMU for subsystem information. It is not used onboard Spacehab.

3. LOSS OF GMT AND MISSION ELAPSED TIME (MET) TO SPACEHAB EXPERIMENTS IS DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX.

The MTU is the only source of synchronized GMT and MET to Spacehab and experiments. This could cause degraded experiment results. @[111501-4981E]

FLIGHT RULES

SECTION 3 - GROUND INSTRUMENTATION REQUIREMENTS

GENERAL

A3-1

GROUND AND NETWORK DEFINITIONS

- A. MCC IS DEFINED AS THE EQUIPMENT AND FUNCTIONALITY PROVIDED BY THE JSC BUILDING 30 COMPLEX AND ASSOCIATED INFRASTRUCTURE AT JSC WHICH PROVIDES POWER, COOLING, AND COMMUNICATIONS TO BUILDING 30. @[062702-5502C]
- B. INTEGRATED NETWORK INCLUDES THE FOLLOWING:
1. THE NASA GROUND TRACKING AND DATA STATIONS AT MILA, DFRC, WLP, PDL, AND INCLUDING JDI.

Even though JDI is part of the Eastern Range operated by the USAF 45th Space Wing at the Jonathan Dickinson Missile Test Annex (JDMTA), for the purposes of this rule it is considered part of the NASA network.

2. THE SPACE NETWORK INCLUDING THE WHITE SANDS COMPLEX (WSC) FACILITY AND FUNCTIONALITY AS WELL AS THE TDRS SATELLITES.
3. GSFC FACILITIES THAT PROVIDE COMMUNICATIONS RELAY AND SCHEDULING: THE MISSION OPS SUPPORT AREA (MOSA), FLIGHT DYNAMICS FACILITY (FDF) AND THE NETWORK CONTROL CENTER (NCC) AND ASSOCIATED INFRASTRUCTURE AT GSFC WHICH PROVIDES POWER, COOLING, AND COMMUNICATIONS TO THOSE FACILITIES.
4. NASA AND USAF RADAR TRACKING SITES AS SHOWN IN THE MATRIX IN RULE {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX. @[ED]
5. COMMERCIAL LINKS CONNECTING JSC, GSFC, WSC, KSC, DFRC, ETC.
6. INTERCONNECTIVITY TO USAF RTS SITES @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-1

GROUND AND NETWORK DEFINITIONS (CONTINUED)

- C. CRITICAL SHUTTLE FLIGHT PHASES ARE DEFINED AS LAUNCH THROUGH GO FOR ORBIT OPS OR INTACT ABORT LANDING AND GO FOR DEORBIT BURN THROUGH WHEELSTOP. @[062702-5502C]
- D. TRAJECTORY PROCESSING IS DEFINED AS THE CAPABILITY OF THE MCC TO TAKE TRAJECTORY DATA FROM VARIOUS SOURCES (RADAR TRACKING, S-BAND DOPPLER, ONBOARD INERTIAL NAVIGATION, ONBOARD GPS) AND IN REAL TIME COMPUTE CURRENT STATE AND PERFORMANCE CAPABILITY THAT ARE USED TO DETERMINE ABORT MODE CAPABILITY, MANEUVER TARGETS, AND TO MAKE OTHER MISSION CRITICAL DECISIONS. REFERENCE RULE {A3-51}, TRAJECTORY PROCESSING REQUIREMENTS. @[062702-5502C]

A3-2

GROUND AND NETWORK OVERALL PHILOSOPHY

- A. MANDATORY REQUIREMENTS: AIR TO GROUND VOICE, COMMAND, HDR TELEMETRY, AND TRAJECTORY PROCESSING DURING CRITICAL PHASES OF FLIGHT IS MANDATORY. THE MCC AND INTEGRATED NETWORK EQUIPMENT AND ASSOCIATED SOFTWARE TO PROVIDE THESE MANDATORY FUNCTIONS MUST BE AVAILABLE AND SCHEDULED TO INITIATE A CRITICAL ACTIVITY. @[062702-5502C]

The MCC and network provide the ability to collect, process, and display the information needed to invoke mission rule decision, analyze subsystem performance to prevent failures, and to relieve the flight crew of the need to monitor subsystems in detail. Command provides the means to configure onboard systems for nominal operations as well as for anomaly resolution. Command is required to provide uplink remedies to systems problems which require off-nominal systems configurations that can be most effectively accomplished or in some cases only accomplished from the ground. A/G voice provides the means to communicate between the flight crew and the flight control team for mission activities, abort region definition, anomaly resolutions, and many other activities.

This rule states a general principle which must be understood in the light of what is technically feasible. For example, the mandatory requirement is not meant to imply that there can be no short gaps since site handovers, etc., will lead to momentary outages. Additionally, the next rule gives greater detail to parts of critical periods when longer outages can be allowed. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-2

GROUND AND NETWORK OVERALL PHILOSOPHY (CONTINUED)

B. REDUNDANCY: @[062702-5502C]

1. SCHEDULING: REDUNDANCY IN MANDATORY MCC AND INTEGRATED NETWORK FUNCTIONS SHALL BE SCHEDULED AND PLANNED TO BE AVAILABLE AT THE INITIATION OF A CRITICAL ACTIVITY.

NOTE: REDUNDANCY IS NOT REQUIRED WHEN SCHEDULING FOR THE TDRSS NETWORK.

TDRSS network redundancy is well demonstrated and tying up resources by scheduling redundant services is not required. Loss of TDRSS service has been demonstrated in practice to be very remote and emergency rescheduling using alternate equipment is very rapid. TDRSS network redundancy is based on having multiple satellites in both eastern and western locations, two independent ground stations, multiple communication paths between WSC and MCC, and full redundancy in scheduling and other supporting equipment. The TDRSS network has more users than can be scheduled so it is prudent to not explicitly schedule redundant TDRSS coverage.

2. LOSS OF REDUNDANCY: REDUNDANCY IS NOT REQUIRED TO INITIATE A CRITICAL ACTIVITY. FOLLOWING A FAILURE THAT CAUSES LOSS OF REDUNDANCY, IF FEASIBLE, THE REMAINING SINGLE STRING SHOULD BE DEMONSTRATED TO BE FUNCTIONAL PRIOR TO THE INITIATION OF A CRITICAL ACTIVITY.

It is prudent to support mission critical operations with redundancy. MCC and Network functions are by design very reliable. Operational history has demonstrated that MCC and Network functional reliability is very high. When operating on a single string of equipment that is demonstrated to be functioning, which is not annunciating an alarm or operating in an anomalous manner, there is a very low probability of failure in the short time duration of a shuttle critical phase. Unless there is direct evidence to conclude a failure is imminent on operating equipment, there is no reason to delay a critical scheduled event for failure of a redundant string. Conversely, if analysis of a failed system clearly indicates a threat to the remaining equipment, it is prudent not to initiate a critical activity if possible.

3. RECOVERY OF LOST REDUNDANCY: RECOVERY OF REDUNDANT EQUIPMENT SHOULD NOT BE ATTEMPTED IF THERE IS RISK TO THE PLANNED T=0 OR DEORBIT TIG.

Recovery of redundant equipment or function generally has a non-zero risk of operator error or other reason causing loss of the functioning, mandatory equipment string. At pre-defined times for launch or deorbit, this risk should not be incurred. @[062702-5502C]

FLIGHT RULES**A3-3****GROUND AND NETWORK DETAILED REQUIREMENTS****A. ASCENT**

1. NOMINAL ASCENT: AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING ARE MANDATORY FROM LIFTOFF THROUGH MET 15 MINUTES. FROM MET 15 MINUTES THROUGH GO FOR ORBIT OPS, IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING. ©[062702-5502C]

IN ADDITION TO MANDATORY S-BAND TWO-WAY VOICE, UHF TWO-WAY VOICE IS REQUIRED AS A BACKUP DURING LAUNCH FROM LIFTOFF THROUGH NOMINAL HANDUP TO TDRS AND IS HIGHLY DESIRABLE THROUGH MILA LOS OR UNTIL RTLS LANDING.

Redundant A/G voice is necessary for abort request and abort region calls and to rapidly convey verbal responses to observed subsystem anomalies and rule violations. The availability of both S-band and UHF ensures that SRB plume, station handovers, and most onboard and ground subsystem failures will not result in disruption of A/G voice capability causing critical calls to be missed. Early in ascent, TDRS is not thought to be acceptable due to antenna look angles, structural blockage, etc. Therefore, MILA, PDL, and JDI provide communications link capability.

The latter stages of ascent, after TDRS handup between 7 and 8 minutes MET, are supported by TDRS. The TDRS network has more user requirements than can be accommodated thus requiring priority scheduling. TDRS schedule should include uninterrupted communications through the latest underspeed MECO that occurs no later than MET 13 minutes. An additional 2 minutes to assess the situation and provide maneuver direction to the crew can be accomplished by a well-practiced MCC team. This means that TDRS scheduling should support through MET 15 minutes at a minimum.

To ensure mission success for rendezvous missions and to resolve any anomalies that may have occurred during ascent, it is prudent and highly desirable to have the maximum available communications capability through OMS-2 cutoff. Following that, to ensure timely anomaly resolution and to provide the maximum efficiency and mission success through the complex tasks of early post insertion (OPS 2 transition, opening payload bay doors, initiating radiator cooling, etc.), communications is vital. Go for Orbit Ops normally occurs at about 1 hr 30 min MET.

From the TDRS perspective, command, telemetry, and voice are either both available simultaneously or not; they are not independent. ©[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

2. RTLS, TAL: CONTINUOUS AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING ARE MANDATORY FOR RTLS OR TAL FOLLOWING ABORT DECLARATION THROUGH INTACT ABORT LANDING INCLUDING POST-LANDING. @[062702-5502C]

This requirement for TAL may be met by the use of an emergency SHO for the TDRS network since landing occurs at approximately MET 37 minutes. RTLS requirements may be covered by scheduling MILA alone. The declaration of an RTLS or TAL abort results in procedures that involve additional risk. MCC support is required and will normally be available throughout the RTLS or TAL. This increased insight into systems performance and additional expertise significantly increases the probability of a successful landing with a vehicle that has already had a major systems failure. A/G voice is required to coordinate any recommendations to the crew and to relay to the crew final weather, runway, landing aid, and major systems status.

3. ATO, AOA: FOR THE PERIOD FROM MET 15 MINUTES THROUGH LANDING FOR AOA OR LANDING FOR FIRST DAY PLS OR THROUGH GO FOR ORBIT OPS FOR ATO, IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING.
4. ASCENT TRAJECTORY PROCESSING SUPPORT:
 - a. ASCENT RADAR TRACKING: DUAL TRACKING IS HIGHLY DESIRABLE FROM EITHER ONE S-BAND AND ONE C-BAND, OR TWO C-BANDS FROM LIFT-OFF THROUGH MECO PLUS 1 MINUTE.

Dual source tracking is desired to allow monitoring of the health of onboard navigation during powered flight, to provide delta state uplink capability to correct extreme onboard navigation errors which could result in unsafe or mission-limiting MECO conditions for an ascent to orbit or an RTLS, and to provide an independent ground navigation source for ascent performance boundary calls. To obtain an accurate post-MECO ground filter vector, a minimum of 1 minute of tracking post-MECO is required for processor convergence. An accurate post-MECO ground filter vector may be used to update onboard navigation before OMS-2 if required to significantly decrease delta-V cost due to planar error for ground-up rendezvous flights, or before OMS-1 or OMS-2 if the gain in delta-V capability would prevent ascent capability downmoding. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

Ground tracking through MECO+1 is highly desirable rather than mandatory because flight history and Mean Time Between Failure (MTBF) data show that the probability of either software or hardware failures corrupting onboard navigation during ascent are extremely small. MTBF studies for the HAINS IMU's, GPC's, and MDM's indicate a probability of loss of two IMU's to be on the order of 10^{-10} . Although recovery of corrupted onboard navigation by means of a powered flight delta state is theoretically possible, and would be attempted if required, success at all times during the ascent is not a certainty. With regard to onboard navigation errors which are not large enough to pose a safety concern, but which could affect the mission, the history of post-MECO state vector updates shows that although there are worthwhile paybacks in propellant margin, their absence would not adversely impact propellant budgets. For these reasons, ground tracking requirements through MECO for due east launches were abandoned by the shuttle program as a cost savings measure. Ground tracking through MECO +1 is only available for high inclination launches. ©[062702-5502C]

Upon removal of the Range Safety destruct package from the external tank, the flight crew/MCC assumes responsibility for public safety during second stage. The tracking navigation state precludes limit line violation due to severe onboard navigation problems (state vector update or manual MECO) and prevents loss of External Tank Impact Point prediction due to telemetry loss/data dropouts. At the existing limits of ground tracking, ET IP no longer endangers North American landmasses or islands.

Ground radar tracking is only highly desirable for NASA purposes during the early phases of ascent as shown by the table in Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX. Note that the Eastern Range has a more constraining requirement. If all east coast radars are functioning, for high inclination launches radar tracking can be extended to nominal MECO +1 minute. For low inclination launches, radar tracking is lost prior to 8 minutes MET. It is desirable to have ground radar verification of the MECO state. ©[ED]

- b. RTLS ENTRY RADAR TRACKING: TRACKING IS HIGHLY DESIRABLE FROM EITHER ONE S-BAND AND ONE C-BAND, OR TWO C-BANDS FROM RTLS MECO TO 100K FEET.

The TSU trajectory processor Kalman filter cannot meet ground accuracy requirements with only one source of tracking data; the filter requires at least two sources. The 100k feet altitude constraint was chosen to allow sufficient time to assess the vehicle energy conditions and to update onboard navigation state (after nominal TACAN acquisition) in order to correct a violation of delta state limits. Dual tracking capability also allows time to GCA to within guidance limits prior to TAEM. ©[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

**GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)**

- c. AOA/PLS: DUAL TRACKING CAPABILITY ABOVE 100K FEET IS HIGHLY DESIRABLE BUT IS NOT SCHEDULED FOR AOA AND PLS DEORBIT. @[062702-5502C]

In the event that a delta state is uplinked, it allows proper onboard verification to be performed through 100k feet (tracking not required below 100k feet).

- d. FD1 PLS ONLY: AT LEAST ONE TDRS OR TWO C-BAND RADAR PASSES ARE REQUIRED TO SUPPORT PRE-DEORBIT STATE VECTOR ACCURACY.

For AOA and PLS deorbits, best effort call up of high speed tracking resources is accepted (ref. Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). The time between launch and landing for an AOA deorbit is short enough to consider onboard navigation autonomous, and although best effort tracking call up will be requested, it is not mandatory. There is a high probability of obtaining PLS tracking support from KSC or EDW area radars on a best effort basis if the ranges are given more than 3 hours advance notice. There is little chance of obtaining such support for a NOR PLS deorbit unless the request is made during duty hours. Tracking support is virtually assured at all three CONUS sites, given 24 hours notice (ref. AEFTP #82 minutes). @[ED]

Post MECO tracking is required for flight day 1 deorbit cases in order to ensure the onboard state vector meets deorbit burn accuracy requirements. For high inclination launches (57 deg and 51.6 deg), at least one TDRS is required for orbit 3 cases, because the ground tracks for orbits 1 through 3 do not permit adequate C-Band coverage (ref. Rules {A4-101}, ONBOARD NAVIGATION MAINTENANCE, and {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX - Note [2]). @[ED]

- e. FOR COMMIT TO LAUNCH AND SCHEDULING PURPOSES, EOM DUAL TRACKING CAPABILITY (TWO C-BANDS OR ONE S-BAND AND ONE C-BAND) FROM ABOVE 100K FEET TO THE GROUND IS NOT MANDATORY. IF ANY OF THE CAPABILITIES LISTED IN PARAGRAPH B3 BELOW ARE NOT EXPECTED TO BE AVAILABLE PRIOR TO DEORBIT TIG, SCHEDULING EOM DUAL TRACKING BECOMES MANDATORY. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)

5. REDUNDANCY FOR ASCENT INCLUDING INTACT ABORTS:

@[062702-5502C]

- a. REDUNDANCY IN EQUIPMENT AND NETWORK SCHEDULING FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING SHALL BE PLANNED AND SCHEDULED FOR LAUNCH THROUGH GO FOR ORBIT OPS OR INTACT ABORT LANDING. NOTE: FOR TDRS SCHEDULING REDUNDANCY IS NOT REQUIRED.
- b. CONSIDERATION WILL BE GIVEN TO ATTEMPTING TO REGAIN FAILED REDUNDANT EQUIPMENT IF THE RECOVERY WILL NOT AFFECT THE REMAINING MANDATORY EQUIPMENT AND RECOVERY PROCEDURES ETRO IS PRIOR TO THE NOMINAL PLANNED TIME FOR COMING OUT OF THE T-9 MINUTE HOLD.
- c. RECOVERY EFFORTS FOR FAILED REDUNDANT EQUIPMENT IN THE MCC AND INTEGRATED NETWORK WILL NOT BE PERFORMED BETWEEN T-9 MINUTES AND COUNTING AND MET 15 MINUTES OR LANDING FOR RTLS OR TAL.

B. DEORBIT/ENTRY

1. PRE-DEORBIT: IT IS HIGHLY DESIRABLE TO HAVE THE MAXIMUM DURATION OF COVERAGE POSSIBLE FOR AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING FROM TIG-4 HR TO DEORBIT DECISION. REDUNDANCY IS DESIRABLE BUT NOT REQUIRED.

Preparing the orbiter for entry includes a number of complex and critical steps such as moding flight software to OPS 3, closing the payload bay doors, activating FES cooling. Having MCC connectivity troubleshoot any anomalies that may occur is very useful. Additionally, MCC is prime to provide deorbit maneuver targets and to assess landing site readiness including weather. Deorbit decision time is normally TIG - 23 minutes. @[062702-5502C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)

2. DEORBIT DECISION: GROUND AND INTEGRATED NETWORK EQUIPMENT FUNCTIONALITY AND SCHEDULING MUST PROVIDE AIR TO GROUND VOICE, COMMAND, TELEMETRY, AND TRAJECTORY PROCESSING FROM THE MCC GO FOR DEORBIT TO POST LANDING. REDUNDANCY FOR MANDATORY FUNCTIONS IS HIGHLY DESIRABLE BUT NOT REQUIRED. @[062702-5502C]

UHF TWO-WAY VOICE IS HIGHLY DESIRABLE DURING ENTRY TO KSC OR DFRC WHEN IN RANGE OF THE GROUND STATION AS A BACKUP TO S-BAND VOICE. S-BAND VOICE IS MANDATORY AS DESCRIBED ABOVE.

Monitoring vehicle systems, energy management, anomaly resolution, and landing site evaluation from touchdown parameters to weather conditions is the primary job of the MCC during shuttle entry.

3. TRAJECTORY PROCESSING SUPPORT FOR ENTRY:

IF ALL OF THE CAPABILITIES LISTED BELOW ARE EXPECTED TO BE AVAILABLE PRIOR TO DEORBIT TIG, C-BAND TRACKING IS NOT MANDATORY. S-BAND TRACKING IS HIGHLY DESIRABLE IN THE ABSENCE OF C-BAND TRACKING. IF DURING THE MISSION ANY OF THE FOLLOWING CAPABILITIES ARE LOST, EOM DUAL TRACKING CAPABILITY BECOMES MANDATORY FOR COMMIT TO DEORBIT:

- a. IMU'S: FULL REDUNDANCY (THREE LRU'S AND ASSOCIATED DPS AND EPS FUNCTIONALITY).
- b. ONBOARD TACAN: AT LEAST TWO-FAULT TOLERANCE IN THE TACAN/GPS SYSTEM AND ASSOCIATED DPS AND EPS FUNCTIONALITY) (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). @[092602-5641]
- c. ONBOARD MLS: FULL REDUNDANCY (THREE IRU'S AND ASSOCIATED DPS AND EPS FUNCTIONALITY) REQUIRED IF MLS IS REQUIRED FOR LANDING (REF. RULE {A3-202}, MLS). @[062702-5502C] @[092602-5641]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-3

GROUND AND NETWORK DETAILED REQUIREMENTS
(CONTINUED)

- d. GROUND TACAN STATIONS: TWO STATIONS AVAILABLE AND CONFIRMED OPERATIONAL WITHIN SPECIFICATIONS (REF. RULE {A8-52B}.2, SENSOR FAILURES), OR ONE STATION AVAILABLE AND CONFIRMED OPERATIONAL WITHIN SPECIFICATIONS (REF. RULE {A8-52B}.2, SENSOR FAILURES) WITH A GPS LRU FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). FAA/USAF SPECIFICATIONS ARE NOT ADEQUATE (REF. NSTS 07700, VOL X, BOOK 3, PARAGRAPH 1.3.1.1.1). ©[062702-5502C] ©[092602-5641]

In order to maximize launch probability by alleviating C-Band tracking data scheduling conflicts with the Eastern Range Operations Control Center (ROCC), the mandatory requirement for scheduling dual source high speed tracking for EOM is eliminated, provided that sufficient redundancy is available (TACAN/GPS and IMU) to correct the navigation state prior to violation of entry guidance limits. If sufficient redundancy is lost during the mission, dual source high-speed tracking becomes mandatory for commit to deorbit. The TSU trajectory processor Kalman filter cannot meet ground accuracy requirements with only one source of tracking data. The filter requires at least two sources. The 100k feet altitude constraint was chosen to allow sufficient time to assess the vehicle energy conditions and to update onboard navigation state (after nominal TACAN acquisition) in order to correct a violation of delta state limits. This requirement also allows time to GCA to within guidance limits prior to TAEM. ©[062702-5502C]

With three functioning IMU's and the associated DPS/EPS equipment, the first failure is fully protected by redundancy management. When two IMU's are available, 95 percent of the cases involving the second failure are properly resolved by the IMU RM which uses the IMU BITE logic.

With three functioning onboard TACAN transceivers and their associated DPS equipment, the first failure is fully protected by redundancy management. When two TACAN's are available, 90 percent of the cases involving the second failure are covered with TACAN self-test. GPS provides additional redundancy to the onboard TACAN transceivers (particularly at the TACAN 1-LRU level) assuming that the conditions in Rule {A8-115}, GPS SYSTEM MANAGEMENT, are satisfied. ©[092602-5641]

With three functioning onboard MLS transceivers and their associated DPS equipment, the first failure is fully protected by redundancy management. When two MLS's are available, a dilemma between the LRU's will remain unresolved unless a BITE had been previously set against one of the LRU's. If the dilemma is unresolved, MLS may not process at all (for range/azimuth dilemmas) or only partially process (for elevation dilemmas). For days when MLS is required, as defined in Rule {A3-202}, MLS, ground tracking is required to resolve dilemmas in order to make the MLS useable. Reference Rule {A8-18A}, LANDING SYSTEMS REQUIREMENTS. ©[062702-5502C] ©[092602-5641]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A3-3****GROUND AND NETWORK DETAILED REQUIREMENTS**
(CONTINUED)

To ensure that valid TACAN data are available, both primary and secondary ground stations must be confirmed to be within programmatically required limits (NASA operational requirements of 1 deg and 0.3 mile per Rule {A8-52B}.2, SENSOR FAILURES, rather than FAA/DOD certification (2.5 deg and 0.5 mile per NSTS 07700, Vol X specification)). With the pre-deorbit ground station checks, full single fault tolerance exists. If both the primary and the secondary ground station were to fail after deorbit, the MCC can uplink another TACAN station. ©[062702-5502C] ©[092602-5641]

If GPS is functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT), then the following failures will result in requiring high speed tracking for EOM

- a. *Any failure in either the onboard IMU's or MLS LRU's.*
- b. *Loss of two-fault tolerance in the GPS/TACAN system.*
- c. *No TACAN ground stations available.*

If GPS is NOT functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT), then the following failures will result in requiring high speed tracking for EOM:

- a. *Any failure in either the onboard IMU's, TACAN's, or MLS LRU's.*
- b. *Only 1 TACAN ground station available. ©[092602-5641]*

S-band data is highly desired because it may provide insight in the case of a TACAN bias, although it cannot by itself be used as a source of "ground truth."

In relaxing the tracking data requirement from mandatory to highly desirable, it is understood and acknowledged to be an acceptable risk to rely totally on TACAN and GPS as required to achieve a safe landing. If the normal ceiling limit exists, and TACAN data is not processed by navigation, and no independent valid tracking data are present, the vehicle is unlikely to achieve the runway unless GPS is incorporated. ©[092602-5641]

4. POST LANDING: GROUND EQUIPMENT WILL PROVIDE FOR AIR TO GROUND VOICE, COMMAND, AND TELEMETRY FROM LANDING UNTIL VEHICLE HANDOVER TO GOM. REDUNDANCY IS NOT REQUIRED.
©[062702-5502C]

A3-4 THROUGH A3-50 RULES ARE RESERVED

FLIGHT RULES

MCC INSTRUMENTATION PRELAUNCH REQUIREMENTS

A3-51 TRAJECTORY PROCESSING REQUIREMENTS @[061396-4005A] @[022802-5198]

- A. HIGH-SPEED TRAJECTORY DETERMINATION:
 - 1. HIGH SPEED S-BAND - HIGHLY DESIRABLE FOR LAUNCH AND LANDING @[061297-6004]
 - 2. HIGH SPEED C-BAND - HIGHLY DESIRABLE FOR LAUNCH AND LANDING
 - 3. KALMAN FILTER PROCESSING - HIGHLY DESIRABLE FOR LAUNCH AND LANDING @[061297-6004]
- B. ARD/AME PROCESSING - MANDATORY FOR LAUNCH @[022802-5198]
- C. EPHEMERIS MAINTENANCE PROCESSING - MANDATORY
- D. ORBIT DETERMINATION PROCESSING:
 - 1. LOW SPEED TRACKING DATA - MANDATORY
 - 2. BATCH RADAR PROCESSING - MANDATORY

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-51 TRAJECTORY PROCESSING REQUIREMENTS (CONTINUED)

- E. DEORBIT PLANNING PROCESSING - MANDATORY
- F. ENTRY PROFILE PROCESSING - MANDATORY
- G. COMMAND/TRAJECTORY INTERFACE PROCESSING - MANDATORY
- H. TRAJECTORY/TELEMETRY AND TELEMETRY/TRAJECTORY INTERFACE PROCESSING - MANDATORY
- I. HIGH SPEED ENTRY RGO AND TAEM PROCESSING - MANDATORY FOR LAUNCH AND LANDING @[022802-5198]
- J. RENDEZVOUS TARGETING PROCESSING - MANDATORY FOR RENDEZVOUS FLIGHT @[061396-4005A]
- K. LAUNCH WINDOW/LAUNCH TARGETING PROCESSING - MANDATORY UNTIL THE LAUNCH TARGET COMMANDS HAVE BEEN GENERATED. THIS ONLY APPLIES TO GROUND-UP RENDEZVOUS AND INERTIALLY TARGETED FLIGHTS. @[061396-4005A]

All mandatory trajectory processing is required to be operational prior to launch, including support processors as well. Any loss of trajectory processing will be assessed in real time in order to determine applicability of the lost capability to the flight at hand.

- L. DOLILU STRUCTURAL LOADS AND TRAJECTORY ANALYSIS TOOLS - MANDATORY UNTIL THE DOLILU I-LOAD HAS BEEN TRANSFERRED INTO THE MCC COMMAND SYSTEM; THEREAFTER, HIGHLY DESIRABLE (REF. RULE {A4-4}, DOLILU OPERATIONS). @[091098-6622C]

DOLILU and Loads assessments are nominally run concurrently by JSC and USA/Systems Integration. In the event that JSC fails to complete analysis after the MCC I-load transfer, USA/Systems Integration becomes prime for providing the remaining prelaunch assessments. This contingency condition is considered acceptable to proceed based on the joint system checkouts that have occurred (L-3 week, L-2 day, and completed launch day verifications). @[091098-6622C]

- M. DESCENT DESIGN SYSTEM (DDS) - MANDATORY @[061396-4005A] @[022802-5198]

FLIGHT RULES

A3-52

MCC INTERNAL VOICE

LOSS OF INTERNAL VOICE LOOPS FD, A/G 1, OIS 232 AND FLIGHT CONTROL OFFICER (FCO), WOULD NOT CAUSE A LAUNCH HOLD BECAUSE OF SUFFICIENT AVAILABLE WORKAROUNDS:

A. MCC FLIGHT CONTROL TEAM COORDINATION CAPABILITY - ONE OF THREE MANDATORY:

1. FD
2. AFD CONF
3. LOOP CONFERENCING

One common voice loop between all MCC flight control team members is required for expedient communication of system conditions/anomalies.

B. A/G TALK CAPABILITY - TWO OF FOUR MANDATORY:

1. A/G 1
2. A/G 2
3. A/G UHF
4. OTHER LOOP WITH KEYING CAPABILITY

Two MCC voice loops with keying capability are required to provide continuous S-band A/G and UHF A/G (ref. Rule {A3-1A}.1.d, GROUND AND NETWORK DEFINITIONS). ©[ED]

C. COMMUNICATIONS INTERFACE WITH LAUNCH TEST DIRECTORS - ONE OF FOUR MANDATORY:

1. OIS 131
2. OIS 232
3. FD (EXTENDED TO LAUNCH SITE)
4. OTHER LOOP PATCHING TO LAUNCH SITE

One MCC voice loop (extended to launch site long lines) is required to call an MCC-initiated countdown hold.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-52

MCC INTERNAL VOICE (CONTINUED)

D. COMMUNICATIONS INTERFACE WITH FCO - TWO OF FOUR MANDATORY:

@[101096-4550]

1. FCO PVT LINE
2. FD (EXTENDED TO FCO)
3. FCO PRIME
4. OTHER LOOP PATCHING TO FCO LONG LINE

A minimum of two MCC voice loops, extended to the Eastern Range 45th Space Wing, are required for FD and FDO voice communication with the FCO. Removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety during second stage flight, with crew-initiated manual MECO replacing range safety command destruct capability. Redundant FCO/MCC communications is therefore mandatory to provide the interaction and situational awareness necessary to implement this requirement. @[101096-4550]

Rules {A3-151C} and D, MCC/KSC/45 SPW INTERFACE, reference this rule.

E. COMMUNICATIONS CAPABILITY WITH REQUIRED ASCENT ABORT SITES -

1 OF 3 MANDATORY: @[111094-1716A] @[ED]

1. LONGLINE (LFP1)
2. INMARSAT
3. COMMERCIAL TELEPHONE

Prelaunch, the MCC must be able to communicate with the required ascent abort landing sites (ref. Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS). This insures that there has not been a change in weather or nav/landing aid status. It also insures that anomalies can be passed to the ground support team and that the runway and airspace are clear for a safe landing. This can be accomplished by insuring that at least one of the communications capabilities listed above are available. @[111094-1716A]

@[051697-6008A]

FLIGHT RULES

A3-53

MCC POWER

A. BUILDING 30M POWER BUSES @[061396 4006A]

BUS A1, A2, B1, B2 - THREE OF FOUR MANDATORY.

All mandatory MCC equipment can be configured to operate on any three of the four power buses. Equipment which cannot tolerate a 20-second power outage is configured on bus A1 or A2. These buses are supported with online UPS (uninterrupted power supply) (critical A power) during ascent. Equipment which can tolerate a 20-second power outage is configured on bus B1 or B2. These buses are supported with backup offline (20-second startup) diesel generators (critical B power) during ascent. @[061396 4006A]

B. BUILDING 30S POWER BUSES

1. POWER BUSES AX1, AX2 - ONE OF TWO MANDATORY.
(SEE NOTE #1)

NOTE #1: IF ONLY ONE POWER BUS IS AVAILABLE, IT MUST HAVE A NON-INTERRUPTIBLE POWER SUPPLY (EITHER UPS OR A RUNNING DIESEL) FEED.

2. POWER BUSES BX1, BX2 - ONE OF TWO MANDATORY.

3. POWER BUSES CX1, CX2 - ONE OF TWO MANDATORY
(SEE NOTE #2)

NOTE #2: MANDATORY FOR FLIGHTS WITH POCC WORKSTATION REQUIREMENTS ONLY; SEE THE FLIGHT SPECIFIC ANNEX.
@[061396-4006B]

All equipment on the A and B buses can be configured entirely onto either single bus, with each capable of carrying the entire load. The AX1 and AX2 buses are supported with UPS (uninterrupted power supply). The BX1 and BX2 buses are backed up with diesels (20-second startup).

The AX buses provide power for most mandatory technical equipment and emergency lighting in the MCC. The BX buses provide power to IPS system, utility outlets, AX1 and AX2 uninterruptible power supplies, and back-up power feed to the AX buses in case of a UPS failure. The CX buses provide power to the third floor POCC consoles.

FLIGHT RULES

A3-53

MCC POWER (CONTINUED)

C. BUILDING 30S AIR HANDLERS @[061396-4006A]

1. SOFT AIR HANDLERS - ONE OF THREE MANDATORY
2. HARD AIR HANDLERS - ONE OF THREE MANDATORY

The hard air handlers provide cooling to the FCR, SVO, GOSR, CDE and fifth floor areas of building 30S. The soft air handlers provide cooling to all other areas not supplied by hard air handlers. One of each type air handler is required to adequately provide cooling for mission essential hardware and personnel. @[061396 4006A]

FLIGHT RULES

MCC EXTERNAL INTERFACE (VOICE DATA) PRELAUNCH REQUIREMENTS

A3-151

MCC/KSC/45 SPW INTERFACE

- A. 7.2-KB LAUNCH/LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE. @[061297-6004]

These circuits provide launch/landing C-band tracking data from 45 SPW/CCC to the MCC. These are redundant circuits providing backup capability; each one capable of carrying the total traffic. @[061297-6004]

- B. 9.6 KB WIND DATA CIRCUIT - ONE OF TWO MANDATORY. @[ED]

NOTE: CHANGES TO HD AFTER STRUCTURAL GO/NO-GO DECISION IS MADE. @[ED]

These circuits support processing of ascent structural loads. There are two redundant circuits providing backup capability; each one capable of carrying the total traffic.

- C. 9.6 KB FCO ABORT SWITCH INTERFACE CIRCUITS - ONE OF TWO MANDATORY @[101096-4551] @[110900-3701]

Removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety during second stage flight. During this timeframe, crew-initiated manual MECO replaces range safety command destruct capability. One of the elements agreed upon to satisfy this requirement is to provide the FCO with the ability to illuminate the orbiter cockpit abort light via pushbutton as an independent method for the FCO to communicate a manual MECO requirement to the crew.

The Launch Commit Criteria states that at least one of two FCO abort light command paths must be available until T-10 seconds. A path consists of one abort switch circuit connected to one of three MCC workstations (FD WFCR-28, FDO WFCR-10, and SVO-9) to enable FCO abort light commanding through the MCC Command System. Ref. Rule {A3-2}, GROUND AND NETWORK OVERALL PHILOSOPHY. The two external FCO abort circuits and the MCC-internal lines to the three workstations go to a patch panel to allow any combination of one abort circuit and one workstation to complete an FCO abort light path. @[110900-3701] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-151

MCC/KSC/45 SPW INTERFACE (CONTINUED)

D. FCO INTERFACES:

1. VOICE INTERFACE - TWO OF FOUR MANDATORY:
 - a. FDO/FCO PRIVATE LINE
 - b. FCO PRIME LOOP
 - c. FD LOOP
 - d. OTHER LOOP PATCHING TO FCO LONG LINE
2. CONTROLLABILITY VERIFICATION - TWO OF FIVE MANDATORY:
 - a. 45 SPW RANGE SAFETY TELEMETRY DISPLAY SYSTEM (RTDS)
 - b. CONTROLLABILITY LIGHT (GNC CONSOLE TO FCO)
 - c. FCO PRIME LOOP
 - d. FDO/FCO PRIVATE LINE
 - e. FD LOOP

During second stage flight, removal of the ET Range Safety Flight Termination System resulted in additional flightcrew responsibility as agents of the 45th Space Wing Commander for public safety, with crew-initiated manual MECO replacing range safety command destruct capability. Redundant FCO/MCC communications are therefore mandatory to provide the interaction and situational awareness necessary to implement this requirement. ©[101096-4551]

During first stage, range safety mission rules outline flight termination criteria and provide the FCO with the ability to determine shuttle controllability status in the event of complete loss of communication with MCC. For purposes of making the controllability determination, range safety launch commit criteria require at least two pathways by which vehicle control status may be confirmed. The available sources include the items listed under paragraph D.2 of this rule. ©[101096-4551]

2. OIS 232/212
3. FD

NOTE: OIS 232 IS USED PRIOR TO T MINUS 20 MINUTES AND OIS 212 IS USED AFTER T MINUS 20 MINUTES AS THE PRIMARY VOICE COMMAND CHANNEL.

Same rationale as Rule {A3-52}, MCC INTERNAL VOICE.

FLIGHT RULES

A3-152

GSFC/STDN INTERFACE

A. SITE TO GSFC:

1. MIL/PDL ONLY 224-KB CIRCUIT - ONE OF TWO MANDATORY.
@[072398-6565A]

One of two redundant circuits is required to support mandatory telemetry from MIL/PDL. Reference Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX, for mandatory site requirements and Rules {A3-1A}.1.b and {A3-1A}.2, GROUND AND NETWORK DEFINITIONS, for HDR/LDR telemetry requirements. @[ED]

2. MIL 9.6-KB S-BAND HIGH SPEED TRACKING DATA CIRCUIT - HIGHLY DESIRABLE. @[061297-6004] @[072398-6565A]

This circuit supports high speed S-band tracking data from MIL.

3. 224-KB CIRCUITS: @[061396-3198]

DFRF - ONE OF ONE MANDATORY. @[092398-6565A] @[ED]

NOTE: MANDATORY ONLY WHEN THE SITE IS THE ONLY SOURCE FOR LANDING TELEMETRY (REF. RULE {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). @[ED]

One circuit is required from each site which is mandatory for telemetry.

B. GSFC TO SITE:

1. 224-KB/56-KB VOICE/COMMAND CIRCUITS, MIL/PDL ONLY - ONE OF TWO MANDATORY. @[061396-3198] @[072398-6565A]

The prime voice command circuit from GSFC to MIL/PDL is a 224-kb line, with a 56-kb circuit as backup. The circuit is required to provide uplink command and voice.

2. UHF ANALOG A/G VOICE CIRCUITS: @[061396-3198]

MIL - ONE MANDATORY

MIL is the only site which UHF A/G and S-band A/G are both mandatory (ref. Rule {A3-102}, INTEGRATED NETWORK FAILURE DECISION MATRIX). The UHF A/G must be sent to GSFC/STDN via analog circuits. @[072398-6565A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-152 **GSFC/STDN INTERFACE (CONTINUED)**

3. DFRF 224-KB COMMAND/VOICE CIRCUIT - ONE OF TWO MANDATORY.
 @[072398-6565A] @[ED]

NOTE: MANDATORY ONLY WHEN DFRF IS THE ONLY SOURCE FOR
 LANDING COMMAND OR S-BAND VOICE (REF. RULE {A3-102},
 INTEGRATED NETWORK FAILURE DECISION MATRIX). @[ED]

This circuit provides the data path for command and S-band voice from GSFC to DFRF.

4. WLPS 224 - KB CIRCUIT @[061396-3198] @[072398-6565A]

WLPS TLM/CMD/VOICE MANDATORY PER RULE {A3-102}, INTEGRATED
NETWORK FAILURE DECISION MATRIX. @[121593-1579] @[ED]

A3-153 **45 SPW/VAFB INTERFACE**

9.6-KB LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE.
@[061297-6004] @[ED]

NOTE: ONLY USED FOR EDW AOA/PLS. @[ED]

This circuit supports high speed tracking data from the west coast for EDW AOA/PLS. @[061297-6004]

A3-154 **45 SPW/WSMR INTERFACE**

2.4-KB LANDING RADAR CIRCUIT - ONE OF TWO HIGHLY DESIRABLE.
@[061297-6004] @[ED]

NOTE: ONLY USED FOR NOR AOA/PLS. @[ED]

This circuit supports high speed tracking data from WSMR for NOR AOA or daily prime opportunity.
@[061297-6004].

FLIGHT RULES

NAVAIDS REQUIREMENTS

A3-201 TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY

A. REDUNDANCY REQUIREMENTS @[020196-1807B]

1. REDUNDANT TACAN TRANSPONDER CAPABILITY IS MANDATORY FOR LAUNCH COMMIT AT THE FOLLOWING SITES:
 - a. RTLS
 - b. PRIMARY TAL IF REQUIRED
 - c. AOA IF REQUIRED
 - d. FIRST DAY PLS IF REQUIRED (ETRO FOR EQUIPMENT OUTAGE MUST BE PRIOR TO DEORBIT DECISION)

NOTE: REF RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS FOR ABORT SITE LAUNCH COMMIT REQUIREMENTS.

2. REDUNDANT TACAN TRANSPONDER CAPABILITY IS MANDATORY FOR PLS (OTHER THAN FIRST DAY PLS), MDF, AND END OF MISSION DEORBIT COMMIT (REF RULE {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS).
3. THE REDUNDANT TACAN TRANSPONDER REQUIREMENT CAN BE SATISFIED BY ONE GROUND STATION WITH DUAL STRING (DS) TRANSPONDERS, BY TWO STATIONS WITH SINGLE-STRING (SS) TRANSPONDER CAPABILITY, OR BY ONE GROUND STATION WITH SINGLE-STRING (SS) TRANSPONDER CAPABILITY AND A GPS LRU FUNCTIONING PROPERLY (REF. RULE {A8-115}, GPS SYSTEM MANAGEMENT). @[020196-1807B] @[092602 5642]

Rules {A2-2}, ABORT LANDING SITE REQUIREMENTS, and {A2-1F}.3, PRELAUNCH GO/NO-GO REQUIREMENTS, reference this rule. @[121593-1590]

Landing site selection will be based on priorities specified in Rule {A2-207}, LANDING SITE SELECTION. @[022201-3857]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A3-201****TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY (CONTINUED)**

GPS provides acceptable redundancy to a TACAN ground station that has only a single-string transponder. In the event that the single-string transponder becomes unavailable, the onboard GPS LRU will provide a means to keep the onboard state vector within the Guidance constraints. This is contingent upon GPS functioning properly (ref. Rule {A8-115}, GPS SYSTEM MANAGEMENT).

©092602-5642]

Landing sites and TACAN's are loaded in the onboard software and can be changed in OPS 1/6/3. Uplink of an acceptable alternate TACAN may be performed to meet redundancy requirements for OPS 6/3 entries. TACAN requirements for EOM and other landing opportunities are not considered in the decision to launch. ©[020196-1807B] ©[022201-3857]

RTLS

TACAN processing is required to protect the guidance-imposed navigation entry constraints for an RTLS. An offline analysis that assumed a launch on time using IMU's and ADTA with nominal performance characteristics and random noise showed that 3-sigma navigation performance violated the entry guidance constraints of downtrack and crosstrack at altitudes of 85k feet and 40k feet, respectively.

TAL (IF REQUIRED) ©[121593-1590]

TACAN is required to protect against navigation dispersions for TAL because neither delta state nor GCA is available without ground tracking. TACAN is the primary source to correct downtrack and crosstrack errors in the navigation state. ©[020196-1807B]

Redundant TACAN transponder capability near the selected TAL site is mandatory for launch to provide adequate navigation. If weather conditions are unacceptable at the primary TAL site, then redundant TACAN transponder capability becomes mandatory near the secondary site.

AOA/FIRST DAY PLS (IF REQUIRED)

Although an AOA landing site is not normally required for launch commit (ref. Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS), the TACAN requirements are shown in the event that an AOA site is required. Redundant TACAN transponder capability is required for the primary AOA landing site only. The navigation state conditions are worse for AOA compared to RTLS or TAL because the vector is 1 hour older and the vehicle requires one or two OMS burns. For a first day PLS, the site may be considered go if equipment outage resulting in less than single-fault tolerance has an ETRO prior to deorbit decision time. ©[121593-1590] ©[020196-1807B]

- B. IN GENERAL, PROGRAM APPROVED TACAN'S (LISTED BELOW FOR END OF MISSION AND INTACT ABORT SITES; NOT IN ORDER OF PRIORITY) THAT MEET THE CRITERIA IN PARAGRAPH C WILL BE USED TO MEET THE REDUNDANCY REQUIREMENTS. CONSIDERATION WILL BE GIVEN TO OTHER TACAN'S THAT MEET THE CRITERIA IN PARAGRAPH C IF THEY PROVIDE A NAVIGATION IMPROVEMENT OVER AN APPROVED TACAN. ©[020196-1807B]

TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN
SELECTION PHILOSOPHY (CONTINUED)

5. BEN GUERIR:
 - BEN GUERIR, BEN (DS)
6. MORON
 - MORON, MRN (SS)
 - ROTA, AOG (DS) @[020196-1807B]
7. ZARAGOZA: @[020196-1807B]
 - ZARAGOZA, ZZA (DS)

Program approved TACAN's refer to those TACAN's listed in NSTS 07700, Volume X, Book 3, controlled by the PRCB, approved by the SASCB for use in the onboard I-loads, or contained in this flight rule. When selecting an alternate TACAN station to meet redundancy requirements, priority will generally be given to program approved TACAN's that meet the criteria in paragraph C. If no program approved TACAN's meet the criteria or other TACAN's that meet the criteria provide a navigation improvement, non-program approved TACAN's may be used to meet the redundancy requirements. Note that in most cases, there will be no program approved alternate TACAN station since both NSTS 07700 and the onboard I-loads only include a primary and secondary TACAN for each site. @[022201-3857]

C. ALTERNATE TACAN'S THAT SATISFY THE FOLLOWING CRITERIA (NOT IN PRIORITY ORDER) MAY BE UPLINKED IN OPS 1/3 TO MEET THE REDUNDANCY REQUIREMENTS IN PART A. @[022201-3857]

NOTE: THESE CRITERIA APPLY TO GROUND STATIONS REQUIRED FOR LAUNCH COMMIT AND COMMIT TO DEORBIT. REFER TO RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA, FOR ELS MINIMUM REQUIREMENTS.

1. NO COCHANNEL INTERFERENCE PREDICTED BELOW 130K FT ALTITUDE.

NOTE: IN SOME CASES, COCHANNEL INTERFERENCE MAY BE ELIMINATED BY POWERING OFF THE INTERFERING STATION(S) FOR THE PERIOD OF SHUTTLE OPERATIONS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-201

**TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN
SELECTION PHILOSOPHY (CONTINUED)**

2. TACAN MUST BE OPERATING PRIOR TO LAUNCH OR DEORBIT COMMIT AS APPLICABLE PER PARAGRAPH A
3. WITHIN 50 NM OF THE RUNWAY.
4. POWER LEVEL ? 1.5K WATTS. @[020196-1807B]
5. NIMA OR FAA TACAN DATABASE COORDINATES MUST BE AVAILABLE AS A MINIMUM. SURVEY DATA IS HIGHLY DESIRABLE, BUT NOT MANDATORY. @[020196-1807B] @[022201-3857]
6. NASA OR FAA CERTIFIED AND ACCURATE WITHIN 0.3 NM AND 1.0 DEGREE (REF RULE {A8-52}, SENSOR FAILURES). CONSIDERATION WILL BE GIVEN TO THE USE OF A TACAN WHICH HAS BEEN EVALUATED VIA GPS EQUIPPED STA BUT WHICH HAS NOT BEEN COMPLETELY CERTIFIED. @[ED]

Alternate TACAN's may be uplinked in OPS 1/3 to satisfy the redundancy requirements for OPS 6/3 entries. The process of selecting an alternate TACAN begins with the TACAN Cochannel Interference Document (NAV-98-4237-032) which includes several potential TACAN stations for space shuttle landing sites. This document contains cochannel interference data which is generated assuming a nominal range-altitude profile, constant power level of 3.5 KW, and an approximation for the shape of the parabolic TACAN signal propagation. This interference data along with the expected groundtrack can be used to approximate the altitude below which a given TACAN station is clear of interference and to determine which TACAN stations must be powered off to reduce or eliminate interference. In addition to the cochannel interference data, the TACAN Cochannel Interference Document lists the type of station (TACAN, VORTAC, VORDME, or DME), data source (survey or NIMA/FAA database), and the distance and direction from the runway.

Once an acceptable TACAN or VORTAC is identified based on runway proximity and cochannel interference, the operating hours and power level are verified to ensure the TACAN will be available during entry. TACAN's used to meet the redundancy requirements must be operational prior to launch commit for RTLS, TAL (if required), and AOA (if required). If first day PLS is required, the TACAN(s) must have an ETRO prior to deorbit decision time. For PLS, MDF, and end of mission, the TACAN(s) used to meet the redundancy requirements must be operating prior to deorbit commit and until touchdown. The TACAN(s) must be available throughout entry to touchdown to ensure continuous TACAN processing.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-201

TACAN REDUNDANCY REQUIREMENTS AND ALTERNATE TACAN SELECTION PHILOSOPHY (CONTINUED)

A maximum distance of 50 nm from the TACAN to the runway is required to ensure TACAN lock-on until MLS acquisition. The groundtrack proximity may also be considered in the alternate TACAN selection process. The minimum power level of 1.5K watts and cochannel interference requirements were chosen to obtain TACAN lock-on by 130K ft, which is the altitude where 3 sigma downtrack error will exceed the guidance constraints if TACAN data is not processed. Interfering TACAN's may be powered off if possible to eliminate predicted interference below 130K ft.

Although survey data is preferred, it is not required, provided data is available from the NIMA/FAA TACAN database. Non-survey coordinates provided by NIMA/FAA are accurate within about 1000 ft. Past TACAN measurement data quality observed during shuttle missions and flight tests may also be considered in the alternate TACAN selection process. ©[020196-1807B] ©[022201-3857]

The FAA or NASA certification requirements are contained in NSTS 07700, Volume X, Book 3. The FAA accuracy requirements are outside those required by space shuttle navigation. Therefore, an FAA controlled TACAN must also meet the 0.3 nm and 1.0 degree accuracy requirements contained in Rule {A8-52}, SENSOR FAILURES. ©[020196-1807B] ©[022201-3857]

D. IF A TACAN GROUND STATION FAILS AFTER LAUNCH OR DEORBIT AND A TACAN THAT MEETS THE CRITERIA IN PARAGRAPH C DOES NOT EXIST, OTHER ALTERNATES (DME'S INCLUDED) MAY BE CONSIDERED FOR UPLINK TO PROVIDE SOME FORM OF BACKUP CAPABILITY.

The criteria in paragraph C is provided to ensure an acceptable TACAN is used to meet the redundancy requirements for commit to launch or commit to deorbit. However, if a TACAN fails after launch or deorbit and a TACAN that meets the criteria in paragraph C does not exist, the best alternate including DME's may be uplinked. Although this alternate may not protect 3 sigma navigation performance, it provides some form of backup capability. ©[020196-1807B]

FLIGHT RULES

A3-202

MLS

REDUNDANT MLS CAPABILITY, INCLUDING AZIMUTH, ELEVATION, AND RANGE DATA, IS REQUIRED FOR THE FOLLOWING: @[070899-6872A]

- A. REDUCED CEILING, VISIBILITY, OR INCREASED RTLS CROSSWIND LIMITS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]) FOR DAYLIGHT, CONCRETE RUNWAY LANDINGS. @[111094-1622B] @[041196-1817B]

Because MLS provides improved navigation and position accuracy with respect to the runway, a reduction in ceiling, visibility or an increase in RTLS crosswind requirements is allowed. However, because of the dependence on MLS during the critical landing phase with reduced ceilings/visibility, combined with the more stringent navigation requirements for concrete runways, single-fault tolerant capability must exist to guarantee MLS availability. Redundant MLS capability can be either the standard primary/backup MLS ground station or two collocated single-string MLS Jr. stations. The relatively less stringent navigation requirements for lakebed runways make it possible to relax the redundancy requirement to zero-fault tolerant. One-sigma onboard navigation position errors improve from approximately 400 feet without MLS to approximately 85 feet after the first MLS measurement, decreasing to just over 50 feet 1-sigma by touchdown. Azimuth and range measurements are required to allow MLS processing, and elevation is required to correct altitude errors. Detailed definitions of ceiling, visibility and RTLS crosswinds are covered in Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. @[111094-1622B] @[041196-1817B]

- B. NIGHT LANDINGS ON ALL CONCRETE RUNWAYS OR NIGHT LANDINGS ON LAKEBED RUNWAYS WITH CEILINGS LESS THAN THOSE SPECIFIED IN RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. @[111094-1622B]

MLS is required due to the loss of visual cues and the related degradation of the crew's ability to visually compensate for navigation dispersions during night landing operations. Because of this requirement, single-fault tolerant capability must exist to guarantee MLS availability (ref. paragraph A rationale) for landings on concrete runways where large lateral dispersions at touchdown are less tolerable than for lakebed runways.

For lakebed landings only, single-string MLS is acceptable if the lowest ceiling is at or above those specified in the Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. The increased ceiling provides additional time for the crew to compensate for navigation dispersions using visual cues. In addition, the larger area provided by the lakebed environment makes navigation dispersions resulting from the possible failure of the single-string MLS more tolerable. @[111094-1622B]

Rules {A2-1F}.3, PRELAUNCH GO/NO-GO REQUIREMENTS; {A2-2}, ABORT LANDING SITE REQUIREMENTS; {A3-203}, LANDING AID REQUIREMENTS; and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule. @[111094-1622B] @[070899-6872A]

FLIGHT RULES

A3-203

LANDING AID REQUIREMENTS

LANDING AIDS (CONCRETE / LAKEBED) @[070899-6881]

	PAPI LIGHTS	AIMPOINT	BALLBAR [1]	XENON LIGHTS	EDGE LIGHTS/ REFLECTORS	ALS	CENTER LINE LIGHTS	RUNWAY REMAINING MARKERS
CDR HUD W/MLS	1 OF 2 HD		HD	RUNWAY LIGHTS AND MARKERS NOT REQUIRED FOR DAYLIGHT LANDINGS				
CDR HUD W/NO MLS	1 OF 2 M		M					
NO CDR HUD	M	HD	M					
NIGHT LANDING	M	N/R	M	M	M	HD	HD	M [2]

@[102402-5786]

[1] BALLBAR IS MANDATORY FOR TAL.

[2] RUNWAY REMAINING MARKERS (RRM'S) ARE MANDATORY FOR NIGHT LANDINGS ON CONCRETE ONLY.

PAPI lights are required at the proper aimpoint position (nominal or close in as recommended) for all lighting and surface conditions. The exceptions are daylight landings where the use of an aimpoint and a HUD will substitute for a PAPI, or when the CDR HUD and MLS are available. PAPI lights allow the pilot to visually acquire the proper outer glide slope with a good degree of accuracy. In daylight, the use of an aimpoint and a HUD (visual glide slope information provided by onboard navigation) will provide the crew with similar cues to the outer glide slope. The combination of the HUD and MLS can also provide the necessary cues for flying the outer glide slope in daylight. In this case, either the PAPI lights or aimpoint are only highly desirable. For purposes of this rule, the MLS capability is required. For specific MLS ground station redundancy and LRU requirements reference Rules {A3-202}, MLS, and {A8-18}, LANDING SYSTEMS REQUIREMENTS. If MLS is not available, then either the PAPI lights or aimpoint are mandatory (PAPI lights preferred). Without MLS, navigation accuracy may not be good enough to provide a reliable crosscheck of the HUD runway overlay for confirming and flying the outer glide slope. PAPI lights are mandatory for night landings or landings without the CDR HUD to help offset the loss of visual cues and references and the degraded ability to compensate for navigation errors. @[070899-6881]

Ball bars are mandatory for TAL sites because of the reduced runway length and width (< 300 feet) as compared to CONUS runways. Without the ball bar, the reduced width of the runway can result in a false visual perception of being too high above the glide slope which can lead to descending through the inner glide slope and landing short of the runway.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A3-203

LANDING AID REQUIREMENTS (CONTINUED)

For daylight CONUS landings where the visual scene is “as trained to,” a ball bar is only highly desirable when both the CDR HUD and MLS are available. MLS plus the CDR HUD provides sufficient cues to allow an accurate transition to the inner glide slope. For purposes of this rule the MLS capability is required. For specific MLS ground station redundancy and LRU requirements, reference Rules {A3-202}, MLS, and {A8-18}, LANDING SYSTEMS REQUIREMENTS. Without MLS, the navigation accuracy (primarily the HUD velocity vector) may not be good enough to guide the pilot on the H/Hdot profile required to capture (Pre-Flare) and fly the inner glide slope through threshold crossing; therefore, a ball bar is mandatory. Ball bars are mandatory for night landings or landings without the CDR HUD to help offset the loss of visual cues and references and the degraded ability to compensate for navigation errors. ©[070899-6881]

Runway remaining markers (RRM's) are only mandatory for night concrete landings. The length of concrete runways and night conditions necessitate the need for RRM's due to the reduced margin of error in determining runway remaining. These markers give the pilot a visual cue to the rollout distance remaining and the brake profile required to stop on the field.

Runway lighting is required for night landings in order for the pilot to see the runway on approach, touchdown, and rollout. The Xenon lights are considered mandatory, as they provide the primary means for lighting the immediate runway area (approach path, threshold, and touchdown point). Runway edge lights/reflectors are mandatory as they provide the primary visual cue for lateral margin during touchdown and rollout. Approach Lighting System (ALS) lights are not mandatory because the Xenon lights, edge lights/reflectors, and PAPI/ball bar requirements suffice for centerline/threshold lighting and targeting cues. Centerline lights are available as a secondary cue at the KSC SLF and are only highly desirable. ©[102402-5786]

FLIGHT RULES

SECTION 4 - TRAJECTORY AND GUIDANCE

PRELAUNCH

A4-1 PERFORMANCE ANALYSES

LAUNCH WILL NOT BE ATTEMPTED IF:

- A. THE PREDICTED USABLE MPS RESIDUALS AT NOMINAL MECO ARE LESS THAN 2 SIGMA PLUS THE MEAN IN-FLIGHT MPS FLIGHT PERFORMANCE RESERVE (FPR).
- B. THE PREDICTED USABLE MPS RESIDUALS PLUS MPS-EQUIVALENT OMS AND RCS ABOVE THE MISSION-SPECIFIC REQUIREMENTS, AS SPECIFIED IN THE FLIGHT-SPECIFIC ANNEX, ARE LESS THAN 3 SIGMA PLUS THE MEAN IN-FLIGHT MPS FPR.

THE PREDICTED USABLE MPS RESIDUALS PLUS MPS-EQUIVALENT OMS AND RCS ABOVE THE MISSION-SPECIFIC REQUIREMENTS, AS SPECIFIED IN THE FLIGHT-SPECIFIC ANNEX, ARE LESS THAN 3 SIGMA PLUS THE MEAN IN-FLIGHT MPS FPR.

NOTE: FOR DIRECT INSERTION FLIGHTS WHERE ALL OF THE PRIMARY MISSION OBJECTIVES (AS DEFINED IN THE FLIGHT-SPECIFIC ANNEX) CAN BE ACHIEVED FROM A 1-SIGMA MECO UNDERSPEED WITHOUT RAISING THE ORBIT, ONLY PARAGRAPH A ABOVE APPLIES.

NOTE: IF THE PRIMARY MISSION OBJECTIVES CANNOT BE ACHIEVED FROM A 1-SIGMA MECO UNDERSPEED WITHOUT RAISING THE ORBIT, RCS (BOTH FORWARD AND AFT) MARGINS MAY BE COMMITTED ALONG WITH THE OMS MARGIN TO RAISE THE ORBIT. IF THIS IS DONE, THE PRIMARY MISSION OBJECTIVES MAY BE DELAYED TO FLIGHT DAY 2 OR LATER. THIS WILL BE EVALUATED ON A FLIGHT-SPECIFIC BASIS AND DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-1 PERFORMANCE ANALYSES (CONTINUED)

- C. THE ET IP CONSTRAINTS AS DEFINED IN RULE {A2-62A}, ET FOOTPRINT CRITERIA, ARE NOT SATISFIED.

Trajectory analysis, using day of launch winds and ET loading estimates, provides performance margins and launch hold capability after the initiation of LOX drainback. To be GO for launch, considering the hold capability, this trajectory analysis must not predict use of any of the mean plus 2 sigma in-flight MPS flight performance reserve (FPR). The use of MPS equivalent OMS propellant above that required to accomplish the specific mission will be allowed to cover up to 1 sigma of the required 3 sigma MPS margin. If the predicted MPS equivalent OMS available plus the MPS residuals at MECO are still less than 3 sigma plus the mean in-flight MPS FPR, launch will be NO-GO. The sigma level (2 or 3 as applicable) plus mean FPR is a propellant level that reflects potential uncertainties in all ascent subsystems at the specified sigma level. We are willing to launch with a slightly increased possibility of low level cutoff (2 sigma vs. 3 sigma) provided the extra sigma is covered in excess OMS such that the nominal mission is protected by 3 sigma, but we are not willing to launch with a guided MECO protection level of less than 2 sigma. On direct insertion flights, should a 2-sigma day occur, OMS propellant cannot be used to make up for the 1-sigma.

MPS shortfall at MECO without scheduling at least one additional OMS burn after OMS-2, with its associated mission objective timeline and tracking impacts. Therefore, as long as the mission objectives can be accomplished from the resulting lower orbit, only 2-sigma MPS plus the mean inflight MPS FPR (reference paragraph {A4-1A}, PERFORMANCE ANALYSES) need be protected.

If the primary mission objective cannot be achieved without raising the orbit, one or more maneuvers will be required. OMS and RCS margins may be used to raise the orbit. The addition of RCS increases the hold time available inside of drainback. However, commitment of RCS to making up part of the 1 sigma may require several maneuvers to be executed and may cause the primary mission objective to be delayed past flight day 1. Therefore, a flight-specific assessment must be done preflight to determine whether the impact of committing the RCS margins is acceptable. The commitment of RCS may be the difference between being able to launch and a launch scrub. It is acceptable to commit RCS prelaunch because the probability of actually having to use it are very small (i.e., requires greater than 2 sigma bad day). Margins are defined as the quantities in excess of the mission completion redlines (ref. Rules {A6-303}, OMS REDLINES [CIL]; {A6-304}, FORWARD RCS REDLINES; and {A6-305}, AFT RCS REDLINES) plus lower priority flight activities as defined in the Flight Specific Rule Annex.

Independent of the capability to support the designed mission, ET protection must be maintained off land as prescribed by Rule {A2-62A}, ET FOOTPRINT CRITERIA. As MPS performance capability is degraded through day-of-launch loadings/winds, holds within drainback, and/or late mass property updates, the designed ET footprint will move up range.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-1 PERFORMANCE ANALYSES (CONTINUED)

- D. ANY SINGLE-ENGINE-OUT INTACT ABORT GAP IS PREDICTED TO EXIST BASED ON LAUNCH DAY WINDS AND PERFORMANCE ASSESSMENTS. GAP CLOSURE METHODS AS OUTLINED IN RULE {A4-56I}, PERFORMANCE BOUNDARIES, SHALL NOT BE EMPLOYED PRELAUNCH TO CLOSE AN EXPECTED GAP. ©[ED]

The launch will not be attempted with a known abort gap. If launch is allowed to proceed with a known gap during intact abort coverage, there will be a period of time during which no intact abort mode will be available. Should an engine fail during this time, loss of mission, vehicle, and crew may result. Options exist for closing an abort gap, such as commitment to AOA shallow, maximum SSME throttles, and relaxing dispersion tolerances. These options are intended only to close a gap that arises post-lift-off due to some unanticipated performance difficulty. They should not be used to allow a launch to proceed since a safety compromise arises from each option.

Rules {A2-1C}, PRELAUNCH GO/NO-GO REQUIREMENTS, and {A2-2}, ABORT LANDING SITE REQUIREMENTS, reference this rule. ©[121593-1590]

FLIGHT RULES

A4-2

LANDING SITE CONDITIONS

LAUNCH WILL NOT BE ATTEMPTED IF ANY REQUIRED ASCENT ABORT LANDING SITE (REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS) RUNWAY AND LANDING CONDITIONS ARE NOT SATISFACTORY. THE LANDING CONDITIONS REQUIRED ARE DEFINED IN RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC], AND {A4-107A}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS. REDESIGNATION TO ALTERNATE SITES, IF ANY, MAY BE USED TO SATISFY RUNWAY AND LANDING CONDITIONS. @[121593-1590] @[111094-1622B]

NOTE: TAL, AOA, AND FIRST DAY PLS SITES MAY NOT BE REQUIRED FOR LAUNCH COMMIT (REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS). SHOULD ALL AOA SITES BE NO-GO, PRESS BOUNDARIES WILL BE BASED UPON ATO/MINIMUM HP/FD1 SHALLOW DEORBIT USING AFT RCS TO THE FD1 AFT RCS SHALLOW PRESS QUANTITY (REF. RULE {A6-305G}, AFT RCS REDLINES). IF A FIRST DAY PLS LANDING SITE IS UNAVAILABLE, THEN THE PRESS BOUNDARY WILL BE BASED UPON ATO/MINIMUM HP/FD2 SHALLOW DEORBIT USING AFT RCS TO THE FD2 AFT RCS SHALLOW PRESS QUANTITY (REF. RULE {A6-305G}, AFT RCS REDLINES), AND FWD RCS IN OPS 2 TO THE FD2 FWD RCS PRESS QUANTITY (REF. RULES {A2-53}, FORWARD RCS USAGE GUIDELINES, AND {A6-304D}, FORWARD RCS REDLINES). ANY SYSTEMS ABORT WILL USE EXISTING TAL/ABORT FROM ORBIT (AFO) CAPABILITY. @[012402-5112B]

Continuous single engine out intact abort landing sites must be available to support an abort condition during ascent. Without these sites, the payload, orbiter and crew may be lost in an abort situation. The redesignation provision documents the capability to employ weather alternate landing sites as a means of satisfying weather, runway, and equipment requirements.

The press boundaries are based on AOA, first day, or second day PLS depending on the availability of landing sites. It is assumed that weather would not prevent a second day PLS since all three CONUS sites would be available. Systems failures requiring early flight termination will be supported by TAL and AFO sites. In some cases, systems failures involving loss of redundancy normally requiring first day PLS will result in second day PLS landings incurring additional risk of failure of the last entry critical system. Rule {A2-1F}.1, PRELAUNCH GO/NO-GO REQUIREMENTS, references this rule. @[121593-1590] @[012402-5112B]

FLIGHT RULES

A4-3

ORBIT CONJUNCTIONS/CONFLICTS

IF U.S. SPACE COMMAND PRELAUNCH COMPUTATION OF MISSES BETWEEN ORBITS (COMBO) ANALYSIS PREDICTS AN ON-ORBIT CONJUNCTION WITHIN 5 KM IN THE RADIAL AND OUT-OF-PLANE DIRECTIONS AND 15 KM IN THE DOWNTRACK DIRECTION DURING THE FIRST 2 HOURS OF THE NOMINAL MISSION, LAUNCH WILL BE HELD UNTIL THE NEXT EVEN MINUTE TO ASSURE CLEARANCE. FOR LAUNCH SLIPS, ADDITIONAL COMBO ANALYSIS WILL BE REQUESTED AND FURTHER HOLDS WILL BE SCHEDULED IN ACCORDANCE WITH THIS FLIGHT RULE. LAUNCH WILL ONLY BE HELD IF RESULTS ARE AVAILABLE PRIOR TO 5 MINUTES BEFORE THE L-9-MINUTE RESUMPTION OF THE COUNT.

The launch will not be conducted into known conditions of potential conflict with an orbiting object. If such conditions are predicted to occur prior to 2 hours MET for the nominal orbit, it is prudent to delay the lift-off to the next even minute to assure sufficient clearance from the object. This action minimizes risk at a minimal cost prior to picking up the count at L-9 minutes. After that, holding launch for such a low probability event would not be prudent. The 5-minute pad is to allow the conjunction information to be evaluated, passed on to the FD, and a hold requested if required.

Notification of potential conflicts can come as early as L-1 day. Additional tracking is taken on the object(s), and subsequent COMBO runs are made to determine if the risk persists. If the risk does persist, a launch slip to the next even minute will eliminate that risk.

Providing COMBO analysis through 2 hours MET and slipping launch for the predicted misses as specified in the rule are based on orbiter insertion errors and trajectory dispersions. The orbiter state errors beyond that time are so large (until sufficient tracking can be taken) that it makes no sense to perform the analysis. Also, 2 hours was chosen because any potential conjunctions after that would be computed with an actual post OMS-2 state vector that the MCC provides U.S. Space Command. The results of the post OMS-2 COMBO analysis would be available by 1:30 MET, allowing at least 1/2 hour to plan a maneuver if required.

Rule {A2-1G}, PRELAUNCH GO/NO-GO REQUIREMENTS, references this rule. (Reference Ascent/Entry Flight Techniques Panel Meeting #101, 6/18/93). ©[051194-1605]

FLIGHT RULES

A4-4

DOLILU OPERATIONS

THE DAY OF LAUNCH I-LOAD UPDATE (DOLILU) OPERATIONS AND STRUCTURAL LOADS EVALUATION WILL BE PERFORMED BY THE MCC-H WITH VERIFICATION FROM USA/SYSTEMS INTEGRATION. THE LOADS AND DOLILU OFFICER (LDO) HAS PRIMARY RESPONSIBILITY TO REPORT FACILITY AND PROCESSOR STATUS AS WELL AS GO/NO-GO EVALUATION TO THE FD AND MOD WHO PROVIDE THAT INFORMATION TO THE NTD OR MMT AS APPROPRIATE. @[091098-6622C]

TO BE GO FOR LAUNCH, THE DOLILU COMMAND LOADS MUST BE BUILT FROM DAY OF LAUNCH JIMSPHERE MEASURED WIND INFORMATION, UPLINKED AND VERIFIED ONBOARD PRIOR TO LAUNCH, AND THE FINAL LAUNCH WIND ANALYSIS PERFORMED PRIOR TO LAUNCH MUST SHOW THAT THE LOADS AND ASCENT TRAJECTORY PARAMETERS ARE WITHIN ESTABLISHED LIMITS. VALID CORRELATION OF MCC-H AND USA/SYSTEMS INTEGRATION RESULTS IS REQUIRED. IT IS HIGHLY DESIRABLE TO HAVE GO EVALUATIONS FROM BOTH MCC-H AND USA/SYSTEMS INTEGRATION FOR ALL WIND ANALYSES, BUT EXCEPTIONS ARE LISTED BELOW:

- A. DISCREPANCIES IN PROCESSOR INTEGRITY RULES OR EXPERIENCE RULES WILL BE RESOLVED BY THE FLIGHT CONTROL TEAM IF POSSIBLE. NOTIFICATION WILL BE MADE TO THE MMT. UNRESOLVED DISCREPANCIES IN THESE RULES REQUIRE A LAUNCH NO-GO.
- B. VIOLATION OF THE SYSTEMS CONSTRAINT RULES IS A LAUNCH NO-GO UNLESS RESOLVED BY THE APPLICABLE PROGRAM ELEMENTS AT THE MMT LEVEL.
- C. DISCREPANCIES BETWEEN THE RESULTS FROM THE MCC-H PROCESSES AND THE USA/SYSTEMS INTEGRATION PROCESSES WILL BE RESOLVED AS FOLLOWS:
 1. FOR ALL DISCREPANCIES THAT FALL WITHIN COMPARISON CRITERIA, MCC-H RESULTS ARE CONSIDERED PRIME FOR MAKING THE GO/NO-GO EVALUATION. @[091098-6622C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-4

DOLILU OPERATIONS (CONTINUED)

2. IF THE DISCREPANCY FAILS COMPARISON CRITERIA AND IS CAUSED BY A WIND FEATURE, A SUBSEQUENT WIND ASSESSMENT SHALL BE USED TO CLEAR THE DISCREPANCY. THE FINAL WIND ASSESSMENT SHALL BE REQUIRED TO PASS COMPARISON CRITERIA PRIOR TO CLEARING THE VEHICLE FOR LAUNCH. @[091098-6622C]
 3. IF THE DISCREPANCY FAILS COMPARISON CRITERIA AND IS CAUSED BY AN ERROR FROM EITHER THE JSC OR USA/SYSTEM INTEGRATION DOLILU SUPPORT ELEMENT, THEN THE GO/NO-GO EVALUATION SHALL BE BASED ON THE CORRESPONDING NON-FAILED ELEMENT.
 4. IF THE CAUSE FOR THE MISCOMPARE IS UNRESOLVED, THE LAUNCH IS NO-GO REGARDLESS OF EITHER SYSTEM'S GO/NO-GO EVALUATION RESULTS.
- D. FOR FAILURE OF MCC-H PROCESSOR AFTER THE DOLILU I-LOAD HAS BEEN TRANSFERRED TO THE MCC COMMAND SYSTEM, LAUNCH MAY PROCEED IF USA/SYSTEMS INTEGRATION IS ABLE TO PROVIDE RESULTS AND THEY ARE GO.
- E. FOR FAILURE OF USA/SYSTEMS INTEGRATION PROCESSOR AFTER THE L-6:15 HR COMPARE WITH MCC-H IS COMPLETE, LAUNCH MAY PROCEED IF THE MCC-H CONTINUES TO BE ABLE TO PROVIDE RESULTS AND THEY ARE GO.

To be GO for launch, the DOLILU I-loads and trajectory must pass all structural loads and trajectory constraints. These constraints are based on SSP vehicle constraints, and there are no means available for the DOLILU process to clear these violations. Therefore, any systems constraint rule or structural loads violation is reported to the MMT as a NO-GO, requiring an MMT waiver for launch to proceed.

Trajectory experience rules are parameter envelopes and are based on the DOLILU-II certification database. Launch day upper wind conditions may cause an experience envelope exceedance. If the reason for the exceedance is identified and acceptable to the flight control team, then rationale to launch may be written by the LDO as a DOLILU exception and processing may proceed. @[091098-6622C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-4**DOLILU OPERATIONS (CONTINUED)**

At JSC only, processor integrity rules evaluate the DOLILU I-load generation processor for convergence and comparison with the trajectory simulation. Singularities inherent in the numerical iteration scheme used to generate the I-loads may result in processor non-convergence and are the result of random wind conditions. If a processor integrity rule fails, DOLILU processing may proceed using an I-load generated from another launch day balloon (L-6:15 or L-3:25) if the reason for the rule failure is understood and no additional processor rule failure occurs (ref. NSTS-08329, Vol. VIII, DOLILU Operations Support Plan (DOSP)). ©[091098-6622C]

A miscompare of USA/Systems Integration and JSC may indicate that there is an error in one of the two processes or that the environment (wind measurement) is not sufficiently stable to allow a valid constraint evaluation to be made. The source of the miscompare must be understood prior to launch.

The DOLILU process uses independent verification (JSC and USA/Systems Integration) of the trajectory and structural loads as one means to control the risks associated with DOLILU operations (ref. Integration Hazard Report INTG-180E). However, a successful launch day comparison between the two for the L-6:15 balloon is sufficient for processing to proceed with only one location's evaluation. This comparison as well as the system verification check-outs that have occurred prior to day of launch are adequate to insure verification integrity. An additional requirement is for JSC to have generated and transferred a DOLILU I-load to the MCC for uplink. ©[091098-6622C]

A4-5 THROUGH A4-50 RULES ARE RESERVED

ASCENT

A4-51

KALMAN FILTER SOLUTION

FOR PURPOSES OF IMPLEMENTING THE LAUNCH - POWERED FLIGHT ONLY - AND LANDING FLIGHT RULES, THE KALMAN FILTER SOLUTION IS CONSIDERED TO BE VALID IF:

The purpose of this rule is to establish quantitative criteria for declaring the Kalman filter solution a valid source for comparing and evaluating the onboard state vector.

- A. AT LEAST TWO AGREEING RADAR SOURCES ARE BEING PROCESSED, OR ONE RADAR HAS BEEN CONFIRMED PRIOR TO THE DUAL SOURCE LOSS.

The Kalman filter processor is designed for multiple radar data processing to achieve accuracy requirements. Since the ground solution is considered the valid source when disagreement occurs between the ground and the onboard, confirmation of data being processed is necessary for confidence in the ground solution.

- B. LESS THAN 20 PERCENT OF THE DATA IS BEING EDITED FROM EITHER SOURCE.

Editing of incoming radar data is indicative of noisy or invalid data. The 20 percent criterion was selected by navigation analysts as a conservative editing limit based on preflight analysis and postflight evaluation for purposes of maintaining the integrity of the ground state solution.

- C. THE STANDARD DEVIATIONS OF ANGLE AND RANGE RESIDUALS ARE LESS THAN THE 2-SIGMA EXPECTED VALUES.

Data statistics are computed in the Kalman processor based upon a prior knowledge about the data sources. The rule criterion was selected by navigation analysts as a conservative standard for solution validity evaluation based on preflight analysis and postflight evaluation.

- D. THE ESTIMATED BIAS IS LESS THAN 300 FEET FOR RANGE AND 0.5 MILLI-RADIAN FOR ANGLES.

Rationale is the same as for paragraph C above.

FLIGHT RULES

A4-52

ARD THRUST UPDATE CRITERIA AND FPR

- A. AN UPDATE TO THE ARD NOMINAL MAIN ENGINE THRUST VALUE WILL BE PERFORMED BY 4:00 MET IF THE ARD ACTUAL MODE NOMINAL MARGIN TREND RATE EARLY IN SECOND STAGE EXCEEDS A REAL-TIME, ARD-COMPUTED DEADBAND. FOLLOWING A THRUST UPDATE, PROTECTION WILL BE MAINTAINED FOR STATISTICAL DISPERSIONS IN ALL ARD FLIGHT PERFORMANCE RESERVE (FPR) COMPONENTS, AS DETAILED IN PARAGRAPH C BELOW. ©[050495-1729D]

When properly modeling vehicle performance, the ARD prediction of current nominal capability (nominal delta V margin) does not vary with time. However, when SSME characteristics and/or vehicle mass properties are mismodeled (i.e., when systems dispersions are present), the nominal margin will trend up or down with time. Analysis shows that at the flight-derived 2 sigma level, an SSME thrust dispersion results in a trend which is significantly larger than the trend due to all other performance-related variables combined. Therefore, it is probable that a trend outside this "deadband" is caused by improper SSME thrust modeling. Abort mode boundary accuracy is heavily dependent on accurate systems modeling and; therefore, the ARD thrust value will be updated in real time, using an empirical relationship between thrust error and trend rate. The deadband is derived from the delta V margin trend due to the root sum square (RSS) of 2 sigma inert weight error, 2 sigma ET LH2 loading error, and the thrust error which could be "masked" by the other dispersions. The update does not eliminate the trend; it merely reduces it to the region where the remaining trend could be due to other factors for which protection is maintained via the ARD FPR. Reference paragraph C of this rule and its associated rationale for thrust sigma-level and deadband values. Implementation details are documented in the Ascent FDO Console handbook (JSC-23255, volume V) and the ARD Support Console Handbook (JSC-24541).

- B. THE ARD SOLUTION WILL BE CONSIDERED INVALID IF THRUST UPDATE REQUIREMENTS EXCEED THE 3-SIGMA SPECIFICATION THRUST DISPERSION LEVEL (10,392 LB CLUSTER, OR 0.74 PERCENT PER SSME) AS DEFINED IN NSTS 07700, VOL X, WITHOUT A CONFIRMING INDICATION. IN THIS CASE, THE ARD WILL BE DECLARED NO-GO AND THE PERMISSION CUE CARD VELOCITIES WILL BE USED FOR MODE BOUNDARY DETERMINATION, BASED UPON THE BEST AVAILABLE STATE VECTOR SOURCE.

Use of this update procedure will generally result in the highest-accuracy ARD solution possible. However, dispersions outside the SSME system specification thrust limit (?6,000 lbs/eng RSS, or 10,392 lbs for the cluster) without a secondary cue are highly unlikely. It then becomes probable that the mis-modeling seen in the ARD is due to a ground configuration problem. If this occurs, the ARD solution will be bypassed in favor of abort mode boundaries based on pre-mission-computed inertial velocities. Potential secondary cues include: Off-nominal onboard thrust factor, differences between the onboard-computed and the prelaunch-expected MECO times (provided the ARD solution agrees with the prelaunch value), SSME system status and failure conditions reported by the Booster Systems Engineer, etc. ©[050495-1729D]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-52

ARD THRUST UPDATE CRITERIA AND FPR (CONTINUED)

C. THE ARD FPR IS CONFIGURED TO PROTECT FOR SYSTEM DISPERSIONS THAT ADVERSELY AFFECT ARD MODELING OF VEHICLE PERFORMANCE. PROTECTION IS PROVIDED FOR ITEMS LISTED BELOW AT THE SPECIFIED STATISTICAL DISPERSION LEVELS. SYSTEM DISPERSIONS ARE OBTAINED FROM A HISTORICAL DATABASE OF FLIGHT-DERIVED DISPERSIONS MAINTAINED IN TABLE 8.1 OF THE SHUTTLE PERFORMANCE ASSESSMENT DATABASE (SPAD, NSTS-08209, VOL I). @[050495-1729D]

ARD FPR COMPONENT	PROTECTION LEVEL (MEAN PLUS)	TYPICAL CONTRIBUTION
ET LOAD ERROR, VAPOR PRESSURE, SSME MIXTURE RATIO	2 SIGMA	29 PERCENT
ORBITER AND ET INERT WEIGHT	2 SIGMA	42 PERCENT
SSME SPECIFIC IMPULSE	2 SIGMA	23 PERCENT
SSME THRUST	2 SIGMA UNTIL 4:00 MET; THEN APPROX 1 SIGMA *	7 PERCENT
SSME THRUST SHAPE	2 SIGMA	< 1 PERCENT

* COMPUTED VIA FLIGHT DESIGN/MCC ARD RECONFIGURATION PROCESS @[080896-4209]

EACH ARD FPR COMPONENT IS COMPUTED INDEPENDENTLY FOR AN ENGINE-OUT AT THE PRESS-TO-ATO BOUNDARY ("AOA FPR"), WITH THE TOTAL AMOUNT DETERMINED BY ROOT-SUM-SQUARING THE SIGMA COMPONENTS AND ADDING THE MEANS. OTHER ABORT BOUNDARIES REQUIRING A SIGNIFICANTLY DIFFERENT FPR QUANTITY (E.G., NEGATIVE RETURN, SINGLE-ENGINE PRESS, AND THE PERFORMANCE CALL) ARE ADJUSTED VIA ARD BIASES.

ARD FPR differs from TDDP FPR, used for pre-flight performance assessment, for several reasons. Pre-flight FPR protects for the total performance impact, from liftoff to MECO, of system dispersions that adversely affect the trajectory. ARD FPR, on the other hand, protects for ARD real-time performance prediction errors caused by system dispersions. For each ARD execution cycle (2 sec), the ARD FPR must protect for future performance degradation due to a dispersion, as well as any MPS propellant mass track errors induced by a dispersion up to the current time. This causes ARD FPR to be a function of MET. Sigma components are RSS'ed and the means are added for the total FPR quantity versus time. The FPR at predicted press-to-ATO MET is loaded into the ARD. This closely matches the FPR quantity for two-engine TAL and press-to-MECO boundaries. Adjustments to ARD biases (Flight Design Product ASAB-25) for negative return, single-engine press, performance low/nominal, and other calls are required since the FPR quantity and/or sigma protection levels are different for these calls. Typical values for ARD and TDDP FPR are approximately 2,400 lbs and 3,800 lbs, respectively. @[050495-1729D]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-52****ARD THRUST UPDATE CRITERIA AND FPR (CONTINUED)**

The SPAD lists flight-derived dispersions that degrade ascent performance in Table 8.1 of Vol 1. These statistics are obtained from post-flight reconstruction analysis of actual systems performance (e.g., SSME thrust, vehicle weight, SRB burnrate, etc.). Pre-flight prediction is compared to post-flight reconstructed performance over multiple flights to obtain dispersion statistics that are used in FPR calculations. The following dispersions listed in SPAD Table 8.1 are not included in ARD FPR since they take place in first stage (i.e., the effects of the dispersions are visible to the ARD through the post-staging state vector): SRB burnrate, SRB Isp, and collectors (forces and moments used to closely match first stage reconstructed trajectory to the best estimated trajectory (BET)). The remaining dispersions are included in ARD FPR, and the effects of each on ARD performance prediction are described below:

©[050495-1729D]

ET load, vapor pressure & SSME mixture ratio: This FPR component is identical to pre-flight ET load, vapor pressure, and mixture ratio protection used in generating TDDP FPR. This specifies the total performance impact of a 2 sigma plus mean combination of these dispersions. Therefore, it is not a function of mission elapsed time. The exact value used is a function of fuel bias at MECO, as predicted from pre-launch reported load or ARD real-time propellant imbalance computations during an SSME performance case.

Orbiter & ET inert weight: This component is calculated by determining the effect of a 2 Sigma plus mean inert weight error on delta V available. This is specified by the rocket equation and is a function of MET (i.e., ET propellant remaining). When calculated in this manner, this component protects for future performance degradation caused by the dispersion. The past performance impact of this dispersion is reflected in the state vector used by the ARD each cycle.

SSME specific impulse (Isp): This item protects for ARD delta V available and exhaust velocity (Vex) errors caused by a 2 sigma plus mean Isp dispersion. The rocket equation is used to calculate the delta V available error caused by the flowrate difference up to current time. Also, the effects of Vex error (a function of Isp dispersion) in the rocket equation are determined. The sum of these composes the ARD Isp protection, and is a function of MET.

SSME thrust: This item protects for ARD delta V available errors (caused by flowrate error) computed from the rocket equation as a function of time. Prior to 4:00 MET, 2 sigma plus mean protection is required. After this time, a thrust update is performed for thrust errors beyond a magnitude specified by the thrust update deadband (approx 4 fps/min). Since thrust errors beyond the deadband are modeled after this point, no FPR protection beyond the deadband is required. A study was conducted to determine the maximum thrust error that could be hidden within the deadband. Other dispersions masking the thrust errors were considered also, but only those causing early ARD boundary errors (i.e., FPR consumption scenarios) were analyzed. The maximum combination is determined each time FPR dispersion levels are re-derived and is converted to a thrust sigma level (approximately 1 sigma; past

©[050495-1729D] ©[080896-4209]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-52

ARD THRUST UPDATE CRITERIA AND FPR (CONTINUED)

values have ranged from 0.88 to 1.24) which is used in the ADR FPR computation from 4:00 MET to MECO. The actual sigma level is documented in Flight Design product ASCT-22A, ARD MCC Trajectory Inputs and Support Tables, and ASCT-47, Final MCC Trajectory Inputs (the day-of-launch version of ASCT-22A). The Ascent FDO's will informally keep the Flight Director Office aware of any change in this value in the course of standard pre-mission preparation. ©[050495-1729D] ©[080896-4209]

SSME thrust shape: This item is specified in the SPAD for a nominal mission profile only (i.e., no engine out). It accounts for differences between predicted (cubic polynomial) and reconstructed thrust magnitude in the throttle bucket and during 3g throttling and fine countdown. Since it is calculated for pre-flight FPR, it specifies the total performance impact of this dispersion and is not a function of MET. Since no 3g throttle phase occurs on an engine-out trajectory (for which ARD FPR is designed), the quantity specified in the SPAD is multiplied by 1/3 to account for the approximate time that this dispersion is present (i.e., the throttle bucket), since the 3g throttling/fine countdown time is approximately 60 sec in duration, and the throttle bucket is about 30 sec long. SSME thrust shape is the smallest component of ARD FPR. ©[051045-1729D]

FLIGHT RULES

A4-53

USE OF MAXIMUM THROTTLES

MAXIMUM THROTTLES WILL BE ENABLED (SPEC 51 ITEM 4) FOR THE FOLLOWING CONDITIONS: @[092195-1770A]

- A. IF AN ENGINE-OUT OCCURS DURING FIRST STAGE BUT AFTER THROTTLE UP, WITH THE THROTTLE OF ONE REMAINING SSME STUCK IN THE THRUST BUCKET, MAX THROTTLE WILL BE ENABLED ASAP PROVIDED RTLS CAPABILITY WILL EXIST AFTER MAX THROTTLE ENABLING.
@[092195-1770A]

For an SSME-out during first stage and a remaining engine stuck in the bucket, the resulting trajectory will be depressed and performance will be much lower than normal. To avoid PEG guidance convergence difficulties in the RTLS flyback solution, max throttles should be enabled ASAP. If max throttles are not enabled, the low altitude drag effects can produce an early RTLS flyback, an extended period of nonconverged steering, and/or unstable throttle commands during flyback. Enabling max throttles increases the altitude at RTLS selection, thus reducing the flyback guidance problems. Additionally, the higher altitude and H-dot reduces the SSME plume heating on the aft end of the vehicle. @[092195-1770A]

- B. IF AN ENGINE-OUT OCCURS DURING FIRST STAGE, MAX THROTTLE WILL BE ENABLED PRIOR TO RTLS SELECTION IF THE H-DOT AT SRB STAGING IS LESS THAN THE PRTLS MINIMUM PERFORMANCE CONSTRAINT (SEE H-DOT VS. VREL PLOT). MAX THROTTLE IS REQUIRED TO AVOID TOTAL PRESSURE (P_{TOTAL}) PROBLEMS FOR DEPRESSED STAGING CONDITIONS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-53****USE OF MAXIMUM THROTTLES (CONTINUED)**

Initiation of a two-SSME RTLS from a depressed trajectory with low vehicle acceleration requires a large velocity to be gained to satisfy the target MECO conditions. The resultant trajectory drops to low altitudes during flyback phase. The low altitude leads to an increase in dynamic pressure and resultant P_{total} deflecting the SSME plume, which causes heating problems on the aft end of the vehicle. An analysis has been performed to determine altitude rates at SRB jettison which represent the minimal depressed trajectories that would cause PRTLS flyback heating problems on the aft end of the orbiter. The H-dot versus V_{rel} plot shows this region over the range of possible velocities, and is applicable to all flights. This altitude rate is called the PRTLS minimum performance constraint and is based on 20 psf P_{total} during flyback.

The 20 psf criteria applies only to off-nominal contingency situations where engine-out staging conditions are outside the one-sigma systems dispersion boundaries. Single engine-out/one-sigma systems dispersion cases are protected to the dispersed P_{total} limit (4 psf), which provides additional thermal protection for vehicle reusability. The 20 psf criteria was baselined for contingency RTLS aborts in 1982 at Ascent Flight Techniques #5 and approved again at the June 1987 SIR. The abort panel examined contingency RTLS heating concerns during 1989 and found ET umbilical tray heating constraints were violated. However, no ET critical 1 failures were identified with a 20 psf P_{total} . The Orbiter Project Office has not yet assessed orbiter heating with a P_{total} greater than the dispersed (non-contingency) limit. The October 4, 1989, PRCB recommended remaining with the 20 psf P_{total} limit rather than the dispersed limit primarily to reduce the need for throttling up to 109 percent during contingency cases.

Thus, if an SSME failure occurs during first stage and the observed altitude rate at SRB staging is less than the minimum performance constraint, maximum throttle will be enabled by item entry prior to selection of RTLS abort. An increase in vehicle acceleration decreases the flyback interval thereby reducing the gravitational losses which allows more effective thrust to satisfy the target conditions. The heating concerns are reduced by increasing the altitude prior to flyback.

Rule {A2-52C}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, references this rule.

C. ABORT GAP CLOSURE @[092195-1770A]

Maximum throttles may be used to eliminate or reduce gaps in "intact abort" capability. Ref. rule {A4-56H}, PERFORMANCE BOUNDARIES, for maximum throttle priority for the specific gap to be closed.

D. TO AVOID POST TAL SELECTION SITE REDESIGNATION WHEN OPERATING ON A SINGLE SSME

Maximum throttles may be used to allow the earliest opportunity to continue to the prime TAL site, rather than redesignating to an inplane ACLS, following the loss of a second main engine. Ref. rules {A4-56F}.2.e, PERFORMANCE BOUNDARIES, and {A2-52C}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, for additional rationale.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-53

USE OF MAXIMUM THROTTLES (CONTINUED)

E. TO MINIMIZE EXPOSURE TO A CONTINGENCY ABORT OR CREW BAILOUT SITUATION: @[092195-1770A]

For the following cases, the additional risk associated with operating the main engines at 109 percent power level is acceptable in order to provide the crew and vehicle a chance to reach a runway (i.e., SE LIMITS or RTLS SE PRESS). Operationally, the increased internal engine pressures and temperatures at 109 percent do increase the likelihood of having an SSME failure (ref AEFTP #108 charts, 12/17/93; AEFTP #124 charts, 06/02/95; and AEFTP #125 charts, 08/04/95). However, commanding the engines to 109 percent power level while the vehicle is in an abort gap is considered less risky than a contingency abort or crew bailout.

1. DURING A TWO ENGINE RTLS OR TAL ABORT WITH A NON-ISOLATABLE MPS HELIUM LEAK PER RULE {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL].

When one engine has failed and another is suspect, maximum throttles may be enabled to reduce the time to MECO and minimize exposure to a contingency abort. In this case, the risk of the suspect engine failing prior to single engine capability outweighs the increased likelihood of having an SSME failure due to the increased pressures and temperatures associated with operating the engines at 109 percent power level. @[092195-1770A]

2. ECAL, BDA, AND DROOP CONTINGENCY ABORTS

Maximum throttles will be used in contingency abort scenarios to increase the probability of reaching a landing site. The risk of crew bailout outweighs the risk of operating the remaining engine at 109 percent power level.

3. IF THE ENGINES ARE COMMANDED TO 104 PERCENT POWER LEVEL DURING RTLS FLYBACK

Once powered pitcharound is complete, the throttle command is initialized to 100 percent for a two engine RTLS and 72 percent for a three engine RTLS. These values are initial settings only and are adjusted during flyback phase to achieve the desired amount of propellant remaining at MECO. If it appears that there will be too much propellant remaining, the throttle command will be reduced. Conversely, if it appears that there will be too little propellant remaining, the throttle command will be increased but limited to 104 percent. If the throttle command is at the limit of 104 percent, maximum throttles will be enabled to allow guidance to command a power level up to 109 percent. It should be noted that guidance will only command the level required to reach the mass target and may not throttle up to the new limit of 109 percent. @[092195-1770A]

FLIGHT RULES

A4-54**ABORT MODE RESPONSIBILITY**

THE GROUND IS PRIME FOR ABORT MODE DETERMINATION.

Until such time that the orbiter GPC's have the memory capability to contain a completely autonomous version of the ARD program and autonomous navigation, the MCC ARD will remain the prime tool for determining abort capabilities. Current onboard abort mode determination capabilities are based on premission flight design data for predicted ascent performance and groundrule flight performance reserves. The crew is only provided with cue card values of inertial velocity that define designed mode boundaries and two tick marks on the ascent traj display that define negative return and two-engine press-to-MECO; all of which are intended for use only in no-communication situations.

The real-time MCC ARD program was defined and implemented with the flexibility to handle all performance-related ascent abort situations. Those situations include:

- a. Complete failure of one or more SSME at any time.*
- b. Performance dispersions visible in the vehicle state (e.g., dispersions in aerodynamics, atmospherics, SRB, performance, winds aloft, time-variant ISP, guidance/navigation/control, and mass track).*
- c. Performance dispersions not visible in the vehicle state (e.g., SSME performance dispersions, OMS/RCS propellant leaks contained onboard).*

The MCC ARD can define multiple or single SSME abort capabilities throughout ascent for any combination of the above-mentioned situations, utilizing either the HSTD filter or telemetry for the current vehicle state. The MCC ARD can also predict downmode abort capabilities through powered flight.

By virtue of the MCC ARD's flexibility in assessing in real time the orbiter's abort capabilities, the independent ground radar tracking, and the current lack of an equivalent autonomous onboard version of the ARD, the ground is therefore prime for all abort mode determinations.

Rule {A2-67}, ARD UPDATE CRITERIA, references this rule.

FLIGHT RULES

A4-55

DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS

A. PERFORMANCE ASSESSMENTS THAT INDICATE ORBITAL CAPABILITY SHALL BE BASED ON THE ABILITY TO ACHIEVE EITHER THE DESIGN MECO UNDERSPEED OR THE CRITICAL MECO UNDERSPEED. THE FOLLOWING CONSTRAINTS DEFINE THE DESIGN MECO UNDERSPEED:

1. ET IMPACT CONSTRAINTS - CRITICAL LAND MASSES SHALL BE PROTECTED FROM THE 3-SIGMA ET IP FOOTPRINT (REF. RULE {A2-62}, ET FOOTPRINT CRITERIA).

2. MINIMUM PERFORMANCE CAPABILITY - THE MAXIMUM UNDERSPEED WHICH WILL SUPPORT THE EARLIEST PRESS TIME WITH EITHER:

a. AN AOA WITH STEEP TARGETS USING AFT RCS TO THE AOA AFT RCS STEEP PRESS QUANTITY @[012402-5112B]

OR

b. AN ATO/MINIMUM HP WITH SHALLOW DEORBIT ON FD 1 USING AFT RCS TO THE FD1 AFT RCS SHALLOW PRESS QUANTITY (REF. RULE {A6-305G}, AFT RCS REDLINES). @[121593-1590]

OR

c. AN ATO/MINIMUM HP WITH SHALLOW DEORBIT ON FD2 USING AFT RCS TO THE FD2 AFT RCS SHALLOW PRESS QUANTITY (REF. RULE {A6-305G}, AFT RCS REDLINES) AND FWD RCS IN OPS 2 TO THE FD2 FWD RCS PRESS QUANTITY (REF. RULES {A6-304D}, FORWARD RCS REDLINES, AND {A2-53}, FORWARD RCS USAGE GUIDELINES). NOTE: THIS OPTION WILL ONLY BE UTILIZED REAL TIME FOR LOSS OF BOTH AOA AND FD1 LANDING SITES, AND THE PRESS TIME WILL NOT BE EARLIER THAN THE AOA OR FD1 "DESIGN." @[012402-5112B]

NOTE: REF. RULE {A2-2}, ABORT LANDING SITE REQUIREMENTS, TO DETERMINE THE BASIS FOR DESIGN UNDERSPEED.

ALL OPTIONS WILL PROTECT THE CG TO THE CONTINGENCY CG ENVELOPE. IF AOA DEFINES THE PRESS BOUNDARY, THE LANDING SITE THAT PROVIDES THE EARLIEST PRESS TIME (PROVIDED IT IS "GO") WILL BE ASSUMED REGARDLESS OF THE LANDING SITE PRIORITIES. @[121593-1590]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-55

DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS (CONTINUED)

3. MINIMUM ALTITUDE CONSTRAINT - THE MAXIMUM UNDERSPEED SHALL BE LIMITED TO A VALUE WHICH PROTECTS AGAINST LOW-ALTITUDE (< 55 NM) TRAJECTORY CONDITIONS BETWEEN OMS-1 CUTOFF AND OMS-2 TIG. @[012402-5112B]
4. MINIMUM SSME NPSP CONSTRAINTS - THE MAXIMUM UNDERSPEED SHALL BE LIMITED TO A VALUE WHICH PROTECTS AGAINST VIOLATION OF SSME NPSP REQUIREMENTS DURING THE MECO SHUTDOWN SEQUENCE.

NOTE: MANUAL THROTTLING MAY BE USED TO SATISFY NPSP LIMITS IF THE RESULTING ADDITIONAL UNDERSPEED CAPABILITY MAINTAINS ALL OTHER REQUIRED PROTECTION. REF. RULE {A4-59F} AND G, MANUAL THROTTLE SELECTION, FOR MANUAL THROTTLE CRITERIA.

5. CG PROTECTION - THE SPECIFICATION CG ENVELOPE, RULE {A4-153}, CG PLANNING, WILL BE RELAXED TO THE CONTINGENCY ENVELOPE IN ORDER TO CONTINUE TO ORBIT.
- B. CRITICAL UNDERSPEED IS DEFINED AS MAXIMUM UNDERSPEED CAPABILITY WITHOUT REGARD TO ET IMPACT PROTECTION OR FLIGHT SOFTWARE MECO PREP THROTTLING FOR NPSP (I.E., ALLOWS MANUAL THROTTLING). CRITICAL UNDERSPEED IS UNRELATED TO AND DOES NOT PROTECT CRITICAL LAND MASSES.

REFERENCE THE ANNEX FLIGHT RULE, SHUTTLE TRAJECTORY AND GUIDANCE PARAMETERS, FOR THE FLIGHT-SPECIFIC DESIGN AND CRITICAL MECO UNDERSPEEDS. @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-55

DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS (CONTINUED)

The design MECO underspeed is usually based on ATO/Min Hp/FD 1 shallow deorbit. In some cases, the design underspeed is based on AOA steep capability. In either case, flight design techniques minimize the time difference between these two boundaries so the loss of an AOA site is not a significant performance risk. The loss of a first day PLS site may require pressing on FD2, but this is a real-time option only and is never part of the "design." Analysis has shown that there is no delay between the FD2 press boundary and the "design" due to being able to commit the Fwd RCS (ref. Rule {A2-53}, FORWARD RCS USAGE GUIDELINES). However, utilizing all of the Fwd RCS above the FD2 Fwd RCS press quantity can result in an earlier press time than the "design." In order to preserve a FD1 PLS option, the press time will not be earlier than the "design" (reference A/E Flight Techniques #178). This modified two engine press boundary would be based on ATO/minimum Hp/FD2 shallow capability, using the Fwd RCS to provide adequate lifetime by raising perigee in OPS 2. RCS press quantities are also modified to include usage to FD2 deorbit. Systems failures requiring early flight termination will be supported by TAL and AFO sites. Reference Rule {A2-2}, ABORT LANDING SITE REQUIREMENTS. ©[121593-1590] ©[012402-5112B]

The landing site that provides the earliest press time is assumed in the minimum performance capability, assuming that the landing site meets all constraints to make it GO. This is done regardless of the landing site priority in order to yield the earliest press time. Since the press calls protect for two-sigma low ascent performance, there is statistically a low probability that an AOA would be required for an SSME-out at the press boundary. Therefore, the Ascent/Entry Flight Techniques Panel determined it appropriate to use the landing site that provides the earliest press time in the assumptions for the press calls, even though it may not be the prime AOA site.

Design underspeed protection of auto MECO prep throttling is provided to satisfy SSME NPSP requirements without any action by the crew. It was determined early in the STS program that, for single-engine-out operation, this underspeed limit is 500 fps, driven by flight software I- and K-loads which determine when the SSME's are commanded to minimum power level. Nominal flight design will protect this constraint in the two-engine press boundaries and associated OMS dump design.

However, if a failure scenario arises in which the 500 fps limit will be exceeded, yet it is still possible to meet the other uphill capability constraints (generally, this requires multiple failures), then manual throttling to minimum power level may be used to assure that NPSP limits are satisfied. This, in turn, avoids a TAL or RTLS abort and may even provide a minimum mission capability. Flights where this technique is available typically involve either high MECO velocity targets or high OMS loads, or both.

Rules {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A2-2}, ABORT LANDING SITE REQUIREMENTS; {A2-52B}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES; and {A4-56}, PERFORMANCE BOUNDARIES, reference this rule. ©[121593-1590] ©[ED]

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES

A. PERFORMANCE NOMINAL/LOW

NOMINAL PERFORMANCE IS DEFINED AS HAVING AN ARD PREDICTED NOMINAL DELTA VELOCITY MARGIN WHICH ENSURES A GUIDED MECO (NO LOW LEVEL CUTOFF) WITH A 3-SIGMA LEVEL OF CONFIDENCE. LOW PERFORMANCE INDICATES LESS THAN A 3-SIGMA GUIDED MECO PROBABILITY.

This assessment is performed in order to determine whether an SSME with a locked throttle (hydraulic or electric) must be manually shut down prior to MECO in order to avoid potential violation of NPSP requirements. If the ARD predicts an underspeed for the current nominal mission mode, then a guided MECO is not assured, and a low-level cutoff is possible. Since the software low-level cutoff timers assume all engines are at the cutoff power level, an engine stuck at a higher level will consume more propellant than the timers protect and may deplete before safe shutdown is achieved. Therefore, if performance is low per this rule, the stuck engine will be manually shut down early, well prior to any depletion possibility. The remaining engines can then be shut down safely from the two-engine cutoff power level. The performance assessment is protected at the 3-sigma level (vs. 2-sigma for most performance boundaries) due to the potentially catastrophic nature of a depletion cutoff.

B. TWO-ENGINE (PRIME TAL) (I.E., TWO-ENGINE BEN GUERIR)

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE DESIRED PRIME TAL RANGE-VELOCITY TARGETS WITHIN CROSSRANGE LIMITATIONS AT MECO. ASSUMPTIONS: SINGLE ENGINE OUT, PROTECTION OF 2-SIGMA MPS FPR, PROTECTION OF 3-SIGMA ENTRY DISPERSIONS, ABORT THROTTLES, AND 15-SECOND ABORT DECISION DELAY.

The first TAL boundary protects 2-sigma FPR as a trade between assurance of a guided MECO and increased exposure to RTLS, which is lower in abort priority. The likelihood of an underspeed is only increased a small amount in backing from 3-sigma to 2-sigma, and the 3-sigma entry protection maintained implicitly in the R-V line can easily accommodate the additional underspeed should a 3-sigma low ascent day actually occur.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-56****PERFORMANCE BOUNDARIES (CONTINUED)****C. RTLS BOUNDARIES:****1. NEGATIVE RETURN**

THIS BOUNDARY REPRESENTS THE LAST OPPORTUNITY TO ABORT RTLS AND STILL ACHIEVE THE DESIRED MECO RANGE-VELOCITY TARGETS. ASSUMPTIONS: SINGLE ENGINE OUT, PROTECTION OF 3-SIGMA MPS FPR, PROTECTION OF 3-SIGMA ENTRY DISPERSIONS, ABORT THROTTLES, AND 15-SECOND ABORT DECISION DELAY.

The negative return boundary protects 3-sigma MPS FPR in order to ensure that an underspeed is not incurred during an RTLS abort. An underspeed during RTLS can adversely affect the ET separation conditions so severely that this protection is warranted. The single-engine-out, 3-sigma entry dispersions, abort throttles, and 15-second decision delay are self-explanatory and are consistent with other abort mode boundary calls.

2. IF AN ENGINE FAILS PRIOR TO THE TWO-ENGINE TAL CALL, AN RTLS ABORT WILL BE SELECTED AT THE LATER OF THE FOLLOWING:

a. 2:30 MET.

b. ASAP AFTER THE MCC HAS CONFIRMED THAT TWO-ENGINE TAL CAPABILITY DOES NOT EXIST (IF THE ENGINE FAILED CLOSE TO THE PERMISSION TWO-ENGINE TAL TIME) BUT NOT LATER THAN 3:40 MET.

Onboard software will not initiate RTLS aborts prior to the SRB separation command at approximately 2:05 MET. Initiation of RTLS aborts prior to 2:30 MET causes guidance to fly at a flight control limit until alpha and beta constraints for ET heating control are released at that time. Because of these limits, the only apparent changes seen by the crew are the CRT display titles, which change from ASCENT to RTLS. Delaying selection until 2:30 MET gives the ground time to confirm the engine-out, allows time for transients due to separation to damp out and for second stage guidance to stabilize, and allows sufficient time for completion of the RTLS fuel dissipation phase. If RTLS is clearly the only abort mode available, selection at 2:30 MET (or the engine-out time, if after 2:30 MET) also maximizes RTLS performance capability by lofting the vehicle as soon as possible following the engine failure.

Some missions are designed such that two-engine TAL capability is reached in first stage or very early in second stage (before 2:30 MET). In these cases, it is desirable to wait until after a good second-stage ARD solution can be obtained to evaluate two-engine TAL capability before committing to an RTLS, because ARD margins in first stage may not be indicative of true performance capability due to the open-loop nature of first stage guidance. 3:40 MET was chosen since it is at this time that RTLS aborts are initiated following an engine-out after the two-engine TAL call (ref. paragraph C.3 above). In most cases, however, the ARD should be computing a good solution by 2:30 MET.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-56****PERFORMANCE BOUNDARIES (CONTINUED)**

3. FOR RTLS ABORTS AFTER THE TWO-ENGINE TAL CALL, RTLS SELECTION WILL OCCUR AT 3:40 MET.

For any RTLS abort (three-engine or two-engine) after the two-engine TAL call, the RTLS abort will be delayed allowing for any systems problems that may dictate TAL over RTLS. The RTLS selection should be made at least 10 seconds prior to negative return in order to preserve the two-engine RTLS capability as well as keep the TAL option as long as possible. As most all shuttle flights have negative return occurring from approximately 3:50 to 4:05 MET, the 3:40 MET RTLS abort initiation will preserve the two-engine case and provide a standard time for late RTLS selection.

Note: During the RTLS/TAL overlap region, the RTLS abort will be performed for systems failures requiring quick return to ground. The TAL abort will be initiated for performance cases.

4. RTLS AND TAL CAPABILITY.

FOR A FAILURE REQUIRING AN ABORT IN THE REGION WHERE RTLS AND TAL CAPABILITY OVERLAP, THE TAL PREFERENCE OVER RTLS MAY BE REVERSED FOR SPECIFIC SYSTEM FAILURES (REF. RULE {A2-54}), RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]).

There is normally an overlap between first two-engine TAL and last RTLS capabilities. Preference of one abort over the other is dictated by Rule {A2-52}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, which is written from a performance standpoint. However, certain failures in orbiter systems may make one mode preferable over the other due to considerations beyond simple performance capability. In these cases, if there is a conflict between the preferred systems abort and the abort priorities rule, the systems abort may be selected since the ability to support the performance abort from a systems standpoint may not exist.

5. SINGLE ENGINE PRESS (RTLS).

THIS BOUNDARY REPRESENTS THE EARLIEST TIME THAT SINGLE ENGINE COMPLETION OF AN RTLS ABORT CAN BE FLOWN VIA AUTO CONTINGENCY ABORT SOFTWARE. THIS BOUNDARY OCCURS WHEN THE VEHICLE H-DOT OF +100 FPS IS REACHED, ASSUMING AN UPRANGE VELOCITY.

The 100-fps positive H-dot is an empirically derived value which protects the orbiter's capability to maintain a positive flight path angle, following a second engine out, such that powered pitchdown and ET separation can be accomplished before dynamic pressure builds up to a point that recontact with the ET would occur after separation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-56****PERFORMANCE BOUNDARIES (CONTINUED)**

D. PRESS-TO-ATO.

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE DESIGN UNDERSPEED (REF. RULE {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS) AT MECO. ASSUMPTIONS: SINGLE ENGINE OUT, PROTECTION OF 2-SIGMA MPS FPR, ABORT THROTTLES, PRE-MECO ATO SELECTION (MAY INVOKE A PRE-MECO OMS DUMP, ABORT MECO TARGETS, AND/OR VARIABLE IY STEERING), AND 15-SECOND ABORT DECISION DELAY.

The design underspeed is used as the criteria that must be met for single engine out cases to "press" uphill. This underspeed protects critical land masses from ET impact per NASA and ESMC agreements. Reference Rule {A2-62}, ET FOOTPRINT CRITERIA, for ET impact constraints.

The MPS FPR assumed is 2 sigma. For most flights, the design underspeed is based on the largest underspeed that can support either AOA steep or ATO/Min Hp with a FD 1 shallow deorbit. Protecting only 1-sigma FPR would not be conservative enough because it would significantly increase the probability of getting an underspeed larger than the design underspeed. ©[121593-1590] ©[012402-5112B]

If the MECO underspeed is larger than the design underspeed, an AOA shallow may be required. As of March 1990, AOA shallow was still not a certified abort mode. Protecting 3-sigma FPR would be too conservative and would significantly delay picking up "press" capability with only a slight statistical improvement in the likelihood of meeting the design underspeed.

The press-to-ATO boundary is assessed only when flight design has baselined a pre-MECO ATO OMS dump. The I-loads must be in the flight software to allow the ATO dump to occur. The addition of an ATO dump allows earlier "press" capability. Therefore, most flights now have an ATO dump baselined. ©[121593-1590] ©[012402-5112B]

E. PRESS-TO-MECO.

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE DESIGN UNDERSPEED, (REF. RULE {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS) AT MECO. ASSUMPTIONS: SINGLE ENGINE OUT, PROTECTION OF 2-SIGMA MPS FPR, ABORT THROTTLES.

Reference the rationale for paragraph D for an explanation of why the design underspeed is used and why 2-sigma MPS FPR is protected. The difference between these two boundaries in most cases is the ATO OMS dump.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

F. SINGLE ENGINE TAL BOUNDARIES

NOTE: IN ALL THE TAL ABORT BOUNDARY DEFINITIONS, AN ELS MAY BE REPLACED BY AN ACLS OR PRIME TAL SITE AND AN ACLS MAY BE REPLACED BY A PRIME TAL SITE.

1. IF NO PRIOR TAL ABORT DECLARED OR TAL SELECTED TO AN IN-PLANE SITE:

- a. DROOP (PRIME TAL OR ACLS - 109):

THE DROOP BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH A TWO-SSME-OUT TRAJECTORY WILL NOT FALL BELOW 265,000 FEET AND TAL GUIDANCE WILL CONVERGE TO THE SELECTED/REDESIGNATED SITE'S MECO TARGETS PRIOR TO THE DESIRED MECO TIME. THIS BOUNDARY ASSUMES TWO SSME'S OUT, MAX THROTTLE, AND 15-SECOND ABORT DECISION DELAY. THE WEATHER AT THE SITE WILL NOT BE A CONSIDERATION WHEN ASSESSING THIS BOUNDARY.

This boundary is the earliest time that TAL guidance can be used on a two-engine-out trajectory. It ensures that the minimum droop altitude will not be violated. Analysis has shown that trajectories that droop below 265,000 feet could result in ET rupture due to aerodynamic heating. If, upon TAL droop declaration, guidance is unconverged, the crew's procedures call for flying manually until guidance does converge. (The likelihood of unconverged guidance in this region was significantly reduced by incorporation of the OI-21 low-thrust-to-weight guidance CR.) This boundary does not ensure the capability to reach a runway. Therefore, the weather at the targeted site is not considered when evaluating this boundary.

- b. SINGLE ENGINE LIMITS:

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH THE DESIRED ACLS OR TAL SITE CAN BE ACHIEVED. ASSUMPTIONS: MAX THROTTLE, A 15-SECOND ABORT DECISION DELAY, MAX RANGING USING LOW ENERGY GUIDANCE (REFERENCE RULE {A2-55}, USE OF LOW ENERGY GUIDANCE) AND 2-SIGMA ASCENT PERFORMANCE, AND UNDISPERSED ENTRY PERFORMANCE. THIS BOUNDARY IS CONTINGENT UPON THE WEATHER/NAVAID STATUS AT THE SITE AS PER RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. @[120894-1663]

Self-explanatory.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

- c. SINGLE ENGINE (PRIME TAL OR ACLS - 104) (e.g., SINGLE BANJUL - 104):

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE DESIRED SITE RANGE-VELOCITY TARGETS WITHIN CROSSRANGE LIMITATIONS AT MECO. (THE DESIRED SITE IS THE ONE THAT PROVIDES THE EARLIEST SINGLE-ENGINE CAPABILITY.) ASSUMPTIONS: PROTECTION OF 2-SIGMA MPS FPR, PROTECTION OF AT LEAST ZERO-SIGMA ENTRY DISPERSIONS, ABORT THROTTLE, AND A 15-SECOND ABORT DECISION DELAY. THE WEATHER AT THE SITE WILL NOT BE A CONSIDERATION WHEN ASSESSING THIS BOUNDARY.

Self-explanatory. These cases, by definition, reach the range-velocity (R-V) target line, however they do so at a lower velocity than the design point. For this reason, entry dispersions are not explicitly protected, although for any given mission the protection level for these constraints (first roll reversal velocity, constant drag phase length, and equilibrium glide boundary margin) may vary from less than 1-sigma to more than 3-sigma (reference 5/18/94 Abort Panel Splinter Meeting). ©[120894-1741]

- d. NEGATIVE (PRIME TAL) (e.g., NEGATIVE BEN GUERIR):

THIS BOUNDARY REPRESENTS THE LAST OPPORTUNITY TO ABORT TO THE PRIME TAL SITE AND STILL ACHIEVE THE DESIRED MECO RANGE-VELOCITY TARGETS WITHIN CROSSRANGE LIMITATIONS. ASSUMPTIONS: TWO SSME'S AT ABORT THROTTLE, PROTECTION OF 2-SIGMA MPS FPR, PROTECTION OF 3-SIGMA ENTRY DISPERSIONS, AND A 15-SECOND ABORT DECISION/TAL RESELECTION DELAY.

Self-explanatory.

2. IF TAL ABORT PREVIOUSLY DECLARED TO AN OUT-OF-PLANE SITE:

- a. DROOP (PRIME TAL OR ACLS - 109) (e.g., DROOP BANJUL - 109):

THIS BOUNDARY IS THE SAME AS IN PARAGRAPH F.1 ABOVE.

- b. SINGLE ENGINE LIMITS:

THIS BOUNDARY IS THE SAME AS IN PARAGRAPH F.1 ABOVE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

- c. SINGLE ENGINE (PRIME TAL OR ACLS - 104) (E.G., SINGLE ENGINE BANJUL - 104):

THIS BOUNDARY IS THE SAME AS IN PARAGRAPH F.1 ABOVE.

- d. NEGATIVE (ACLS) (E.G., NEGATIVE BANJUL):

THIS BOUNDARY REPRESENTS THE LAST OPPORTUNITY TO ABORT TO THE ACLS AND STILL ACHIEVE THE ACLS WITHIN CROSSRANGE LIMITATIONS USING LOW-ENERGY GUIDANCE. ASSUMPTIONS: PROTECTION OF 0-SIGMA MPS FPR, PROTECTION OF 0-SIGMA ENTRY DISPERSIONS, MAX THROTTLE, AND A 15-SECOND RESELECTION/ DECISION DELAY. @[120894-1663]

This boundary assumes 0 sigma for both MPS FPR and entry dispersions in order to allow the latest capability to redesignate to make it to an ACLS. Not doing this would possibly create a second engine out gap. This boundary will not be assessed if the SINGLE ENGINE TAL - 109 boundary has been reached.

- e. SINGLE ENGINE (PRIME TAL - 109) (E.G., SINGLE ENGINE BEN GUERIR - 109):

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE RANGE-VELOCITY TARGETS AT MECO FOR THE PRIME SITE. ASSUMPTIONS: PROTECTS 2-SIGMA MPS FPR, PROTECTS AT LEAST ZERO-SIGMA ENTRY DISPERSIONS, AND MAX THROTTLE. @[120894-1741]

This boundary is different from the single engine TAL boundaries for the in-plane cases because it assumes max throttles versus nominal throttles. Using max throttles allows the earliest opportunity to continue to the prime TAL site and not have to risk possible control problems caused by a large yaw maneuver required to head to the ACLS. Reference Flight Rule {A2-52C}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, for more details on using max throttles for this case. If this boundary has not been reached yet and the NEGATIVE ACLS boundary has been crossed, this call will be made on 0 sigma MPS to close the gap. These cases, by definition, reach the range-velocity (R-V) target line; however, they do so at a lower velocity than the design point. For this reason, entry dispersions are not explicitly protected, although for any given mission, the protection level for these constraints (first roll reversal velocity, constant drag phase length, and equilibrium glide boundary margin) may vary from less than 1-sigma to more than 3-sigma (reference 5/18/94 Abort Panel splinter meeting). @[120894-1741]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

3. LAST AUTO TAL:

THIS BOUNDARY REPRESENTS THE LAST OPPORTUNITY TO ABORT TO AN ACLS/PRIME TAL SITE, REMAIN IN AUTO, AND STILL ACHIEVE THE DESIRED MECO RANGE-VELOCITY TAL TARGETS (WITHIN CROSSRANGE LIMITATIONS IF APPLICABLE). ASSUMPTIONS: ONE SSME AT ABORT THROTTLE; TWO OR THREE SSME'S AT 65 PERCENT THROTTLE, PROTECTION OF 3-SIGMA ENTRY DISPERSIONS, 15 SECOND ABORT DECISION DELAY, AND PROTECTION OF THE CONTINGENCY CG BOX.

4. LAST LATE TAL:

THIS BOUNDARY REPRESENTS THE LAST OPPORTUNITY TO MANUALLY MECO AT A VELOCITY WHICH WILL ALLOW FOR AN ENTRY TO AN ELS/ACLS. ASSUMPTIONS: MANUAL MECO, PROTECTION OF THE CONTINGENCY CG BOX, AND POST-MECO ROLL TO HEADS-UP.

G. SINGLE ENGINE OPS 3: @[120894-1743A]

THIS BOUNDARY REPRESENTS THE EARLIEST TIME THAT THE CREW WILL PERFORM THE 2 ENGINE OUT DROOP PROCEDURE FOLLOWING A SECOND SSME FAILURE.

1. IF LAST ECAL/BDA CAPABILITY OCCURS AFTER THE DROOP BOUNDARY (REF. PARAGRAPH F.1.a), THE SINGLE ENGINE OPS 3 BOUNDARY WILL BE BASED ON THE EARLIEST OF THE FOLLOWING:

- a. LAST ECAL/BDA CAPABILITY (WITHOUT REGARD TO WEATHER)
- b. THE SINGLE ENGINE LIMITS BOUNDARY (REF. PARAGRAPH F.1.b)
- c. FIRST DOWNRANGE ELS LOW ENERGY CAPABILITY. THIS ELS CAPABILITY ASSUMES THE FOLLOWING:
 - (1) MAXIMUM THROTTLES,
 - (2) 2 SIGMA LOW MPS PERFORMANCE,
 - (3) USE OF AUTO LOW ENERGY GUIDANCE FOR ENTRY (REF. RULE {A2-55} FOR LOW ENERGY GUIDANCE),

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

- (4) THE ELS MEETS MINIMUM EMERGENCY LANDING FACILITY CRITERIA (REF. RULE {A2-264}, EMERGENCY LANDING FACILITY CRITERIA. @[120894-1743A]
2. IF LAST ECAL/BDA CAPABILITY OCCURS BEFORE THE DROOP BOUNDARY, THE SINGLE ENGINE OPS 3 BOUNDARY WILL BE BASED ON DROOP. @[120894-1743A]

This boundary allows the use of ECAL capability past the point where droop capability begins, and reflects the priority of ECAL over droop/bailout as set by the A/E FTP in July 1994. This delays the point where the two engine out second stage procedure ends. This option allows the crew to use the ECAL procedures and attempt a landing versus doing the two engine out droop procedure which results in a bailout. This option on a high inclination mission is much preferred over bailout in the North Atlantic Ocean. Another consideration in this boundary is the first ELS capability with "stretch" (use of low energy guidance). However, if the ELS weather does not meet the minimum weather criteria for an ELS, it is unusable as an ELS and the ELS capability will not be considered in the determination of the boundary. A landing at an ELS is considered preferable over landing at ECAL/BDA because of the automated entry procedures and the slightly more benign entry conditions. The Single Engine Limits boundary is the first capability to a TAL or ACLS using "stretch" (use of low energy guidance). This has a higher priority over an ECAL.

If ECAL/BDA capability ends prior to droop then this call will be based on droop capability.
@[120894-1743A]

H. SINGLE ENGINE PRESS-TO-MECO: @[120894-1743A]

THIS BOUNDARY REPRESENTS THE EARLIEST TIME AFTER WHICH AUTO GUIDANCE WILL ACHIEVE THE CRITICAL UNDERSPEED (REF. RULE {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS) AT MECO. ASSUMPTIONS: TWO ENGINES OUT, PROTECTION OF 2-SIGMA MPS FPR, AND ABORT THROTTLE.

The single-engine press-to-MECO (SEPTM) boundary is based on critical, rather than design, underspeed since ET impact constraints protected in the design underspeed do not apply to multiple-engine-out scenarios (ref. Rule {A2-62E}, ET FOOTPRINT CRITERIA). Abort throttles are assumed since Rule {A2-52C}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES, implies that we will not use max throttle to avoid a TAL downmode as long as auto TAL is available, and normally SEPTM occurs well prior to the last TAL. 2-sigma FPR is protected per the rationale for the other uphill boundaries.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

I. PERFORMANCE DISPERSIONS/GAPS: @[120894-1743A]

1. UPHILL CAPABILITY CONSISTS OF HAVING AN ARD-PREDICTED UNDERSPEED WHICH IS LESS THAN EITHER THE DESIGN OR CRITICAL UNDERSPEED, WHICHEVER APPLIES TO THE GIVEN CASE AS PROVIDED BY RULE {A2-62E}, ET FOOTPRINT CRITERIA. ASSESSMENT ASSUMES ABORT THROTTLES, PROTECTION OF 2-SIGMA MPS FPR, AND MAY INCLUDE A PRE-MECO ATO ABORT IF APPLICABLE.

Uphill capability as defined will guarantee AOA steep or ATO day 1 or day 2 shallow D/O capability as well as the other items listed in Rule {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS, and will keep the ET from impacting on critical land masses as defined in Rule {A2-62D}, ET FOOTPRINT CRITERIA. An RTLS or TAL abort will be required if the ARD predicted underspeed is greater than that which protects critical land masses or the critical underspeed, whichever is most constraining. As in the press boundaries (ref. paragraphs D, E, and G), protection of 2-sigma MPS FPR is required in order to account for possible ascent performance dispersions. @[121593-1590]

2. TAL/RTLS GAP MANAGEMENT FOR LOSS OF UPHILL CAPABILITY WITH THREE ENGINES OPERATING:
 - a. IF AN ENGINE IS STUCK IN THE THROTTLE BUCKET OR IF MORE THAN ONE ENGINE IS SUSPECT, A TAL ABORT TO THE PRIME SITE WILL BE INITIATED UPON REACHING THE EARLIER OF THE FOLLOWING:
 - (1) TWO-ENGINE PRIME TAL CAPABILITY (TWO AT 104 PERCENT) PLUS EITHER OF THE FOLLOWING:
 - (a) TWO-ENGINE ACLS TAL CAPABILITY, EVALUATED FOR A GOOD ENGINE OUT (ASSUMPTIONS: 2-SIGMA MPS FPR, MAX THROTTLES, MAX RANGING USING LOW ENERGY GUIDANCE. @[120894-1663])
 - (b) TWO-ENGINE NEGATIVE RETURN, EVALUATED FOR A GOOD ENGINE OUT (ASSUMPTIONS: 3-SIGMA MPS FPR, MAX THROTTLES, MAX UNDERSPEED TO THE R/V LINE)

OR

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-56****PERFORMANCE BOUNDARIES (CONTINUED)**

(2) NEGATIVE RETURN MINUS 10 SECONDS (TWO AT 104 PERCENT)

NOTE: EVALUATION OF THE CAPABILITY TO THE ACLS WILL BE INDEPENDENT OF THE ACLS GO/NO-GO STATUS.

A TAL or RTLS abort will be required for loss of uphill capability. In the TAL/RTLS overlap region either of the two abort modes may be utilized. If more than one engine is suspect, there is considerable risk of multiple engine failures. Therefore, TAL is the preferred abort mode because of reduced powered flight time and earlier single engine completion capability.

For cases with an engine stuck in the throttle bucket, an RTLS is undesirable for several reasons. With three engines operating, the RTLS fuel dissipation attitude is not readjusted for subsequent engine failures, and the resulting altitude versus range profile and time of powered pitcharound may be incorrect, with the most significant contributor being the impact on the altitude profile during fuel dissipation phase. Therefore, the failure of a healthy engine during the RTLS fuel dissipation phase may result in a MECO underspeed. For the failure of a healthy engine after powered pitcharound, sufficient performance may not be available on the remaining 1-2/3 engines, again resulting in a MECO underspeed. For example, analysis showed that late in the STS-26 RTLS profile (at approximately 9 minutes MET) there existed only a 10- to 20-second window where a single engine failure would result in acceptable MECO conditions.

For these reasons, a TAL abort will be performed. RTLS capability will be maintained as long as operationally practical, without affecting subsequent TAL performance, by delaying TAL selection until both 1-2/3 engine ACLS TAL capability and 2 good engine prime TAL capability are available.

The ACLS evaluation will be made assuming maximum throttles and low-energy guidance in order to allow TAL selection, and therefore avoid an RTLS, at the earliest possible time while still protecting for any one engine failure. The low-energy guidance capability correlates directly to a specific underspeed for each TAL site and inclination. Two-sigma MPS performance will be protected to provide a level of confidence that an acceptable underspeed will result. @[120894-1663]

If 1-2/3 engine negative return occurs prior to 1-2/3 engine ACLS TAL capability, the TAL abort call will be based on that time since a contingency abort is then the only option should a good engine fail. This evaluation is made using maximum throttles and the maximum allowable underspeed to the R/V line in order to extend 1-2/3 engine RTLS capability as long as possible prior to entering the single-engine-out abort gap. This underspeed, 300 fps, correlates to the minimum time constraint of 12 seconds from powered pitchdown to MECO, ensuring acceptable ET SEP conditions. Three-sigma MPS FPR is protected to provide confidence that this underspeed will not be exceeded, since the data used to determine this boundary is produced during the design cycle and does not account for day-of-launch conditions. The consequences of violating RTLS ET SEP constraints can be catastrophic.

When an abort gap exists between negative return and two-engine prime TAL capability, the TAL abort is still preferred and the gap will be accepted since the RTLS would result in an abort gap a few seconds after initiation, as explained above.

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

This rule is only applicable during powered flight; therefore, the GO/NO-GO status of the ACLS is not a factor since pre-MECO selection of this site serves only to minimize exposure to a pre-MECO contingency abort (similar to the droop criteria). The actual landing site will be selected post-MECO.

- b. FOR ALL OTHER CASES, IF A TAL/RTLS ABORT GAP EXISTS (TWO-SSME CAPABILITY) AT NEGATIVE RETURN MINUS 10 SECONDS, AN RTLS ABORT WILL BE EXECUTED AT THAT TIME. OTHERWISE, A TAL ABORT WILL BE INITIATED AT TWO-ENGINE TAL CAPABILITY.

An RTLS abort will be required for single engine failures which occur prior to two-engine TAL capability as the performance loss will not support any other intact abort mode. With the loss of uphill capability, an RTLS or TAL abort will have to be performed. If two-engine prime TAL capability is not achieved prior to negative return, an RTLS abort is executed in order to avoid flying a single-engine-out intact abort gap. Without stuck throttles or suspect engines, the RTLS profile is flown without the problems outlined in paragraphs H.2a. A post-RTLS abort engine failure will be handled by guidance successfully with no single-engine-out intact abort gaps. The abort decision is made 10 seconds prior to negative return in order to provide time for the TAL capability evaluation to be made. With two-engine TAL capability, the TAL abort will be executed at the two-engine TAL boundary. In this case, the systems RTLS capability is traded away in order to provide earliest two-engine-out capability.

Reference Ascent FTP # 42, March 1988.

3. GAP MANAGEMENT FOR POSITIVE UPHILL CAPABILITY:

NOTE: IF APPLICATION OF THE FOLLOWING MEASURES FAILS TO CLOSE THE GAP, IT WILL STILL BE FLOWN THROUGH PROVIDED UPHILL CAPABILITY REMAINS ON THE CURRENT ENGINE CONFIGURATION. SHOULD AN ENGINE(S) SUBSEQUENTLY FAIL IN THE GAP, A CONTINGENCY PROCEDURE WILL BE REQUIRED SUCH AS ACCEPTING PLS LANDING AT A NO-GO SITE, AN AUTO TAL TO ANY AVAILABLE SITE EVEN IF THE SITE HAS BEEN DECLARED NO-GO FOR INTACT ABORT PURPOSES, ACCEPTING TAL/LATE TAL TO AN ELS, ATTEMPTING AN ABORT TO AN EAST COAST SITE OR BERMUDA ISLAND, OR BAILOUT.

- [3] FOR THE TWO-ENGINE-OUT CASE, CRITICAL UNDERSPEED IS ALREADY COMMITTED IN THE SINGLE-ENGINE PRESS BOUNDARY PER PARAGRAPH {A4-56H}, PERFORMANCE BOUNDARIES, AND, HENCE, DOES NOT CONTRIBUTE TO SINGLE-ENGINE GAP CLOSURE PRIORITIES. @[ED]

Gap closure priorities are established to balance exposure to contingency abort against acceptance of flight conditions which otherwise are undesirable for a variety of individual reasons. Gaps in intact abort capability may arise during powered flight due to a number of possible systems or environmental problems including stuck throttles, degraded SSME performance (i.e., Pc sensor shift), low-performing SRB's, unacceptable TAL weather, etc. In such cases, options which increase available delta V are brought into play in order to either close or minimize the gap. These options include both pre-MECO and post-MECO commitments. In general, the post-MECO options and pre-MECO "theoretical" options (those whose effects cannot be directly measured pre-MECO but are related to assumed capabilities) are preserved as long as some other directly-measurable option exists such as use of maximum throttles, commitment of OMS ballast, or acceptance of larger MECO underspeed; otherwise,

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-56****PERFORMANCE BOUNDARIES (CONTINUED)**

we would be relying on capabilities that are not certain to exist until the true MECO state is determined. This general rule is traded against factors such as weather, program-approved abort site usage, and risk to vehicle and crew in order to establish the precise priorities for the individual gap closure scenarios. Specifically,

- a. Auto TAL to the ACLS (if available per rules and performance) may be utilized to close any intact abort gap before committing to maximum throttles (per Program Office agreement that we will not use maximum throttles to avoid the ACLS). Otherwise, if the ACLS is down, it reverts to ELS status and becomes the lowest-priority option.*
- b. ET footprint encroachment on critical land masses will be accepted before any other direct gap closure action is taken (such as use of max throttles or commitment of OMS ballast); however, if a TAL option exists to a Space Shuttle Program-recognized TAL site, TAL will be accepted before allowing the ET footprint to impact critical areas. The additional stress placed on the SSME's by operation at maximum throttle is considered more hazardous than the concerns associated with possible ET impact on critical land masses.*

Note that waiving ET constraints is a no-impact decision in terms of risk to the shuttle vehicle itself; therefore, when applicable, this is the first option used.

- c. OMS ballast may be committed after ET impact limits are waived but prior to use of maximum throttle. Use of OMS ballast can result in a vehicle CG outside the nominal envelope limits to which operation is certified, but keeps it within the contingency envelope which preserves adequate thermal and control margins. Thus, this mode is considered safer than maximum throttle operation. It is, however, an action that directly affects the shuttle itself (albeit a relatively benign effect); therefore, it is prioritized after waiver of ET impact constraints.*
- d. Accept press to a less than fully GO AOA or PLS site. ©[121593-1590]*
- e. Maximum throttle is the last pre-MECO directly-measurable option in terms of recovery of programmatic "intact abort" capability. Since other options involve post-MECO commitments, revert to contingency (non-intact abort) operations and/or trade off probability of success. Use of maximum throttle is allowed at this point to minimize exposure to these other regimes. This is consistent with the groundrule that maximum throttles will only be utilized to regain intact capability or to avoid a post-TAL-selection site redesignation.*
- f. Since the remaining options all involve only post-MECO commitments (with the exception of Late TAL execution), their priority regarding pre-MECO gap closure is fairly meaningless - in reality, no commitment of any kind is made until the true MECO condition is evaluated. Therefore, operationally, the total delta-V effect of the remaining priorities will be committed all at once if it becomes necessary to further close a gap. However, to determine the total gap closure delta V available, the individual items considered are as follows, in the order in which we would prefer to have to utilize them:*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-56

PERFORMANCE BOUNDARIES (CONTINUED)

- (1) *Late TAL capability to either a prime TAL site or ACLS will be utilized to close a gap between last Auto TAL and earliest steep AOA; i.e., prior to commitment to AOA-Shallow. Therefore, if AOA-Shallow and Late TAL capabilities overlap, the “press” boundary will be based on reaching the end of the Late TAL window. The Late TAL will not, of course, be actually executed unless the assumed performance loss occurs.*
- (2) *When applicable, allowable MECO underspeed will be increased to the AOA-Shallow limit. AOA-Shallow is highly undesirable due to the more severe entry thermal environment and the sensitivity to navigation dispersions (target line is close to skipout boundary and ranging becomes highly sensitive to flight path angle). While it nominally results in recovery of vehicle and crew, AOA-Shallow is not considered a certified intact abort from a programmatic point of view.*
- (3) *Low energy guidance extends TAL capability to MECO underspeed conditions off the R-V line. AOA-Shallow is considered higher priority than low energy guidance because AOA-Shallow has been subjected to much more thorough engineering analysis, is less stressful thermally, provides for help from the MCC in dealing with entry navigation dispersions, and the AOA-Shallow boundary is more clearly defined. ©[120894-1663]*
- (4) *All MPS performance reserves will be assumed available for delta-V purposes (“nominal performance”). To this point, performance boundaries have been predicated on protection of 2-sigma reserves, thus providing a high confidence that we do not commit to a mode which statistically probable systems and performance dispersions will not allow to be successfully completed. Committing to boundaries on nominal performance assures only a 50 percent chance of being correct; thus it forms the lowest-priority option.*

NAVIGATION UPDATES

A. ASCENT PRE-MECO

WHEN AN INDEPENDENT NAVIGATION SOURCE IS AVAILABLE, A NAVIGATION UPDATE WILL BE EXECUTED TO ALLOW ITS INCORPORATION PRIOR TO MECO MINUS 30 SECONDS TO PRESERVE MECO CONDITIONS NECESSARY FOR A NOMINAL FLIGHT. DELTA STATE UPDATES WILL BE INITIATED FOR THE FOLLOWING GROUND MINUS ONBOARD VELOCITY DIFFERENCES: @[121296-4177D]

- | | |
|--------------------------|---|
| 1. DELTA U DOT > 50 FPS | 3. DELTA V DOT > 40 FPS |
| 2. DELTA U DOT < -50 FPS | 4. DELTA V DOT < -NOMINAL
(REF. THE ANNEX FLIGHT
RULE, TRAJECTORY AND
GUIDANCE PARAMETERS) |

@[ED]

To the extent possible, it is desirable to maintain the onboard navigated state to provide MECO conditions acceptable for nominal flight execution. However, it is undesirable to update the onboard navigation with a reasonable probability of degrading the onboard state. The onboard powered flight navigation evaluation is performed by the delta state processor which determines the ground filter minus onboard state differences. Preflight analysis has established a 3-sigma uncertainty in the delta state velocity differences of 30 fps per axis. Estimated onboard velocity error at MECO resulting from a 3-sigma IMU performance is 20 fps worst axis. Definition of update limits equal to the sum of the 3-sigma delta state and IMU uncertainties provides reasonable assurance that an update will improve the onboard state. Because of the OMS budget limitation, nominal flight execution is most sensitive to downtrack velocity errors (i.e., underspeed MECO). To reduce the probability of ascent downmoding, the downtrack velocity update limit is defined by the RSS of the 3-sigma delta state and IMU uncertainties. For ascent performance critical missions, the downtrack velocity update limit is defined by the underspeed magnitude at MECO which would allow continuation of a nominal orbit insertion. Nominal flight execution is relatively insensitive to crosstrack errors, requiring no update limit. Thus, a delta state update will be initiated for apparent radial velocity errors exceeding ± 50 fps or downtrack velocity errors exceeding +40 fps or -X fps where X represents the allowable underspeed magnitude for nominal insertion with a maximum value of -40 fps. The update will be incorporated at least 30 seconds prior to MECO to allow the second stage guidance to adjust the steering solution to regain the desired target conditions.

Rule {A2-60}, NAVIGATION UPDATE CRITERIA, references this rule.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-57

NAVIGATION UPDATES (CONTINUED)

B. ASCENT POST-MECO AND PRE-OMS-1

WHEN AN INDEPENDENT NAVIGATION SOURCE IS AVAILABLE, A PRE-OMS-1 NAVIGATION UPDATE WILL BE PERFORMED IF THE GROUND EVALUATION OF THE MANEUVER DELTA V REQUIRED TO ACHIEVE THE SELECTED ASCENT MODE UTILIZING CURRENT ONBOARD NAVIGATION EXCEEDS DELTA V AVAILABLE. @[121296-4177D]

In the AME evaluation of the desired ascent mode for OMS-1, the initial cycle assumes OMS-1 and -2 execution utilizing the current onboard navigated state. If the delta velocity requirement exceeds that available, then the AME automatically recycles to determine the delta velocity requirement assuming the OMS-1 and -2 execution utilizing the ground filter state. If the required delta velocity on the recycle is less than that available, then a pre-OMS-1 update is performed to prevent ascent downmoding.

C. PRTL5

WHEN AN INDEPENDENT NAVIGATION SOURCE IS AVAILABLE, A NAVIGATION UPDATE WILL BE EXECUTED PRIOR TO POWERED PITCHDOWN (MINUS 20 SECONDS) TO PRESERVE MECO CONDITIONS NECESSARY FOR ET SEPARATION AND GLIDE RETURN TO LAUNCH SITE. A DELTA STATE UPDATE WILL BE INITIATED FOR ANY OF THE FOLLOWING GROUND MINUS ONBOARD POSITION AND VELOCITY DIFFERENCES: @[121296-4177D]

- | | |
|---------------------------|---------------------------|
| 1. DELTA U > +11,000 FT | 5. DELTA V > +27,000 FT |
| 2. DELTA U < -7000 FT | 6. DELTA V < -7000 FT |
| 3. DELTA U DOT < +100 FPS | 7. DELTA V DOT > +100 FPS |
| 4. DELTA U DOT > -50 FPS | 8. DELTA V DOT < -40 FPS |

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-57

NAVIGATION UPDATES (CONTINUED)

The powered flight phase of an RTLS must deliver the vehicle to a state from which the glide phase can be successfully performed to return to the runway and land. Thus, during flyback phase of an RTLS, the onboard navigation must be maintained to preserve an acceptable energy condition at MECO. Analytical studies have been performed to determine the maximum position and velocity errors allowable to obtain cutoff within the 3-sigma energy boundaries of the target range/velocity line. The energy boundaries allow for wind and aero dispersions during the glide return. Deviation of the allowable navigation errors are documented in MDTSCO Transmittal Memo 1.4-TM-D1332-152, dated June 16, 1980. The resulting error envelope is defined by limits in radial and downtrack position and velocity. The position error limits are +11,000/-7,000 feet in the radial axis and +27,000/-7,000 feet in the downtrack axis. The velocity error limits are +100/-50 fps in the radial axis and +100/-40 fps in the downtrack axis. If any ground minus onboard position or velocity difference exceeds the corresponding limit, a delta state update will be executed at least 20 seconds prior to powered pitchdown to allow adjustment of the steering solution to satisfy target conditions at pitchdown initiation.

D. BFS

A BFS NAVIGATION UPDATE WILL BE PERFORMED BY VECTOR TRANSFER AFTER EACH PASS UPDATE TO ENSURE ACCEPTABLE NAVIGATION STATUS RELATIVE TO THE PASS.

During powered ascent, the PASS and BFS independently navigate the current vehicle state. Because of differences in IMU selection logic, the resultant states may not agree. Thus, if a PASS update is required, the uplinked deltas may not be appropriate for correcting the BFS state. To properly correct the BFS via uplink would require switching the telemetry input to the delta state processor, a minimum delay of 20 seconds to allow the back difference logic to determine the BFS velocity deltas, and an additional delay of 15 to 20 seconds for command generation and uplink execution. Should a BFS engage be required during this time, vehicle transients would likely occur. To avoid disruption of the PASS monitoring and reduce the exposure to potential vehicle transients, it is desirable to perform a vector transfer to the BFS after each PASS update.

E. POST-MECO PRIOR TO A COMMIT TO ORBIT:

FOR A DECLARED OR PROBABLE AOA, A NAVIGATION UPDATE WILL BE PERFORMED PRE-OMS-2 IF THE ONBOARD AND GROUND FILTER SOLUTIONS FOR SEMI-MAJOR AXIS DIFFER BY MORE THAN 12,000 FEET AT MECO PLUS 12 MINUTES AND ONE OF THE FOLLOWING IS SATISFIED: ©[072601-4528]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-57****NAVIGATION UPDATES (CONTINUED)**

1. ONBOARD ERROR INDICATED BY A CHANGE IN THE ONBOARD/GROUND FILTER SEMI-MAJOR AXIS COMPARISON BETWEEN MECO AND MECO PLUS 12 MINUTES WHICH EXCEEDS 6000 FEET.
2. HIGH SPEED TRAJECTORY SOLUTION DEVIATION FROM THE ONBOARD DURING ASCENT.

THE MCC SHALL DETERMINE THE STATE VECTOR SOURCE TO BE USED FOR THE NAVIGATION UPDATE (EITHER GROUND FILTER OR GPS) . @[072601-4528]

A navigation update will be performed prior to OMS-2 for a declared or probable AOA to protect an onboard downtrack error exceeding 20 nm at entry interface. The primary monitoring parameter is the difference in the onboard and ground knowledge of orbital semi-major axis, delta alpha. At MECO +12 minutes, a 12,000 feet delta alpha uncertainty indicates a 20 nm downtrack uncertainty will exist at entry interface. The allowable threshold should be reduced by the ground solution uncertainty to establish a delta alpha update limit. The ground solution at MECO +12 minutes is based on the resultant ascent high speed filter output plus OMS-1 maneuver confirmation. Assuming 3-sigma IMU for maneuver confirmation, the ground solution uncertainty is 9,600 feet. As a result, the update limit for delta alpha should be 2,400 feet. However, a limit value this tight would result in a 90 percent probability of performing an uplink and a 40 percent chance of degrading the onboard state. To reduce the probability of having to do an uplink, the limit value is specified as 12,000 feet.

To decrease the chance of degrading the onboard state, secondary cues will be used to confirm a delta alpha difference is due to an onboard error. Thus, for a declared or potential AOA, a navigation update will be performed before OMS-2 if the ground and onboard difference in delta alpha exceeds 12,000 feet at MECO +12 minutes and an onboard error is indicated by one of the following conditions: @[072601-4528]

- a. *The delta alpha comparison changes by more than 6,000 feet between MECO and MECO +12 minutes.*
- b. *Onboard trajectory deviation from the high speed tracking solution during powered ascent.*

GPS provides additional insight into ground and onboard navigation errors. GPS state vectors will be more accurate than the ground solution if off-nominal IMU data is used for maneuver confirmations. TDRS tracking data residuals can be utilized to confirm what is the most accurate semi-major axis source after the OMS-1 maneuver. GPS provides several navigation solutions between OMS-1 and OMS-2 as long as it is verified to be functioning properly (no hardware problems or commfaults, no extended periods of high FOM, and no extended periods of less than four satellites tracking). The GPS navigation update can be performed by a ground vector uplink or crew item entry once in OPS 3 for the AOA abort. Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. @[072601-4528]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-57

NAVIGATION UPDATES (CONTINUED)

- F. FOR RENDEZVOUS MISSIONS, A STATE VECTOR UPDATE WILL ONLY BE PERFORMED PRE-OMS-2 FOR MECO CROSSTRACK VELOCITY (WDOT) DIFFERENCES BETWEEN THE GROUND AND ONBOARD VECTORS GREATER THAN 6 FT/SEC, PROVIDED THAT THE FOLLOWING CRITERIA ARE MET:
1. DETERMINATION OF A GOOD GROUND NAVIGATION STATE VECTOR, BASED UPON A MINIMUM OF 30 SECONDS OF GOOD QUALITY POST-MECO TRACKING DATA.
 2. DETERMINATION THAT THE STATE VECTOR UPDATE WILL DECREASE THE NPC DELTA V BY 6 FT/SEC OR MORE.

For rendezvous missions, the OMS propellant budget provides for a nominal plane change (NPC) maneuver to correct out-of-plane dispersions. Out-of-plane dispersions resulting from navigation errors incurred during ascent can be partially corrected by OMS-2 steering, resulting in a savings of propellant required for the NPC maneuver. In-plane dispersions are far less costly to the propellant budget, since they can be corrected with later phasing maneuvers. In an attempt to minimize the NPC propellant requirement and thus increase the propellant margins for rendezvous, a state vector update may be performed prior to OMS-2.

Flight data has shown the post-MECO ground state vector accuracy to be within 3 ft/sec in the crosstrack velocity component, provided that no anomaly in the ground tracking or the ground navigation processing occurred after MECO. The standard deviation of the onboard state vector crosstrack error at MECO computed from flight data is about 10 ft/sec. If telemetry is available during powered flight, onboard crosstrack differences in both position and velocity can be observed during ascent. This, together with the confirmation of a good post-MECO ground state vector, provides a good assurance that the state vector update will improve the onboard state vector in the crosstrack component.

The ground navigation HSTD processor requires time to converge to a good state vector solution after the change to free flight processing mode following MECO. Sixty seconds of tracking data processing is desirable to provide an accurate state vector for onboard uplink. If the convergence time is less than 30 seconds, performing a state vector update for the purpose of removing out-of-plane dispersions should not be considered.

FDO procedures performed pre-OMS-2 include the determination of the differences in the NPC delta V between using the onboard and ground state vector. The 6 ft/sec threshold was based on the ground state vector accuracy. ©[012694-1555]

FLIGHT RULES

A4-58

AUTO GUIDANCE NO-GO

AUTO GUIDANCE WILL BE DECLARED NO-GO AND BFS ENGAGE INITIATED FOR CONDITION A, MANUAL GUIDANCE/THROTTLE WILL BE INITIATED FOR CONDITIONS IN PARAGRAPHS B THROUGH D:

Within ascent guidance, multiple tasks and subtasks are executed in a designed sequence. The execution may be based on time, sensed trajectory condition, or mission event. Some tasks have an internal check to ensure the logical solution is reasonable and within a predefined tolerance of desired target conditions. If a task or subtask fails to get executed in the design sequence, the ascent guidance function is considered unreliable. Likewise, if a task fails to satisfy an internal solution check for an unreasonable number of consecutive cycles, the guidance function is considered failed.

Rule {A2-59}, BFS ENGAGE CRITERIA, references this rule.

A. ROLL MANEUVER NOT INITIATED AS SCHEDULED.

Initially in first stage flight, the boost guidance task will command a constant pad attitude. The constant command is maintained until the relative velocity exceeds the I-load value for PPOLY2. The termination of vertical rise is indicated by a command roll maneuver to rotate the Orbiter tail downrange. Failure to initiate the roll maneuver at the corresponding relative velocity indicates incorrect subtask sequencing within the boost guidance task. For this failure, the BFS will be engaged since the onboard displays are inadequate for the crew to manually execute the roll/pitch profile through the critical high Q-bar regime.

B. GUIDANCE NOT CONVERGED FOR 10 SECONDS DURING MM 103 AND MM 601 AFTER INITIAL CONVERGENCE.

During the standard ascent mode (MM 103) and the return-to-launch site mode (MM 601), internal checks are made with the PEG task to ensure the current steering solution and resultant predicted burnout state are converged within an acceptable envelope of the desired target conditions. At the initiation of each mode, the convergence checks are nominally passed within two or three guidance cycles (4 to 6 seconds). After initial convergence, a sudden change in the actual acceleration (engine failure) will cause the convergence checks to nominally fail for one guidance cycle. Allowing two guidance cycles as pad, 10 seconds is the longest reasonable interval for PEG to fail convergence. Failure to achieve convergence for more than 10 seconds indicates an internal problem which prevents the PEG solution from satisfying the target conditions. Manual guidance/throttle will be initiated for this failure.

C. THROTTLE COMMAND NOT DECREASED TO MAINTAIN $3g$ ACCELERATION.

During second stage guidance, the g-limiting task determines the average acceleration experienced since the previous guidance cycle. If the sensed acceleration exceeds an I-load limit value ALIM2, g-limiting is activated to decrease the throttle command proportional to the acceleration error. The throttle command is decremented until the sensed acceleration decreases below another I-load limit, ALIM1.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-58

AUTO GUIDANCE NO-GO (CONTINUED)

A constant throttle command with acceleration exceeding ALIM2 indicates the g-limiting task is not being executed. Manual guidance/throttle will be initiated for this failure.

Rules {A2-64C}, MANUAL THROTTLE CRITERIA, and {A4-59}, MANUAL THROTTLE SELECTION, reference this rule. ©[092195-1770A]

D. STATIC OR INCREASING T_{GO} FOR 10 SECONDS DURING MM 104 AND MM 105.

During the orbit insertion guidance, there is no direct onboard indication of a PEG convergence problem. If the PEG solution is not obtaining the desired target conditions, the solution is modified to determine a new required velocity change. An increasing time-to-go (TGO) for five guidance cycles indicates unreasonable modifications within the PEG solution. A static TGO for 10 seconds indicates the PEG task has not been executed for five guidance cycles. Manual guidance will be initiated for this failure.

Rule {A2-64A}, MANUAL THROTTLE CRITERIA, references this rule.

A4-59

MANUAL THROTTLE SELECTION

MANUAL THROTTLE WILL BE INITIATED FOR THE FOLLOWING CONDITIONS:

A. FAILURE TO INITIATE/TERMINATE THRUST BUCKET COMMANDS FOR FIRST STAGE q CONTROL.

During first stage flight, the boost throttling task provides an open-loop throttle command to limit maximum dynamic pressure and gain desired performance. When the relative velocity exceeds an I-load value of QPOLYJ, the throttle command is set to an I-load value of THROTJ if SRB performance is nominal, and the segment index J is incremented by 1. For off nominal SRB performance, adaptive guidance throttling adjusts either THROT2 or THROT3 depending on whether performance is high or low. If SRB performance is high, the THROT2 level (throttle command between about Mach 0.4 and 0.7) is reduced (approximately 21 percent for 3 sigma hot SRB's). If SRB performance is low, the THROT3 level (throttle command between about Mach 0.7 and Mach 1.3) is increased (approximately 6 percent for 3 sigma cold SRB's). Since there is no crew insight onboard into SRB performance, manual throttles should not be invoked at QPOLY2 or QPOLY3 simply to match the nominal throttle bucket based on the THROTJ I-loads. ©[092195-1770A]

Manual throttles shall only be invoked if guidance fails to throttle back at QPOLY3 or fails to throttle up to maximum power level at QPOLY4. If manual throttles are invoked during the throttle bucket, throttles shall remain under manual control until second stage guidance has been evaluated and declared "GO". ©[092195-1770A]

A4-59

MANUAL THROTTLE SELECTION (CONTINUED)

- B. FAILURE TO ACHIEVE FUEL DISSIPATION THROTTLE COMMAND ON INITIATION OF RTLS.

The current throttle command for the fuel dissipation phase of powered RTLS is established by the SSME-out safing task or the RTLS initialization task depending on the number of active SSME's. If a SSME failure has previously occurred, the throttle command should have been set to an I-load value KMAX by the SSME-out safing task. If no engine failure has occurred, the RTLS initialization task sets the throttle command to a level equal to two thirds of KMAX. Thus, if the current throttle command in the RTLS fuel dissipation phase is not equal to KMAX (two SSME's active) or two thirds KMAX (three SSME's active), then the SSME-out safing task or RTLS initialization task was not properly executed.

©[092195-1770A]

- C. INITIATION OF A TWO-SSME RTLS WITH ONE SSME THROTTLE STUCK IN THE THRUST BUCKET. RETURN TO AUTO THROTTLE WILL BE INITIATED DURING FLYBACK PHASE ON GROUND CALL AFTER CONFIRMATION OF GUIDANCE CONVERGENCE.

During the fuel dissipation phase of an RTLS, the PEG flyback predictions assumes a vehicle thrust acceleration equivalent to a desired throttle command. With two engines active with one throttle stuck at the thrust bucket level, the actual vehicle acceleration is less than assumed. After the powered pitcharound (i.e., flyback initiation), the PEG guidance senses the lower acceleration and becomes unconverged as it attempts to adjust the steering solution. During this interval, it is possible (although unlikely) for PEG to issue an erroneous MECO command. As a precaution to protect against an inadvertent shutdown, manual throttle must be selected prior to flyback initiation. Since there is no direct indication of when flyback initiation will occur, manual throttle should be selected at initiation of RTLS. To avoid a manual MECO, a ground call for return to AUTO throttle will be made after guidance has reconverged with a stable solution.

- D. INCORRECT THROTTLE COMMAND FOR TAL OMS DUMP CONTROL.
- ©[092195-1770A]

Beginning with OI-8D, flight software provides for an automatic throttledown following TAL abort selection in order to maximize capability to complete the pre-MECO OMS dump. This throttling action is cued by two site-specific I-loads that define the threshold throttledown velocities for either two- or three-engine operation. If the appropriate throttledown command is not issued, the software is not performing correctly, and manual throttle will be exercised to perform the same function. Alternately, when an SSME failure is not recognized by guidance, the throttle-down may be erroneously commanded based on the three-engine throttle down velocity. Manual throttles may be used to prevent or correct this erroneous throttle-down. This philosophy is consistent with paragraphs A and B above.

©[092195-1770A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-59 MANUAL THROTTLE SELECTION (CONTINUED)**

E. THROTTLE COMMAND NOT DECREASED TO MAINTAIN 3-G ACCELERATION.

The 3-g acceleration-limiting logic is provided to assure that vehicle loads do not exceed design constraints. Therefore, manual throttle will be invoked to protect this limit if the flight software fails to do so. Reference the rationale for Rule {A4-58C}, AUTO GUIDANCE NO-GO, for further background.

F. ANY TIME CSS IS SELECTED.

As a conservative guideline, any time the AUTO guidance is unacceptable for vehicle attitude control, it should not be allowed to control the main engines. If the vehicle attitude is not maintained to satisfy the guidance solution, the guidance may go unconverged and potentially could issue an undesired MECO command. Thus, to avoid an inadvertent shutdown, manual throttle should be selected whenever CSS takeover is initiated.

Rule {A2-64A}, MANUAL THROTTLE CRITERIA, references this rule.

G. THROTTLES WILL BE MANUALLY COMMANDED TO THE MINIMUM POWER LEVEL AT 2 PERCENT PROPELLANT REMAINING IF THE EXPECTED MECO UNDERSPEED EXCEEDS THE VALUE ASSURING EXECUTION OF FLIGHT SOFTWARE MECO PREP THROTTLING:

1. TWO OR THREE ENGINES ON: 500 FPS
2. ONE ENGINE ON: 250 FPS ®[092195-1770A]

Flight software MECO preparation throttling is triggered by K-loaded timing values. When the guidance-computed TGO becomes less than TGO_FCD K-load, the MPS guidance cutoff task begins cyclic execution. This task determines when to command the SSME's to the cutoff power level, and assumes that they will remain at that setting for K-load DT_MIN_K seconds. However, the software also assumes a guided MECO will result and has no way of compensating for an impending early (low-level) cutoff. Therefore, for predicted MECO underspeeds greater than a threshold value, a low-level shutdown may be commanded before the engines reach the desired cutoff throttle setting. In such instances, the throttles will be manually retarded to the minimum power level shortly before MECO to provide the required safe shutdown configuration.

Under most circumstances, the onboard propellant remaining computation is sufficiently accurate to use as a throttledown cue. Ascent/Entry Flight Techniques #62 determined in January 1990 that 2 percent propellant remaining provided a generic value that covered both the pre-MECO dump and no-dump cases. However, the flight software computation is inaccurate when off-nominal mixture ratios are involved, due to the buildup of unusable LOX or LH₂; the software senses the extra mass but does not recognize it as unusable. Likewise, the onboard mass estimation algorithm in first stage assumes all

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-59

MANUAL THROTTLE SELECTION (CONTINUED)

engines are operating at the commanded power level; therefore, an engine locked before the bucket will consume more propellant than the mass tracking function accounts for. This leads to the second stage software believing it has more propellant than is actually available.

Although the resultant mass dispersions are a function of the size and direction of the mixture ratio upset or the depth and length of the bucket, the 2 percent propellant remaining cue still provides sufficient time to throttle down. (Reference Flight Rule {A5-112}, MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN.) @[ED]

H. FOR LOW LH2 NPSP PER FLIGHT RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP.

Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP, addresses scenarios requiring manual throttles. Manual throttles will be maintained and a manual MECO required for the flow control valve anomaly case. Uphill capability will be evaluated at each throttle setting. Two-engine and single-engine performance boundaries will be made based on minimum power level as time permits. Since this dynamic throttle profile is difficult to model, two-engine and single-engine capability may not be evaluated accurately until the failure actually occurs.

Manual throttles will be selected prior to aborting TAL for a LH2 leak. OI-8D software (STS-38 and subs) automatically throttles the engines down if TAL is selected above an I-loaded inertial velocity. To prevent the software from throttling the engines down when there is an LH2 tank leak, manual throttles are selected prior to selecting TAL. Once TAL is selected, the throttles will be returned to auto where they will stay at 104 percent until 3 g's are reached. Three-g throttling may cause engine failures but this is an accepted risk to avoid vehicle structural damage. Operating the SSME's at 104 percent results in a higher inertial velocity at MECO than if the SSME's had been throttled down to 67 percent. @[092195-1770A]

I. A TAL UNDERSPEED IS PREDICTED AND CAN BE REDUCED BY FLYING AT A LOWER THROTTLE SETTING. THROTTLES WILL BE RETARDED TO MINIMUM POWER LEVEL WHEN THE PERFORMANCE GAIN IS MAXIMIZED.

The slope of the TAL range-velocity target line results in a point in the powered flight trajectory where MPS propellant margins may be increased by flying at a reduced throttle setting. As the throttle is retarded, the powered flight time is extended which in turn results in a MECO position which is farther downrange than would have occurred at a higher power level. The farther downrange position equates to less distance to the TAL site at MECO, and hence, a lower MECO target velocity. This in turn translates to increased MPS margin since less delta V is required to reach the smaller target velocity. Early in powered flight, gravity losses at the lower throttle are large and offset any R-V target benefit; however, eventually sufficient velocity is achieved such that the inverse is true; i.e., the smaller target velocity offsets the gravity losses, which diminish with time and the square of the current velocity.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-59****MANUAL THROTTLE SELECTION (CONTINUED)**

In real time, the MCC ARD can determine when this boundary condition is reached, and subsequently when the performance gain is maximized. The FDO will then call for throttledown to minimize the R-V underspeed. Improving proximity to the R-V line in this manner reduces the likelihood of requiring low-energy guidance during entry, and is especially critical for out-of-plane sites where high crossrange severely limits underspeed tolerance. ©[120894-1663]

Note that this procedure will not be utilized unless an underspeed is predicted at the current power level.

Rules {A4-55}, DESIGN AND CRITICAL MECO UNDERSPEED DEFINITIONS; and {A5-112}, MANUAL THROTTLE DOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN, reference this rule. ©[ED]

- J. THREE ENGINES RUNNING AND TWO STUCK THROTTLES PRIOR TO TAL OR RTLS ABORT.
1. TAL: SELECT MANUAL THROTTLES, ABORT TAL, SELECT AUTO THROTTLES.
 2. RTLS: SELECT MANUAL THROTTLES, MINIMUM THROTTLES, WAIT 10 SECONDS, ABORT RTLS, SELECT AUTO THROTTLES.

For TAL, it is undesirable to throttle down the good engine due to the guidance transients which may occur and the fact that little time would be gained to perform the abort dump. Therefore, manual throttles will be selected to prevent an automatic throttledown when TAL is declared. This action is not required if TAL is declared early enough that automatic throttling will not occur at abort selection. However, since there is no disadvantage to selecting manual throttles for this short period of time, manual throttles will always be selected for consistency. AUTO throttles will be reselected after TAL is declared.

For three-engine RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of an early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-59

MANUAL THROTTLE SELECTION (CONTINUED)

- K. TO MAINTAIN THROTTLES AT 109 PERCENT POWER LEVEL DURING THE FLYBACK PHASE OF AN RTLS ABORT.

When maximum throttles are enabled (SPEC 51 Item 4), guidance replaces the maximum power level (KMAX) of 104 percent with 109 percent. However, during the flyback phase, the commanded power level (KCMD) is not simply set to KMAX but is adjusted to achieve the desired mass conditions at MECO (assuming CSS or manual throttles did not occur anytime during flyback). For two engines running, the typical throttle command during flyback is about 100 percent and is unaffected by KMAX. Therefore, if 109 percent power level is desired during the flyback phase of an RTLS abort, manual throttles are required.

Reference Rule {A4-53E.1}, USE OF MAXIMUM THROTTLES; and Rule {A5-151D.3}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL].

- L. IF A LOWER SSME POWER LEVEL IS REQUIRED SUBSEQUENT TO ENABLING MAXIMUM THROTTLES.

When maximum throttles are enabled (SPEC 51 Item 4), guidance replaces the maximum power level (KMAX) of 104 percent with 109 percent. If throttle selection is auto and 3-g throttling is not active, the commanded power level (KCMD) is set to the new maximum power level of 109 percent (except during RTLS flyback phase, see paragraph K. above). If a lower power level is required subsequent to enabling maximum throttles, manual throttles must be selected and the lower power level commanded manually. (Note, if throttle selection is auto, the fine count throttle setting will be commanded regardless if maximum throttles have been enabled). A second SPEC 51 Item 4 will not reset the maximum or commanded power level to 104 percent. Therefore, the lower power level must be commanded manually. Once the desired power level is reached, throttles can be returned to auto. However, a subsequent engine failure with auto throttles selected will result in the commanded power level being reset to 109 percent.

Rule {A2-64A}, MANUAL THROTTLE CRITERIA, references this rule.

FLIGHT RULES

A4-60

MANUAL SHUTDOWN CRITERIA

IF THE ONBOARD PREDICTED MET OF MECO IS 2 SECONDS DIFFERENT THAN THE GROUND PREDICTED MET OF MECO AND IF CONFIRMED BY OBSERVED NAVIGATION VELOCITY ERRORS, A MANUAL SHUTDOWN WILL BE INITIATED AT THE GROUND-COMPUTED TIME.

If the ground predicted MET of MECO is 2 seconds different than the onboard predicted MET of MECO, a manual shutdown will be initiated on the ground-computed value to maintain the capability to achieve a nominal mission. A difference in the onboard and ground predicted times indicates an auto MECO will not achieve the target cutoff conditions. An early cutoff may require downmoding because of OMS performance limitations. A late cutoff may cause the desired thrust direction for OMS-1 to be radially downward and/or retrograde. The uncertainty in the ground prediction is estimated to be ± 0.9 second. This value is the RSS of the computational uncertainties of ± 0.6 second for 3-sigma ground navigation accuracy, and ± 0.5 second for onboard response to throttledown commands. Allowing a 1-second pad to ensure detection of a true onboard error and rounding to a whole number, a 2-second tolerance is enforced.

Reference: CA4-79, Ascent Flight Techniques Meeting #35, dated March 27, 1979. Rule {A2-60}, NAVIGATION UPDATE CRITERIA, references this rule.

A4-61

THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP

- A. BASED ON RECOMMENDATION FROM THE BOOSTER SYSTEM ENGINEER, AN ABORT REGION DETERMINATOR (ARD) ADJUSTMENT WILL BE MADE FOR:
1. THRUST LIMITING FLAG SET.
 2. Pc SENSOR SHIFT.
 3. ELECTRONIC LOCKUP.
 4. HYDRAULIC LOCKUP.
 5. HPOT EFFICIENCY LOSS.
 6. LH₂ FLOW METER SENSOR SHIFT.
 7. LPFT DISCHARGE TEMPERATURE SHIFT.
 8. NOZZLE LEAKS.

The ARD FPR is designed to cover only those SSME failures that are not detectable with engine instrumentation, but are sufficient to cause performance degradation. Therefore, it is necessary to model in the ARD those failures with performance impacts that exceed FPR coverage. Reference Rule {A5-110}, SSME PERFORMANCE DISPERSION. ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-61

THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP
(CONTINUED)

B. A PERFORMANCE-LIMITED SSME WILL BE SHUT DOWN EARLY, OR A MAIN ENGINE CONTROLLER CHANNEL TURNED OFF, BASED ON BOOSTER SYSTEMS ENGINEER (BSE) CONFIRMATION OF THE FAILURE AND ARD PERFORMANCE EVALUATION FOR THE FOLLOWING CASES:

1. LOW MIXTURE RATIO:

Preservation of the ATO region by early shutdown of an SSME has priority over a possible abort downmode to an AOA.

IF THE FOLLOWING CRITERIA ARE MET, THE AFFECTED SSME WILL BE SHUT DOWN EARLY TO PROTECT 3-SIGMA ATO CAPABILITY OR THE DESIGN UNDERSPEED, WHICHEVER IS THE MOST CONSTRAINING:

a. THE ACTUAL NOMINAL MARGIN INDICATES LOSS OF ATO CAPABILITY.

The ARD's actual mode nominal margin is a prediction of MECO underspeed on a 2-sigma bad day. This prediction can be used to determine if ATO capability exists. This rule refers to the design underspeed as a criterion for pressing uphill with a performance-limited SSME. In addition, the dispersed-performance protection level (3-sigma) is stated explicitly for uphill capability assessment.

b. THE HYPOTHETICAL AOA MARGIN (REFLECTING THE SICK ENGINE OUT) IS DECREASING.

The ARD's hypothetical mode AOA margin is the indicator of when continued sick engine operation will degrade performance. As long as the margins are increasing, the three-engine configuration is improving MECO conditions. When the margins start trailing off, the sick engine is degrading uphill capability. If the hypothetical nominal margin is greater than the actual nominal value; i.e. it is better to have two healthy engines than two healthy and one sick, the bad engine will be shut down.

c. THE HYPOTHETICAL NOMINAL MARGIN IS GREATER THAN THE ACTUAL NOMINAL MARGIN.

Rationale is the same as for paragraph b above.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-61 THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP (CONTINUED)

2. Pc SENSOR SHIFT (HIGH OR LOW)

FOR A Pc SENSOR SHIFT THE AFFECTED MAIN ENGINE CONTROLLER CHANNEL WILL BE TURNED OFF BY THE CREW TO PROTECT 3-SIGMA ATO CAPABILITY (i.e., AVOID AOA) OR THE DESIGN UNDERSPEED, WHICHEVER IS THE MOST CONSTRAINING. THIS PROCEDURE WILL NOT BE IMPLEMENTED IF IT WILL CAUSE ENGINE SHUTDOWN OR NOT CORRECT THE PERFORMANCE DISPERSION (REF. RULE {A5-110}, SSME PERFORMANCE DISPERSION, FOR CASES THAT CAUSE ENGINE SHUTDOWN). @[ED]

Large Pc shift can cause mixture ratio excursions that will result in a LOX or LH₂ depletion prior to ATO capability. Generally, the bad Pc sensor can be isolated and turned off with the other sensor returning the mixture ratio to a nominal value. This rule refers to the design underspeed as a criterion for pressing uphill with a performance-limited SSME. In addition, the dispersed-performance protection level (3-sigma) is stated explicitly for uphill capability assessment.

3. HYDRAULIC OR ELECTRICAL LOCKUP

AN SSME IN HYDRAULIC OR ELECTRICAL LOCKUP WHEN COUPLED WITH LOW VEHICLE PERFORMANCE MAY BE MANUALLY SHUT DOWN TO PREVENT A VIOLATION OF THE ENGINE LO₂ NET POSITIVE SUCTION PRESSURE (NPSP) REQUIREMENTS NEAR MECO. IF THE ARD PREDICTED DELTA V MARGIN AFTER SRB SEPARATION INDICATES LOW PERFORMANCE, THE NONTHROTTLING ENGINE WILL BE SHUT DOWN AT $V_T > 23K$ FPS. @[061297-4892]

For low performance in first stage with one or more engines in hydraulic or electrical lockup, there is potentially insufficient LOX at MECO to support the stuck engine's shutdown from the higher throttle level. This results in a LOX depletion and subsequent uncontained engine damage.

C. FOR A THREE-ENGINE RTLS, AUTO GUIDANCE WILL BE PRESERVED BY SHUTTING DOWN PERFORMANCE-LIMITED SSME WHEN THE PROBLEM IS IDENTIFIED BUT NOT LATER THAN POWERED PITCHDOWN (PPD) MINUS 40 SECONDS TO PROTECT A 3-SIGMA GUIDED MECO (RTLS MARGIN > 0 FPS). CRITERIA FOR ET SEPARATION PROPELLANT CONDITIONS WILL NOT BE CONSIDERED WHEN DETERMINING SSME SHUTDOWN REQUIREMENTS DURING AN RTLS.

Manual throttle, manual guidance, and early manual turnaround during an RTLS is more risky than shutdown of a performance-limited SSME. There is no real-time determination of propellant conditions at ET separation currently available. It is highly desirable to protect a 3-sigma guided MECO. This will be done at the possible expense of executing an RTLS ET separation with a slightly heavier tank.

FLIGHT RULES

A4-62**OMS-1/OMS-2 EXECUTION**

THE OMS-1 AND/OR OMS-2 TARGETS AND TIG WILL BE SELECTED TO ACHIEVE THE HIGHEST PRIORITY MISSION MODE POSSIBLE. ALLOWABLE UNDERSPEEDS FOR EXECUTION OF NOMINAL TARGETS WILL ENSURE ACCOMPLISHMENT OF HIGH PRIORITY MISSION OBJECTIVES. THE AME WILL BE USED TO DETERMINE THE HIGHEST PRIORITY MISSION MODE THAT CAN BE ACHIEVED.

For standard insertion flights, the nominal OMS-1 and OMS-2 targets are designed to be performance optimized. The nominal targets will be executed and the nominal flight profile flown only if there is sufficient fuel available to perform the required on-orbit burns and the deorbit burn. Otherwise, the highest priority mission mode that can be supported by the fuel available will be executed. (Reference Rule {A2-52D}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES.)

For direct insertion flights, a range of underspeeds will result in no OMS-1 being required but the apogee is lower than nominal. For these cases, assuming no OMS leaks have occurred, it is desired to circularize at the resulting pre-OMS-2 apogee altitude with the OMS-2 burn. The details for this case with and without OMS propellant problems are in Flight Rule {A4-103}, OFF-NOMINAL ORBITAL ALTITUDE RECOVERY PRIORITIES, and its rationale.

The AME will be used in real time to determine the highest priority mission mode that can be achieved. Actual post-MECO state vectors and actual OMS quantities are used by the AME. Should the MOC be unavailable, the backup method for determining the correct targets is the crew chart in the Ascent Checklist.

A4-63 THROUGH A4-100 RULES ARE RESERVED

FLIGHT RULES

ORBIT

A4-101 ONBOARD NAVIGATION MAINTENANCE

ADEQUATE NAVIGATION AND MANEUVER DEFINITION WILL BE MAINTAINED ONBOARD TO PROVIDE RUNWAY LANDING CAPABILITY AFTER LOSS OF COMMUNICATION.

This rule reflects a management decision to provide for safe deorbit and landing capability in the event of a total loss of communications between the vehicle and the ground. The on-orbit navigation state must be maintained within the defined uncertainty. The maximum acceptable downtrack error is 20 nm, predicted to deorbit TIG. Twenty nm is thought to be the maximum safe energy error that can be steered out after 130,000 feet altitude (see rationale for Rule {A4-151}, IMU ALIGNMENT). The current onboard state vector is propagated to the next day prime deorbit TIG to determine if the resulting state is within limits. Periodic state vector updates are uplinked to the vehicle whenever the propagated downtrack error approaches the limit.

A4-102 MINIMUM ORBITAL LIFETIME

THE DEORBIT MANEUVER WILL BE SCHEDULED AT LEAST 48 HOURS PRIOR TO ORBITAL DECAY TO EI TO PROVIDE 24-HOUR WAVE-OFF CAPABILITY. THE ATTITUDE PROFILE WILL BE PLANNED AND ORBIT ADJUST MANEUVERS SCHEDULED, AS REQUIRED, TO MEET THE DESIRED ORBITAL LIFETIME. THE PERIGEE ALTITUDE AT DEORBIT TIG SHALL NOT BE LESS THAN 80 NM.

Uncertainties in the MCC atmospheric model and onboard state vector integration make it difficult to model orbital decay at low altitudes. Planning a deorbit within 24 hours of decay to EI is considered unsafe due to these uncertainties. Protecting 48 hours beyond the deorbit TIG provides a 1 day wave-off capability to cover potential systems problems or forecasted bad weather at the time of the deorbit/landing.

Although perigee altitudes less than 80 nm may be acceptable based on orbital lifetime if the apogee altitude were high enough, uncertainties in the models and vector integration resulted in the determination of 80 nm as the lowest acceptable perigee at the planned time of deorbit.

When a time-critical estimation of the minimum perigee is required, the determination of the minimum perigee will be made utilizing a generic H_a versus H_p plot using the following "worst case" decay assumptions: 30 percent drag uncertainty, 200,000 lb orbiter weight, 2500 ft² frontal area, 28.5 degree inclination, 0 degree argument of perigee, and 240 by 10⁻²² watts/m²/hertz solar flux (f10.7).

If time permits, a real-time assessment of the minimum perigee altitude will be performed based on the actual apogee, orbiter weight, inclination, planned attitude timeline, solar flux, and a 30 percent drag uncertainty.

(Ref. Entry Flight Techniques Panel Minutes #34.)

FLIGHT RULES

A4-103

OFF-NOMINAL ORBITAL ALTITUDE RECOVERY PRIORITIES

NOTE: IF THE PROPELLANT MARGINS ALLOW FOR THE COMPLETION OF THE RENDEZVOUS PROFILE FOLLOWING INSERTION TO AN OFF-NOMINAL ORBIT, THEN THIS RULE DOES NOT APPLY.

A. RECOVERY OPTIONS FROM A 105 NM CIRCULAR ATO ORBIT, IN ORDER OF PRIORITY ARE:

1. USE OMS-3 AND OMS-4 TO OBTAIN NOMINAL ORBIT IF PROPELLANT IS AVAILABLE. STEEP DEORBIT CAPABILITY MUST BE PROTECTED FROM THE NOMINAL ORBIT.
2. CIRCULARIZE AS HIGH AS POSSIBLE AT AN ORBITAL ALTITUDE WHICH PROTECTS STEEP DEORBITS AND SATISFIES MISSION CONSTRAINTS. REFERENCE THE FLIGHT RULES ANNEX FOR FLIGHT-SPECIFIC ALTITUDE REQUIREMENTS.
3. RAISE ORBIT ELLIPTICALLY ONLY IF MANDATORY PAYLOAD CONSTRAINTS HAVE JUSTIFIED PREFLIGHT THAT THIS IS REQUIRED. IN THIS CASE, STEEP DEORBIT CAPABILITY TO ALL CONUS OPPORTUNITIES MUST BE PROTECTED THROUGH EOM PLUS 2 DAYS AND ELS DEORBIT OPPORTUNITY GAPS MUST NOT EXCEED 4.5 HOURS.

B. RECOVERY OPTIONS FOR DIRECT INSERTION INTO LOWER THAN NOMINAL ORBITS:

1. IF NO PROPELLANT PROBLEMS EXIST, CIRCULARIZE AT APOGEE ALTITUDE WITH OMS-2 (105 NM MINIMUM). FOR LARGER MECO UNDERSPEEDS WHICH REQUIRE AN OMS-1, CIRCULARIZE AT 105 NM. USE THE PRIORITIES IN PARAGRAPH A TO RECOVER FROM THE LOWER ORBIT.
2. IF PROPELLANT PROBLEMS DO EXIST, RAISE PERIGEE TO THE MINIMUM PERIGEE WITH OMS-2. CONSIDERATION WILL BE GIVEN TO RAISING PERIGEE ABOVE THE MINIMUM, DEPENDING ON PROPELLANT AVAILABILITY, MISSION REQUIREMENTS, AND DEORBIT REQUIREMENTS. REFERENCE THE ANNEX FLIGHT RULE, TRAJECTORY AND GUIDANCE PARAMETERS, FOR THE FLIGHT-SPECIFIC MINIMUM HP. @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-103

OFF-NOMINAL ORBITAL ALTITUDE RECOVERY PRIORITIES (CONTINUED)

The above is the Space Shuttle Program position on recovering from insertion into an ATO orbit and was agreed upon at the On-orbit Flight Techniques Meeting #78. It is much more desirable from the STS operations point of view to raise the orbit to a circular orbit. This eliminates the large variations in deorbit delta V that are possible from an elliptical orbit. It is quite possible not to have the delta V available to deorbit to an emergency landing site (ELS) from an elliptical orbit which has been optimized for a continental United States (CONUS) landing. Also, the deorbit delta V varies from one opportunity to the next as well as one day to the next due to the apsidal rotation. The deorbit delta V from a circular orbit is fairly constant throughout the flight. The fairly constant deorbit cost makes it much easier to handle propellant budget redlines in real time. For relatively small MECO underspeeds on a direct insertion, if there are no propellant problems, the plan to circularize at the current apogee altitude with OMS-2 was recommended for two reasons. First, it allows us to execute the STS preference of going into a circular orbit. Also, it is more efficient to circularize at the apogee altitude and deorbit from there than it is to fly the nominal mission. Therefore, for the MECO underspeed cases with apogee greater than 105 nm, the plan to use OMS-2 to circularize at the apogee altitude results in "creating" more OMS propellant for on-orbit activities. If propellant problems do exist, the rule calls for raising perigee to the minimum perigee (min Hp) in order to minimize propellant usage. The min Hp guarantees orbit stay capability up through the flight day 1 PLS opportunity. If the perigee is only raised to the min Hp, it may have to be raised higher at a later time to satisfy Rule {A4-102}, MINIMUM ORBITAL LIFETIME.

The elliptical orbit constraints were reviewed and approved at the Entry Flight Techniques Panel Meeting #40. Because of the large amount of analysis required to support flying in an elliptical orbit, it was recommended that this be done only in cases where the mandatory payload requirements have justified preflight that this is required. It was determined that a 4.5-hour gap in ELS deorbit capability was an acceptable compromise since "anytime" deorbit capability from the resulting elliptical orbit may not be available. Typical gaps in ELS deorbit opportunities from a circular orbit average 1 hour long. It was felt by the community that, for mandatory payload requirements, we could increase the exposure to gaps to three orbits without an ELS deorbit opportunity. The three orbits were then converted to time to make it easier to implement. It was agreed that we should protect steep deorbit capability to all CONUS sites from the elliptical orbits. This would allow the standard protection desired for a thermally safe entry and protect for deorbit to one of the other CONUS sites should weather make the PLS NO-GO. This deorbit capability must be provided for all the possible days of the mission to allow for an early or delayed landing.

DOCUMENTATION: Orbit Flight Techniques Panel Meeting #78 and Entry Flight Techniques Panel Meeting #40.

Rule {A4-62}, OMS-1/OMS-2 EXECUTION, references this rule.

FLIGHT RULES

A4-104

OMS LEAK/PERIGEE ADJUST

- A. FOR THE CASE OF AN OMS PROPELLANT TANK LEAK, AN OMS BURN TO DEPLETION WILL BE EXECUTED AS FOLLOWS:
1. IF PROPELLANT FROM THE GOOD POD CAN SUPPORT NEXT PLS DEORBIT WITH STEEP TARGETS FROM THE CURRENT ORBIT, THE LEAKING PROPELLANT WILL BE BURNED OUT OF PLANE IMMEDIATELY.
 2. IF PROPELLANT FROM THE GOOD POD CAN SUPPORT AT LEAST ONE CONUS DEORBIT OPPORTUNITY WITH SHALLOW TARGETS BUT NOT WITH STEEP TARGETS FROM THE CURRENT ORBIT, A PERIGEE ADJUST MANEUVER WILL BE PERFORMED IMMEDIATELY IF:
 - a. IT WILL REDUCE THE DEORBIT DELTA V ON THE PRIME AND BACKUP (IF AVAILABLE) DEORBIT OPPORTUNITIES TO THE PLS WITHIN THE NEXT 48 HOURS (MINIMUM OF ONE PLS OPPORTUNITY EACH DAY FOR THE NEXT 2 DAYS), AND
 - b. THE DEORBIT DELTA V AFTER THE PERIGEE ADJUST MANEUVER IS SUPPORTABLE WITH THE NONLEAKING OMS PLUS ARCS ABOVE AFT QUANTITY 1 (NO FRCS).
- OTHERWISE, AN OUT-OF-PLANE MANEUVER WILL BE PERFORMED IMMEDIATELY.
3. IF THE PROPELLANT FROM THE GOOD POD CANNOT SUPPORT AT LEAST ONE CONUS DEORBIT OPPORTUNITY WITH SHALLOW TARGETS FROM THE CURRENT ORBIT, A PERIGEE ADJUST MANEUVER WILL BE PERFORMED IMMEDIATELY WITH THE FOLLOWING EXCEPTION:

IF THE LEAK RATE IS EXTREMELY SLOW AND BOTH THE LEAK RATE AND POD THERMAL ENVIRONMENT ARE STABLE, PERFORM PERIGEE ADJUST AT THE OPTIMUM PERIGEE ADJUST TIG. HOWEVER, ANY INCREASE IN LEAK RATE OR CHANGE IN THERMAL ENVIRONMENT INDICATIVE OF POD FREEZEUP REQUIRES AN IMMEDIATE BURN.
 4. THE PROPELLANT FROM THE GOOD POD INCLUDES OMS FROM THE NON-LEAKING SIDE PLUS ARCS TO OMS TANK FAIL QUANTITY FOR SHALLOW OR AFT QUANTITY 1 FOR STEEP (PROTECTING FOR 48-HOUR ON-ORBIT STAY ON VRCS, ONE DEORBIT PREPARATION, AND TWO 15-SECOND ULLAGE BURNS), PLUS FRCS. FRCS WILL NOT BE CONSIDERED FOR USE DURING THE DEORBIT BURN, BUT MAY BE USED DURING A PERIGEE ADJUST.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104

OMS LEAK/PERIGEE ADJUST (CONTINUED)

5. FOR THE CASE OF AN OMS PROPELLANT TANK LEAK WITHIN FOUR ORBITS OF DEORBIT, COMPLETION OF THE PERIGEE ADJUST WITH THE FRCS WILL BE AN MCC CALL.
6. FOR THE CASE OF AN OMS PROPELLANT TANK LEAK WITHIN TWO ORBITS OF DEORBIT, IF THE MCC IS UNABLE TO CONFIRM A VALID ONBOARD STATE VECTOR AFTER THE BURN (FROM EITHER IMU DATA OR GPS), DEORBIT WILL BE DELAYED UNTIL THE GROUND TRACKING STATE VECTOR USED FOR THE DEORBIT MANEUVER COMPUTATION INCLUDES AT LEAST ONE REPEAT OF ANY TRACKING STATION. @[072601-4529]
- B. FOR THE CASE OF AN OMS PROPELLANT TANK LEAK DURING THE TIMEFRAME OF A PAYLOAD DEPLOY, THE ACTIONS FOR THE DIFFERENT UPPER STAGES ARE LISTED BELOW:
 1. IUS DEPLOY:
 - a. IF THE LEAK IS DETECTED PRE-UMBILICAL RELEASE, RESTOW AND BURN THE LEAKING SYSTEM TO DEPLETION PRIOR TO CONTINUING DEPLOY OPERATIONS. PARAGRAPH A OF THIS RULE WILL BE USED TO DETERMINE THE REQUIRED BURN. THE DETERMINATION OF SHALLOW DEORBIT CAPABILITY WILL ASSUME THAT THE PAYLOAD WILL BE DEPLOYED PRIOR TO DEORBIT.
 - b. IF THE LEAK IS DETECTED POST-UMBILICAL RELEASE, PERFORM EMERGENCY DEPLOY PROCEDURES UP TO EXECUTING THE MANEUVER TO THE SEPARATION BURN ATTITUDE. THEN:
 - (1) IF THE GOOD SYSTEM WILL SUPPORT DEORBIT TO SHALLOW TARGETS FROM THE POSTDEPLOY/MINIMUM SEPARATION ORBIT, PERFORM MINIMUM SEPARATION ASAP FROM THE LEAKING SYSTEM (SEND MASTER SAFE IF MINIMUM SEPARATION NOT COMPLETED). THEN, BURN LEAKING SYSTEM TO DEPLETION ASAP OUT-OF-PLANE.
 - (2) IF THE GOOD SYSTEM WILL NOT SUPPORT DEORBIT TO SHALLOW TARGETS FROM THE POSTDEPLOY/MINIMUM SEPARATION ORBIT, SEND "MASTER SAFE". THEN PERFORM "RECOVERY FROM MASTER SAFE" THROUGH RCS ENABLE. THEN:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104

OMS LEAK/PERIGEE ADJUST (CONTINUED)

- (a) IF THE LEAK IS EXTREMELY SLOW AND THERE ARE NO POD THERMAL EFFECTS BEING SEEN (BOTH ARE MCC CALLS), REPLACE THE NOMINAL/MINIMUM SEPARATION WITH AN ASAP 2 FPS RETROGRADE MANEUVER. THEN PERFORM PERIGEE ADJUST AT THE OPTIMAL PERIGEE ADJUST TIG.
 - (b) IF THE CREW HAS NO CONTACT WITH MCC, OR IF MCC DETERMINES THE LEAK IS FAST OR POD THERMAL EFFECTS ARE SEEN, PERFORM PERIGEE ADJUST ASAP.
 - (c) ASAP FOLLOWING THE PERIGEE ADJUST (EITHER AT OPTIMAL TIG OR THE ASAP TIG), IF THE PERIGEE ADJUST WAS ? 57 FPS, MANEUVER TO IUS VIEWING ATTITUDE AND COMPLETE "RECOVERY FROM MASTER SAFE" PROCEDURE TO RESTART MISSION SEQUENCING. IF IN CONTACT WITH MCC, CONSIDERATION WILL BE GIVEN TO LOWERING PERIGEE BELOW 95 NM (90 NM MINIMUM) TO OBTAIN 57 FPS FROM THE LEAKING POD.
 - (d) IF PERIGEE ADJUST DELTA V IS < 57 FPS, MASTER SAFE RECOVERY WILL ONLY BE ON MCC CALL.
2. PAM-D, PAM-D2, OR FRISBEE DEPLOY:
- a. IF THE LEAK IS DETECTED PREDEPLOY, ABORT THE DEPLOY AND PERFORM OMS BURN TO DEPLETION. PARAGRAPH A WILL BE USED TO DETERMINE THE REQUIRED BURN. THE DETERMINATION OF SHALLOW DEORBIT CAPABILITY WILL ASSUME THE PAYLOAD WILL BE DEPLOYED PRIOR TO DEORBIT.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104

OMS LEAK/PERIGEE ADJUST (CONTINUED)

- b. IF THE LEAK IS DETECTED POSTDEPLOY, BURN THE LEAKING OMS PROPELLANT ACCORDING TO THE FOLLOWING GUIDELINES. PARAGRAPH A WILL BE USED TO DETERMINE THE REQUIRED BURN. IF THE LEAKING OMS IS TO BE BURNED OUT OF PLANE, PERFORM A MINIMUM SEPARATION MANEUVER ASAP AFTER DEPLOY, THEN PROCEED TO BURN THE LEAKING PROPELLANT OUT OF PLANE IMMEDIATELY. IF THE LEAK RATE IS FAST AND THE LEAKING OMS PROPELLANT IS TO BE BURNED RETROGRADE, TIG CAN BE NO EARLIER THAN DEPLOY PLUS 15 MINUTES AND A MINIMUM DELTA V OF 18 FPS IS REQUIRED. CONSIDERATION WILL BE GIVEN TO LOWERING PERIGEE BELOW 95 NM (90 NM MINIMUM) TO OBTAIN 18 FPS. IF THE LEAK RATE IS EXTREMELY SLOW AND THE GOOD POD CANNOT SUPPORT ANY CONUS DEORBIT TO SHALLOW TARGETS, THE FOLLOWING ACTIONS WILL BE PERFORMED:
- (1) FOR ASCENDING NODE DEPLOYMENTS, REPLACE SEPARATION MANEUVER WITH A MINIMUM SEPARATION MANEUVER, GO TO WINDOW PROTECTION ATTITUDE (WPA), AND THEN BURN RETROGRADE AT THE NEXT OPTIMUM PERIGEE ADJUST TIG.
 - (2) FOR DESCENDING NODE DEPLOYMENTS, REPLACE SEPARATION MANEUVER WITH A PERIGEE ADJUST MANEUVER AT THE NEXT OPTIMUM PERIGEE ADJUST TIG (18 FPS MINIMUM).

3. RMS DEPLOY: **TBD**

The basic philosophy that is reflected in these rules is that the safety of the orbiter and the crew are first priority. Since the leak rate and thermal effects of an OMS propellant tank leak cannot be reliably predicted, the leaking propellant must be dumped ASAP. Reliable leak rates cannot be predicted because of the inability to determine or predict whether helium and/or propellant is leaking from the tank. In addition, if the propellant tank pressure decays to below the tank fail limit (fuel = 216 psia, oxidizer = 151 psia), there is no guarantee (regardless of the leak rate) that the tank can be repressurized to above these limits. If the repressurization does not work, the tank is considered failed and is unusable for the perigee adjust. Since thermal effects of a leak cannot be predicted, the propellant must be dumped to prevent the pod from the possibility of freezing, thus rendering both the OMS and RCS systems unusable. The rate of propellant sublimation varies as a function of which propellant is leaking, the location of the leak, the distribution of the propellant within the pod, and the thermal environment. As a result, the sublimation rate cannot be reliably predicted. Therefore, if the pod were to freeze there is no way to determine when the RCS will be available for entry.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104**OMS LEAK/PERIGEE ADJUST (CONTINUED)**

The determination of steep capability includes OMS from the nonleaking side, FRCS, and ARCS to AFT quantity 1. Flight Rule {A2-108}, CONSUMABLES MANAGEMENT, indicates that deorbit will be shallowed to protect entry usage. Therefore, for steep capability to exist, the full entry usage must be protected. For determination of shallow deorbit capability, the ARCS may be used to the OMS tank fail quantity. OMS tank fail quantity does not protect the total entry requirements. However, this propellant will be used to achieve a shallow deorbit to CONUS, if required.

If the good pod can support deorbit to a CONUS site using steep targets, the leaking OMS should always be burned out of plane (OOP) regardless of the leak rate as soon as possible. This will result in having many CONUS deorbit opportunities available that can be supported (to steep targets) with the remaining propellant after the leaking OMS burn.

The delta V of the perigee adjust maneuver is intended to obtain $H_p = 95$ nm and to reduce the propellant to the point where leakage into the pod will be minimized. This technique will usually result in one of two cases: (a) propellant not depleted at targeted H_p or (b) depletion of propellant and engine cutoff before reaching 95 nm. If the fuel is depleted before the perigee reaches 95 nm, the FRCS may be used to attempt to achieve the target perigee altitude at a later time.

If fuel remains after reaching the 95 nm target, an out-of-plane burn will be performed to reduce the propellant to the minimum safe quantity.

If the propellant available in the "good pod" can support a PLS deorbit with shallow targets but not steep targets, the leaking propellant may be burned either out-of-plane or retrograde. An out-of-plane burn everywhere in the orbit would guarantee at least shallow deorbit capability to the PLS. However, if the perigee adjust is performed in the right portion of the orbit, the deorbit delta V can be decreased. This would then allow a steeper than a shallow entry.

Therefore, a retrograde window is computed by determining where a perigee adjust will decrease the deorbit delta V to the PLS on the prime and backup opportunities. This window is also constrained by the amount of propellant available in the nonleaking OMS and the ARCS above AFT quantity 1 which will be used to support the deorbit. FRCS is not included in determining the window because it would require the use of a "fast flip" during the deorbit burn which is highly undesirable. The inverse of the retrograde window, the OOP TIG window, is what is actually provided to the crew on the trajectory message. If the "good pod" can support shallow but not steep deorbit and TIG for the leaking OMS burn is in the OOP TIG window, the crew will burn out-of-plane.

For high altitude flights, all the OMS on the leaking side may not be enough to get perigee down to 95 nm. In these cases, the maximum delta V available from the OMS will be used to lower perigee as much as possible and this value will be used in determining the OOP TIG window.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-104****OMS LEAK/PERIGEE ADJUST (CONTINUED)**

However, if shallow deorbit capability does not exist from the good OMS pod, it is imperative that a perigee adjust be performed from the leaking pod. The perigee adjust burn must be performed immediately in order to guarantee deorbit with one exception: If the leak rate is "slow" enough to guarantee supporting the optimum perigee adjust opportunity, and the pod thermal environment will also support, the burn will be performed at the optimum point to enhance CONUS landing capability. For this case, a maneuver to an LVLH retrograde burn attitude will be performed immediately and maintained. If there is any uncertainty in the leak rate computations or pod thermal environment will not support the opportunity, the perigee adjust will be performed immediately in order to guarantee deorbit to a landing site. Any leaks detected by the crew through the FDA is considered a fast leak. It is possible that the only deorbit capability available after the perigee adjust is performed is to a southern hemisphere ELS. The crew will be informed whether shallow deorbit capability currently exists.

The ground will also send up the delta times from the ascending node for the opening and the closing of the OOP TIG window. The crew will use this information for the case of an OMS leak while out of communications coverage with the ground. If the TIG is inside the OOP TIG window, the crew will execute the OMS burn out of plane. Otherwise, the OMS burn will be a perigee adjust maneuver. If the OMS burn is performed out of plane, the FRCS may be burned retrograde at the optimum perigee adjust TIG on a later orbit.

If the engine cutoff occurs before the desired perigee, it may or may not be desirable to complete the burn with the FRCS if deorbit will occur within the next four orbits. This is dependent upon the position in the orbit where the perigee adjust is executed. If perigee is in the wrong place in the orbit, completing the burn with the FRCS may actually increase the deorbit delta V. However, if the perigee adjust is executed near the optimum TIG, it will be better to complete in order to lower the deorbit delta V. The FDO will have to determine in real time whether completion on the FRCS is required.

If the orbiter state is well known at the perigee adjust maneuver, the onboard guidance and navigation will properly model the maneuver with sensed velocity changes from the IMU's. A confirmation of the maneuver will be performed by the MCC. In this case, onboard GNC is believed to be good and one orbit of tracking is not required to obtain a state vector for the deorbit maneuver computation.

@[072601-4529]

GPS provides an accurate state vector shortly after an orbit adjust maneuver as long as it is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking 4 satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. Possible deorbit delays due to ground navigation requirements can be avoided by using GPS for the post-burn state vector confirmation and deorbit maneuver computation. @[072601-4529]

Experience has shown that one orbit of tracking data will provide a state vector of sufficient quality upon which to compute a deorbit maneuver. Therefore, if after completion of the perigee adjust burn insufficient time is available to obtain the necessary tracking, the deorbit maneuver will be slipped to provide enough time to obtain the vector.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104

OMS LEAK/PERIGEE ADJUST (CONTINUED)

For the case of an OMS leak during the timeframe of a deploy, the most expedient means of dumping the leaking propellant will be executed. With a deployed payload, concern is not only with the actual perigee adjust maneuver and the resulting deorbit considerations, but must also take into consideration the separation dynamics between the payload and the orbiter. When possible, restowing or aborting the deploy eliminates having to solve critical problems simultaneously. Therefore, the procedures have been written to use the most conservative approach in all cases to optimize the chances of getting the orbiter ready to perform the OMS burn ASAP. For the cases where the deploy is aborted, the same logic discussed above will be used in determining whether to burn out of plane retrograde. The reason for assuming the payload will be deployed prior to deorbit is that it is not justified to protect for multiple payload failures that will not allow for deployment or jettison while working an OMS leak. Also, the delta V available increases due to decreased orbiter weight. This serves to increase the chance that shallow deorbit capability will exist from the current orbit and not force a retrograde burn. A retrograde burn performed in the wrong phase in the orbit could force a southern hemisphere landing. This maximizes the chance for a deorbit to a CONUS site. For the cases where the payload is ready for deploy, it was determined that it is best to proceed with the deploy in order to decrease the orbiter weight and therefore increase the efficiency of the remaining propellant.

*For the IUS cases, once the payload is elevated at 29 degrees, restowing the IUS uses functions that have just been verified to operate while deploy requires the additional use of umbilical release and SUPER*ZIP functions. Once the umbilicals have been released, however, it is best to proceed with the deploy since the payload is almost ready for deploy. Performing the perigee adjust postdeploy places the orbiter in front of and below the IUS at SRM-1 TIG. A minimum of 57 fps is required from the perigee adjust in order to ensure orbiter safety. This minimum delta V would ensure a closest-point-of-approach (CPA) distance of no less than 30 nm between the orbiter and the IUS post-SRM-1. This assumes a worst case pointing error at SRM-1 of 1.8 degrees for the IUS. Failure to obtain the minimum delta V would place the orbiter closer than 30 nm to the IUS at CPA and would require the IUS to be master safed.*

When an OMS leak is detected postdeploy for a spin-stabilized deployable (PAM-D, PAM-D2, and Frisbee), separation dynamics must be considered. If the leaking OMS is to be burned out of plane, performing a minimum separation burn (posigrade) ASAP after the deploy will provide acceptable separation dynamics. The leaking OMS can then be burned out of plane with no consequences. If the leaking OMS is to be burned retrograde, separation dynamics dictate that a retrograde burn not be performed prior to deploy plus 15 minutes. If the leak rate is fast, the separation burn is replaced with a perigee adjust burn of at least 18 fps (to protect for the 10X tile erosion limit) at the nominal separation TIG. If the leak rate is extremely slow, the perigee adjust should be burned at the optimum TIG to enhance the CONUS landing capability. For a descending deploy, this can be accomplished by replacing the nominal separation burn with a perigee adjust (18 fps minimum) at the optimum TIG. For an ascending deploy, the optimum perigee adjust TIG is after PKM ignition. Therefore, a minimum separation burn must be performed at the nominal separation TIG to protect for the 10X tile erosion limit, and a perigee adjust can be performed at the next optimum perigee adjust TIG.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-104 OMS LEAK/PERIGEE ADJUST (CONTINUED)

If executing the perigee adjust after a deploy requires less than the above stated minimum delta V's to reach 95 nm, consideration will be given in real time to taking perigee as low as 90 nm using delta V from the leaking pod in order to achieve the minimum delta V. This consideration will protect for 48-hour orbit lifetime from the resulting orbit and will not normally be exercised if it jeopardizes the ability to deorbit to a CONUS site by increasing the required deorbit delta V.

Rule {A6-51P}, OMS FAILURE MANAGEMENT [CIL], references this rule.

A4-105 MINIMUM TIME OF FREE FALL

TIME BETWEEN DEORBIT MANEUVER CUTOFF AND 400K FEET MUST BE 9 MINUTES.

The minimum time required for execution of the checklist procedures between deorbit burn cutoff and EI is 9 minutes. These procedures include maneuvering to the EI minus 5 minute attitude, powering down the OMS gimbals, executing the FRCS dump (when required), verifying switch positions, and starting the remaining APU's.

FLIGHT RULES

A4-106

DEBRIS AVOIDANCE CRITERIA FOR PREDICTED
CONJUNCTIONS (HC) @[070899-6888A] @[022201-3911A]

A. A DEBRIS AVOIDANCE MANEUVER MAY BE PERFORMED IF THE RISK OF COLLISION IS GREATER THAN THE OPERATIONAL IMPACT OF PERFORMING THE MANEUVER. THE CRITERIA FOR DETERMINING THE RELATIVE RISK OF COLLISION VERSUS THE OPERATIONAL IMPACT OF THE MANEUVER IS OUTLINED BELOW:

1. YELLOW THRESHOLD

FOR A PROBABILITY OF COLLISION (P_c) GREATER THAN 10^{-5} BUT LESS THAN 10^{-4} :

A MANEUVER WILL BE PERFORMED UNLESS IT RESULTS IN MORE THAN MINIMAL IMPACTS TO OPERATIONS OR MISSION OBJECTIVES. THE REQUIREMENT FOR THE MANEUVER WILL BE BASED ON THE PROBABILITY OF COLLISION VS THE IMPACT OF THE MANEUVER.

IF COVARIANCE DATA IS UNAVAILABLE, THE YELLOW THRESHOLD WILL BE BASED ON A PREDICTED MISS DISTANCE BETWEEN ?1 KM X ?7 KM X ?7 KM (?0.5 NM X ?3.8 NM X ?3.8 NM) AND ?0.5 KM X ?4 KM X ?4 KM (?0.3 NM X ?2.2 NM X ?2.2 NM) (DEFINED IN UVW COORDINATES RELATIVE TO THE SHUTTLE AS RADIAL X ALONG-TRACK X OUT-OF-PLANE).

2. RED THRESHOLD

FOR A PROBABILITY OF COLLISION GREATER THAN 10^{-4} :

A MANEUVER WILL BE PERFORMED UNLESS IT RESULTS IN SHUTTLE REFLIGHT, VEHICLE HARDWARE DAMAGE, ADDITIONAL EVA, OR CREATES ADDITIONAL RISK FOR THE CURRENT OR FUTURE CREW OR VEHICLE. THE REQUIREMENT FOR THE MANEUVER WILL BE BASED ON PROBABILITY OF COLLISION VS THE IMPACT OF THE MANEUVER. @[070899-6888A] @[022201-3911A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-106

DEBRIS AVOIDANCE CRITERIA FOR PREDICTED CONJUNCTIONS (HC) (CONTINUED)

IF COVARIANCE DATA IS UNAVAILABLE, THE RED THRESHOLD WILL BE BASED ON A PREDICTED MISS DISTANCE LESS THAN $0.5 \text{ KM} \times 4 \text{ KM} \times 4 \text{ KM}$ ($0.3 \text{ NM} \times 2.2 \text{ NM} \times 2.2 \text{ NM}$) (DEFINED IN UVW COORDINATES RELATIVE TO THE SHUTTLE AS RADIAL \times ALONG-TRACK \times OUT-OF-PLANE). ©[022201-3911A]

USSPACECOM predicts close conjunctions between the shuttle and any other orbiting object that can be tracked and periodically transfers state vector and at-conjunction object position covariance matrices to JSC for those conjunctions within an "alert box" defined by a 2 km radial distance from the shuttle, 25 km along track, and 25 km out-of-plane. JSC uses this data along with the shuttle covariance and state vector to compute the probability of collision (P_c). ©[070899-6888A]

A P_c between 10^{-5} and 10^{-4} is considered high enough commensurate with other program risks that a maneuver will be performed unless the operational and mission impacts are more than minimal. Examples of minimal operations impacts include but are not limited to:

- a. Minor consumables usage
- b. Minor rearrangement of the timeline
- c. Interruption of pre- or post-sleep

A P_c greater than 10^{-4} is considered high enough that a maneuver should be performed unless it would result in the loss of high priority objectives, which have reflight implications, or increase the overall risk to the current or future crew or vehicle. Examples of potential risk increases, which should be considered, include but are not limited to: ©[022201-3911A]

- a. Loss of high priority objectives as defined in the flight specific flight rules annex which may have reflight implications
- b. Vehicle hardware damage or damage to payloads that may require reflight
- c. Additional EVA
- d. Critical consumables usage
- e. Interruption of crew sleep prior to EVA, RNDZ, entry or other critical activity ©[070899-6888A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-106

DEBRIS AVOIDANCE CRITERIA FOR PREDICTED CONJUNCTIONS (HC) (CONTINUED)

Note that because collision avoidance maneuvers are small in magnitude, typically 1 or 2 m/sec, such a maneuver can normally be included in the plan without causing loss of primary objectives, hardware damage, additional EVA, or excessive use of consumables. For those rare instances where a maneuver cannot be performed without significant impact, the flight control team must trade those operational impacts of the maneuver versus the estimated risk of collision. Note that the Pc may be high enough that a maneuver will be performed even when there are operational impacts, if the risk of collision is deemed higher than the risk associated with the operational impact. This means that an EVA could be terminated early, consumables margins may be used, or crewmembers awakened if the risk of collision warrants these operational impacts. ©[070899-6888A] ©[022201-3911A]

If covariance data is unavailable, the red and yellow thresholds will be based on predicted miss distance. For a predicted miss distance of 1 km x 7 km x 7 km, the risk of collision is commensurate to the yellow threshold. For a predicted miss distance of 0.5 km x 4 km x 4 km, the risk of collision is commensurate to the red threshold. When using miss distance as the collision avoidance criteria, the flight control team will consider trends in miss distances, shuttle state vector updates, and object state vector updates to qualitatively assess the uncertainty in the miss distances at the time of the conjunction. The requirement for a maneuver will be based on the magnitude of and confidence in the predicted miss distances compared to the estimated risk associated with the operational impact of the maneuver.

- B. IF A DEBRIS AVOIDANCE MANEUVER IS PERFORMED, THE RESULTANT PROBABILITY OF COLLISION WITH THE DEBRIS OBJECT BEING AVOIDED WILL BE LESS THAN 10^{-7} . IF COVARIANCE DATA IS UNAVAILABLE, THE DEBRIS AVOIDANCE MANEUVER WILL ENSURE THAT THE MISS DISTANCE WITH THE DEBRIS OBJECT LIES OUTSIDE OF THE YELLOW THRESHOLD MANEUVER BOX.

Performing a debris avoidance maneuver can be a significant impact to operations; therefore, when one must be executed, there should be a sufficient assurance that another will not be necessary immediately afterward. When calculating the post-debris-avoidance-maneuver probability of collision with the debris object, only the change in miss distance should be incorporated. The increase in shuttle uncertainty due solely to the debris avoidance maneuver should not be included in the calculation. If the change in uncertainty due solely to the debris avoidance maneuver is included in the post maneuver calculation, it is possible that a debris avoidance maneuver could be accomplished which does not sufficiently increase the miss distance with the debris object even though the probability of collision is less than 10^{-7} .

The collision avoidance maneuver may be performed even if it introduces a future conjunction with another object. A future conjunction, although undesirable, does not diminish the need to avoid the present conjunction. ©[022201-3911A]

FLIGHT RULES**A4-107****PLS/EOM LANDING OPPORTUNITY REQUIREMENTS**

A. ALL OF THE FOLLOWING CRITERIA ARE REQUIRED FOR A PLS (OTHER THAN FIRST DAY PLS, REF. RULE {A2-1F}, PRELAUNCH GO/NO-GO REQUIREMENTS) MDF, OR EOM LANDING OPPORTUNITY (NOT IN PRIORITY ORDER):

1. NASA CONUS SITE: KSC, EDW, NOR. FOR NO-COMM PLS PLANNING, EDW IS PREFERRED.

Only the three prime NASA CONUS sites should be considered for PLS or EOM. The daily PLS planning results in a crew message for no-comm execution if total communications are lost; ref. Rule {A11-52}, LOSS OF BOTH VOICE AND COMMAND. In the case of other problems, ground evaluation of the landing site can be made very shortly before deorbit burn. However, for the no-comm case, the crew may be required to execute a deorbit to a site that was picked many hours previously. Since EDW weather is in general much more stable than KSC and additional lateral and longitudinal margins are available in the case of poor navigation (likely for a no-comm entry) or other orbiter systems problems, EDW is the preferred no-comm PLS site when all other considerations are equal. ©[ED]

2. WIND AND WEATHER CONDITIONS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]) ©[120894-1622B]

3. ACCEPTABLE ENTRY ANALYSIS INCLUDING:

NOTE: ENTRY ANALYSIS IS NOT PERFORMED FOR DAILY NO-COMM PLS SELECTION.

- a. APPROACH AND LAND TRANSITION (REF. RULE {A4-156}, HAC SELECTION CRITERIA).
- b. NORMALIZED TOUCHDOWN DISTANCE (REF. RULE {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION). ©[072795-1788A]
- c. MAXIMUM TIRE SPEED, ROLLOUT MARGIN, AND BRAKE ENERGY CONSTRAINTS (REF. RULE {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-107

PLS/EOM LANDING OPPORTUNITY REQUIREMENTS
(CONTINUED)

- d. NZ AND Q-BAR CONSTRAINTS (REF. RULE {A4-207}, ENTRY LIMITS). @[072795-1788A]

Rule {A4-112}, LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA, requires accurate lower level atmospheric data that is used for analysis of the entry trajectory to ensure safety. The main gear tires are certified to 225 knots groundspeed. This constraint may limit the allowable tailwind based on the predicted EAS and density altitude. Violation of brake energy and rollout constraints may result, in dispersed cases, in runway departure or excessive braking requirements that could lead to tire fires. Rule {A2-6A}, LANDING SITE WEATHER CRITERIA [HC], references this rule. Since the no-comm PLS landing would be executed many hours after the site had been selected, entry analysis using environmental observations are not relevant and therefore will not be performed. @[071494-1621A] @[120894-1622B] @[ED]

4. ENTRY CROSSRANGE LESS THAN DISPERSED OR THE THERMAL CROSSRANGE LIMIT, WHICHEVER IS MORE CONSTRAINING.

The dispersed crossrange limit represents the vehicle capability to converge to nominal conditions by TAEM interface (Mach 2.5) assuming 3-sigma combinations of navigation, atmosphere, energy, and winds. All planned and acceptable entries must have a crossrange which is less than the dispersed crossrange limit. Landing sites with crossrange between the dispersed and undispersed limits should not be considered. (Ref. the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS.) @[ED]

The flight specific thermal crossrange limit protects the upper surface thermal constraints for high crossrange entries. During high crossrange entries, the orbiter maintains a roll angle for a long period of time to reduce crossrange prior to the first roll reversal. Heading rates incurred by non-zero roll attitudes will be sensed by the FCS pitch rate gyros as small positive pitch rates. As a result, the FCS will maintain an angle of attack somewhat less than that desired as it attempts to compensate for this pseudo pitch rate. This results in increased heating to the upper surface, which may result in excessive structural temperatures. The actual thermal crossrange limit is flight specific. (Ref. the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS.) @[071494-1621A] @[ED]

5. SUFFICIENT GROUND EQUIPMENT SUPPORT INCLUDING REDUNDANCY MUST BE PROVIDED TO SATISFY A/G VOICE, TELEMETRY, TRACKING, AND COMMAND REQUIREMENTS AND FULL REDUNDANCY TO NAVIGATION AIDS AS SPECIFIED IN SECTION 3. NOTE: TRACKING SUPPORT IS NOT SCHEDULED FOR THE DAILY PLS OPPORTUNITY. IF A PLS IS REQUIRED, TRACKING SUPPORT WILL BE ON A "BEST EFFORT" BASIS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-107

PLS/EOM LANDING OPPORTUNITY REQUIREMENTS
(CONTINUED)

6. DAYLIGHT LANDING (SUNRISE MINUS 15 MINUTES TO SUNSET PLUS 15 MINUTES) UNLESS THE CREW IS SPECIFICALLY TRAINED FOR NIGHT LANDING.

All crews receive pilot pool training for night landing, and an emergency landing at an augmented landing site is reasonably assured of success. However, unless the crew is specifically trained for night landing, the additional risk should be avoided.

7. CREW SCHEDULING CONSTRAINTS MUST BE MET FOR PLS PLANNING, AT LEAST 7 HOURS BUT NOT GREATER THAN 16 HOURS, BETWEEN THE SCHEDULED WAKE-UP AND LANDING TIME FOR BOTH SHIFTS IF THE FLIGHT IS DUAL SHIFT. FOR DAILY PLS SELECTION, THE CONSTRAINT MAY BE RELAXED TO AT LEAST 5 HOURS BETWEEN SCHEDULED WAKEUP (CDR AND PLT ONLY) AND LANDING TIME IF THIS GIVES A BACKUP (ONE ORBIT LATE) OPPORTUNITY.

The Crew Scheduling Constraints Document (Appendix K of the Space Shuttle Crew Procedures Management Plan) contains the 7 to 16 hour wakeup-to-landing workday limit. That same document also gives limits to shifting crew sleep times. For next PLS situations, a backup opportunity is important since the use of the PLS will be driven by a systems failure that dictates coming out of orbit that day. Therefore, the orbit late increases the probability of landing on that day, allowing a wave-off for further systems anomalies, vehicle configuration, or weather violations. The minimum of 5 hours between scheduled wakeup and landing ensures the full deorbit preparation timeline (4 hours) plus the additional hour between deorbit and landing. Other activities, such as cabin stowage and postsleep would have to overlap with the deorbit preparation or be provided by a shift in the crew sleep period.

- B. RULE {A2-207}, LANDING SITE SELECTION, WILL BE USED TO CHOOSE BETWEEN SITES THAT MEET ALL REQUIREMENTS IN PART A. THE FOLLOWING ADDITIONAL CRITERIA LISTED BELOW, IN ORDER OF PRIORITY, WILL BE USED TO FURTHER CHOOSE BETWEEN LANDING SITES/OPPORTUNITIES:

1. BACKUP (ONE ORBIT LATE) OPPORTUNITY TO ANY CONUS SITE.

A one-orbit late landing opportunity to any of the three CONUS landing sites is particularly important in determining the daily PLS site since next PLS rules are driven by orbiter system failures that dictate coming out of orbit that day.

2. BACKUP OPPORTUNITY TO THE PLS.

A backup opportunity to the PLS is desirable since all of the ground facilities and team are on station and prepared for the landing and the higher priority site would be achieved in the event of a wave-off for one orbit.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-107

PLS/EOM LANDING OPPORTUNITY REQUIREMENTS (CONTINUED)

3. POSTLANDING OPERATIONS.

If all of the above criteria are met at more than one site, the site will be selected based on the post-landing convoy, payloads, and vehicle turnaround support. Also note that many orbiter malfunctions in entry critical systems have specific landing site requirements and this may drive the landing selection at a higher priority than this rule.

4. ENTRY CROSSRANGE < DTO CROSSRANGE LIMIT.

On flights which have entry aerodynamic DTO's/PTI's manifested, the site or opportunity that will allow these tests to be performed is desired. The DTO crossrange is more constraining than the dispersed crossrange limit in an attempt to account for the dispersion imposed on the crossrange due to guidance lockout during the execution of the PTI's. The DTO crossrange limit is last on the priority list due to the maturity of the aerodynamic data base resulting from a long history of successful entry DTO flights. Reference the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS, for the limit.

©[ED]

Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC], references this rule. ©[120894-1622B]

C. FOR DAILY PLS FOR NO-COMM DEORBIT PLANNING, TO MAINTAIN A CONUS LANDING SITE, CONSIDERATION MAY BE GIVEN TO THE FOLLOWING: RELAXATION OF WEATHER CRITERIA TO ACLS CONDITIONS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]), REASONABLE MODIFICATIONS TO CREW SCHEDULING CONSTRAINTS, NIGHT LANDING, AND SMALL VIOLATIONS OF DISPERSED CROSSRANGE.
©[120894-1622B]

Relaxation to ACLS weather conditions, small variances to crew sleep scheduling, acceptance of night landing, and small exceedances of dispersed crossrange may be allowed to pick a CONUS site for the no-comm next PLS opportunity. Since the weather forecasts are for several hours in the future, there is the opportunity for improvement. Landing at one of the CONUS sites (ref. Rule {A2-207}, LANDING SITE SELECTION) generally provides communications, command, tracking, landing aids, and ground site support. Also, facilities are available to mate the orbiter to the SCA, thereby minimizing any vehicle turnaround and scheduling impacts. Additionally, CONUS landings avoid the political and logistical ramifications of landing in a foreign country. Somewhat degraded conditions are acceptable for daily PLS planning rather than picking a non-CONUS site even including the ACLS sites such as Ben Guerir, Hawaii, or Guam.

FLIGHT RULES

A4-108

TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS

TIRE SPEED, BRAKE ENERGY, AND ROLLOUT MARGIN CONSTRAINTS ARE DEFINED AS FOLLOWS: @[072795-1788B]

Rollout margin and brake energy limits are identified in order to ensure that the orbiter can stop within the runway limitations. The touchdown tire speed limit, in combination with the crosswind limits (ref. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]), provides protection against tire failure during touchdown and rollout. Rollout margin is meant to account for the environmental and procedural variations that can directly impact the vehicle stopping distance. Brake energy limits protect the capability of the brakes to stop the orbiter (ref. Entry FTP Meeting #35, 9/11/87). @[072795-1788B]

A. CALCULATION ASSUMPTIONS:

1. THE PREDICTED TOUCHDOWN TIRE SPEED IS COMPUTED AT THE EVALUATION TOUCHDOWN EAS. @[072795-1788B]
2. DRAG CHUTE IS NOT CONSIDERED. @[050495-1745D]
3. DEROTATION IS ASSUMED AT 180 KEAS AT 2.2 DEGREES/SEC, REF RULE {A2-206}, DEROTATION SPEED. @[050495-1745D]
4. BRAKING INITIATION IS AFTER MIDFIELD AT 140 KGS OR AT 5000 FEET REMAINING, WHICHEVER IS FIRST, AT A MAXIMUM DECELERATION OF 9 FT/SEC/SEC. THE FOLLOWING EXCEPTIONS ARE ALLOWED:
 - a. IF BRAKE ENERGY IS VIOLATED, IT IS ACCEPTABLE TO DELAY BRAKE APPLICATION TO 120 KGS AS LONG AS ROLLOUT MARGIN ALLOWS AND BRAKE APPLICATION IS NOT DELAYED PAST 5000 FT REMAINING. THIS IS PREFERRED OVER RUNWAY REDESIGNATION.
 - b. IF ROLLOUT MARGIN IS VIOLATED, IT IS ACCEPTABLE TO BEGIN BRAKE APPLICATION AS SOON AS NOSE GEAR TOUCHDOWN OCCURS BUT NOT EARLIER THAN 225 KGS, AND AS LONG AS BRAKE ENERGY IS NOT VIOLATED. @[050495-1745D]

A4-108

**TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS
(CONTINUED)**

- B. TIRE SPEED - PREDICTED GROUND SPEED NOT TO EXCEED 214 KGS AT THE EVALUATION TOUCHDOWN EAS. (REF RULE {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION).
@[072795-1788B]

Rule {A4-112}, UPPER AND LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA, requires accurate lower level atmospheric data than is used for analysis of the entry trajectory to insure safety. The 214 KGS predicted touchdown speed limit is based on providing a minimum of 11 KTS margin from the 225 KGS orbiter tire certification limit given in the Orbiter Vehicle End Item Specification. The 11 KTS margin is derived from the RSS of air data system (3 sigma), winds (3 sigma), and piloting (< 1 sigma) dispersions. The short field speedbrake logic may be used to gain tire speed margin if the predicted tire speed with nominal speedbrake logic is > 214 KGS, but ? 225 KGS (ref. Rule {A4-110}, AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION). The probability of exceeding the 225 KGS certification limit depends on the landing site, touchdown evaluation velocity, wind, atmospheric conditions and persistence, ADTA errors/biases, and pilot-induced dispersions. Full 3 sigma protection does not always exist for this limit, nor does it exist for tailscrape. The 214 KGS operational limit and the short field speedbrake option were chosen because they provide a good balance between protecting for high speed landings, and for low speed tailscrape/derotation concerns. Using the short field option provides an additional 10 KTS protection against high speed landings, but at the expense of reducing tailscrape margin (ref. AEFTP #121, 1-20-95).

During tire certification, off-limits testing on the dynamometer indicated tire margin at groundspeeds greater than 225 KTS. However, the dynamometer is not a good predictor of tire wear, and the off-limits testing was not sufficient to be acceptable for certification by the vendor. Severe damage was observed (loss of tread prior to peak load), but the tire held air after multiple landings. Convair 990 tests on the modified surface at KSC and the cleaned EDW concrete runway have also demonstrated some minimal tire wear margin at certification limits. As expected, there is very significant increase in tire wear with speed beyond the certification limit and with higher crosswind. Results of several "worst-on-worst" cases at 225 KGS with 20 KTS steady state crosswind on the Edwards runway were mixed; some passed and some failed. Additional high speed tests were made at speeds up to 240 KGS, and 15 KTS crosswind, after which the tire continued to hold air. Engineering analysis indicates these test conditions represent the absolute tire wear limit. The tire vendor agrees that the Convair 990 data is the best available for predicting tire wear, but will not support using the results of these tests to increase the certified limit for this tire (ref. SPRCB, 5-31-95). @[072795-1788B]

- C. BRAKE ENERGY - ALL CASES MUST MEET THE BRAKE ENERGY LIMITS BELOW (WORST BRAKE) : @[072795-1788B]

NOTE: FOR APPLICATION OF THIS RULE, ABORTS INCLUDE RTLS, TAL, AND AOA. @[050496-1774A] @[050495-1745D]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-108

**TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS
(CONTINUED)**

1. OPERATIONAL NWS - BOTH CONSTRAINTS BELOW MUST BE SATISFIED:
 - a. 42M FT-LB WITH NWS (82M FT-LB FOR ABORTS).
 - b. 70M FT-LBS WITHOUT NWS (ASSUMING DIFFERENTIAL BRAKING) ON AT LEAST ONE "GO" RUNWAY AT THE LANDING SITE (82M FT-LB FOR ABORTS).
2. TOTAL FAILURE OF NWS:
 - a. IF PRE-DEORBIT - 42M FT-LB ASSUMING DIFFERENTIAL BRAKING.
 - b. IF POST-COMMIT TO DEORBIT AND EXPECTED BRAKE ENERGY PREDICTED TO EXCEED 42M FT-LB, THEN RUNWAY REDESIGNATION (SAME COMPLEX) WILL BE CONSIDERED PRIOR TO MACH 6 IN ORDER TO REDUCE THE CROSSWIND.

To be conservative, the drag chute shall not be used in the brake energy calculations. Engagement of the barrier is to be avoided, if possible. Therefore, in the calculation of brake energy, neither of these devices is considered. ©[050495-1745D]

Flight experience shows a potential of about 5 KEAS delay on the initiation of derotation from the desired speed of 185 KEAS using beep trim. Derotation initiation is assumed to be 180 KEAS. Desired commanded rate is 1.5 deg/sec, but actual results from flight data show that 2.2 deg/sec average derotation rate results. Together, these constants define the earliest nose gear touchdown speed and, thus, the earliest speed at which brakes should be applied. Failure of beep trim resulting in a delayed manual derotation is an additional failure that is not considered in this analysis but is thought to be a small effect in any case that can be covered by either drag chute or other dispersions. ©[050495-1745D]

Brake energy must not exceed limits for the same cases that the rollout margin has been met. Flight experience on STS-39 demonstrated an average maximum deceleration rate of 9.5 ft/sec² with the carbon-carbon brakes. The 9.0 ft/sec² assumption is conservative to allow for systems variations. Crews train for braking initiation at 140 knots or midfield, whichever is later. Exceptions to this is when braking has not begun and the vehicle reaches the 5k feet remaining marker. The crew will always begin braking at the 5k-foot marker, regardless of groundspeed. From flight experience, it has been demonstrated that the crew can safely delay braking initiation until 120 knots groundspeed. Also, the orbiter brakes and associated equipment (anti-skid) are certified to 225 (ref. CR 26-621-0055) kgs so under extreme circumstances braking may be allowed up to that speed provided the nose gear is down. ©[050495-1745D]

FLIGHT RULES

A4-108

TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS
(CONTINUED)

The 42M ft-lb limit for EOM was determined to protect against tire blowout plug deflating the tire shortly after wheel stop (ref. BF Goodrich Engineering Report ER-5448, FSC 97153). The 82M ft-lb limit for aborts allows for the generally heavier weight of payload return and shorter abort runways (ref. Specification - Structural Carbon Brake Assembly, MLG, Orbiter MC621-0075). This higher limit is also allowed for a contingency return on FD 1 with the typically heavyweight vehicle. The risk of a tire fire is incurred for brake energies above 70M ft-lb (ref. Carbon Brake Development Test Summary - Engineering Report 6055, 8/21/87). This limit will be used for the non-abort case where a late failure takes away nosewheel steering capability. Brake energy capability of 82M ft-lb has been demonstrated in testing.

Crosswinds directly increase the brake energy when differential braking is used for lateral control during rollout. Also, for loss of NWS, brake application at speeds above 140 knots will be required for lateral control which also adds to the brake energy.

After commitment to the deorbit burn, the options available for reducing the brake energy are limited. Should the NWS fail after this commitment, runway redesignation will be considered prior to Mach 6. Redesignation will not be considered if the brake energy reduction is not significant or if the alternate runway is less desirable for other reasons (no landing aids, runway conditions, etc.). Runway redesignation will not be recommended later than Mach 6 in order to protect against inducing a trajectory energy error which is not corrected by TAEM interface.

D. ROLLOUT MARGIN @[072795-1788B]

THE MINIMUM REQUIRED ROLLOUT MARGIN FOR A SITE TO BE "GO" ARE AS FOLLOWS:

NOTE: FOR ROLLOUT MARGIN VIOLATIONS, SHORT FIELD SPEED BRAKE SHOULD BE USED IF IT WILL MAKE A RUNWAY GO FOR ROLLOUT MARGIN, AND IT REMAINS GO FROM THE BRAKE ENERGY, TOUCHDOWN MARGIN, AND TOUCHDOWN SPEED REQUIREMENTS. @[050495-1745D]

1. FOR RUNWAYS WITHOUT A BARRIER:

PREDICTED ROLLOUT MARGIN ? 2000 FEET MEASURED FROM THE END OF THE USABLE OVERRUN

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-108

TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS (CONTINUED)

2. RUNWAY WITH A BARRIER:

PREDICTED ROLLOUT MARGIN ? 0 FEET FROM THE BARRIER

NOTE: THE USE OF THE SHORTFIELD SPEEDBRAKE SHOULD BE CONSIDERED IF THE ROLLOUT MARGIN IS LESS THAN 600 FEET USING THE NOMINAL SPEEDBRAKE RETRACT OPTION. @[050495-1745D]

Monte Carlo analysis in April 1992 and reconfirmed in October 1994 determined that less than 1000 feet (600 feet) are required to protect for the environmental and procedural variations in order to prevent crossing the end of the defined runway. This analysis accounted for landing gear deploy altitude variations, trajectory errors at preflare, 3-sigma ADTA errors, density altitude variations, surface wind changes, and variations in the design head/tail upper level wind profile. Also assumed was perfect execution of the braking procedures as described in paragraph A. However, the 1000-foot margin was chosen to provide additional protection for other procedural variations and dispersions outside those used in the Monte Carlo analysis. @[050495-1745D]

For runways without a barrier, an equivalent overrun of 1000 feet is protected. This overrun protects for loss/decreased braking or stopping capability or significant dispersions which result in a longer rollout. Therefore, a 2000-foot margin is required from the end of the usable overrun (load-bearing surface). At Ben Guerir, consideration will be given to use of the 1500 feet of packed dirt when it is dry and load bearing.

Engaging the barrier is undesirable because it can possibly result in damage to the main gear doors, air data probes, and a limited number of tiles. However, barrier engagement is safe at speeds up to 100 kgs. This rule would, on a nominal day with no dispersions and nominal drag chute deployment, result in an orbiter stopping more than 1400 feet from the barrier. On a nondispersed day when the drag chute fails, this rule would allow an orbiter stop at the barrier (no engagement). Barrier engagement would occur only on a day when the drag chute fails and dispersions result in a long rollout. Since barriers are only present at TAL sites, and the resultant damage to orbiter tiles, gear doors, ADTA, etc. is only a turnaround issue, the risk of barrier engagement is considered acceptable in order to launch on a given day.

Rules {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS; {A10-23A}, APU ENTRY START TIME; and {A10-71}, HYDRAULIC SYSTEM CONFIGURATION, reference this rule. @[050495-1745D] @[072795-1788B]

FLIGHT RULES

A4-109

DEORBIT PRIORITY FOR EOM WEATHER

FORECAST VIOLATIONS (REF. RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]) AT THE NOMINAL EOM TIME WILL RESULT IN SELECTION OF ONE OF THE FOLLOWING OPTIONS LISTED IN ORDER OF PRIORITY:
@[120894-1622B]

- A. DEORBIT TO PLS AT NOMINAL EOM TIME OR ONE OR MORE ORBITS LATE TO ALTERNATE RUNWAYS (IF REQUIRED FOR WINDS, SUN ANGLE, OR ISOLATED CLOUD COVERAGE).
- B. DEORBIT TO PLS EARLY ON EOM DAY.
- C. DEORBIT TO PLS 24 HOURS LATE.
- D. DEORBIT TO PLS DAILY OPPORTUNITY PRIOR TO NOMINAL EOM DAY.
- E. DEORBIT TO SLS.
- F. RELAX WEATHER CRITERIA.

Deorbit to the primary landing site is always desirable due to convoy/ground operations support and crew familiarity. Options A through D provide a priority list of options to deorbit to the primary landing site. Should it not be possible to deorbit to the primary site, the secondary landing site will be utilized (option E). Weather criteria will be relaxed real time should both the primary and secondary landing sites be unacceptable.

Rule {A2-207}, LANDING SITE SELECTION, and Rule {A2-301}, CONTINGENCY ACTION SUMMARY, reference this rule.

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION

- A. AIMPOINT SELECTION - AIMPOINT EVALUATION WILL ASSUME AUTO SPEEDBRAKE AND WILL NOT MODEL ANY MANUAL PROCEDURES DESIGNED TO INCREASE TOUCHDOWN DISTANCE. ©[072795-1788B]
1. IF THE PREDICTED TOUCHDOWN POINT USING THE NOMINAL AIMPOINT IS < 1000 FEET PAST THE RUNWAY THRESHOLD, THEN THE CLOSE-IN AIMPOINT WILL BE SELECTED.
 2. IF THE PREDICTED TOUCHDOWN POINT IS < 1000 FEET PAST THE RUNWAY THRESHOLD FOR BOTH THE NOMINAL AND CLOSE-IN AIMPOINTS, THE RUNWAY IS NO-GO. FOR DAYLIGHT LAKEBED LANDINGS ONLY, IF AFTER APPLYING ALL TECHNIQUES (CLOSE-IN AIMPOINT, ALTERNATE RUNWAY) THE PREDICTED TOUCHDOWN POINT IS STILL < 1000 FEET, CONSIDERATION SHALL BE GIVEN TO RELAXING THE 1000-FOOT CONSTRAINT RATHER THAN DELAYING DEORBIT OR SELECTING AN ALTERNATE LANDING SITE.
 3. FOR RTLS WITH LIGHT RAIN SHOWERS IN THE APPROACH CORRIDOR (RULE {A2-1C}.4, PRELAUNCH GO/NO-GO REQUIREMENTS), IF THE PREDICTED TOUCHDOWN POINT IS < 2000 FEET PAST THE RUNWAY THRESHOLD FOR BOTH NOMINAL AND CLOSE-IN AIMPOINTS, THE RUNWAY IS NO-GO. ©[ED]

NOTE: MANUAL SPEEDBRAKE RETRACTION AT 3000 FEET AGL MAY BE CONSIDERED TO ACHIEVE THE 2000-FOOT MINIMUM TOUCHDOWN ENERGY.
©[020196-1808A]

This rule is designed as a planning guide and represents crew and flight controller inputs developed over many flights. All of these criteria were discussed at Flight Techniques and other meetings.

A TD point 1000 feet from the runway threshold was selected to accommodate variations in actual TD point from prelanding predictions due to off-nominal EAS, landing gear deploy altitude, and deviations from the forecast wind profile. With the increased margins available on a lakebed runway, the risks of landing closer to the threshold are significantly reduced. Therefore, engineering judgment may be used to accept a TD point of less than 1000 feet in order to avoid an otherwise NO-GO situation on a lakebed runway if no increased risk is identified. Factors involved in making this assessment include visibility restrictions, underrun characteristics (hardness, surface conditions, obstructions, etc.), the availability of landing aids, wind persistence predictions, and pilot (e.g., STA) judgment and recommendations. Due to visibility restrictions at night, however, the 1000-foot criterion always applies to night landings on lakebed runways.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

There are two aimpoints used to locate the base of the outer glide slope, one at 7500 feet from the threshold (nominal) and one at 6500 feet from the threshold (close-in). Aimpoint selection is based on an evaluation of the predicted TD point and speedbrake setting using current and forecast winds, density altitude, and orbiter weight. The descent design system (DDS) and the Approach and Landing Plan (ALP) processor are used to compute these parameters. ©[072795-1788B]

Tile damage due to showers encountered during fly back could result in a loss of up to 1000 feet of touchdown distance. Typical touchdown distances carry adequate margin to protect this type of energy loss. A dispersed entry that is flown through a shower on a day that predicted touchdown conditions are at the limits specified in Rule {A4-110}, AIMPOINT EVALUATION VELOCITY, AND SHORT FIELD SELECTION, could result in a vehicle touchdown on the edge of the underrun. The touchdown distance is increased for RTLS to handle the tile damage combined with the other dispersions. ©[020196-1808A] ©[062801-4307C]

4. IF THE PREDICTED SPEEDBRAKE RETRACT CALCULATION INDICATES THAT THE SPEEDBRAKE WILL BE COMMANDED CLOSED (15 PERCENT) AT BOTH 3000 FEET AGL AND 500 FEET AGL USING THE NOMINAL AIMPOINT, THEN THE CLOSE-IN AIMPOINT MAY BE SELECTED TO ACHIEVE A PREDICTED TOUCHDOWN POINT CLOSER TO THE GUIDANCE TARGET (NOMINALLY 2500 FEET) AND POSSIBLY GAIN ADDITIONAL SPEEDBRAKE, PROVIDED THAT ROLLOUT MARGIN AND BRAKE ENERGY CONSTRAINTS (REF. RULE {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS) ARE STILL SATISFIED. ©[072795-1788B] ©[020196-1808A] ©[101096-4210]

Approach and landing guidance was designed to control the orbiter's TD energy state by modulating the speedbrake. Using the speedbrake retract I-loads, guidance will command a speedbrake position that should result in a targeted energy state at TD of 195 knots EAS (205 KEAS heavyweight) at 2500 feet past the runway threshold. At 3000 feet AGL, if guidance predicts that the TD energy state will be less than that targeted, the speedbrake will be commanded fully closed. In this case, selecting the close-in aimpoint will provide an additional 1000 feet of energy margin at TD and may result in carrying a small amount of speedbrake for energy control. The preference for open speedbrake and touchdown as close as possible to the 2500 foot guidance target does not preclude considering either aimpoint for other reasons, such as conditions which result in a different aimpoint recommendation from the STA. Rollout margin and brake energy requirements, as specified in Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS, must still be satisfied after selection of the close-in aimpoint. If selection of the close-in aimpoint results in violation of these criteria, the nominal aimpoint will be used. ©[101096-4210]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

5. IF THE PREDICTED DYNAMIC PRESSURE BELOW 3000 FEET AGL EXCEEDS THE ALLOWABLE LIMIT (REF. RULE {A4-207}, ENTRY LIMITS), THEN THE CLOSE-IN AIMPOINT MAY BE SELECTED IN CONJUNCTION WITH THE NOMINAL SPEEDBRAKE RETRACT OPTION TO REDUCE THE DYNAMIC PRESSURE TO WITHIN ALLOWABLE LIMITS. AS A LOWER PRIORITY OPTION, CONSIDERATION WILL BE GIVEN TO SELECTING THE CLOSE-IN AIMPOINT IN CONJUNCTION WITH THE SHORT FIELD SPEEDBRAKE RETRACT OPTION IF IT IS REQUIRED TO REDUCE DYNAMIC PRESSURE TO WITHIN ALLOWABLE LIMITS. FOR EITHER CASE, THE TOUCHDOWN POINT, ROLLOUT MARGIN, AND BRAKE ENERGY CONSTRAINTS MUST BE SATISFIED. ©[062801-4307C]

Selection of the close-in aimpoint may be used as a method for reducing the maximum dynamic pressure (q -bar) under 3000 ft AGL. When the speedbrake retracts and adjusts at 3000 ft/500 ft AGL respectively, it is possible for the maximum dynamic pressure to increase above limits specified in Rule {A4-207}, ENTRY LIMITS, under unique wind conditions. A reduction in the peak q -bar may be achieved by inducing a lower equivalent airspeed profile with larger speedbrake settings from the selection of the close-in aimpoint. If the close-in aimpoint alone does not reduce the peak q -bar below the limit, then the short field speedbrake may be selected in conjunction with the close-in aimpoint to further increase the speedbrake setting to meet the q -bar constraint provided that doing so does not make a NO-GO runway GO based on touchdown margin. The short field option cannot be used to improve touchdown conditions since it removes touchdown energy. Since the short field option removes touchdown energy, the close-in aimpoint/nominal speedbrake option is preferred over the close-in aimpoint/short field option to clear a q -bar violation. If selection of the close-in aimpoint with either the nominal or short field option results in any rollout margin violation or brake energy constraint violation as specified in Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS, the runway will be NO-GO. ©[062801-4307C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110 AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

B. EVALUATION VELOCITY AND SHORT FIELD SELECTION - THE THREE EVALUATION TOUCHDOWN VELOCITIES ASSOCIATED WITH THE TWO SPEEDBRAKE RETRACT OPTIONS ARE DEFINED IN THE FOLLOWING TABLE:

TABLE A4-110-I - EVALUATION TD EAS AND SHORT FIELD SELECTION

SPDBRK RETRACT OPTION	CONDITIONS/SELECTION CRITERIA	EVALUATION TD EAS-KTS			
		I-LOAD SET:		-18°OGS (HEAVYWEIGHT)	
		LANDING WEIGHT - KLB:		220 [3]<WT<245	WT ? 245
NOMINAL	NOMINAL EVALUATION TD EAS	195 [1]		205 [1]	
	IF THE TD POINT AT 195 KEAS <1000 FT FOR BOTH NOMINAL AND CLOSE-IN AIMPOINTS	185	N/A	N/A	
	IF ASCENT INTACT ABORT SITE TD MARGIN IS THE ONLY FACTOR CONSTRAINING LAUNCH	N/A		195	N/A
SHORT FIELD	WILL BE SELECTED TO ACHIEVE THE NECESSARY ROLLOUT MARGIN, BRAKE ENERGY, TIRE SPEED LIMITS, OR Q-BAR LIMITS (MAY BE USED WITH CI AIMPT FOR Q-BAR VIOLATION).	185 [1]	195 [1]	205 [2]	

©[062801-4307C]

- [1] GUIDANCE TARGETS FOR 2500 FT DOWNRANGE.
- [2] THIS OPTION CANNOT BE USED FOR TIRE SPEED MARGIN, BUT MAY BE USED FOR ROLLOUT MARGIN, DYNAMIC PRESSURE MARGIN, OR BRAKE ENERGY. FOR THIS WEIGHT ONLY, THE TOUCHDOWN TARGET IS 1500 FEET DOWNRANGE.
- [3] GLIDESLOPE IS BASED ON THE WEIGHT SWITCHPOINT I-LOAD WHICH IS NOMINALLY 220 KLBS, BUT MAY BE SLIGHTLY MORE OR LESS ON A FLIGHT-SPECIFIC BASIS. REF THIS RATIONALE. ©[072795-1788B]

The intent of modeling the TD prediction so that it assumes auto speedbrake and does not model manual procedures such as high EAS on the outer glide slope is to ensure that nonstandard procedures are not used in order to make the touchdown conditions GO. ©[072795-1788B]

There are also two speedbrake retract options, nominal and short field, which are used to control touchdown tire speed, rollout margin, brake energy, and maximum dynamic pressure under 3000 ft AGL. The short field logic dissipates 1000 feet of touchdown energy, which can be equated to a reduction of 10 knots in touchdown speed. The rollout margin, brake energy, maximum dynamic pressure, and tire speed parameters are also computed by DDS and ALP during real-time approach and landing analysis. ©[062801-4307C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

The touchdown speed prediction is a function of which I-load set (heavyweight or lightweight) onboard guidance has selected, and the speedbrake retract option (nominal or short field). The weight switch point I-load which distinguishes a lightweight vehicle from a heavyweight vehicle is normally 220,000 lbs. During pre-flight design, when the predicted weight is near 220,000 lbs, the switch point I-load may be either 222,000 or 218,000 lbs to make the flight-day I-load more predictable. With the normal speedbrake retract option selected, guidance will target all lightweight vehicles to touch down at 195 kts, and all heavyweight vehicles to touch down at 205 kts. With the short field speedbrake retract option selected, guidance will target lightweight TD at 185 KEAS and heavyweight at 195 KEAS. The intent is to use the same flight rule evaluation touchdown speed in approach and landing analysis as is used in onboard guidance. The touchdown speed design targets provide an energy reserve which takes into account such factors as tailscrape, nose gear slapdown limits, atmospheric effects, manual procedures, and orbiter center-of-gravity. Evaluation speeds may vary from the guidance target for very light or very heavy vehicles, and for other operational concerns as discussed below.

The short field speedbrake retract logic was designed to permit landing and stopping safely on the shorter TAL runways. It may also be selected on any landing opportunity to provide additional tire speed margin on hot or tailwind days. When the short field option is selected, guidance will decrease the targeted TD energy by 1000 ft, which is equivalent to landing 10 kts slower at the nominal 2500 ft downrange TD distance. For operational and training reasons, selecting the short field option for any reason should cue the CDR to target TD speed at 185 KEAS for lightweight landings, or 195 KEAS for heavyweight landings (provided that the weight is < 245,000 lbs).

Because of the reduced nose gear slapdown loads with weights less than 200,000 lbs, it is acceptable to plan for a touchdown of 185 kts rather than 195 kts. However, operationally, it is desirable to land at 195 knots rather than 185 knots for lightweight cases to reduce the number of landing speeds that crews must train for. For this reason, with an orbiter weight less than 200k lbs, both the nominal and close-in aimpoints will be evaluated at 195 knots prior to evaluation of 185 knots as the targeted TD EAS. Use of 185 knots is preferable to delaying deorbit (Ascent/Entry Splinter Flight Techniques Panel, Landing/Rollout #1, June 20, 1990). ©[072795-1788B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-110

AIMPOINT, EVALUATION VELOCITY, AND SHORT FIELD SELECTION (CONTINUED)

For the heavyweight case, it may be preferable to evaluate touchdown at 195 knots if inadequate TD margin is achieved at 205 knots at the intact abort site, rather than delay a launch. For landing weights \geq 245k lbs, TD evaluations should use a touchdown speed of 205 keas due to orbiter tailscape restrictions. ©[072795-1788B]

Under unique wind conditions, the short field speedbrake logic may be selected in conjunction with the close-in aimpoint to clear dynamic pressure violations above the limits specified in Rule {A4-207}, ENTRY LIMITS, provided that an adequate touchdown margin is maintained. The reduction of the maximum dynamic pressure is a byproduct of the larger speedbrake retract commands that result from the selection of the short field speedbrake option with the close-in aimpoint. Selecting the short field option with the close-in aimpoint is preferable over manual speedbrake techniques. ©[062801-4307C]

The short field logic should only be selected to achieve the necessary tire speed margin, rollout margin, dynamic pressure margin, or brake energy limits, and not to improve TD margin. Using short field to improve touchdown conditions essentially reduce the touchdown energy, which is in conflict with the decisions of the 1991 landing performance panel. ©[062801-4307C]

If entry analysis shows TD ground speed $>$ 214 kts using the short field option, that runway will be NO-GO for landing. When the short field logic is selected for tire speed margin, the crew will be notified of the 10 kt slower target/evaluation TD EAS.

Reference Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC], references this rule. ©[072795-1788B]

FLIGHT RULES

A4-111

RUNWAY ACCEPTABILITY CONDITIONS (CONTINUED)

- a. *Due to the large load bearing requirements of the orbiter, structural failures are not acceptable on any runway surface. Fissures or cracks, which may lead to or be evidence of structural failures, are not allowable. Potholes are not acceptable owing to the possibility of tire or strut damage caused by impact. Standing water, snow or ice on any runway surface may result in hydroplaning, loss of traction, and loss of brake effectiveness.* ©[062702-5149C]

Grooves on a runway are designed to provide drainage of water from the runway surface. Flooding occurs when the water cannot be shed quickly enough and the grooves fill. Any depth of water above this point is defined as standing water (depth of water above the runway surface, not including groove depth). The Shuttle Landing Facility at KSC is considered grooved although the 3500 feet at each end of the runway are ungrooved and treated with a Skidabrader™ Shotpeening Process. The A/E FTP#176 members concluded that the effects of landing in the ungrooved region and/or rolling across the grooved/ungrooved transition zones on a wet KSC runway (grooves not flooded) were not significant enough to alter the desired landing profile. These conclusions were based on LRC tire track testing, SES evaluations, and the assumption that significant lateral excursions could not occur since the time spent in the ungrooved region at high speeds was of a very short duration and occurred with light main gear loading.

- b. *Visible moisture on an ungrooved concrete runway may also result in a loss of lateral directional control. The orbiter MLG tires can lose up to 75 percent of the dry friction value at high speeds on a wet ungrooved runway. Ref A/E FTP #176.*
- c. *Wet, slushy lakebed surface materials thrown up during landing and roll out can result in orbiter damage. Reference Entry FTP #42 and A/E FTP #176.*

- B. FOR EMERGENCY LANDINGS, THE CONDITIONS IN PARAGRAPH A WILL BE CONSIDERED IN RUNWAY SELECTION IF MORE THAN ONE SITE IS AVAILABLE.

Contingency aborts (e.g., ECAL, emergency deorbit) do not require the same level of dispersion protection as NEOM or Intact Abort landings. In addition, emergency landings typically only have capability to one site, so runway NO-GO criteria are not appropriate. In the event overlapping coverage does exist (e.g., ECAL), runway condition should be considered when selecting the landing site. Emergency landings include, but are not limited to, ACLS, ECAL, and ELS sites. Ref A/E FTP #176.

UPPER AND LOWER LEVEL MEASURED WIND AND
ATMOSPHERIC DATA @[062801-4423]

A. UPPER LEVEL WINDS

UPPER LEVEL MEASURED WINDS (HAC ACQUISITION TO 10K FEET) ARE USED TO ASSESS HAC SELECTION OPTIONS AND TRANSITION TO APPROACH AND LANDING GUIDANCE.

PREDEORBIT: A SOURCE FOR ACCURATE UPPER LEVEL MEASURED WINDS IS HIGHLY DESIRABLE FOR EOM. IT IS HIGHLY DESIRABLE THAT THE SOURCE ENCOMPASS ALTITUDES FROM HAC ACQUISITION AND BELOW FOR THE HAC SELECTION ASSESSMENT AND IT IS OBTAINED NO MORE THAN 6.5 HOURS FROM TOUCHDOWN.

B. LOW LEVEL WINDS @[111094-1622B]

LOWER LEVEL MEASURED WINDS (0 TO 10K FEET) ARE USED TO ASSESS TOUCHDOWN, ROLL OUT, AND BRAKE ENERGY CONDITIONS IN ORDER TO SUPPORT COMMIT TO LAUNCH OR DEORBIT DECISIONS.

1. PRELAUNCH: A SOURCE FOR ACCURATE LOWER LEVEL MEASURED WINDS IS MANDATORY FOR RTLS, TAL AND AOA(IF REQUIRED) WITH THE FOLLOWING EXCEPTIONS: @[020196-1799A]

IF A SOURCE FOR LOWER LEVEL WINDS IS NOT AVAILABLE AT BEN GUERIR, BEN 36 WITH CLOSE-IN AIMPOINT WILL BE USED UNLESS UNUSUAL WIND CONDITIONS ARE SUSPECTED.

2. PREDEORBIT: A SOURCE FOR ACCURATE LOW LEVEL MEASURED WINDS IS MANDATORY FOR FD1 OR FD2 PLS, NEXT PLS, AND EOM. IT IS HIGHLY DESIRABLE THAT THE SOURCE FOR LOWER LEVEL WINDS IS OBTAINED NO MORE THAN 4.5 HOURS FROM TOUCHDOWN.

NOTE: FOR AOA OR FD1 PLS TO NORTHRUP, STANDARD BALLOON DATA IS NOT AVAILABLE. FOR THESE CASES, THE WIND PROFILERS DATA (IF AVAILABLE) AND FORECAST WINDS WITH THE 62 STANDARD ATMOSPHERE WILL BE USED FOR TOUCHDOWN AND ROLLOUT ANALYSIS. @[020196-1799A]

C. ATMOSPHERIC CONDITIONS @[062801-4423]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-112

UPPER AND LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA (CONTINUED)

A SOURCE FOR ACCURATELY MEASURING ATMOSPHERIC CONDITIONS FROM 0 TO 10K FEET IS MANDATORY WHEN INVERSIONS ARE SUSPECTED IN ORDER TO OBTAIN A MORE DETAILED AND RELIABLE FORECAST NEEDED TO SUPPORT COMMIT TO LAUNCH AND DEORBIT DECISIONS FOR EOM AND INTACT ABORT SITES.

A source of accurately measured upper level wind conditions at the landing site is highly desirable to support detailed landing analysis of the dynamics that can be expected while flying the HAC and the expected transition altitude from TAEM guidance to Approach and Landing guidance. Sources that can provide this type of detailed wind measurements include radio theodolites, rawinsondes, and jimspheres. Other resources, such as the STA, T-38, and balloon releases from surrounding areas, may be used to confirm the detailed wind measurements. It is highly desirable that the measured wind data encompass altitudes from HAC acquisition and below to analyze the expected guidance transition altitude, the expected maximum dynamic pressure on the HAC, and the expected HAC altitude errors, specifically the Altitude Error Low parameter. Wind measurements taken 6.5 hours prior to touchdown are not expected to change beyond the wind accuracies that assure acceptable TAEM performance and acceptable guidance transition. TAEM wind accuracy requirement studies have shown wind measurement errors of approximately 35 knots at HAC altitudes can be tolerated. Under all circumstances, wind measurement accuracies and the applicability of wind measurements taken up to 6.5 hours from touchdown will remain an SMG decision. ©[062801-4423]

A source of accurately measured lower level wind conditions at the landing site is necessary to support detailed landing analysis of touchdown, roll out, and brake energy conditions as part of the prelaunch GO/NO-GO decision process. The measured wind data at the landing site is also crucial to support an accurate and detailed forecast of the low-level altitude winds (0 to 10K feet). Sources that can provide this type of detailed wind measurements include radio theodolites, rawinsondes, and jimspheres. Since wind persistence is a function of the dynamics of the atmosphere, the number of wind measurements required will remain an SMG decision. When temperature inversions or wind shears are suspected, a source for accurately measuring atmospheric conditions is needed to support a more detailed forecast. Without measured atmospheric data, but with low-level local wind measurements, a wind shear could be detected and/or possibly be forecast based on previous measurements and other weather observation equipment.

A statistical analysis of postflight data from STS-26 to STS-103 shows that touchdown energy predictions from the touchdown-4.5 hour balloon are representative of the actual touchdown conditions. The change in the 3-sigma dispersions that can be expected from the touchdown-4.5 hour balloon to the touchdown-1 hour balloon is less than 150 ft. The statistics from these flights were taken on day of landing where meteorological conditions were benign enough to allow deorbit. To invoke the minimum wind measurement requirements in this rule implies that trajectory and touchdown predictions from the last available balloon are benign and sufficient touchdown margins exist. Other resources, such as the STA, may be used to confirm the last available trajectory and touchdown predictions. ©[062801-4423]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-112

UPPER AND LOWER LEVEL MEASURED WIND AND ATMOSPHERIC DATA (CONTINUED)

The detailed landing analysis of both forecast and current conditions is critical for short runways such as TAL sites. If weather conditions are favorable in that no low-level shears are suspect, the requirement for measured atmospheric data is waived, but detailed wind measurements are still required to support the landing analysis. The Ben Guerir exception minimizes the use of the Moron TAL site, which has a shorter runway and smaller ascent abort window. Although low-level wind data are mandatory to determine speedbrake setting, touchdown location, brake energy, aimpoint selection, etc., the special Flight Rules FRCB (September 6, 1988) determined that these data are not mandatory for BEN 36 because of the extensive overrun available on this end of the runway. ©[111094-1622B]

In order to save money, the Program agreed not to release balloons at Northrup in the prelaunch timeframe. If Northrup is the prime AOA site, touchdown and rollout analysis will be based on the forecast winds aloft which are made from the balloon data from the semi-daily releases from Holloman AFB. If the White Sands wind profilers data are available, it will be used for the touchdown and rollout analysis. Furthermore, analysis showed that the 62 standard and the monthly mean atmosphere showed only slight differences in the touchdown and rollout constraints. Therefore, for procedural simplicity, it was decided that the 62 standard atmosphere would be used. ©[020196-1799A]

Rules {A2-1}, PRELAUNCH GO/NO-GO REQUIREMENTS; {A2-2}, ABORT LANDING SITE REQUIREMENTS; and {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS reference this rule. ©[111094-1622B]

A4-113

OMS-2 TARGETING

FOR GROUND UP RENDEZVOUS MISSIONS, OMS-2 TARGET PERIGEE WILL BE USED TO OPTIMIZE RENDEZVOUS PHASING. OMS-2 PERIGEE MAY BE AS LOW AS 105 NM (OR 85 NM WITH SSP APPROVAL). ©[022201-3801]

OMS-2 is used for orbital insertion as well as the first rendezvous phasing maneuver. In order to accomplish this, orbital perigee post OMS-2 can range from 105 nm to 307 nm. OMS-2 can also compensate for small MECO underspeeds and still preserve the rendezvous. With Space Shuttle Program approval, post OMS-2 perigee can go as low as 85 nm in order to improve launch window duration, but with a propellant penalty due to drag. ©[022201-3801]

A4-114 THROUGH A4-150 RULES ARE RESERVED

FLIGHT RULES

ENTRY PLANNING

A4-151

IMU ALIGNMENT

DEORBIT WILL NOT BE ATTEMPTED IF THE IMU ATTITUDE ERROR AT ENTRY INTERFACE IS PREDICTED TO BE GREATER THAN 0.5 DEGREE FOR NOMINAL DEORBIT, DEORBIT WILL BE DELAYED IF THE ERROR IS > 0.25 DEGREE, IN ORDER TO PERFORM AN IMU ALIGNMENT TO CORRECT ERRORS TO < 0.25 DEGREE. FOR CONTINGENCY SITUATIONS, ERRORS BETWEEN 0.25 DEGREE AND 0.5 DEGREE ARE ACCEPTABLE.

Acceptable IMU attitude errors for entry were derived based on two factors, the post-blackout navigation downtrack error and the angle of attack errors.

- a. *Navigation downtrack error - An analysis presented at Entry Flight Techniques Panel Meeting #6 on 11/9/77 established IMU alignment error limits as follows:*
 - (1) *For a contingency in which exceeding system performance margins is necessary during entry, the maximum IMU RSS misalignment allowed at EI is 0.5 degree (flight safety limit; STS-4, EFTP 3). A misalignment at EI of 0.5 degree would result in navigation errors that, although corrected at TACAN acquisition (~M7), would result in adjustments to the entry trajectory that could exceed the venting control limit of 300 psf in the transonic region (ref. Rule {A4-207A}.2, ENTRY LIMITS). Errors greater than 0.5 degree will violate the 342 psf flight control design limit for dynamic pressure in the M5 to M3 region. The 0.5 degree misalignment corresponds to a downrange error of 10 nm at an altitude of 130,000 feet, which violates the delta state update limits (ref. Rule {A4-204B}, DELTA STATE POSITION UPDATES), but is within the TACAN capability to correct. ©[ED 1*
 - (2) *The 0.25 degree RSS limit is intended to protect system performance margins during entry. A maximum misalignment at EI of 0.25 degree under worst case conditions protects the limiting parameter, a dynamic pressure of 300 psf, that conforms to compartment venting constraints in the transonic region. The 0.25 degree misalignment corresponds to a downrange error of approximately 6 nm at an altitude of 130,000 feet, which is within TACAN capability to correct and does not violate the delta state update criteria.*
- b. *Angle of attack errors - Another consideration was angle of attack error. An extensive series of runs was made on the SPS ? 1 and FSL to define the loss of control boundary as a function of angle of attack errors. Results of these studies were presented at Flight Techniques. Angle of attack errors can come from IMU alignment errors and winds. Tolerance to angle of attack errors is a function of aerodynamic variations, FCS response, and RCS jet authority/availability. With worst case winds, three-sigma AERO variations, and two yaw RCS jet failures, simulation runs indicated a potential loss of control. Therefore, it was required to minimize the IMU contribution to angle of attack error, 0.5 degree was deemed to be the maximum allowable with 0.25 degree highly desirable.*

A4-152 DEORBIT BURN TARGETING PRIORITIES

- A. THE DEORBIT BURN WILL BE TARGETED TO MEET AS MANY OF THE FOLLOWING OBJECTIVES AS POSSIBLE, IN ORDER OF PRIORITY FROM HIGHEST TO LOWEST, USING THE AVAILABLE OMS PROPELLANT, AS DEFINED BY RULE {A6-356}, DEORBIT PLANNING CRITERIA, WHILE KEEPING THE CG IN THE NOMINAL BOX AS DEFINED BY RULE {A4-153}, CG PLANNING. ©[081497-4178B]
1. STEEP TARGETS WITH 3-SIGMA N-CYCLES
 2. OMS TANK LANDING CONSTRAINTS (< 21.2 PERCENT OX, 21.1 PERCENT FU)
 3. LANDING WEIGHT ? FLIGHT RULE LIMIT
 4. RCS COMPLETION AT SAFE HP
 5. TWO MIN TIG SLIP FOR NO-FAIL DEORBIT
 6. OMS TANK FAIL HPS ? SAFE HP
 7. ONE DOWNMODE OPTION FROM TIG THROUGH CUTOFF
 8. MAXIMIZE TIG SLIP UP TO 5 MIN FOR ONE ENGINE FAIL CASE
 9. AOS DURING THE BURN
- B. IF STEEP TARGETS CANNOT BE ACHIEVED WITH THE AVAILABLE OMS, THE FOLLOWING ACTIONS WILL BE TAKEN IN ORDER OF PRIORITY TO ACHIEVE STEEP TARGETS WITH 3-SIGMA N-CYCLES.
1. TARGET USING MAXIMUM POSSIBLE OMS, DOWN TO ZERO USABLE OMS (AS DEFINED IN RULE {A6-301}, OMS USABLE PROPELLANT) IN THE CRITICAL OMS SYSTEM. ©[081497-4178B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-152 DEORBIT BURN TARGETING PRIORITIES (CONTINUED)**

2. CG MANAGEMENT TECHNIQUES SHOULD BE UTILIZED TO MAXIMIZE THE AVAILABLE PROPELLANT WHILE MAINTAINING THE CG WITHIN NOMINAL LIMITS (REF RULE {A4-153}, CG PLANNING). @[081497-4178B]
 3. PERFORM A MULTI-STAGE DEORBIT BY EXECUTING AN FRCS AND/OR ARCS PERIGEE ADJUST WITH PROPELLANT ABOVE THE MCR PER RULE {A6-355}, OMS PROPELLANT DEFICIENCY FOR DEORBIT. IT IS HIGHLY DESIRABLE THAT THIS MANEUVER(S) OCCUR AT LEAST TWO ORBITS PRIOR TO DEORBIT TIG. IT MAY BE PERFORMED < TWO ORBITS BEFORE DEORBIT IF TELEMETRY COVERAGE WILL PROVIDE FOR MANEUVER CONFIRMATION.
 4. IF IT IS NOT POSSIBLE TO PERFORM A PERIGEE ADJUST PRIOR TO DEORBIT, COMPLETE THE BURN WITH AFT RCS DOWN TO AFT QTY 1 AND, IF REQUIRED, ALL FRCS REMAINING POST BURN. OPERATIONALLY, THE AFT RCS CAN BE BURNED SIMULTANEOUSLY WITH THE OMS.
- C. IF STEEP TARGETS WERE NOT ACHIEVED THROUGH THE ACTIONS IN PARAGRAPH B, OTHER CONUS DEORBIT OPPORTUNITIES SHOULD BE CONSIDERED IF THE REQUIRED DEORBIT DELTA-V WOULD ALLOW THE ACHIEVEMENT OF STEEP TARGETS. IF STEEP TARGETS TO A CONUS SITE CANNOT BE ACCOMPLISHED, THE FOLLOWING ACTIONS WILL BE TAKEN TO ACHIEVE SHALLOW TARGETS.
1. TARGETED PREBANK UP TO 90 DEGREES WITH 3-SIGMA N-CYCLES
 2. TARGETED PREBANK OF 90 DEGREES WITH MINIMUM N-CYCLES TO PREVENT SKIPOUT (N-CYCLE = 2)
 3. INCREASE THE AMOUNT OF RCS PROPELLANT AVAILABLE FOR A PERIGEE ADJUST OR ARCS COMPLETION SUCH THAT ONLY TANK EXPULSION EFFICIENCY (RULE {A6-305A}, AFT RCS REDLINES, ON-ORBIT SINGLE AFT RCS POD QUANTITY REDLINE) IS PROTECTED POST DEORBIT.
 4. IF POSSIBLE, INCREASE THE AVAILABLE PROPELLANT BY EXPANDING THE CG LIMITS TO THE CONTINGENCY BOX.
 5. BURN THE OMS TANKS TO DEPLETION. @[081497-4178B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-152 DEORBIT BURN TARGETING PRIORITIES (CONTINUED)**

6. INCREASE THE AMOUNT OF RCS PROPELLANT AVAILABLE FOR A PERIGEE ADJUST OR ARCS COMPLETION SUCH THAT ONLY AFT QTY 2 (RULE {A6-305D}, AFT RCS REDLINES, AFT RCS QUANTITY 1 AND 2) IS PROTECTED POST DEORBIT. ©[081497-4178B]
- D. CONTINGENCIES REQUIRING RAPID TARGETING WILL BE TARGETED TO THE PRIMARY THRUSTERS OPTIMUM SOLUTION, OR THE 2 OMS/1 OMS CROSSOVER POINT IF 2 OMS ARE AVAILABLE.

This rule establishes the methods that will be used to target the deorbit burn in order to achieve an acceptable entry. The order has been established to minimize the impact to crew safety and maximize vehicle integrity.

Paragraph A:

The deorbit maneuver TIG will be chosen to meet as many of the objectives listed in paragraph A as possible, in order of priority. The TIG will occur no earlier than RCS optimum minus 1 minute, and no later than the two OMS optimum.

*All targeting in paragraphs A and B uses 3-sigma N-cycles. An N-cycle is defined as the number of guidance cycles after the initiation of closed loop guidance before the first non-zero roll command. Three sigma N-cycles are flight specific since the inclination and seasonal effects are factors used to define the specific N-cycle. The 3-sigma N-cycle provides protection from getting **zero N-cycles with** a minimum initial bank of 25 degrees at closed loop guidance initiation, in the presence of 3-sigma dispersions. Targeting with steep targets and the 3-sigma N-cycles will assure nominal entry heating levels, correct convergence onto the drag profile, and protection of recovery prebank capability.*

OMS propellant quantities at landing should be less than 21.2 percent oxidizer, 21.122 percent fuel to prevent exceeding OMS/RCS pod structural loads. (Ref. SODB, Volume I, Shuttle Systems Performance and Constraints Data, Section 3.4.3.3, OMS Constraints/Limitations.) Violation of the tank landing weight constraint may cause structural damage. ©[081497-4178B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-152****DEORBIT BURN TARGETING PRIORITIES (CONTINUED)**

Priority A.4 protects RCS completion at Safe Hp. If a failure(s) disabled both OMS engines below Safe Hp, the burn could be completed with the remaining propellant through the RCS jets. If a failure(s) disabled both OMS engines prior to Safe Hp, the shuttle would be in an orbit with at least 48 hours of lifetime, and the deorbit burn could be retargeted to optimize for the RCS engines. ©[081497-4178B]

Two minutes of no-fail TIG slip protects for a case like a switch misconfiguration where no actual failures have occurred.

The OMS Tank Fail Hp's are the altitudes at which an OMS tank can fail and the targets can still be achieved using all of the remaining resources (remaining OMS, recovery prebank to the 2950 degree Fahrenheit wing leading edge temperature limit, ARCS to Aft Qty 1, and FRCS). If the tank fail Hp is below Safe Hp, there is a window where the orbiter is too low to stop the burn (Safe Hp), but too high to complete the burn using the remaining propellant. It is desirable that this window not exist; therefore, Tank Fail Hp should remain above Safe Hp if possible.

One downmode option from TIG through cutoff means that the burn can be completed in the event that the primary engines are lost (i.e., 2 OMS to 1 OMS, or 1 OMS to RCS).

The most efficient place to burn in the event that an OMS engine is lost is at the 1 OMS optimum point. TIG may be backed up from this point to gain TIG slip or comm if higher priority objectives can still be accomplished.

Paragraph B:

The actions in paragraph B allow steep targets to be achieved while still protecting the nominal RCS entry propellant redlines. The maximum usable OMS as defined by the critical system will be used for deorbit in order to protect steep targets. The burn will be targeted to cutoff when the 0 lbs usable quantity has been reached in either system, thereby protecting the tanks from being depleted.

CG management techniques as defined in Rule {A4-153}, CG PLANNING, may allow more propellant to be made available for the deorbit burn. For planning purposes, the CG at Mach 3.5 must be maintained within the nominal box. ©[091098-6717]

The ARCS and/or FRCS perigee adjust at least two orbits prior to deorbit allows both burn confirmation and collection of some tracking data to take out the resulting trajectory dispersions. The RCS perigee adjust is acceptable within two orbits of deorbit if a valid burn confirmation can be performed. Accurate ground modeling of the burn is achievable with this confirmation, assuring valid state vector confidence to target the subsequent deorbit burn.

If a perigee adjust could not be performed prior to deorbit, ARCS completion with propellant down to AFT Quantity 1 and, if required, a fast flip to burn the FRCS to depletion is preferred over targeting a shallow entry because it preserves steep targets with no impact to vehicle integrity. ©[081497-4178B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-152

DEORBIT BURN TARGETING PRIORITIES (CONTINUED)

Paragraph C: @[081497-4178B]

Prior to implementing the actions in paragraph C, it may be best to deorbit to another CONUS opportunity if steep targets can be achieved. Wave off capability and orbital geometry will be the deciding factors in whether this is a feasible option. The actions in paragraph C allow for shallow targets which reduce the propellant required for deorbit. @[081497-4178B]

Targeted prebank up to 90 degrees shallows the targets and reduces the propellant required for deorbit. This targeting priority assures drag profile convergence, but results in higher vehicle heat loads and compromises recovery prebank capability. The heat load induced by a shallow entry increases with crossrange; therefore, low crossrange opportunities should be utilized if a heat load analysis cannot be performed.

In a time critical situation, once it has been determined that some amount of prebank is required, targeting 90 degrees prebank should be considered because pre-mission products are already available. If a prebank other than 90 degrees is selected, then recovery prebank tables must be generated in real time, using a time consuming and rarely exercised procedure.

*The use of minimum N-cycle in conjunction with a targeted prebank of 90 degrees will further reduce the deorbit delta-V. The use of minimum N-cycles provides protection from skipout, which is defined as **zero N-cycles** with an initial bank of 60 deg at closed loop guidance initiation, in the presence of 3-sigma dispersions. The resulting entry is thermally more severe and converges on the drag profile later in the entry phase.*

The aft RCS propellant tanks are not certified for use below 20 percent during zero-G operation. If used below 20 percent prior to $N_z = 0.05g$, there is a risk that the tanks may fail, leaving no RCS propellant available for entry control.

Expanding the CG box out to the contingency limits may allow access to propellant that was previously limited by the Y CG limit. The contingency box may allow expansion from the nominal Y CG limit but for the forward end of the X CG box, the nominal and contingency limits are the same.

Burning the OMS tanks to depletion may destroy the engines and will only be performed after all other targeting options have been exhausted.

ARCS completion down to AFT Quantity 2 only protects low Q -bar attitude control to the point where no-yaw jet capability is possible ($N_z = 0.05g$).

Paragraph D:

In emergency targeting or contingency targeting cases, the primary thrusters optimum solution, or the 2 OMS/1 OMS crossover solution, will be used because it can be quickly executed within the limitations of the current deorbit targeting processor. Time may not be available for a detailed analysis of the targeting. @[081497-4178B]

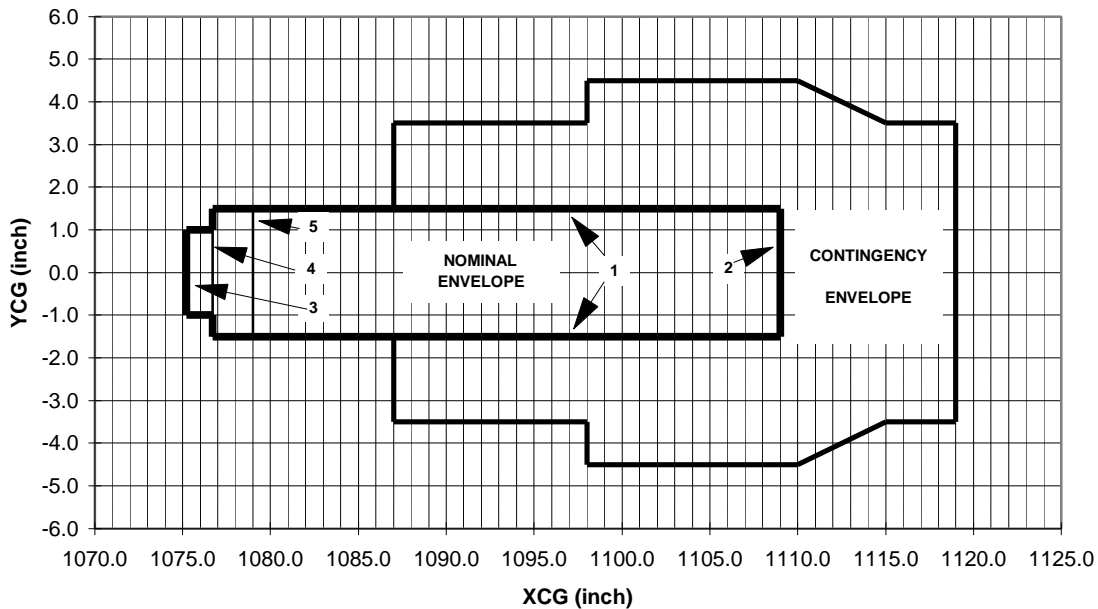

FLIGHT RULES

A4-153

CG PLANNING

A. CG ENVELOPE:

1. CONTINGENCY CG ENVELOPE.
2. NOMINAL CG ENVELOPE: @[091098-6715]

NOTES:

- [1] VERIFIED AERO BOUNDARY.
- [2] DESIGN ENVELOPE AFT LIMIT.
- [3] FORWARD LIMIT FOR EOM, ATO, AND AOA (X=1075.2 INCHES).
- [4] FORWARD LIMIT FOR GRTLs FOR ANGLE OF ATTACK < 30 DEGREES AND FOR TAL (X=1076.7 INCHES).
- [5] FORWARD LIMIT FOR GRTLs FOR ANGLE OF ATTACK > 30 DEGREES (X=1079.0 INCHES).
- [6] NOMINAL CG ENVELOPE REFLECTS A 1-INCH UNCERTAINTY FOR X CG AND A 0.5-INCH UNCERTAINTY FOR Y CG. @[091098-6715]

The contingency CG envelope represents the loss of control CG boundary for OMS tank fail cases. Vehicle control beyond the nominal CG envelope, yet within the contingency CG boundary, assumes all four yaw jets are available. Due to elevon saturation, there must be no jet failures to ensure vehicle control within the contingency envelope.

No structural or thermal assessments of the vehicle have been made for CG conditions beyond the nominal envelope. Entry at these conditions could result in significant damage to the airframe and/or thermal protection system even when the vehicle is within limit flight conditions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-153****CG PLANNING (CONTINUED)**

The X CG values which correspond to the Y CG values of 3.5 inches and 4.5 inches represent the breakpoints of the generic elevon schedules. The boundaries of the contingency CG box include an uncertainty of ± 1.0 inch for X CG at the forward end of the contingency box. The uncertainty for the Y CG is ± 0.5 inch.

The contingency CG envelope boundaries were derived from an analysis matrix which included: fixed mass properties; light and heavyweight vehicles; 0 and 30 percent turbulence models; and aero variations of nominal LVAR 9, LVAR 19, bent airframe, and pitching moment.

This rule also contains the nominal CG envelope that was developed to trade off the X vs. Y CG location, when required during real-time operations, in conjunction with orbiter CG management rules. In addition, the CG envelope is used preflight to evaluate the projected end of mission CG location and, if required, adjust planning to assure that the CG is within the given boundaries. The nominal CG envelope reflects the prelaunch measurement errors (± 1 inch for X, ± 0.5 inch for Y).

The CG boundaries, as they exist today, have evolved since prior to STS-1 and are a result of many iterations of analyses performed by both the JSC and Rockwell International Corporation (RIC) aerodynamic communities, and of numerous Entry Flight Techniques discussions. The shape and dimensions of the boundaries have changed many times as a function of the assumptions made and the orbiter aerodynamic data used in their generation, and they may continue to change and expand as more is learned about the orbiter capabilities.

In general, the Y limits plus and minus are constrained by lateral trim requirements. The forward X limits represent lateral-directional stability constraints and the aft X limits represent longitudinal trim requirements as constrained by thermal limits on the body-flap and elevons. The lateral trim and stability requirements for Y CG were based on flight control system performance with the following aerodynamics stress case: 1.5 yaw jets for trim, 3-sigma lateral variation set 19, L/D tolerance, auto bodyflap, $+0.00025$ Clo and -0.00025 Cno bent airframe coefficients, 3-degree aileron trim, 15-degree angle of attack, and 275 psf dynamic pressure at Mach 3.5, using Flight Assessment AERO Data (FAD) 14 from STS 41-D. ©[081497-4178B]

AERO/FCS stress testing has certified the CG limits to ± 2 inches Y CG for X CG's from 1075.7 to 1110 inches and to ± 1.5 inches Y CG for X CG's from 1074.2 to 1075.7, thus exceeding the original certified end item (CEI) CG specification. However, because of mass properties uncertainties of approximately ± 1 inch in X CG and ± 0.5 inch in Y CG, the CG boundaries depicted in the flight rule nominal CG envelope are observed at Mach 3.5 for planning purposes; that is, ± 1.5 inches Y CG for X CG's from 1076.7 to 1109 inches and ± 1 inch Y CG for X CG's from 1075.2 to 1076.7. ©[081497-4178B] ©[091098-6715]

The increase to the forward X CG limit and the associated Y CG limit was a result of analysis presented by Boeing North American Flight Control and Loads groups at the 145th Ascent/Entry Flight Techniques on December 19, 1997. ©[091098-6715]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-153****CG PLANNING (CONTINUED)**

- B. THE PLANNED ORBITER CG THROUGHOUT THE ENTRY PROFILE MUST BE WITHIN THE CG LIMITS. THE COMPUTATION OF THE CG ASSUMES NOMINAL CONSUMABLE USAGE, ENTRY MANEUVERS, AND A FORWARD SHIFT OF OMS PROPELLANT DURING ENTRY.

For real-time and preflight planning purposes, this rule states the assumptions involved for computation of the nominal EOM orbiter CG's (SODB, Volume II, section 3.0, Constraints and Limitations). The CG is to be calculated using a typical consumables profile which reflects the most realistic entry conditions.

- C. EOM PLANNING - ONLY THE CG MANAGEMENT TECHNIQUES LISTED IN PARAGRAPHS D THROUGH F WILL BE USED TO MANAGE THE EOM CG WITHIN THE CONTINGENCY CG ENVELOPE (REF. PARAGRAPH A). CONSIDERATION WILL BE GIVEN TO EXTENDING THE FLIGHT, IF ADDITIONAL MANAGEMENT WILL MINIMIZE VIOLATION OF THE NOMINAL CG ENVELOPE. ©[081497-4179B]

Paragraph A represents the certified operational envelope, and analysis of performance beyond this envelope is not complete. It is of the highest priority to contain the entry CG within the orbiter control trim capability. All CG management techniques will be used to protect this constraint.

Staying in orbit longer will allow use of orbit management techniques. These tools include generation of extra water and use of additional ARCS propellant.

- D. X CG MANAGEMENT TECHNIQUES INCLUDE THE FOLLOWING:

1. RETAINING OR DUMPING ADDITIONAL POTABLE WATER.

Keeping/dumping potable water can move the X CG about 1 inch for every 375 lb of water retained/dumped for a 220,000-lb orbiter. Water dumps move the X CG further aft.

2. OPTIMIZING THE CRYO MANAGEMENT PLAN (REF. RULE {A9-256}, CRYO O2/H2 TANK QUANTITY BALANCING)

The cryo management plan can be optimized to produce a more aft CG. This is accomplished by maintaining mission margin in the center manifold, or by using the forward tanks earlier than planned.

3. RETAINING OR DUMPING FRCS. WHEN CG AND LANDING WEIGHT CONSTRAINTS ARE MET, THE FRCS WILL BE DUMPED TO ZERO. ©[081497-4179B]

Since the FRCS tanks are significantly forward of the vehicle X CG, retaining/dumping forward propellant is a powerful tool for control of the X CG. For a 220,000-lb orbiter, the X CG can be changed by about 1 inch for every 280 lb of FRCS retained/dumped. FRCS dumps move the X CG aft. If an FRCS dump does not cause the CG envelope to be violated, then the dump should be performed. Dumping the FRCS to zero will keep landing weight to a minimum and aid in vehicle processing time.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-153****CG PLANNING (CONTINUED)**

4. MANAGEMENT OF OMS PROPELLANT USAGE IN DEORBIT TARGETING (REFERENCE RULE {A4-152}, DEORBIT BURN TARGETING PRIORITIES, FOR PRIORITIES): @[081497-4179B]
 - a. INCREASE OMS PROPELLANT USAGE TO MOVE THE CG FORWARD.

Backing up TIG from the optimum one OMS or two OMS TIG will use extra OMS propellant and move the X CG forward. For a 220,000-lb orbiter, 620 lb of OMS propellant usage will move the X CG forward by 1 inch. If additional propellant usage is required for CG control, the out-of-plane wasting technique can also be used to increase propellant usage.

- b. DECREASE OMS PROPELLANT USAGE TO MOVE THE C.G. AFT.

OMS propellant can be retained by burning at the optimum OMS time. Burning at the optimum leaves most OMS available in the aft, short of targeting with a prebank. Targeted prebank can be used to decrease the deorbit propellant usage even more. For a 220,000-lb orbiter, 620 lb of OMS propellant retention moves the X CG aft by 1 inch. (Reference Rule {A4-152}, DEORBIT BURN TARGETING PRIORITIES, for priorities.) @[081497-4179B]

5. OMS BALLAST MANAGEMENT - OMS BALLAST WILL BE RETAINED TO PROTECT THE FORWARD LIMIT OF THE CG ENVELOPE AT ANY POINT IN THE ENTRY PROFILE. THE AMOUNT OF OMS USED FOR BALLASTING WILL BE DETERMINED ASSUMING:
 - a. OMS PROPELLANT USED TO THE BALLAST BASELINE QUANTITY (REF A/E FLIGHT TECHNIQUES #67, MAY 1990).
 - b. ARCS PROPELLANT USED TRAPPED PLUS GAUGE ERROR (REF RULE {A6-305}, AFT RCS REDLINES).
 - c. FRCS DUMPED TO ZERO, UNLESS THE CAPABILITY TO PERFORM THE DUMP IS LESS THAN SINGLE FAULT TOLERANT.

OMS ballast is required when the X CG violates the forward end of the CG envelope. The OMS ballast required for forward X CG protection may not be used for the deorbit burn. Usage beyond the nominal profile will move the X CG forward. Therefore, the forward CG limit will be protected for the full entry redline. The OMS ballast is nominally computed assuming the FRCS is dumped to zero. Consideration should be given to depleting the FRCS prior to the deorbit burn if the post burn dump has been jeopardized by previous failures. @[081497-4179B]

FLIGHT RULES

A4-153

CG PLANNING (CONTINUED)

E. Y CG MANAGEMENT TECHNIQUES INCLUDE THE FOLLOWING:

1. MANAGING THE ARCS PROPELLANT BY UTILIZING THE RCS CROSSFEED CAPABILITY. RCS CROSSFEED WILL NOT BE USED TO IMPROVE THE ORBITER CG DURING DEORBIT AND ENTRY.

Use of the RCS crossfeed capability is effective for lateral control of the CG. Propellant from one aft pod may be used to feed the thrusters of both aft pods. RCS crossfeed is also used to balance RCS propellants or null the Y CG. For a 220,000-lb orbiter, 225 lb of ARCS can change the Y CG by 0.1 inch. To preclude tying OMS and RCS tanks, the RCS crossfeed will not be done during the deorbit burn and entry because the same set of propellant crossfeed lines would need to be used in the case of OMS engine failure or an RCS downmode during the deorbit burn.

2. MANAGING THE OMS PROPELLANT BY UTILIZING THE FOLLOWING PROCEDURES:

- a. USING OMS CROSSFEED DURING SINGLE OMS ENGINE BURNS.

NOTE: OMS CROSSFEED MAY BE USED TO MANAGE OMS PROPELLANT WHEN DOWNMODING FROM A TWO-ENGINE BURN TO A SINGLE ENGINE AS A RESULT OF AN ENGINE FAILURE.

Using the OMS crossfeed capability allows control of the Y CG at a rate of about 0.1 inch for every 225 lb of OMS for an orbiter weighing 220,000 lb.

- b. USING OMS MIXED CROSSFEED FOR OMS PROPELLANT TANK FAILURES. THIS REQUIRES MEMORY READ/WRITE PROCEDURES.

If fuel or oxidizer is trapped in a tank, it is possible to control the Y CG by using fuel or oxidizer from a good pod with fuel or oxidizer from the failed pod. However, a memory read/write procedure is required to properly control the valves.

- c. PERFORMING A PORTION OF A TWO ENGINE BURN FROM A SINGLE POD FOR A SPECIFIED DELTA V.

This provides a powerful means of CG control, and procedurally, the crew can reconfigure to straight feed for the remaining portion of the burn.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-153 CG PLANNING (CONTINUED)

F. COMBINATION X CG AND Y CG MANAGEMENT TECHNIQUES INCLUDE THE FOLLOWING:

1. USING THE OMS PROPELLANT TO ALTER THE CG'S BY MODIFYING THE PROPELLANT PLAN OR MAGNITUDE OF THE SCHEDULED OMS MANEUVERS.

Changing the tanks which are used for a given burn controls the propellant imbalance and lateral CG, while changing the magnitude of the burn alters the total propellant load. For an orbiter weighing 220,000 lb, each 225 lb of left-right imbalance causes a Y CG shift of about 0.1 inch. Each 620 lb of OMS will change the X CG by about 1 inch. @[081497-4179B]

2. USING THE OMS/RCS INTERCONNECT.

The left and right pod interconnect schedule can be modified to achieve the desired Y CG. OMS imbalance can be managed by feeding OMS to RCS to minimize the Y CG imbalance. Recall that, for a 220,000-lb orbiter, 225 lb of OMS retention can shift the Y CG by about 0.1 inch. X CG management can be affected via interconnect of RCS with OMS for attitude control maneuvers, thus controlling the X CG using nominal mission ops. OMS usage affects the X CG more than the RCS. For a 220,000-lb orbiter, 620 lb of OMS interconnect will affect the X CG by about 1 inch. @[120393-ED] @[081497-4179B]

A4-154 DOWNTRACK ERROR

DEORBIT WILL NOT BE ATTEMPTED WITH ORBITER STATE VECTOR DOWNTRACK ERRORS IN EXCESS OF 20 NM.

Prior to STS -1, analysis was performed and presented to Flight Techniques that indicated a 20 nm downtrack error was the maximum that could be steered out by AUTO guidance between 130,000 feet and TAEM interface in the presence of three-sigma lift-to-drag variations and worst case winds. The requirement to recover the energy error between 130,000 feet and TAEM interface was chosen because neither TACAN acquisition nor delta state update could be guaranteed to occur above 130,000 feet and because of large uncertainties in energy recovery capability (due to winds and lift-to-drag variations) after TAEM interface. This rule and Rule {A4-151}, IMU ALIGNMENT, are correlated.

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, and Rule {A11-52}, LOSS OF BOTH VOICE AND COMMAND, reference this rule. @[ED]

FLIGHT RULES

A4-155

SUN ANGLE LIMITS AND GLARE CRITERIA FOR INNER AND OUTER GLIDE SLOPES

A. SUN ANGLE LIMITS

FOR A RUNWAY TO BE GO, SUN POSITION ON FINAL MUST NOT BE WITHIN 10 DEGREES OF CENTERLINE IN AZIMUTH AND FROM 0 TO 20 DEGREES ELEVATION.

These criteria were established to preclude direct sunlight from obstructing the crew's vision on final approach.

B. SUN GLARE CRITERIA

FOR INNER AND OUTER GLIDESLOPES, SUN GLARE PREDICTIONS WILL BE CONSIDERED IN RUNWAY SELECTION IF MORE THAN ONE ACCEPTABLE RUNWAY IS AVAILABLE. THE PRESENCE OF SUN GLARE DOES NOT MAKE A RUNWAY NO-GO.

Sun glare occurs when the film of dirt from SRB separation and Sun angle on cabin windows causes diffuse forward scattering of sunlight. The worst scattering occurs when the Sun is at an angle of 40 degrees from the normal to the window. Glare drops in intensity for angles greater than or less than this. Sun glare is predicted if the Sun position on final approach is between 30 and 50 degrees from the normals to the CDR's or the PLT's front windows. Flight experience indicates that glare may be a problem, and it may in some cases create enough of a nuisance to justify trying to avoid it, assuming winds and weather permit and nav aids and landing aids criteria are met. Sun glare should, therefore, be considered in runway selection when more than one choice of runway is available, but it should not have the weight of a GO/NO-GO criterion. The very large angular extent of the glare zones and the impossibility of accurately predicting its severity would restrict landing opportunities if Sun glare were a GO/NO-GO criterion.

FLIGHT RULES

A4-156

HAC SELECTION CRITERIA

A. FOR THOSE APPROACHES THAT TRANSITION TO APPROACH AND LANDING GUIDANCE BY 9,000 FT ALTITUDE, THE OVERHEAD HAC APPROACH IS GENERALLY PREFERRED OVER THE STRAIGHT-IN HAC APPROACH. ©[021998-6510]

USE TABLE A4-156-I BELOW TO DETERMINE IF OTHER HAC SELECTION OPTIONS SHOULD BE CONSIDERED. THE 6-DEGREE-OF-FREEDOM (DOF) SIMULATION RESULTS (WHEN AVAILABLE) WILL TAKE PRECEDENCE OVER 3-DOF RESULTS.

TABLE A4-156-I - OVERHEAD HAC EVALUATION CRITERIA

3-DOF		6-DOF		HAC SELECTION OPTION
MAX HAC ALT ERROR LOW (FT)	MAX QBAR (PSF)	MAX HAC ALT ERROR LOW (FT)	MAX QBAR (PSF)	
? 3,700	? 290 [1]	? 4,500	? 315 [1]	OVERHEAD HAC NO-GO [2]
? 2,700	N/A	? 3,500	N/A	STRAIGHT-IN HAC PREFERRED [3]
? 1,700	N/A	? 2,500	N/A	DELAYED CSS PREFERRED [4]
? 1,700	? 290 [1]	? 2,500	? 315 [1]	NO RESTRICTIONS

NOTES:

- [1] THE QBAR CRITERION APPLIES ONLY TO HAC'S ? 300 DEG, FROM HAC INITIATION TO 20,000 FT ALTITUDE AGL.
- [2] THE OVERHEAD HAC IS NO-GO IF EITHER THE ALTITUDE ERROR OR QBAR CRITERION IS VIOLATED.
- [3] THE STRAIGHT-IN HAC IS PREFERRED OVER THE OVERHEAD HAC TO PROVIDE A MORE BENIGN TRAJECTORY. HOWEVER, IF THE OVERHEAD HAC IS SELECTED, REFER TO [4] BELOW.
- [4] NOMINAL CSS ACTIVATION SHOULD BE DELAYED UNTIL THE ONBOARD HAC ALTITUDE ERROR LOW IS NO LONGER DIVERGING (APPROXIMATELY 180 DEG HAC TURN REMAINING).

The approach and landing guidance transition altitude is an indication of the ability to control energy around the HAC based on the input upper level winds and atmosphere. Before transitioning to approach and landing guidance, four constraints must be satisfied. These constraints are altitude, lateral position, Qbar, and flight path angle limits referenced to the outer glideslope profile. The earliest altitude to transition is 10,000 ft, and 9,000 ft is considered high enough to preclude significant trajectory deviations on the outer glideslope. The evaluation will be performed by Flight Dynamics Entry Analysis tools using measured and forecasted wind data and AUTO flight control/AUTO speedbrake.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-156****HAC SELECTION CRITERIA (CONTINUED)**

Overhead HAC's are generally preferred over straight-in HAC's because they provide the best geometry for allowing clean-up of the onboard navigation state by TACAN and because they provide an energy downmode option. However, Table A4-156-I provides special considerations for HAC selection that provide margin to compensate for the severe conditions of the day. These conditions and corresponding criteria were presented to the Ascent/Entry Flight Techniques Panel #137 on February 27, 1997, and were developed in response to an analysis that showed TAEM guidance may be unable to limit HAC max Q_{bar} and/or altitude error low for larger HAC's (over approximately 300 degrees) due to N_z limiting. ©[021998-6510]

The Q_{bar} limit for HAC's > 300 deg specified in Table A4-156-I is an additional constraint to the Q_{bar} limit for Mach < 1 specified in Flight Rule {A4-207A}.2, ENTRY LIMITS. These constraints provide 3-sigma protection against violating the certified structural and GN&C Q_{bar} limit of 375 psf (333 KEAS) in the subsonic region as defined in SODB Volume V. For smaller HAC turns (under 300 degrees), Flight Rule {A4-207A}.2, ENTRY LIMITS, provides adequate Q_{bar} protection because the vehicle will not encounter N_z command limiting, and Q_{bar} will stay within the guidance I-loaded Q_{bar} limit of 350 psf (321 KEAS).

The altitude error low constraints defined in Table A4-156-I were the result of an analysis done using a modified Monte Carlo technique that varied the vehicle navigation state, navigation sensor inputs and atmosphere, but did not vary the winds. The 6-DOF 50-cycle Monte Carlo results showed that at a predicted altitude error low of 5,000 ft or more, all 50 cases experienced a HAC shrink, a significant percentage of which were full HAC shrink, and some cases were seen where the HAC phase was delayed. Although many of the cases were able to achieve a nominal approach and landing guidance transition, an altitude error low of 5,000 ft is being set as the limit of entry guidance capability due to the extremely dynamic nature of the resulting trajectory and its sensitivity to additional dispersions. Exceeding the 4,500 ft (6-DOF) maximum altitude error low criteria results in greater than an approximately 80 percent chance of triggering a HAC shrink at KSC 15 (approximately 50 percent at EDW 04), but provides 500 ft of protection from the 5,000 ft limit. Exceeding the 3,500 ft (6-DOF) maximum altitude error low criterion results in greater than 35 percent chance (approximately 1-sigma protection) of triggering a HAC shrink, but provides 1,500 ft of protection from the 5,000 ft limit. These backoffs provide margin to protect for limitations in the analysis which cannot take into account wind persistence or the full range of real-world HAC geometries, runway directions, and wind direction and magnitudes. The 3,700 ft overhead NO-GO and 2,700 ft straight-in preferred 3-DOF limits from Table A4-156-I are based on an average 3-DOF to 6-DOF TAEM simulation bias of 800 ft determined during this same analysis.

The intent of delaying nominal CSS activation is to avoid unnecessary trajectory perturbations for HAC's that are predicted to be dynamic and/or have low performance margin. Analysis of HAC altitude errors from a small sample of flights (four) with large HAC's indicates CSS flight results in trajectories with maximum HAC altitude errors low approximately 2,000 ft greater than 3-DOF real-time predictions. The 1,700 ft limit (3-DOF) in Table A4-156-I provides 2,000 ft of CSS dispersion protection against exceeding the 3,700 ft maximum altitude error low limit (3-DOF) used to NO-GO overhead HAC's. ©[021998-6510]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-156

HAC SELECTION CRITERIA (CONTINUED)

Predicted altitude errors low in excess of 2,500 ft (6-DOF) are indicative of guidance Nz limiting which results in a nose-low pitch attitude. Any additional nose-low pitch attitude errors beyond the guidance Nz command while guidance is Nz limited will likely result in substantial performance degradation (faster airspeed, higher Nz, greater altitude rate, more roll, steeper flight path angle, etc.). The most performance-critical region of TAEM is HAC initiation, so it is especially prudent to minimize deviations from guidance during the initial portion of the HAC. Once the guidance Nz command is no longer limited, the vehicle's pitch attitude will get shallower and the HAC altitude error will stop diverging and soon begin to converge. However, it is not necessary to wait until the HAC altitude error is converging to engage CSS, since substantial performance degradation is unlikely after the vehicle's pitch attitude has shallowed. The best tools for determining if the altitude is diverging from its reference are onboard, so identifying when CSS can be taken is best performed by the crew. ©[021998-6510]

The 3-DOF evaluation will be accomplished with the Descent Design System (DDS) and the 6-DOF evaluation will be accomplished with the Spacecraft Trajectory Analysis and Mission Planning Simulation (STAMPS). In the event that there is a conflict in meeting the criteria in Table A4-156-I between the 3-DOF and 6-DOF evaluations, the results of the 6-DOF evaluation will be favored due to the higher fidelity of the processor (reference STF no. DFD-97-4235-016, dated March 12, 1997).

Note: Adjusting for the nose-low pitch attitude due to guidance Nz command limiting by manually biasing the guidance Nz command and pitching up is not recommended because of the potential for violating the GN&C upper angle of attack defined in the SODB Volume V. ©[021998-6510]

- B. IF NONE OF THE OPTIONS IN PARAGRAPH A ALLOWS TRANSITION TO APPROACH AND LANDING GUIDANCE BY 9,000 FEET ALTITUDE, THEN CONSIDER A 24-HOUR WAVE-OFF AND/OR USE OF THE SECONDARY LANDING SITE TO ACHIEVE NOMINAL APPROACH AND LANDING GUIDANCE TRANSITION, CONSISTENT WITH RULE {A2-202}, EXTENSION DAY GUIDELINES. ©[021998-6510]

Delaying 1 day increases the probability of going to the PLS and of having acceptable heading alignment phase guidance capability.

- C. IF NONE OF THE OPTIONS IN PARAGRAPH A OR B ALLOW TRANSITION TO APPROACH AND LANDING GUIDANCE BY 9,000 FEET ALTITUDE, THEN CONSIDER USE OF THE HIGHEST PRIORITY RUNWAY/HAC OPTION THAT MEETS THE TRANSITION CRITERIA BY 6,000 FEET ALTITUDE. ©[021998-6510]

Transition to approach and landing guidance is forced at 5,000 feet altitude, whether or not the four transition constraints have been met. A 6,000-foot transition altitude indicates the AUTO system satisfied the four constraints late in the transition period, which should allow for acceptable landing conditions even with additional dispersions. ©[061297-6006]

Rule {A2-202}, EXTENSION DAY GUIDELINES, references this rule. ©[061297-6006]

FLIGHT RULES

A4-157 ENERGY DOWNMODING

THE STRAIGHT-IN OR MINIMUM ENERGY POINT (MEP) OPTION WILL BE SELECTED WHEN A VALID KALMAN FILTER SOLUTION OF ENERGY CROSSES THE ENERGY VERSUS R-GO DOWNMODE CRITERIA. THE MEP SHOULD NOT BE SELECTED BETWEEN HAC INTERCEPTION AND REACHING THE 180-DEGREE POINT ON THE SPIRAL. THE ONBOARD ALERT WILL BE HONORED IF THE MCC SOLUTION IS UNAVAILABLE.

MEP selection is an energy downmode option which will decrease R-GO by approximately 6 miles. This call should be made only when the ground Kalman filter solution is valid. The ground solution is prime for calling the straight-in or MEP options. If MEP is selected between HAC intercept and 180-degree point on the HAC, guidance may add 360 degrees to the HAC causing unexpected approach geometry and more energy problems.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-158****MANEUVER EXECUTION MATRIX (CONTINUED)**

OVERBURN SHUTDOWN CRITERIA - December 1979 Flight Techniques determined that a 3-sigma low OMS engine performance would increase a nominal deorbit 2-OMS burn duration by approximately 3 seconds (6 seconds for 1-OMS) and that a 2000 micro-G accelerometer error would increase the maneuver time by 5 seconds (10 seconds for 1-OMS). The onboard guidance will account for off-nominal OMS engine performance and adjust the burn time as necessary to achieve the targeted conditions assuming a good navigation state. However, if IMU accelerometer errors are present, the velocity to be gained will be updated incorrectly such that the targeted conditions may not be met. If the accelerometer error is in the direction to result in an underburn, the burn will be completed using the RCS jets. If the accelerometer error is in the direction to result in an overburn, a manual shutdown will be performed at the pre-burn TGO plus 5 seconds for 2-OMS (10 seconds for 1-OMS) to avoid overburns greater than 20 fps. ©[011295-1691]

Terminating at $T_{GO} = 0$ is sufficient for on-orbit and uphill maneuvers. If the maneuver is targeted and cannot be overburned, any residuals will need to be trimmed.

EARLY C/O MNVR COMP CRITERIA - Nominal, ATO, and AOA OMS-1 maneuver completion is required to attain a safe insertion orbit. Nominal OMS-2 completion to a perigee of Min Hp (ref. the Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS) is required for a safe orbital lifetime of 24 hours, assuming OMS-1 apogee of 150 nm or, 3 orbits assuming OMS-1 apogee of 105 nm. An AOA OMS-2 is a deorbit and, since perigee is already less than Safe Hp, the maneuver must be completed to attain EI targets. ©[ED]

Any orbital maneuvers considered critical should be completed due to the criticality. Also, based on the definition of a critical maneuver, it cannot be rescheduled. Therefore, if the maneuver is not completed at that time, severe consequences may result. A payload separation maneuver is critical for crew safety. Therefore, the maneuver should be completed to at least a minimum separation to guarantee less than 10X tile damage.

A noncritical maneuver should not be completed manually since it can be rescheduled if necessary. Also, this allows time to determine the failure which caused the maneuver to terminate early.

Deorbit burns that cut off at a perigee greater than Safe Hp will be retargeted for a subsequent deorbit one orbit later or up to 24 hours later since the orbital lifetime allows the delay. Deorbit burns that cut off at perigee less than Safe Hp should be completed at all costs to attain EI conditions since the perigee is unsafe for orbital lifetimes of reasonable lengths to retarget.

RCS TRIM - Ascent and deorbit burns are large and all uphill and EI targets will be met within allowable tolerances if the delta V imparted is within 2 fps. Specifically, a 2 fps underburn for deorbit equates to a 30 nm energy error at EI, which is an acceptable error, well within guidance capability to converge by $M = 12$. Uphill delta-V accuracy requirements are even less critical, and 2 fps is deemed very achievable.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-158 MANEUVER EXECUTION MATRIX (CONTINUED)**

Critical orbital maneuvers should be completed to 0.2 fps due to their criticality and since the maneuver cannot be rescheduled to make up for the trim errors. Additionally, it is important to trim payload separation maneuvers to within 0.2 fps of the design limit to meet tile damage limit criteria.

It is not necessary to trim noncritical orbital maneuvers precisely. Two fps was selected since PEG-7 guidance can achieve this for an OMS burn without any RCS trimming.

MANUAL TAKEOVER, MNVR INHIBIT, OR TERMINATION CRITERIA - A 5-degree attitude deadband is the largest available, and an ignition attitude error or deviation greater than this indicates flight control malfunction. Nominal ATO and AOA OMS-1 and -2 are time-critical burns sequenced such that the ignition attitude may not have been attained. For out-of-attitude cases or attitude deviations during the maneuver, the maneuver should still be performed (i.e., not inhibited or terminated), but performed manually. The deorbit burn attitude is entered in a controlled, timely manner, and the maneuver can be postponed for an unacceptable attitude error. A maneuver inhibit should be accomplished for attitude errors greater than 5 degrees. If ignition has occurred, maneuver completion is important, and a manual takeover should be performed for deviations greater than 5 degrees.

Critical maneuvers should be completed once started. Payload separation maneuvers should be completed to at least minimum separation delta-velocity. This is due to the definition of a critical burn. Critical maneuvers should not be executed until the vehicle attitude error is less than 5 degrees or until the end of the TIG slip window, whichever occurs first. If the attitude error during the maneuver drifts outside 5 degrees, the crew should take over and manually steer the vehicle towards the correct attitude.

Noncritical orbital maneuvers should not be executed if the vehicle is not in attitude. Also, if the vehicle drifts out of attitude during the maneuver, the maneuver should be terminated. A later maneuver can be scheduled to correct errors imparted to the trajectory if necessary.

A4-159 ORBITER LANDING WEIGHT

A. THE FOLLOWING CONDITIONS ARE ASSUMED FOR THE CALCULATION OF THE ORBITER EOM LANDING WEIGHT: ©[081497-4179B]

The resulting calculations of X CG, Y CG, and landing weight are reported as the expected EOM conditions. The X CG and Y CG data used from this step are used in the DEL PAD.

1. THE PLANNED DEORBIT BURN IS SUCCESSFUL AND THE DESIRED OMS BALLAST REMAINS ONBOARD AS THE RESIDUAL.

Assumes a nominal deorbit burn and entry for EOM conditions. ©[081497-4179B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-159

ORBITER LANDING WEIGHT (CONTINUED)

2. UNPLANNED PAYLOAD RETURN WEIGHT MUST BE ? ATO LANDING WEIGHT, AND DEORBIT OPPORTUNITIES MUST MEET THE ORBITER THERMAL CRITERIA FOR NOMINAL EOM. ©[041196-1789B] ©[081497-4179B]
 3. FLIGHT SPECIFIC EXCEPTIONS TO ANY OF THE ABORT OR END OF MISSION LANDING WEIGHT LIMITS WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX WITH ASSOCIATED SSP WAIVERS OBTAINED, AS REQUIRED.
- * NOTE: THE ATO LANDING WEIGHT LIMITS ARE REDUCED TO PROTECT THE ENTIRE XCG ENVELOPE FOR ALL ATO OPPORTUNITIES AND ALL SEASONS. HEAVIER LANDING WEIGHTS MAY BE ACCEPTABLE BUT MUST BE EVALUATED ON A MISSION-SPECIFIC BASIS. ©[101096-4211A]

Any flight with a manifest that results in an intact abort or EOM landing weight greater than currently certified limits must have a waiver specifying the limit for that flight. The 230 KLB high inclination ATO weight limit protects for shallow deorbit on the most thermally stressful ATO deorbit opportunities for all seasons and all XCG's. ATO deorbit opportunities may exist for which a 233 KLB downweight would be acceptable, but to exceed the 230 KLB limit, these opportunities must be determined by pre-flight analysis and be documented in the flight rules annex. Flight-specific exceptions to the landing weight limits are documented in Flight Rules Annex rule, TRAJECTORY AND GUIDANCE PARAMETERS. When OMS ballast techniques are required, the first priority is protecting the forward X CG limit; therefore, the OMS ballast required for protecting forward X CG may not be reduced to achieve the landing weight limit. OMS propellant in excess of the ballast may be used to reduce the orbiter landing weight. (Ref. PRCB S40522J.) Early mission termination may result in a landing weight that slightly exceeds the unplanned payload return limit due to nonpropulsive consumables still onboard. ©[101096-4211A]

The thermal cross range limit for end-of-mission deorbit opportunities is determined preflight. In the event of early mission termination and unplanned payload return, a thermal evaluation will be conducted for the available deorbit opportunities, if time permits (i.e., next PLS or MDF). Deorbit opportunities will be selected for crossrange and approach geometry which result in thermally acceptable entries. If none of the available deorbit opportunities are within thermal limits, the opportunity with the minimum thermal violation will be selected. The landing weight capability limits are defined in NSTS 07700, Volume III (updated by PRCBD NO. S052638Q). The NSTS 07700, Volume X landing weight limits, which are certification requirements, will eventually become the new landing weight limits once certification and/or the orbiter thermal envelope expansion occurs. The orbiter thermal limits are documented in SOD, Volume V (NSTS 08934), Orbiter Flight Capabilities Envelopes. ©[041196 1789B] ©[101096-4211A]

DELTA-T UPDATE CRITERIA

A DOWNTRACK CORRECTION TO THE STATE VECTOR AND A BFS NAVIGATION VECTOR TRANSFER WILL BE PERFORMED BETWEEN DEORBIT AND 300,000 FEET IF A VALID DELTA-T SOLUTION EXISTS, NAVIGATION SYSTEM ANOMALIES INDICATE A HIGH LIKELIHOOD OF NAVIGATION ERRORS, AND THE INSTANTANEOUS DOWNTRACK ERROR COMPUTED BY THE DELTA-T PROCESSOR IS GREATER THAN 8 NM. FOR ERRORS LESS THAN 8 NM, NO UPDATE WILL BE REQUIRED.

An entry navigation Monte Carlo analysis performed from TIG through touchdown, utilizing the Oracle entry navigation simulation, indicated that there is no onboard navigation requirement for delta-T update for navigation downtrack error less than 8 nm (see minutes for Ascent/Entry Flight Techniques Panel Meeting #71 held September 21, 1990). Eight nm is the expected 3-sigma downrange error resulting from the sensor error models and initial navigation error assumptions selected for this study. These initial conditions have been used consistently for Oracle studies since before STS-1. The maximum downtrack error observed at EI for STS-1 through STS-31 was 2 nm.

Studies performed using the Entry Navigation Reconstruction program indicate that, due to unmodeled aerodynamic accelerations, the incorporation of large delta-T corrections several minutes after initial IMU processing can result in a diverging navigation state. This study indicated that 300,000 feet represents a minimum safe altitude for incorporating delta-T updates.

At least one C-band radar is required for the generation of the delta-T downtrack correction. In order for the computed delta-T to be considered valid, agreement between the AOS and LOS computed values is required. Data processed from a second independent C-band source, if available, can be used to confirm the presence of a large onboard state error. The accuracy of the delta-T solution is degraded by the presence of large radial or crosstrack errors. The Ground Navigation Officer will analyze the C-band tracking data residuals and signature to determine whether the delta-T correction will be valid.

Large onboard navigation state errors observed during the delta-T tracking pass can be caused by an inaccurate onboard navigation state vector prior to deorbit, multiple IMU failures, poor IMU performance, or the erroneous execution of navigation related crew procedures. The presence of a large onboard navigation state error should be presaged by such a problem.

FLIGHT RULES

A4-202

DEORBIT BURN COMPLETION

THE FOLLOWING TECHNIQUES, IN ORDER OF PRIORITY, WILL BE UTILIZED IN THE EVENT OF DELTA V DEFICIENCY AT OMS CUTOFF FOR THE DEORBIT MANEUVER.

- A. TRIM WITH THE ARCS, NOT TO EXCEED ARCS QUANTITY 1.
- B. TRIM WITH THE FORWARD RCS TO DEPLETION.
- C. PREBANK TO THE REDESIGNATION CONTINGENCY LIMIT FOR THE PRIME LANDING SITE (PROTECTS THERMAL CONSTRAINT OR NO GREATER THAN 135-DEGREE PREBANK).
- D. REDESIGNATE TO THE BACKUP SITE (IF AVAILABLE) WITH PREBANK TO THE REDESIGNATION CONTINGENCY LIMIT (NORTHROP FOR EDWARDS PLS).
- E. TRIM WITH THE AFT RCS, NOT TO EXCEED ARCS QUANTITY 2.
- F. PREBANK AS REQUIRED UP TO 180 DEGREES.

This rule was developed in various working group meetings to define the procedures for completing the deorbit burn after all OMS downmode options have been exercised and ARCS fuel to the ARCS entry redline has been used. The deorbit burn completion cue cards incorporate the techniques, according to the defined priorities.

ARCS propellant is budgeted, including entry DTO's, PTI's, etc., in option A for burn completion. If the targets can be accomplished using the fuel down to ARCS quantity 1, the vehicle integrity and crew safety have not been compromised. This ARCS option is preferred to the FRCS because no large attitude change is required, nor is the execution of the more complicated FRCS burn procedure required.

Option B is trimming with the FRCS. This propellant, if not used for trimming the burn, is either dumped prior to entry or maintained for ballast. Use of the FRCS fuel is preferred over an equivalent prebank. The thermal effects of the prebank are considered more severe than execution of the FRCS trim procedures.

Options C and D incorporate use of the prebank to obtain atmospheric capture while maintaining ARCS quantity 1 fuel. Use of the prebank stresses the TPS. Option C limits the prebank to the redesignation limit while maintaining the capability to land at the prime site. The redesignation limit will not be greater than 135 degrees of prebank, or exceedance of a thermal limit based on 35 mission wing leading edge reuse temperature constraint (TBD degrees F). Current analysis tools use a simplified thermal model which overpredicts wing leading edge temperature by 150 degrees F. For analysis purposes, the wing leading edge thermal limit will be 2950 degrees F. Option D calls for a prebank to the redesignation limit to the backup

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-202****DEORBIT BURN COMPLETION (CONTINUED)**

landing site (if available). Vehicle turnaround may be lengthened due to the lack of postlanding support at the backup landing site. The computations of L OMS Hp, R OMS Hp, PRI Hp, and B/U Hp will assume the delta Hp due to prebank to the redesignation limit, regardless of whether a backup site is available or not.

Option E uses fuel below the ARCS entry redline, down to ARCS quantity 2. This provides enough fuel for attitude control to $Q\text{-bar} = 20$ psf. After $Q\text{-bar} = 20$, aerodynamic control is possible but risky without the yaw jets. NO YAW JET is now a certified entry mode.

The last option calls for using prebank between the redesignation limit up to the maximum of 180 degrees. This is the last resort since the use of maximum prebank and no yaw jet control after $Q\text{-bar} = 20$ psf indicate that the capability to reach the landing site, vehicle stability, TPS integrity, and crew safety are being compromised. Preserving this prebank (from the redesignation limit to 180 degrees) as the very last option also provides some margin in case the FRCS burn does not provide the delta V predicted.

A4-203**ENTRY NAVIGATION UPDATE PHILOSOPHY** @[072601-4530B]

A. GPS WILL BE USED TO CORRECT ONBOARD NAVIGATION ERRORS THAT EXCEED FLIGHT RULE LIMITS (REF RULES {A4-204}, DELTA STATE POSITION UPDATES, AND {A4-205}, DELTA STATE VELOCITY UPDATES) WHEN GPS IS VERIFIED TO BE FUNCTIONING PROPERLY AND THE FOLLOWING CRITERIA ARE SATISFIED: @[062702-5439]

1. GPS VERSUS GROUND FILTER UVW POSITION DIFFERENCES ? 3000 FEET FOR EACH COMPONENT ABOVE 130 KFT ALTITUDE AND ? 1000 FEET FOR EACH COMPONENT BELOW 130 KFT ALTITUDE.
2. GPS COMPUTED VERSUS ACTUAL TACAN RANGE DIFFERENCES ? 0.5 NM FOR TACAN STATIONS OPERATING WITHIN ACCEPTABLE LIMITS (REF RULE {A8-52B}.2, SENSOR FAILURES).

THE GROUND DELTA STATE PROCESSOR WILL BE USED AS A SECOND PRIORITY TO CORRECT ONBOARD NAVIGATION ERRORS. @[062702-5439]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-203****ENTRY NAVIGATION UPDATE PHILOSOPHY (CONTINUED)**

A GPS update or a delta state update will be performed to correct onboard state vector errors that exceed flight rule limits. The ground delta state update process assumes the following: the ground Kalman filter solution is valid (reference Rule {A4-51}, KALMAN FILTER SOLUTION), state vector errors are linear with time, velocity errors are constant, ground and onboard runways agree, and the onboard navigation update time will be close to the predicted update time. Navaid inhibits are required for velocity delta state updates and navigation corrections after HAC intercept. After a delta state update is performed, it is possible that the remaining onboard navigation errors would have to be corrected with an additional delta state update. The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. If GPS receiver performance has been good, the decision to perform a GPS update instead of a delta state update is made based on state vector differences between GPS and the ground filter. The criteria for acceptable UVW position differences were discussed at the AEFTP #182 on February 15, 2002 and were established based on: 1) the amount of onboard navigation error correction and associated delta state update accuracy, 2) ground filter errors at initial low elevation tracking angles, 3) onboard Navaid processing and guidance capability after a biased GPS state vector update, and 4) the desire to have a simple two-tier console limit procedure which reflects the increased accuracies at lower altitudes. Once the criteria for GPS versus ground filter position differences have been satisfied, a direct verification that GPS is acceptable for the update has been performed. This is the primary method for GPS state vector confirmation. Ground filter velocity output is very noisy throughout the entry period and is therefore not used in the criteria for evaluating the GPS vector. Significant errors in the GPS velocity components without a corresponding error in the position components or the FOM value would be a rare condition. ©[062702-5439]

Another crosscheck on GPS position accuracy is the difference between GPS computed and actual TACAN range measurements. The MCC has a ground processor that computes equivalent TACAN measurements based on downlisted GPS state vectors. If the TACAN ground station is confirmed to be within acceptable limits (ref. Rule {A8-52B}.2, SENSOR FAILURES), the difference between the GPS computed and actual TACAN range measurements should not be more than 0.5 nm. The 0.5 nm range check accounts for small spec errors in the GPS vector at the FOM = 5 limit (0.1 nm) and for potential spec-level calibration errors in both the TACAN LRU (0.1 nm) and ground station hardware (0.3 nm). Navaid inhibits are not required before a GPS navigation update. Once GPS state vector accuracy has been confirmed with ground filter solutions, a GPS update would provide a more accurate onboard navigation correction in a timelier manner compared to the delta state update process. ©[072601-4530B] ©[062702-5439]

A4-203

ENTRY NAVIGATION UPDATE PHILOSOPHY (CONTINUED)

- B. GPS OR VELOCITY DELTA STATE UPDATES WILL REQUIRE CSS MODE TO PREVENT EXCESSIVE TRANSIENT MANEUVERS. @[072601-4530B]

If a GPS update is incorporated with metering logic overridden or a total delta state update is incorporated, the velocity corrections put a step function into the flight control system. The transients caused by the step function can cause large maneuvers which could overstress the vehicle or cause loss of control. Going CSS when a GPS (with metering overridden) or velocity delta state update is incorporated allows the crew to manually filter transients.

- C. POSITION DELTA STATE UPDATES OCCURRING NEAR TAEM INTERFACE (M = 5 TO M = 2.5 FOR EOM AND AOA AND M = 5 TO M = 3.2 FOR RTLS) WILL REQUIRE CSS TO PREVENT EXCESSIVE TRANSIENT MANEUVERS.

Entry guidance is targeted towards a specific set of end conditions at TAEM interface. For any given position error, the correction needed to satisfy the interface conditions grows as you approach TAEM. Going CSS for a delta state update close to TAEM interface allows the crew to filter the guidance commands to keep from overstressing the vehicle.

- D. DELTA STATE UPDATES WILL NORMALLY NOT BE PERFORMED AFTER HAC ACQUISITION. HOWEVER, IF VISUAL CONTACT WITH THE RUNWAY CANNOT BE MAINTAINED BY THE CREW, GPS OR DELTA STATE UPDATES WILL BE CONTINUED AS LONG AS THE ONBOARD STATE VECTOR CAN BE IMPROVED.

After HAC intercept, a delta state update will normally not be performed if the crew has visual contact with runway because transients caused by a delta state could prove distracting. Also, the external data sources (TACAN, BARO, MLS) would need to be deselected in order to allow the ground processor to compute the proper corrections. A GPS update may be performed after HAC intercept to allow the crew to fly good guidance commands. @[072601-4530B]

FLIGHT RULES

A4-204

DELTA STATE POSITION UPDATES

- A. FOR POSITION COMPONENT EXCEEDANCE, A GPS OR THREE-COMPONENT (POSITION ONLY) UPDATE WILL BE EXECUTED (REF RULE {A4-203}, ENTRY NAVIGATION UPDATE PHILOSOPHY). ©[072601-4531] ©[062702-5440]

The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values.

- B. POSITION REQUIREMENTS:

RTLS				EOM			
	DELTA POSITION (FT)				DELTA POSITION (FT)		
	X	Y	Z		X	Y	Z
H > 100K FT...	18K	18K	6K	H > 130K FT...	48K	48K	12K
H < 100K FT...	6K	6K	3K	H < 130K FT...	6K	6K	6K
				H < 90K FT...	6K	6K	3K

This rule contains the criteria for performing a position-only delta state update to correct the onboard navigation for both GRTLS and end of mission. The delta state processor is a ground processor that compares the onboard vector to time-correlated radar tracking data and outputs the deltas in runway Cartesian coordinates. This data is observed on the ground as three components of position and three components of velocity. The position update limits were set in order to meet guidance imposed navigation accuracy requirements (ref. STS 81-0366, appendix A, Navigation Performance Requirements). These accuracy requirements were identified to ensure auto guidance capability to achieve the runway after correcting the onboard navigation state. The guidance requirements are ramp functions of altitude, but in order for a ground operator to observe six error components on a constantly updating digital display and compare them to variable error limits, it was necessary to simplify the update criteria. When the errors observed in the onboard state exceed the limits defined in this rule, a GPS or delta state update is initiated on the ground. For GRTLS, the two tier set of limits was chosen with a breakpoint at 100,000 feet altitude, since it is desired to remove state errors before TAEM initiation. The limits above 100,000 feet altitude are tighter than for EOM, since there is little ranging control exercised in GRTLS until TAEM, which is initiated at M=3.2 or around 92,000 feet altitude. For EOM, the guidance requirements dictate that the errors be under control and decreasing with altitude by around 130,000 feet, the point at which TACAN's are usually incorporated into the onboard navigation state. Therefore, this point was chosen as the breakpoint for the EOM three-tier update criteria.

©[072601-4531]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-204****DELTA STATE POSITION UPDATES (CONTINUED)**

The third tier was added for EOM to allow a further breakdown of allowable altitude error. Instead of a delta-Z limit of 3k feet at an altitude of 130,000 feet, a 6k-foot error is permitted between 130,000 and 90,000 feet, and then the 3k limit applies below 90,000 feet altitude. This additional limit may preclude the likelihood of an unnecessary delta state update to correct a delta-Z error that could be reduced by the use of DRAG processing in the more accurate lower region of the onboard altitude atmospheric model. TACAN processing will not have much effect on the altitude error unless the orbiter passes over the TACAN ground station so that the majority of the range measurement is altitude rather than downtrack and crosstrack.

Rule {A4-151}, IMU ALIGNMENT, and Rule {A4-206}, NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF), reference this rule.

A4-205**DELTA STATE VELOCITY UPDATES**

DUE TO ONBOARD DRAG ALTITUDE UPDATING, THE DELTA STATE VELOCITY COMPONENTS ARE NOT SUFFICIENTLY ACCURATE TO MONITOR THE ONBOARD VELOCITY ERRORS; THEREFORE, THE ONBOARD VELOCITY ERRORS WILL BE EVALUATED USING GPS AND THE RADAR HIGH SPEED FILTER VELOCITY ERRORS. AN ONBOARD VELOCITY UPDATE WILL BE PERFORMED FOR A VELOCITY ERROR > 75 FPS IN ANY COMPONENT. RADAR VELOCITY 3 SIGMA UNCERTAINTIES OF UP TO 60 FPS COULD RESULT IN ONBOARD VELOCITY ERRORS OF UP TO 135 FPS PRIOR TO A GROUND UPDATE. IF A DELTA STATE VELOCITY UPDATE IS REQUIRED, DRAG ALTITUDE UPDATING WILL BE INHIBITED TO ASSURE VALID COMPUTATION OF PROPAGATED VELOCITY ERRORS, AND A SIX-COMPONENT UPDATE (POSITIONS AND VELOCITIES) WILL BE EXECUTED. GPS WILL BE USED TO CORRECT ONBOARD VELOCITY ERRORS IF GPS IS VERIFIED TO BE FUNCTIONING PROPERLY. NAVAID INHIBITS ARE NOT REQUIRED FOR A GPS UPDATE (REF RULE {A4-203}, ENTRY NAVIGATION UPDATE PHILOSOPHY). @[072601-4532] @[062702-5441A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-205

DELTA STATE VELOCITY UPDATES (CONTINUED)

An update of onboard velocity will be performed for velocity errors > 75 fps in any runway component. This number was chosen to meet a flight control system requirement when the FCS is using navigation-derived air data, while at the same time, considering the radar 3-sigma velocity uncertainty of 60 fps. Drag altitude updating of the onboard navigation must be inhibited prior to computing a velocity delta state since it corrupts the computation of velocity errors in the delta state processor. Two sets of state vector errors are available on a ground display in runway coordinates. The output of the high speed radar filter is referred to as local deltas, whereas, the output of the delta state processor is referred to as propagated deltas. The local deltas represent the current state errors. The propagated deltas represent the expected state errors at some time in the future; these deltas are used to generate a delta state update. They are computed assuming that the state errors are linear, that the current velocity errors are constant over some short period of time, and that the update will be applied at the end of that time. Since the velocity errors are computed from changes in position, any external update, such as drag altitude updating, will mask the true state error and cause the velocity delta to be wrong. Therefore, external navigation aids have to be inhibited prior to computing a delta state update involving velocities. Any time a velocity update is required, a position and velocity delta update will be executed, since velocity errors will also cause position errors.

The use of GPS to correct onboard navigation errors is preferred over the delta state update process as long as GPS is verified to be functioning properly (no hardware problems or commfaults, low FOM, tracking four satellites). Caution should be taken when using GPS state vectors with FOM's >5 (650 feet position error one sigma) since the estimated position error increases rapidly with higher FOM values. The three-sigma velocity accuracy requirement for GPS is 0.1 meters/sec for the horizontal and vertical components when GPS is operating in the Precise Positioning Service (PPS) mode and satisfying the assumptions for Table 3.4.1-1 of the System Requirements Document for Orbiter GPS Navigation System (SSD94D0096). Postflight analyses have confirmed very good GPS state vector accuracies in the TACAN processing region. Radial, downtrack, and crosstrack position and velocity differences between GPS and the USA Navigation Best Estimated Trajectory (BET) product have been less than 200 feet and 2 fps, respectively the majority of the time. Navaid inhibits are not required before a GPS navigation update. ©[072601-4532]

FLIGHT RULES

A4-206

NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF)

This rule provides direction to the crew and ground for the management of external sensor data incorporation into the navigation filter. It assumes that the crew AIF switches are initially in INHIBIT for TACAN and BARO and in AUTO for drag altitude processing. The rule is presented in matrix form to facilitate correlation of various situations to the action to be taken for those situations.

A. TACAN-INITIAL PROCESSING (INITIALLY IN INHIBIT):

	RATIO <1	RATIO >1		1-LOCK
		BAD TACAN	BAD STATE VECTOR	
EARLY NO COMM (V _{REL} > 6000 [1] FPS H > 130K FT)	REMAIN IN INHIBIT	REMAIN IN INHIBIT	REMAIN IN INHIBIT	REMAIN IN INHIBIT
COMM	GROUND CALL; AUTO [3]	GROUND CALL; INHIBIT IF STATION, SWITCH TO B/U CH IF LRU, ? STATE UPDATE AS REQD	GROUND CALL; ? STATE OR FORCE RETURN TO AUTO WHEN RATIO <1	GROUND CALL; DESELECT MISSING TACAN'S (RESELECT NON-FAILED TACAN LRU'S WHEN 2 LOCK)
LATE NO COMM (V _{REL} < 6000 FPS, H < 130K FT)	AUTO	TROUBLESHOOT TO DETERMINE CAUSE OF EDITING A. SWITCH GROUND STATIONS B. CHECK IMU STATUS C. OBSERVE RESIDUAL, RATIO BEHAVIOR D. MONITOR WITH HSI		WAIT UNTIL V _{REL} <5500 FPS [2] THEN DESELECT MISSING TACAN'S (DO NOT FORCE)
		AUTO	FORCE	

NOTES:

- [1] FOR RTLS, V_{REL} < 6500 FPS.
- [2] FOR RTLS, V_{REL} < 4700 FPS.
- [3] EVEN THOUGH THE RATIO IS < 1, TACAN DATA WILL NOT BE ACCEPTED IF GROUND RADAR INDICATES THAT INCORPORATION OF DATA WILL DEGRADE THE NAVIGATION STATE. (REFERENCE RULE {A8-52}, SENSOR FAILURES.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A4-206****NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE
(AIF) (CONTINUED)**

This matrix defines the actions to be taken for initial TACAN processing. For a nominal entry, the TACAN AIF switch is in INHIBIT and the TACAN transceivers are turned to the primary site TACAN channel with the rotary switch in the GPC position. When two TACAN LRU's have locked up, RM passes data to the navigation filter; but, because the AIF control is in INHIBIT, the data will not be processed by navigation. This configuration allows the ground to evaluate the TACAN data compared to radar tracking data and to give the crew a GO to mode the AIF switch to AUTO, so that navigation may process TACAN if it is acceptable. This plan also protects the validity of the ground delta state computation in the event that a ground- initiated vector update is required. (The ground delta state processor requires that external data not be taken in since it assumes that the state errors are linear). The early NO-COMM row of the rule matrix supports this mode of operation by having the crew wait for COMM in order to have ground assistance. However, there is a limit to how long the crew should wait before they try to independently troubleshoot the lack of good TACAN data. For EOM, this limit was chosen to be about 130k feet, which corresponds to a V_{rel} of approximately 6000 fps. At this altitude, it is becoming more urgent to correct the vehicle state since the footprint is shrinking (for RTLS, 130k feet altitude corresponds to a V_{rel} of approximately 6500 fps)

In the COMM row, for TACAN data that agrees with the navigation, the ratios will be less than one. Upon ground evaluation of the TACAN data and of the onboard vector compared to tracking data, a GO will be given for the crew to go to AUTO. However, if the ground evaluation shows that incorporation of the TACAN data will degrade the navigation state, the TACAN data will be held out until it will improve the onboard state. Analysis shows that ground station biases greater than 0.3 nm. in range or 1 degree in bearing can result in position delta state limit violations (ref. Rule {A4-204}, DELTA STATE POSITION UPDATES) in the absence of all other navigation error sources. If the ground determines that the TACAN data compared to the tracking data indicates a bias on all three LRU's greater than 0.3 nm or 1 degree, the recommendation will be to try another ground station. If, at the TACAN 2-LRU level, the average LRU measurement error (based on tracking) is greater than 0.3 nm or 1 degree and RM limits are not exceeded, the larger biased LRU will be deselected. Multiple LRU biases can escape RM detection and still significantly degrade the navigation state. LRU deselection will be performed only if that action will reduce the bias in the selected measurement to less than 0.3 nm or 1 degree.

One of two failures can cause the ratios to be greater than one. Either the TACAN or the state vector could be at fault. If the ground-station-to-tracking compares are good, then the fault lies with the onboard system. If the fault lies with the onboard system and the delta state update criteria are exceeded, an update will be initiated. If the ground determines that the vehicle state is erroneous and the TACAN residuals indicate that forcing the data will correct the state error, then the crew will be advised to force the data until the ratio is less than one at which time they will be advised to return to AUTO. Otherwise, a delta state update will be performed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-206

**NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE
(AIF) (CONTINUED)**

The final entry in the COMM row deals with only one LRU locking up. At initial acquisition, the onboard redundancy management requires that two LRU's be locked on before data is passed to navigation. If only one LRU locks on, the crew/ground should verify that the data is good for that LRU, and the crew should deselect the missing LRU's to override the two-lock requirement. Once data is processed initially, the range two-lock restriction is satisfied, but two LRU's are still required to be locked on prior to processing bearing data. Therefore, it is advisable to wait until two LRU's are locked on prior to reselecting non-failed LRU's. This provides RM protection for both range and bearing. However, if the ground deems it necessary to process data from one LRU, then this procedure would be used and, during the period of one LRU lock, the ground would carefully monitor the quality of the data from the single LRU.

In the NO-COMM case, the crew must make decisions in the operations of the AIF controls independently from the ground. The NO-COMM case may be assumed by the crew if they are entering to a landing site that has no COMM with the ground or to a site that has COMM, but COMM has not been established by $V_{rel}=6000$ fps. If the TACAN deltas on the HSD look good and the ratios are less than one, then the crew should mode the AIF switch to AUTO. If the ratio is greater than one, the crew must use onboard displays to determine whether the TACAN or state vector is bad. The following procedures are available to the crew:

- a. Switch ground stations - The onboard I-loads for the TACAN table are such that, with the rotary switch in the GPC position, the landing site TACAN should be acquired. If data is not acquired or if the ratio is greater than one, the crew may execute item 5 on GN: SPEC 50 to select the alternate or backup TACAN and evaluate that data. If the ratios for the alternate station are less than one, then the problem is probably with the prime TACAN ground station. If the ratios are greater than one, it would probably indicate a bad navigation state, although there is a very small probability that two or more LRU's would fail in the same manner.
- b. Check IMU status - If the IMU mission performance has been nominal and a good IMU alignment was performed pre-deorbit, and no IMU failures have occurred during entry, it is unlikely that the navigation state could be in error by a sufficient magnitude to cause ratios greater than one. Therefore, the TACAN data should be suspect. However, if the IMU's have had problems or an alignment was not performed pre-deorbit, or an IMU has failed RM during entry, the crew should suspect that the navigation state is in error.
- c. Observe residual/ratio behavior - If the residuals/ratios are steady or show a constant trend, it is likely that the navigation state is in error. If the residuals/ratios are erratic, it is likely that the TACAN data is erroneous.
- d. Monitor with HSI - The crew can select raw TACAN data to drive the HSI and compare the range and bearing with the navigated position and a visual estimate of the real position. This would be a difficult procedure since the values on the HSI will be continually changing and the magnitude of the errors would have to be so large that the source of the error should have already been detected by one of the other methods.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-206

NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE
(AIF) (CONTINUED)

The final situation in the NO-COMM row is the case where only one LRU locks on. In this case, the crew should wait as long as possible before the footprint shrinks to the point that the state error really has to be removed (5500 fps for EOM and 4700 fps for GRTLS). At this point, the nonlocked on LRU's should be deselected and the data from the single LRU passed to navigation by moding the AIF switch to AUTO. It should not be moded to FORCE to protect the navigation from bad TACAN data.

B. TACAN - POST CONVERGENCE (INITIALLY IN AUTO):

	RATIO <1	RATIO >1	
		BAD TACAN	BAD STATE VECTOR
COMM	GROUND CALL; AUTO	GROUND CALL; INHIBIT IF STATION, SWITCH TO B/U CH IF LRU, ? STATE UPDATE IF REQ'D. (BACK TO AUTO IF RATIO <1)	REMAIN IN AUTO PERFORM A ZERO ? STATE UPDATE. IF RATIO STILL >1; FORCE
NO COMM	GROUND CALL; AUTO	TROUBLESHOOT TO DETERMINE CAUSE OF EDITING A. OBSERVE RESIDUAL, RATIO BEHAVIOR B. CHECK IMU STATUS C. MONITOR WITH HSI D. SWITCH TACAN STATIONS	
		REMAIN IN AUTO	REMAIN IN AUTO PERFORM A ZERO? STATE UPDATE. IF RATIO STILL >1; FORCE

This rule shows the actions to be taken once TACAN data has been processed by navigation. For a nominal entry, the crew action would be to remain in AUTO for either COMM or NO-COMM since the ratio should not grow above one. If, for any reason, the ratio does become greater than one, then the ground or the crew can utilize the same techniques to isolate the problem as were used at initial acquisition. If the problem is bad TACAN data, the actions are the same as at initial acquisition. If the problem is the navigation state, the procedures change slightly in that a zero delta state update is performed prior to applying the same procedure used for the initial acquisition case. This is done to reinitialize the covariance if TACAN data has already been processed and it is required to force TACAN in order to fix the navigation state, since the processing of TACAN data might have converged the covariance matrix to the point where even forcing the TACAN data would not remove the state errors.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-206

NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE
(AIF) (CONTINUED)

C. BARO (INITIALLY INHIBIT):

	RATIO <1	RATIO >1		NOT PASSING RM
		BAD BARO	BAD STATE VECTOR	
COMM	GROUND CALL; AUTO [1]	GROUND CALL; REMAIN IN INHIBIT	GROUND CALL: FORCE	GROUND CALL; PRIME SELECT
NO COMM	AUTO	TACAN OK: REMAIN IN INHIBIT NO TACAN: IF RATIO STEADY, FORCE IF RATIO ERRATIC, AUTO		WAIT UNTIL M <0.9, THEN PRIME SELECT (DO NOT FORCE)

NOTE:

- [1] EVEN THOUGH THE RATIO IS < 1, BARO DATA WILL NOT BE ACCEPTED IF THE GROUND RADAR INDICATES THAT INCORPORATION OF THE DATA WILL DEGRADE THE NAVIGATION STATE.

This matrix shows the actions to be taken to manage the processing of baro altitude data in the navigation. Initially, the BARO AIF switch will be in INHIBIT. The ground will evaluate the baro data and, if the ratio is less than one and the data will improve the navigated altitude channel, then the crew will be advised to mode the AIF switch to AUTO. If comparison to radar indicates that the baro data will degrade the navigation altitude channel, then the crew will be asked to hold off incorporating baro until the ground determines that the data will improve the navigation state. If the baro data is bad and the ratio is > 1, the crew will be advised to remain in INHIBIT until the data improves or the delta state limit is exceeded. If the onboard state is bad, the ground will observe the error and baro residual; and, if the errors are such that forcing the data will improve the state, the crew will be asked to mode the AIF switch to FORCE until the ratio becomes less than one, at which time they should return to AUTO. Otherwise, a delta state update will be initiated. If RM is not passing data to navigation, the ground will assist the crew in deselecting ADTA's if required, evaluate the data, and have the crew mode to AUTO.

In the NO-COMM case, the crew should go to AUTO around M=2.5 when the ratio is < 1 and onboard evaluation indicates valid baro data. Going to AUTO earlier does not provide any benefit to navigation since baro data is not processed by navigation until $V_{rel}=2500$ fps. If the ratio is > 1 and valid TACAN data is being processed, then the AIF switch should remain in INHIBIT. If TACAN data is not being processed, the requirement for baro data is even stronger, but the only method of crew evaluation is to monitor the baro residuals on the horizontal situation display. If they appear steady and reasonable considering past navigation performance, the crew should mode the AIF control to FORCE until the ratio becomes < 1 and then return to AUTO. If they are erratic or unreasonable based on past navigation performance, the AIF switch should be left in AUTO. The final situation in the NO-COMM row is the case where RM is not passing valid data. The crew should evaluate the ADTA's and prime select the best data source when subsonic. The AIF switch should be moded to AUTO in order to edit the data, should the ratio become greater than one.

FLIGHT RULES

A4-206

NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF) (CONTINUED)

TACAN and BARO data will be incorporated to PASS and BFS after MCC GO. Processing sensors to both systems ensures the best BFS state vector should an engage be required and eliminates multiple state vector transfers during periods of high crew workload. Analysis shows that, if the BFS is engaged near touchdown with the BFS NAV errors experienced on some flights, achieving the runway may not be possible.

Shuttle flight history and FAA TACAN reliability data assert that a sudden sensor bias or failure less than RM and filter edit criteria but large enough to degrade NAV is unlikely, especially after STA prelanding checks and after MCC has determined the data good. BARO system failures are more likely to occur during probe deploy before data is available for ground evaluation. Additional protection against such failures is provided by a tight postprocessing covariance matrix which prevents errors from growing rapidly, affording sufficient time to inhibit the bad sensor on MCC call.

Analysis has shown that, even while processing sensors to PASS and BFS, two-level IMU diagnosing capability is retained. If, at the IMU 2 level and processing sensors, one IMU's performance is worse than the other, the MCC can identify the worse-performing IMU by evaluating differences between the individual PASS (three-string NAV) states and radar tracking. The difference in PASS and BFS selection schemes (averaging versus low-number-select) allows evaluation by observation of PASS and BFS select states.

If radar tracking is not available as in a TAL, ELS or ground filter NO-GO, the MCC has the same data available to the crew. The ground may assist to the best of its ability, but sensor incorporation without radar tracking is a crew call. In this situation, TACAN and BARO will be incorporated to PASS and BFS since no advantage can be gained by withholding sensor data from either system.

A4-206

NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF) (CONTINUED)

- D. DRAG ALTITUDE - INCORPORATION OF DRAG ALTITUDE DATA INTO NAVIGATION IS MANDATORY. THE DRAG AIF CONTROL WILL BE INITIATED IN THE AUTO MODE. IF REPETITIVE DATA EDITING OCCURS, THE AIF CONTROL WILL BE SWITCHED TO THE FORCE MODE. HOWEVER, FOR GRTLS DATA INCORPORATION IS NOT MANDATORY. THE AIF CONTROL WILL BE INITIATED AND LEFT IN AUTO MODE.

Incorporation of drag altitude into navigation is mandatory. Drag updating begins during blackout when the ground can offer no assistance in evaluating the data or aiding the crew in deciding to allow drag altitude to update the navigation state. Since the drag altitude is derived from IMU data, the validity of the measurement is dependent on the quality of the IMU data. Since there is no way for the crew to independently evaluate the IMU data, it was decided to set the drag AIF switch to AUTO. If the combined navigation/drag updating performance is within 8 sigma, which is equivalent to about 80,000 feet altitude, the drag will pass the edit criteria and will be incorporated into the navigation state without incident. If the performance is worse than 8 sigma, editing will occur and the crew procedure will be to mode the AIF switch to FORCE to incorporate the drag altitude and thus bound the altitude error growth. For GRTLS, drag altitude would probably never be edited, since the IMU performance from the time of lift-off to execution of the GRTLS would not degrade to the point to cause editing. Further, on a GRTLS, TACAN data is acquired very high in the trajectory or just after drag processing is initiated; and, since TACAN is a more powerful measurement source, it would correct the state such that drag editing should not occur. Also, tracking data should be available and any error that would cause drag data to be edited would result in a violation of the delta state update criteria. For these reasons, it was decided to leave the drag AIF switch in the AUTO mode.

FLIGHT RULES

A4-207

ENTRY LIMITS

A. THE FOLLOWING LIMITS ARE APPLICABLE TO THE ENTRY AND LANDING FLIGHT PHASES. THE CG MUST BE KEPT WITHIN NORMAL LIMITS (REFERENCE RULE {A4-153}, CG PLANNING). THE MCC WILL MONITOR THE PARAMETERS BELOW AND ADVISE THE CREW TO PREVENT EXCEEDENCES. @[050495-1531B]

1. NZ LIMITS (THE MOST CONSTRAINING OF THE FOLLOWING):
@[091098-6716A]

a. ORBITER WEIGHT ? 211 KLB: THE NZ LIMIT IS 2.5 G.

b. ORBITER WEIGHT > 211 KLB: THE NZ LIMIT IS DETERMINED AS FOLLOWS:

$$NZMAX = 4.563 - (9.778 \times 10^{-6} \times WT)$$

c. 1076.7 > ORBITER XCG ? 1075.2, QBAR ? 325, MACH < 1, THE NZ LIMIT IS DETERMINED AS FOLLOWS:

$$NZMAX = 4.71 - (0.0068 \times QBAR), \text{ WHERE } QBAR \text{ IS DETERMINED FROM PREDICTIONS MADE BY 6-DOF STAMPS SIMULATION.}$$

NOTE: FOR PRE-DEORBIT PLANNING PURPOSES, A 0.2 g LOAD FACTOR BIAS IS SUBTRACTED FROM THE ABOVE STRUCTURAL LIMITS TO PROTECT FOR DISPERSIONS AND ASYMMETRY DURING A ROLLING MANEUVER.

Orbiter normal load factor limits are defined in the SODB (JSC-08934) Volume V. The MCC will evaluate the planned entry profile to ensure these load factor limits are not exceeded. When in the CSS, the crew must implement active load factor monitoring and avoidance procedures when required. The MCC will advise the crew of what limits to protect. To protect for wind dispersions on the heading alignment cone (HAC), the operational Nz limit is reduced by a bias for planning purposes. The value of the bias is derived by averaging differences between flight and real-time predicted data.

The analysis performed by Boeing North American Flight Control and Loads groups (presented at the 145th Ascent/Entry Flight Techniques on December 19, 1997) to expand the forward X CG limit resulted in an additional constraint on orbiter NZ limit. For flights predicted to be in this region, the NZ limit is also a function of Qbar. The operational NZ limit will be the most constraining. The X CG is evaluated at Mach=3.5. @[091098-6716A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-207

ENTRY LIMITS (CONTINUED)

ORBITER NORMAL LOAD FACTOR LIMITS

2. $Q\text{-BAR} < 350 \text{ PSF (321 KEAS) FOR MACH} < 1$

$Q\text{-BAR} < 330 \text{ PSF (312 KEAS) DURING LANDING GEAR DEPLOYMENT}$

The Q-bar restrictions are designed to protect the structural integrity of the orbiter and to ensure flight within the integrated guidance, navigation, and control envelopes. The Q-bar profile gives a good indication of whether or not the guidance is being stressed in trying to fly the reference profile. For real-time evaluation purposes, evaluation of the subsonic region is important because it includes the dynamics of flying the HAC with the winds of the day. The certified Q-bar limit of 375 psf in the subsonic region is documented in SODB Volume V. The TAEM guidance will limit normal acceleration commands to stay within the maximum Q-bar limit which is I-loaded to 350 psf. This provides for the 25 psf Air Data System accuracy listed in the SODB. The 350 psf limit is used DOL/DOE because it indicates a stressed trajectory, protects for events not being simulated (CSS, wind persistence), and it protects against flying a trajectory which could indicate an airspeed > 321 KEAS (350 psf).

During approach and landing, guidance indirectly controls dynamic pressure by controlling the equivalent airspeed, which is related to dynamic pressure. The 330 psf (312 KEAS) limit on maximum dynamic pressure at gear deploy is covered in the SODB 3.4.2.1-6.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-207

ENTRY LIMITS (CONTINUED)

- B. THESE ATTITUDE CONSTRAINTS WILL NOT BE EXCEEDED IN AUTO OR CSS MODE. THE MCC WILL MONITOR THESE PARAMETERS AND ADVISE THE CREW TO PREVENT EXCEEDENCES.
1. ANGLE OF ATTACK (ALPHA DEG) VERSUS MACH NUMBER.
 2. IF STEADY STATE SIDESLIP EXCEEDS 2 DEGREES AND ONE OR MORE YAW JETS FIRE CONTINUOUSLY OR IF THE SIDESLIP EXCEEDS THE TWO-JET CAPABILITY PER THE "BETA ESTIMATOR" (SCALED AY), THE CREW WILL MANUALLY TRIM TO REDUCE RCS JET FIRING ($2 < M < 12$).

The orbiter must be operated within the specified angle of attack constraints to maintain control in pitch and roll/yaw axes, to meet structural requirements during venting, to assure hinge moment limits for aerosurfaces are not exceeded, and to remain within guidance limits due to interaction with roll angle in solving range and drag equations.

Large steady state sideslip can lead to loss of control. If jets are required to maintain vehicle trim, they will have reduced effectiveness during dynamic flight phases where their force is required; reduced stability margins and control problems may result. Also, there will be a large increase in RCS propellant usage. ©[050495-1531B]

Rule {A4-107}, PLS/EOM LANDING OPPORTUNITY REQUIREMENTS, references this rule.

G. PRIOR TO MSBLS ACQ IF MCC HAS TM AND CONFIRMS LATERAL NAV ERRORS > 8000 FT OR H ERRORS > 500 FT	CSS PITCH, ROLL/YAW	INCORPORATION OF MSBLS	POTENTIAL TRAJECTORY TRANSIENT
H. FAILURE OF AUTOLAND GUIDE TO ENGAGE PRIOR TO 6000 FT ALT	CSS PITCH, ROLL/YAW	NONE	MANUAL LANDING IS PREFERRED
I. FOR UNEXPLAINED OR UNCOMFORTABLE TRANSIENTS OR TRAJECTORY CONDITIONS	CSS PITCH, ROLL/YAW	CREW OPTION	NONE

@[021998-6513A]

NOTE: [1] AUTO RE-ENGAGE IS NOT CONSIDERED TO BE A REQUIREMENT AFTER TAEM INTERFACE (M=2.5).

The rationale for each condition is contained in the rule under the remarks.

FLIGHT RULES

A4-209

AERO TEST MANEUVERS

AERO TEST MANEUVERS WILL NOT BE ATTEMPTED IF THE CROSSRANGE AT ENTRY INTERFACE IS GREATER THAN THE DTO CROSSRANGE LIMIT (REF. THE ANNEX FLIGHT RULE, TRAJECTORY AND GUIDANCE PARAMETERS) UNTIL THE FIRST ROLL REVERSAL HAS BEEN COMPLETED AND THE ORBITER ENERGY STATE AND DRAG PROFILE ARE NOMINAL. VALID TELEMETRY IS REQUIRED FOR EVALUATION OF THE ORBITER ENERGY STATE. ®[ED]

For the purposes of this rule, any PTI that inhibits entry guidance is considered an aero test maneuver. Since entry guidance is locked out, there is no attempt to follow the optimal energy profile or to respond to roll reversals. High crossrange at entry interface requires optimum bank angle and energy control to ensure a manageable energy state at TAEM interface. If energy is nominal and the orbiter is on the nominal drag profile, guidance will be able to manage energy properly, even under given dispersions. Valid telemetry is needed to verify that the energy and drag profiles are within limits.

Rule {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, references this rule.

FLIGHT RULES

A4-210

EOM ENTRY DTO/RUNWAY SELECTION PRIORITIES

DTO 805, CROSSWIND LANDING PERFORMANCE, WILL BE EXECUTED AS A DTO OF OPPORTUNITY. DTO 805 WILL NOT BE A CONSIDERATION IN SELECTING LANDING SITES OR RUNWAYS. IF CROSSWINDS ARE OBSERVED TO BE 10 KNOTS OR GREATER AS THE ORBITER APPROACHES THE HAC, DRAG CHUTE DEPLOY WILL BE DELAYED UNTIL POST NOSE GEAR TOUCHDOWN TO ACCOMPLISH DTO 805. ©[022201-3801]

No drag chute, braking, or nose wheel DTO's are scheduled. Drag chute deploy will be per nominal flight rules (ref Rules {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES, and {A10-144}, DRAG CHUTE DEPLOY CONSTRAINTS), unless the crosswind DTO is likely to be performed. In this case, drag chute deploy will be delayed until post nose gear touchdown to allow for pilot handling evaluation of the orbiter without any complications that drag chute dynamics may induce. Nominal touchdown speed is 195 keas with derotation performed using the beep trim switch at 185 keas, or manually (if beep trim fails) at 175 keas. Drag chute nominal deploy is immediately prior to the initiation of derotation. However, the drag chute DTO program has cleared drag chute deploy as early as 15 keas prior to the initiation of derotation. ©[102402-5804C]

All ISS rendezvous flights have a probability of a night landing which would mean that the crosswind limit is 12 knots. Therefore, DTO 805, Crosswind Landing Performance Evaluation, which requires a crosswind of 10 knots or greater at touchdown, is not likely to be achieved. With this small window of environmental conditions, it is not prudent to change landing sites (e.g., from KSC to EDW) to attempt DTO 805. Also, programmatic priorities make it highly desirable to land at KSC to avoid the cost and risk associated with ferry operations. Since a decision to change from KSC to EDW would have to be made approximately 2 to 4 hours before landing, it is unlikely that confidence in wind forecasts would be such that landing at EDW solely to achieve DTO 805 is prudent. ©[022201-3801] ©[102402-5804C]

POLICY

- A. MEMORANDUM OF AGREEMENT (MOA) 15E-2-8, BETWEEN THE 45TH SPACE WING (45 SW) AND THE JOHN F. KENNEDY SPACE CENTER (KSC) FOR MISSILE/SPACE VEHICLE SAFETY ON KSC AND THE EASTERN RANGE (ER), EFFECTIVE NOVEMBER 2, 1995, DELINEATES THE AGENCY RESPONSIBLE FOR MISSILE/SPACE VEHICLE FLIGHT AND GROUND SAFETY FOR LAUNCHES FROM THE ER AND KSC AND IDENTIFIES CERTAIN RESPONSIBILITIES ASSOCIATED WITH MISSILE/SPACE VEHICLE MISHAPS. RANGE SAFETY REQUIREMENTS ARE CONTAINED IN EWR 127-1, MARCH 31, 1995. @[053096 PRCB-4001]
- B. RANGE SAFETY POLICIES AND PROCEDURES ARE SPECIFIED IN SECTION 1 OF EWR 127-1. CONSISTENT WITH SECTION 1.4, SPECIFICALLY PARAGRAPHS 1.4.1 AND 1.4.1.3, THE 45 SW COMMANDER HAS AUTHORIZED REMOVAL OF THE RANGE SAFETY SYSTEM (RSS) FROM THE EXTERNAL TANK (ET) FOR PRESENTLY DESCRIBED STS FLIGHT CONFIGURATIONS, PAYLOADS, AND TRAJECTORIES, BASED ON A RISK ASSESSMENT WHICH ASSUMES THE VEHICLE IMPACT POINT WILL BE STOPPED BEFORE REACHING WELL DEFINED LIMIT LINES. ANY FUTURE STS FLIGHT VEHICLE MODIFICATIONS AND/OR NEW TRAJECTORIES MUST BE ANALYZED TO ENSURE PUBLIC RISKS HAVE NOT INCREASED BEYOND ACCEPTABLE LEVELS. IN THE EVENT OF AN UNACCEPTABLE PUBLIC RISK INCREASE, FLIGHT DESIGN MODIFICATIONS OR INSTALLATION OF A RANGE SAFETY FLIGHT OR THRUST TERMINATION SYSTEM WILL BE REQUIRED TO REDUCE THE RISK TO AN ACCEPTABLE LEVEL. THE 45 SW COMMANDER RETAINS OVERALL RESPONSIBILITY FOR PUBLIC SAFETY IN ACCORDANCE WITH EWR 127-1, SECTION 1.3.1. THE FLIGHT CREW COMMANDER (CDR) AND PILOT (PLT) BECOME AGENTS OF THE 45 SW COMMANDER FOR PUBLIC SAFETY DURING THE PORTION OF FLIGHT AFTER SOLID ROCKET BOOSTER SEPARATION AND PRIOR TO MAIN ENGINE CUTOFF. THIS AGENT RELATIONSHIP NECESSITATES THAT ALL CDR'S AND PLT'S RECEIVE INITIAL AND RECURRING TRAINING THAT IS APPROVED BY THE 45 SW AND DOCUMENTED AS PART OF THE NASA CERTIFICATE OF FLIGHT READINESS (COFR) PROCESS. 45 SW RANGE SAFETY FLIGHT PLAN APPROVAL IS CONTINGENT UPON APPROVED AND DOCUMENTED TRAINING AS EVIDENCED IN THE COFR PROCESS.
- C. THE FOLLOWING MISSION RULES SUPPLEMENT EWR 127-1 AND THE RANGE SAFETY OPERATIONS REQUIREMENTS DOCUMENT AND OPERATIONS SUPPLEMENT. THESE RULES IMPLEMENT THE U.S. AIR FORCE (USAF) POLICY OF ADVANCING THE NATION'S COMMITMENT TO LEADERSHIP IN THE EXPLORATION AND USE OF SPACE AT MINIMUM RISK TO THE FLIGHT CREWS, GENERAL PUBLIC, AND PROPERTY. THEY PROVIDE ACTION GUIDANCE TO PERSONNEL RESPONSIBLE FOR EXECUTING THIS POLICY. @[053096 PRCB-4001]

FLIGHT RULES**A4-253****DEFINITIONS** @[081497-6306A]

THIS SECTION CENTRALIZES DEFINITIONS RELATED TO THESE FLIGHT RULES TO FACILITATE CLARITY IN THE RULES THEMSELVES. @[053096 PRCB-4001]

- A. FLIGHT TERMINATION SYSTEM (FTS): THE FTS NEUTRALIZES SOLID ROCKET BOOSTER (SRB) THRUST WITH A SINGLE LINEAR SHAPED CHARGE PER SRB WHICH SPLITS THE SOLID ROCKET MOTOR CASES. ANALYSIS SHOWS THAT THIS ACTION ALSO CAUSES DISPERSAL OF THE EXTERNAL TANK (ET) PROPELLANTS. THE FLIGHT TERMINATION SYSTEM IS PROTECTED FROM UNAUTHORIZED COMMANDS BY THE DIGITAL RANGE SAFETY COMMAND SYSTEM (DRSCS). THE DRSCS "ARM" AND "FIRE" COMMANDS ARE FORMATTED BY CRYPTO HARDWARE IN THE ER RANGE OPERATIONS CONTROL CENTER (ROCC). THE COMMANDS ARE RECEIVED AND DECODED BY FLIGHT INTEGRATED RECEIVER DECODERS (IRD'S) IN EACH SRB. THE CODES FOR A PARTICULAR FLIGHT BECOME UNCLASSIFIED AT SRB SPLASHDOWN OR UPON TRANSMISSION OF COMMANDS ANY TIME AFTER SRB IGNITION. THE "ARM" COMMAND, WHICH IS PREPARATORY TO THE "FIRE" COMMAND, ACTIVATES A WARNING LIGHT IN THE ORBITER AND IRREVERSIBLY CHARGES THE PYROTECHNIC INITIATOR CONTROLLERS (PIC'S). WHEN FLIGHT TERMINATION ACTION IS REQUIRED, THE FCO WILL TRANSMIT THE "FIRE" COMMAND IMMEDIATELY AFTER THE "ARM" COMMAND.
- B. VEHICLE PERFORMANCE DATA: FOR THE PURPOSE OF THESE RULES, VEHICLE PERFORMANCE DATA ARE DEFINED AS FOLLOWS:
1. VEHICLE BEHAVIOR DATA
 - a. PRIMARY CUE: REMOTE TELEVISION PRESENTATION TO FCO
 - b. SECONDARY CUE: RADAR SKIN TRACK A-SCOPE DISPLAY (MINIMUM OF TWO CONFIRMING SITES), OR VERBAL BREAKUP REPORT FROM EITHER THE AIRBORNE OR GROUND VISUAL OBSERVERS.
 - c. TERTIARY CUES: REAL-TIME TELEMETRY (HIGH ATTITUDE RATES OR PREMATURE SEPARATION INDICATORS FOR SRB'S OR ET), THE SOLID ROCKET BOOSTER TRACKING SYSTEM (INDICATIONS OF SEPARATION RATES BETWEEN SRB'S AS SHOWN BY TRAJECTORY DETERMINATION DATA), OR SIMULTANEOUS LOSS OF S-BAND DOWNLINK AND AT LEAST ONE C-BAND TRANSPONDER. @[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-253

DEFINITIONS (CONTINUED) @[081497-6306A]

2. TRAJECTORY DETERMINATION DATA: TRAJECTORY DETERMINATION WILL BE BASED ON RADAR TRACKING, OPTICAL TRACKING, AND TELEMETRY (NAVIGATION AND GUIDANCE) DATA THAT HAVE BEEN SELECTED BY THE ROCC REAL-TIME PROCESSORS. @[053096 PRCB-4001]
- C. CONTROLLABILITY LIMITS: THE VEHICLE IS DEFINED TO BE UNCONTROLLABLE IF PITCH OR YAW RATES GREATER THAN FIVE DEGREES/SECOND ARE EXPERIENCED FOR FIVE SECONDS.
- D. CONTROLLABILITY WARNING LIGHT: A WARNING LIGHT ON THE FCO CONSOLE ACTIVATED BY THE JSC GUIDANCE, NAVIGATION AND CONTROL (GNC) OFFICER WHEN THE VEHICLE IS DETERMINED TO BE OUT OF CONTROL. THE LIGHT SERVES TO MINIMIZE FCO RESPONSE TIME IN SITUATIONS INVOLVING AN UNCONTROLLABLE VEHICLE, AND IS APPLICABLE ONLY DURING FIRST STAGE.
- E. ABORT REQUEST COMMAND: THE ABORT REQUEST SWITCH, LOCATED ON THE FD, FDO, AND FCO CONSOLES, INITIATES TRANSMISSION OF COMMANDS FROM THE MCC COMMAND SYSTEM TO ILLUMINATE THE ABORT LIGHT IN THE ORBITER COCKPIT.
- F. ABORT LIGHT: A WARNING LIGHT IN THE ORBITER COCKPIT, ILLUMINATED VIA THE ABORT REQUEST COMMAND, WHICH SERVES AS A CUE FOR THE FLIGHT CREW TO TAKE SOME ABORT ACTION. FOR IMMINENT RANGE SAFETY MECO LINE VIOLATIONS, THE REQUIRED CREW ACTION IS A MANUAL MECO PER THE PROCEDURES DESCRIBED IN THESE RULES.
- G. FIRST STAGE: ORBITER POWERED FLIGHT FROM SRB IGNITION THROUGH SRB SEPARATION.
- H. SECOND STAGE: ORBITER POWERED FLIGHT AFTER SRB SEPARATION.
- I. AMBER ZONE: CALLED BY THE FCO WHEN THE TRAJECTORY EXCEEDS THE 3-SIGMA VERTICAL OR LATERAL ENVELOPE IN FIRST STAGE. INVOKES THE CONTROLLABILITY RULE, AND IS ONLY APPLICABLE IN FIRST STAGE.
- J. IIP: INSTANTANEOUS, VACUUM IMPACT POINT.
- K. ILL: IMPACT LIMIT LINE. THE PRIMARY AND SECONDARY ILL'S PROTECT THE IMMEDIATE LAUNCH AREA AND OTHER LAND MASSES AGAINST DEBRIS FOOTPRINT ENCROACHMENT DURING FIRST STAGE. @[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-253 DEFINITIONS (CONTINUED) @[081497-6306A]

- L. SRB NLE: THAT TIME FROM LIFTOFF ON A NOMINAL TRAJECTORY (i.e., WITHIN THE 3-SIGMA TRAJECTORY ENVELOPE) BEYOND WHICH BREAKAWAY SRB'S CAN "NO LONGER ENDANGER" LAND UNDER ANY SUBSEQUENT SRB BEHAVIOR. @[053096 PRCB-4001]
- M. FCO: FCO IN THESE RULES REFERS TO EITHER THE ER FLIGHT CONTROL OFFICER (FCO) OR THE SENIOR FCO (SFCO). WHERE APPLICABLE, THE SPECIFIC INDIVIDUAL POSITION IS IDENTIFIED IN THESE RULES.
- N. MCC: THE MISSION CONTROL CENTER AT JSC. AS USED IN THESE RULES, MCC ALSO REFERS TO THE FLIGHT DIRECTOR (FD), SPACECRAFT COMMUNICATOR (CAPCOM), AND/OR FLIGHT DYNAMICS OFFICER (FDO) PERSONNEL LOCATED IN THE MCC. PRIMARY COMMUNICATION BETWEEN THE FCO AND THE MCC IS CARRIED OUT WITH THE FDO. WHERE APPLICABLE, THE SPECIFIC INDIVIDUAL POSITION IS IDENTIFIED IN THESE RULES.
- O. MECO LINES AND GATES: MECO LINES, WHICH ARE APPLICABLE ONLY IN SECOND STAGE, IDENTIFY AREAS UPON WHICH THE VEHICLE'S IIP MAY NOT ENCROACH. THEY ARE REPRESENTED AS SOLID LINES ON FCO AND MCC DISPLAYS. SINCE OVERFLIGHT OF SOME LAND MASS IS ALWAYS REQUIRED FOR THE STS VEHICLE TO ACHIEVE ORBIT, SOME MECO LINES WHICH STRICTLY PROTECT ALL AREAS OF THESE LAND MASSES ARE PRESENTED AS DASHED LINES ON THE DISPLAYS AND ARE REFERRED TO AS GATES. FOR STS FLIGHTS, THREE GATES ARE APPLICABLE, AS DESCRIBED BELOW:
1. HATTERAS GATE (APPLICABLE FOR HIGH-INCLINATION MISSIONS ONLY): THE HATTERAS GATE PROTECTS POPULATED ISLANDS AND EXTENSIVE MARITIME TRAFFIC OFF THE COAST OF NORTH CAROLINA.
 2. NEWFOUNDLAND GATE (APPLICABLE FOR HIGH-INCLINATION MISSIONS ONLY): THE NEWFOUNDLAND GATE PROTECTS THIS LOW POPULATION CANADIAN PROVINCE. NOMINAL OR NEAR-NOMINAL FLIGHTS WILL ROUTINELY PASS THROUGH THIS GATE.
 3. AFRICAN GATE (APPLICABLE FOR ALL MISSIONS): THE AFRICAN GATE PROTECTS THE LAND MASSES OF AFRICA, EUROPE, AND SOUTH AMERICA. NOMINAL OR NEAR-NOMINAL FLIGHTS WILL ROUTINELY PASS THROUGH THIS GATE. @[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-253 DEFINITIONS (CONTINUED) @[081497-6306A]

- P. DESTRUCT LINES: EQUIVALENT TO MECO LINES, BUT APPLICABLE DURING THE SHORT TIME LATE IN FIRST STAGE (FROM T+120 SEC TO SRB SEP) WHEN THE FTS IS STILL AVAILABLE FOR USE. THESE LINES ALSO APPLY IN FIRST STAGE IF VALID FOOTPRINT DATA IS LOST PER RULE {A4-258}, FLIGHT TERMINATION/MANUAL MECO CRITERIA, PART C.4. @[053096 PRCB-4001]
- Q. CODEWORDS: THERE ARE THREE STS-RELATED CODEWORDS, AS DESCRIBED BELOW. CODE WORDS, WHEN USED, ARE EXCHANGED OVER THE FD AND FCO PRIME LOOPS.
1. UNCONTROLLABLE: THIS UNIQUE CODE WORD WILL BE USED BY THE FD TO ADVISE THE FCO THAT THE VEHICLE IS UNCONTROLLABLE.
 2. MANUAL MECO: THIS UNIQUE CODE WORD WILL BE USED BY THE FCO TO ADVISE THE MCC THAT AN IMMEDIATE MANUAL MECO IS REQUIRED.
 3. ARM/FIRE: THIS UNIQUE CODE WORD WILL BE USED BY THE FCO TO ADVISE THE MCC THAT THE FTS HAS BEEN ACTIVATED.
- R. COMMUNICATION CIRCUITS: THREE PRIMARY COMMUNICATION CIRCUITS ARE USED BETWEEN THE FCO AND THE MCC: THE FD LOOP, THE FCO PRIME LOOP, AND THE FCO PRIVATE LINE. WHERE TWO REDUNDANT LOOPS ARE LISTED IN THESE RULES, OTHER LOOP/LONG LINE PATCHING MAY BE USED TO PROVIDE THIS REDUNDANCY IF NECESSARY. @[081497-6306A]
- S. VEHICLE BREAKUP: SEPARATION OF VEHICLE PARTS AS DETERMINED VISUALLY OR BY RADAR TRACK OF MULTIPLE TARGETS.
- T. CATASTROPHIC FAILURE: VEHICLE PITCHES OVER OR BREAKS UP, AS SHOWN BY VEHICLE PERFORMANCE DATA.
- U. VARIABLE IY: AN ABORT-TO-ORBIT (ATO) TARGETING METHOD USED ON SOME MISSIONS IN WHICH THE VEHICLE STEERS TO AN ORBITAL PLANE/INCLINATION LOWER THAN THE NOMINAL TO IMPROVE DOWNRANGE PERFORMANCE. IF EXCURSION TOWARD A RANGE SAFETY LIMIT LINE OCCURS DUE TO THE ORBITAL PLANE TARGET BEING CORRUPTED, AN ATO ABORT WHICH INVOKES VARIABLE IY CAN POTENTIALLY ELIMINATE THE RANGE SAFETY PROBLEM.
- V. CSS: MANUAL SHUTTLE FLIGHT CONTROL (CONTROL STICK STEERING), AS OPPOSED TO AUTO-GUIDANCE FLIGHT CONTROL.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-253 **DEFINITIONS (CONTINUED)** @[081497-6306A]

W. BFS ENGAGE: FLIGHT CREW ACTIVATION OF THE BACKUP FLIGHT SYSTEM (BFS), USED FOR TOTAL FAILURE OF THE QUAD-REDUNDANT PRIMARY AVIONICS SOFTWARE SYSTEM (PASS). @[053096 PRCB-4001]

A4-254 **FCO TO MCC WARNING NOTIFICATION**

THE VEHICLE'S FLIGHT MAY DEVIATE SIGNIFICANTLY FROM NOMINAL AND STILL REMAIN WITHIN SAFE LIMITS. IF THE CRITERIA BELOW ARE EXCEEDED, THE FCO WILL WARN THE MCC, AND THE MCC WILL RESPOND WITH CALLS OR REQUESTED CREW ACTION. VIOLATION OF THESE CRITERIA INDICATES THAT THE VEHICLE IS DEVIATING SIGNIFICANTLY FROM ITS NOMINAL TRAJECTORY. @[053096 PRCB-4001]

A. TRAJECTORY EXCEEDS 3-SIGMA (LATERAL OR VERTICAL) IN FIRST STAGE:

1. FCO MAKES AN "AMBER ZONE" CALL ON BOTH THE FD AND FCO PRIME LOOPS. THE CONTROLLABILITY RULE IS INVOKED.
2. AFTER AN AMBER ZONE CALL, A PROMPT CONTROL STATUS RESPONSE IS REQUIRED FROM THE FD TO THE FCO ON THE FD LOOP. IF THE VEHICLE IS UNDER CONTROL, THE FD WILL RESPOND "GOOD CONTROL." IF THE VEHICLE IS UNCONTROLLABLE, THE FD WILL RESPOND VIA CODEWORD, AND THE JSC GNC OFFICER WILL RESPOND WITH THE CONTROLLABILITY WARNING LIGHT.

B. POST-SRB SEP, TRAJECTORY EXCEEDS 3-SIGMA LATERAL:

1. FCO MAKES TRAJECTORY DEVIATION CALLS ON THE FCO PRIME LOOP.
2. FDO RESPONDS WITH TRAJECTORY ASSESSMENT CALLS.
3. IF THE TRAJECTORY CONTINUES TO DEVIATE TOWARD A MECO LINE, THE PROXIMITY TO THE LINE WILL BE EVALUATED:
 - a. FCO WILL CALL "HALFWAY TO THE LINE" WHEN THE IIP IS APPROXIMATELY HALFWAY BETWEEN THE 3-SIGMA LEFT/RIGHT TRAJECTORY AND THE NEAREST MECO LINE.
 - b. FREQUENT ESTIMATES OF TIME REMAINING UNTIL MECO LINE VIOLATION WILL BE PROVIDED BY FDO ON THE FD LOOP BASED ON MCC PREDICTOR BUG SOFTWARE.

FLIGHT RULES

A4-254 FCO TO MCC WARNING NOTIFICATION (CONTINUED)

4. IF TRAJECTORY DEVIATIONS CONTINUE AFTER ACTION BY THE MCC (REFERENCE RULE {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS), MANUAL MECO PROCEDURES WILL BE INITIATED BY THE MCC WHEN THE IIP IS 30 SEC FROM THE MECO LINE. @[053096 PRCB-4001] @[081497-6306A]
5. IF MECO HAS NOT YET OCCURRED UPON IIP CONTACT WITH A MECO LINE, FCO WILL INITIATE THE ABORT REQUEST COMMAND (ABORT LIGHT) AS AN INDICATION TO THE CREW THAT AN IMMEDIATE MANUAL MECO IS REQUIRED. THE MANUAL MECO CODEWORD WILL BE VERBALLY TRANSMITTED TO THE MCC SIMULTANEOUSLY ON THE FD AND FCO PRIME LOOPS. @[053096 PRCB-4001]

A4-255 MCC TO FCO REPORTING

THE MCC WILL ADVISE THE FCO OF OFF-NOMINAL VEHICLE PERFORMANCE OR OF EVENTS THAT SIGNIFICANTLY AFFECT RANGE SAFETY AS THEY OCCUR. THE INFORMATION WILL BE PROVIDED BY THE FDO ON THE FCO PRIME LOOP WITH THE FCO PRIVATE LINE AS BACKUP, EXCEPT AS SPECIFICALLY NOTED BELOW:

- A. CONTROLLABILITY STATUS (FIRST STAGE ONLY): MADE BY FD ON THE FD LOOP, USING EITHER THE WORDS "GOOD CONTROL," IF THE VEHICLE IS UNDER CONTROL, OR USING THE CODEWORD TO INDICATE UNCONTROLLABLE. IF THE VEHICLE IS UNCONTROLLABLE, THE JSC GNC OFFICER WILL ALSO RESPOND WITH THE CONTROLLABILITY WARNING LIGHT.
- B. ANY DECISION TO ABORT THE FLIGHT: ATO, TAL, RTLS, ANY CONTINGENCY ABORT, FAST SEPARATION, ETC.
- C. ANY SSME FAILURE.
- D. ANY CONDITIONS WHICH COULD RESULT IN ET LAND IMPACT, PLUS A PREDICTED IMPACT LOCATION, IN AS NEAR REAL-TIME AS POSSIBLE.
- E. WHEN RANGE SAFETY LIMIT AVOIDANCE ACTIONS ARE BEING IMPLEMENTED (RULE {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS), FREQUENT ESTIMATES OF TIME TO VIOLATION WILL BE PROVIDED BY THE FDO ON THE FD LOOP. WHEN THE IIP IS 30 SEC FROM THE MECO LINE, MANUAL MECO PROCEDURES WILL BE INITIATED. @[081497-6306A]
- F. ANY OTHER PERTINENT INFORMATION. @[053096 PRCB-4001]

FLIGHT RULES

A4-256

CONTROLLABILITY

- A. THIS RULE APPLIES ONLY DURING THE SRB THRUSTING PERIOD, AFTER LAUNCH TOWER CLEARANCE. @[053096 PRCB-4001]
- B. THE USAF AND NASA, IN CONSIDERING THE NATIONAL INTERESTS IN THE SHUTTLE PROGRAM AND THE CONSEQUENCES OF FLIGHT TERMINATION ACTION, HAVE JOINTLY AGREED TO THE FOLLOWING (REFERENCE MOA 15E-2-8):
1. THE NON-PUBLIC RISKS ASSOCIATED WITH CONTINUED FLIGHT OF A CONTROLLABLE VEHICLE IF THE PRIMARY IMPACT LIMIT LINE IS VIOLATED HAVE BEEN ASSESSED BY THE USAF AND ACCEPTED BY NASA FOR KSC, AND BY THE 45 SW FOR CAPE CANAVERAL AIR STATION (CCAS).
 2. THE PUBLIC RISKS ASSOCIATED WITH FLIGHT BEYOND THE SECONDARY ILL ARE UNACCEPTABLE.
 3. IF THE VEHICLE IS DECLARED TO BE UNDER CONTROL AND IS SUBSEQUENTLY DECLARED UNCONTROLLABLE, THE FCO WILL TAKE ACTION WHEN THE APPLICABLE FLIGHT TERMINATION LINE IS VIOLATED (PRIMARY OR SECONDARY).
- C. GENERAL
1. ALTHOUGH THE ACTUAL TRAJECTORY MAY DEVIATE SIGNIFICANTLY FROM THE NOMINAL DURING THE SRB THRUSTING PERIOD, THE VEHICLE MAY NOT EXCEED CONTROLLABILITY LIMITS.
 2. AS LONG AS THE MCC CAN CONFIRM TO THE FCO THAT THE CONTROLLABILITY LIMITS HAVE NOT BEEN EXCEEDED, OR IN THE CASE OF LOSS OF COMMUNICATION BETWEEN THE MCC AND THE FCO, THE FCO CAN DETERMINE THAT THESE LIMITS HAVE NOT BEEN EXCEEDED, THE FCO WILL ALLOW THE FLIGHT TO CONTINUE EVEN IF THE PRIMARY ILL IS VIOLATED.
 3. IF NEITHER THE MCC NOR THE FCO CAN DETERMINE THE PITCH OR YAW RATES, THE FCO WILL ASSUME THAT THE LIMITS HAVE NOT BEEN EXCEEDED AND ALLOW THE FLIGHT TO CONTINUE EVEN IF THE PRIMARY ILL IS VIOLATED.
 4. FLIGHT TERMINATION ACTION WILL BE TAKEN BY THE FCO WHEN, BASED ON ASSESSMENT OF ALL AVAILABLE DATA, THE SECONDARY ILL FLIGHT TERMINATION CRITERIA ARE VIOLATED, REGARDLESS OF THE CONTROLLABILITY STATUS. @[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-256

CONTROLLABILITY (CONTINUED)

- D. DECLARATION OF LOSS-OF-CONTROL: THERE ARE TWO EQUIVALENT METHODS BY WHICH THE MCC CAN COMMUNICATE LOSS OF CONTROL TO THE FCO, AS FOLLOWS: @[053096 PRCB-4001]
1. THE CONTROLLABILITY WARNING LIGHT. VERBAL CONFIRMATION OF LOSS-OF-CONTROL WILL ACCOMPANY LIGHT ACTIVATION.
 2. VERBAL NOTIFICATION OF LOSS-OF-CONTROL, GIVEN BY THE FD VIA CODE WORD TO THE FCO OVER THE FD LOOP.
- E. LOSS OF TWO SSME'S: UNDER THE FOLLOWING CONDITIONS THE FCO WILL USE DISCRETION, BIASED TOWARDS NO ACTION:
1. LOSS OF TWO SSME'S IS CONFIRMED EARLY IN FLIGHT.
 2. THE VEHICLE REMAINS CONTROLLABLE.
 3. THE VEHICLE STAYS WITHIN THE MISSION-SPECIFIC TWO-ENGINE-OUT DELTA-AZIMUTH ENVELOPE.
 4. THE VEHICLE TRANSITIONS THROUGH THE REGION OF MAXIMUM DYNAMIC PRESSURE (MAX Q) WITHOUT BREAKUP.
 5. THE DEBRIS FOOTPRINT APPROACHES OR JUST CROSSES THE SECONDARY ILL LATE IN THE SRB BURN.
 6. THE FCO CONFIRMS THAT THE VEHICLE IIP IS STILL MOVING DOWN RANGE. @[053096 PRCB-4001]

FLIGHT RULES

A4-257

FLIGHT TERMINATION/MANUAL MECO EVALUATION

A. GENERAL @[053096 PRCB-4001]

1. THE FCO WILL EVALUATE ALL DATA SOURCES (E.G., RADARS, TELEMETRY, OPTICAL TRACKERS, FORWARD OBSERVER, TV, ETC.) PLUS INFORMATION RECEIVED FROM THE MCC TO DETERMINE THE REQUIRED ACTION.
2. TIME PERMITTING, A DECISION TO INITIATE FLIGHT TERMINATION WILL BE REACHED AFTER COORDINATION BETWEEN THE FCO AND THE SFCO.
3. TIME PERMITTING, THE MCC WILL BE ADVISED OF IMPENDING FLIGHT TERMINATION PRIOR TO INITIATION OF THE FLIGHT TERMINATION COMMANDS.
4. IN ALL INSTANCES, THE FCO WILL MAKE A DECISION CONCERNING CONTINUED FLIGHT OR TERMINATION BASED ON INTERPRETATION OF REAL-TIME EVENTS AND STS MISSION RULES, ALL AVAILABLE DATA SOURCES, AND SOUND JUDGMENT.

B. LOSS OF DATA/COMMUNICATIONS

1. TOTAL LOSS OF ALL FCO VEHICLE PERFORMANCE DATA: THE FCO WILL BE UNABLE TO DETERMINE IF FLIGHT TERMINATION/MANUAL MECO CRITERIA ARE VIOLATED AND WILL NOT TAKE FLIGHT TERMINATION/MANUAL MECO ACTION. IF MCC STILL HAS DATA, RANGE SAFETY LIMIT AVOIDANCE ACTIONS (RULE {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS) WILL CONTINUE TO BE TAKEN, INCLUDING MANUAL MECO IF NECESSARY.
2. TOTAL LOSS OF ALL MCC DATA: THE MCC WILL BE UNABLE TO DETERMINE THE VEHICLE STATUS.
 - a. IF FCO STILL HAS DATA, FCO WILL PROVIDE MCC WITH ESTIMATES OF TIME TO MECO LINE VIOLATION, INCLUDING "30 SEC TO THE LINE." AT THAT TIME, IF COMM IS AVAILABLE, MCC WILL INITIATE MANUAL MECO PROCEDURES.
@[053096 PRCB-4001] @[081497-6306A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-257

FLIGHT TERMINATION/MANUAL MECO EVALUATION (CONTINUED)

- b. FCO WILL INITIATE THE ABORT REQUEST COMMAND (ABORT LIGHT) IF THE IIP CONTACTS A MECO LINE AS AN INDICATION TO THE CREW THAT AN IMMEDIATE MANUAL MECO IS REQUIRED. THE MANUAL MECO CODEWORD WILL BE VERBALLY TRANSMITTED TO THE MCC SIMULTANEOUSLY ON THE FD AND FCO PRIME LOOPS AS A SECOND INDICATION, IF COMM IS AVAILABLE. @[053096 PRCB-4001]
 3. AFTER TOWER CLEAR AND PRIOR TO SRB SEP
 - a. AMBER ZONE AND LOSS OF FCO/MCC COMM: THE FCO WILL DETERMINE BY REAL-TIME TELEMETRY IF THE VEHICLE IS CONTROLLABLE AND ACT IN ACCORDANCE WITH RULE {A4-256}, CONTROLLABILITY.
 - b. LOSS OF TELEMETRY AT MCC AND ROCC: THE VEHICLE WILL BE ASSUMED TO BE UNDER CONTROL AND VIOLATION OF THE PRIMARY ILL WILL BE ALLOWED. MCC WILL ATTEMPT TO CONFIRM CONTROLLABILITY WITH THE ORBITER CREW AND ADVISE THE FCO.
 - c. LOSS OF FCO/MCC COMM AND FCO TELEMETRY: THE VEHICLE WILL BE ASSUMED TO BE UNDER CONTROL AND VIOLATION OF THE PRIMARY ILL WILL BE ALLOWED.
 4. LOSS OF FCO/MCC COMM AFTER SRB SEP: FCO WILL REQUIRE MCC/CREW ACTION IN ACCORDANCE WITH RULES {A4-258}, FLIGHT TERMINATION/MANUAL MECO CRITERIA, PART E, AND {A4-259}, FLIGHT TERMINATION/MANUAL MECO ACTION.
 5. RADAR INDICATES BREAKUP AND TELEMETRY INDICATES VEHICLE UNDER CONTROL: THE VEHICLE WILL BE ASSUMED TO BE INTACT AND THE FCO WILL ACT IN ACCORDANCE WITH RULE {A4-256}, CONTROLLABILITY.
- C. CONFLICTING DATA: IN THE EVENT OF A CONFLICT IN MECO LINE PROXIMITY ASSESSMENT BETWEEN THE MCC AND FCO WHEN BOTH HAVE VALID TRAJECTORY DETERMINATION DATA, THE FCO IS PRIME FOR DETERMINATION OF BOTH THE PROXIMITY TO THE LINE AND THE POTENTIAL REQUIREMENT FOR MANUAL MECO. @[053096 PRCB-4001]

FLIGHT RULES

A4-258

FLIGHT TERMINATION/MANUAL MECO CRITERIA

FLIGHT TERMINATION ACTION AND FLIGHT TERMINATION CRITERIA, AS SPECIFIED IN EWR 127-1, ARE SUPERSEDED BY THIS RULE. FLIGHT TERMINATION WILL BE INITIATED, OR A MANUAL MECO REQUESTED, BY THE FCO ONLY IF CONTINUATION OF THE FLIGHT VIOLATES THE CRITERIA SPECIFIED IN THIS RULE. ©[053096 PRCB-4001]

- A. PRIOR TO SRB IGNITION: AFTER SSME IGNITION, PAD ABORTS ARE POSSIBLE. FIRE OR OTHER CATASTROPHIC EVENTS MAY BE APPARENT FROM VEHICLE BEHAVIOR DATA. UNDER NO CIRCUMSTANCES WILL THE FCO TAKE FLIGHT TERMINATION ACTION PRIOR TO SRB IGNITION.
- B. SRB IGNITION TO TOWER CLEAR (7 SEC): IF A CATASTROPHIC FAILURE OCCURS, THE FCO WILL TAKE FLIGHT TERMINATION ACTION TO PREVENT INTACT IMPACT, CONTAIN THE SRB'S, AND DISPERSE THE ET PROPELLANTS.
- C. TOWER CLEAR TO SRB NLE:
 - 1. THE FCO WILL TAKE FLIGHT TERMINATION ACTION WHEN TRAJECTORY DETERMINATION SOURCES INDICATE THAT THE VEHICLE HAS VIOLATED FLIGHT TERMINATION CRITERIA, SUBJECT TO RULE {A4-256}, CONTROLLABILITY.
 - 2. IF A CATASTROPHIC FAILURE OCCURS, THE FCO WILL TAKE FLIGHT TERMINATION ACTION TO PREVENT INTACT IMPACT, CONTAIN THE SRB'S, AND DISPERSE THE ET PROPELLANTS.
 - a. FOR VEHICLE PITCH OVER, A FLIGHT TERMINATION DECISION WILL BE BASED ON TRAJECTORY DETERMINATION DATA CONFIRMED WITH MCC INDICATION OF NEGATIVE HDOT (DOWNWARD ALTITUDE RATE), OR THE PRIMARY VEHICLE BEHAVIOR DATA CUE.
 - b. FOR VEHICLE BREAKUP, A FLIGHT TERMINATION DECISION WILL BE BASED ON THE PRIMARY VEHICLE BEHAVIOR DATA CUE, TWO SECONDARY VEHICLE BEHAVIOR DATA CUES, OR BOTH ONE SECONDARY AND ONE TERTIARY VEHICLE BEHAVIOR DATA CUE. ©[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-258

FLIGHT TERMINATION/MANUAL MECO CRITERIA
(CONTINUED)

3. FOR STS MISSIONS EQUIPPED WITH THE SRB RADAR BEACON TRACKING SYSTEM (SRBTS), FLIGHT TERMINATION ACTION WILL BE DELAYED TO ALLOW MAXIMUM SEPARATION OF THE ORBITER AND THE SEPARATED ELEMENTS IF POSITIVE TRACK OF BOTH SRB'S CONFIRMS THE SRB'S ARE NOT ENDANGERING PUBLIC SAFETY AND THE DEBRIS ELLIPSE HAS MOVED OFF LAND. @[053096 PRCB-4001]
 4. IF CONSIDERED VALID BY THE FCO, THE DEBRIS ELLIPSE DISPLAY WILL BE THE SOLE CRITERIA FOR DETERMINING FLIGHT TERMINATION LINE VIOLATION. IF THE DEBRIS ELLIPSE DISPLAY IS CONSIDERED TO BE INVALID BY THE FCO, ALL OTHER VALID DISPLAYS MUST CONFIRM THE FLIGHT TERMINATION CRITERIA VIOLATION. FLIGHT TERMINATION ACTION UNDER THESE CRITERIA IS SUBJECT TO RULE {A4-256}, CONTROLLABILITY.
- D. SRB NLE TO SRB SEPARATION: THE FCO WILL TAKE FLIGHT TERMINATION ACTION WHEN TRAJECTORY DETERMINATION SOURCES INDICATE THAT THE VEHICLE HAS VIOLATED FLIGHT TERMINATION CRITERIA, SUBJECT TO RULE {A4-256}, CONTROLLABILITY.
- E. SRB SEPARATION TO MECO: THE FCO WILL CALL FOR MANUAL MECO ONLY WHEN VALID TRAJECTORY DETERMINATION SOURCES INDICATE A MECO LINE IS VIOLATED. A MANUAL MECO CALL WILL BE PRECEDED BY NOTIFICATION IN ACCORDANCE WITH FLIGHT RULE {A4-254}, FCO TO MCC WARNING NOTIFICATION, AND WILL BE EXECUTED PER RULE {A4-259}, FLIGHT TERMINATION/MANUAL MECO ACTION.
- F. LANDMASS OVERFLIGHT GATES
1. A NOMINAL VEHICLE THAT VIOLATES A GATE WILL NOT REQUIRE MANUAL MECO ACTION, AND THE IIP WILL BE ALLOWED TO PASS THROUGH THE GATE.
 2. WHILE LIMIT LINE AVOIDANCE ACTIONS ARE BEING TAKEN, MANUAL MECO WILL NOT BE INVOKED UNTIL VIOLATION OF A SOLID MECO LINE. @[053096 PRCB-4001]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-258

FLIGHT TERMINATION/MANUAL MECO CRITERIA (CONTINUED)

3. IF THERE IS IRREFUTABLE EVIDENCE THAT THE VEHICLE IS NON-NOMINAL AND CANNOT PROCEED TO AN ACCEPTABLE INTACT OR CONTINGENCY ABORT MODE AS DETERMINED BY THE MCC, THE MCC/CREW WILL REACT PER RULE {A4-260}, RANGE SAFETY LIMIT AVOIDANCE ACTIONS. IF, AFTER EXECUTION OF AVAILABLE RECOVERY OPTIONS, THE VEHICLE STATUS IS CONFIRMED UNRECOVERABLE, MANUAL MECO WILL BE INITIATED TO PRECLUDE VIOLATION OF THE GATE. @[053096 PRCB-4001]

4. IF THE VEHICLE STATUS IS UNKNOWN OR RECOVERABLE OR PROCEEDING TO AN ACCEPTABLE INTACT OR CONTINGENCY ABORT, THE IIP WILL BE ALLOWED TO PASS THROUGH THE GATE.

G. EXCLUSIONS FOR GUIDANCE MODE TRANSITION

1. THIS RULE IS DESIGNED TO PROTECT A VEHICLE AGAINST FLIGHT TERMINATION ACTION DURING THE TRANSITION FROM USE OF THE DEBRIS FOOTPRINT DESTRUCT CRITERIA, WITH ITS ASSOCIATED ILL'S, TO THE USE OF THE IIP/DESTRUCT LINE CRITERIA, WHICH OCCURS AT APPROXIMATELY T + 120 SEC. THE FTS IS STILL AVAILABLE FOR USE UNTIL SRB SEP (APPROXIMATELY T + 125 SEC), AT WHICH TIME THE DESTRUCT LINES BECOME MANUAL MECO LINES.

2. A CONTROLLABLE VEHICLE NOT IN VIOLATION OF EITHER THE BACKUP ILL IN THE IMMEDIATE LAUNCH AREA OR THE SINGLE ILL'S WHICH EXTEND UP THE COAST FROM THE LAUNCH AREA MAY SUBSEQUENTLY BE IN VIOLATION OF THE IIP DESTRUCT/MECO LINE AFTER IT IS DISPLAYED AT APPROXIMATELY T + 120 SECONDS. NEITHER FLIGHT TERMINATION ACTION NOR MANUAL MECO ACTION WILL BE REQUIRED IF THE FOLLOWING CRITERIA ARE SATISFIED:

a. VEHICLE ATTITUDES ARE STABLE.

b. THE IIP IS NOT MOVING FURTHER INTO THE VIOLATION REGION.

c. THE IIP BEGINS TO MOVE TOWARD THE NON-VIOLATION REGION FOLLOWING SRB SEPARATION AND INITIATION OF SECOND STAGE GUIDANCE. @[053096 PRCB-4001]

FLIGHT RULES

A4-259

FLIGHT TERMINATION/MANUAL MECO ACTION

- A. FLIGHT TERMINATION ACTION: FLIGHT TERMINATION ACTION IS APPLICABLE DURING FIRST STAGE ONLY AND IS ACCOMPLISHED VIA FCO COMMAND ACTIVATION OF THE FTS. @[081497-6306A]
- B. MANUAL MECO PROCEDURE: MANUAL MECO ACTION IS APPLICABLE DURING SECOND STAGE ONLY AND IS PERFORMED BY THE FLIGHT CREW UPON DIRECTION FROM THE MCC OR FCO, AS SPECIFIED BELOW. @[053096 PRCB-4001]
1. THE FDO WILL CALL "15 SEC TO MANUAL MECO" WHEN THE IIP IS 30 SECONDS FROM THE MECO LINE.
 2. AT THAT TIME, CAPCOM WILL CALL TO CREW "15 SECONDS TO MANUAL MECO, RETURN TO AUTO (IF CSS), PREPARE FOR MANUAL MECO." THE RETURN TO AUTO FLIGHT CONTROL ALLOWS ACTIVATION OF AUTO THREE-SSME OUT CONTINGENCY LOGIC.
 3. ONCE A GOOD ONBOARD CONFIGURATION IS CONFIRMED, MCC WILL CALL FOR "MANUAL MECO NOW." FD AND/OR FDO WILL SEND THE ABORT REQUEST COMMAND (ABORT LIGHT) AS AN ADDITIONAL CUE.
 4. IF FOR ANY REASON, THE IIP CONTACTS THE MECO LINE, THE FCO WILL INITIATE THE ABORT REQUEST COMMAND (ABORT LIGHT) AND WILL TRANSMIT THE MANUAL MECO CODEWORD (REF. PARAGRAPH D, BELOW) TO THE MCC AT THAT TIME.
- C. TWO CUES ARE REQUIRED FOR THE CREW TO INITIATE MANUAL MECO. IMMEDIATE MANUAL MECO ACTION IS REQUIRED WHEN ANY OF THE FOLLOWING CRITERIA ARE MET:
1. "FIFTEEN SEC TO MANUAL MECO" CALL AND "MANUAL MECO NOW" CALL.
 2. "FIFTEEN SEC TO MANUAL MECO" CALL AND ABORT LIGHT. NOTE: IF THE ABORT LIGHT WAS ALREADY ON WHEN "15 SEC TO MANUAL MECO" CALL WAS MADE, MANUAL MECO ACTION WILL BE TAKEN AFTER 15 SEC.
 3. ABORT LIGHT ON AND "MANUAL MECO NOW" CALL. @[053096 PRCB-4001]
 4. ANY OTHER CUES AS APPROPRIATE. @[081497-6306A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-259 **FLIGHT TERMINATION/MANUAL MECO ACTION (CONTINUED)**

D. MANUAL MECO CODEWORD @[081497-6306A]

1. THE MANUAL MECO CODEWORD IS USED BY THE FCO TO INDICATE TO THE MCC THAT AN IMMEDIATE MANUAL MECO IS REQUIRED. WHEN USED, IT IS TRANSMITTED VERBALLY OVER BOTH FD AND FCO PRIME LOOPS SIMULTANEOUSLY.
2. UPON MCC RECEIPT OF THE CODEWORD, CAPCOM WILL IMMEDIATELY NOTIFY THE CREW WITH THE FOLLOWING CALL: "MANUAL MECO NOW, MANUAL MECO NOW." @[053096 PRCB-] @[081497-6306A]

A4-260 **RANGE SAFETY LIMIT AVOIDANCE ACTIONS**

THE FOLLOWING PRIORITIZED ACTIONS WILL BE TAKEN BY THE MCC AND/OR CREW IN ORDER TO PRECLUDE VIOLATION OF RANGE SAFETY DESTRUCT CRITERIA. @[053096 PRCB-4001]

A. FIRST STAGE:

1. STATE VECTOR UPDATE, IF TRAJECTORY DEVIATION IS DUE TO ERRONEOUS ONBOARD NAVIGATION.
2. ENGAGE CSS (APPLICABLE ONLY AFTER 90 SECONDS MET) AND MANUALLY FLY AWAY FROM LIMIT LINES AS DESCRIBED UNDER PART B.3 BELOW.
3. BFS ENGAGE, IF TRAJECTORY DEVIATION IS DUE TO ERRONEOUS GUIDANCE.

NOTE: BFS ENGAGE WILL ONLY BE USED IF IT IS KNOWN THAT IT WILL CORRECT THE DEVIATION. BFS ENGAGE SEVERELY LIMITS POTENTIAL SECOND STAGE ACTIONS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A4-260 **RANGE SAFETY LIMIT AVOIDANCE ACTIONS (CONTINUED)**

B. SECOND STAGE:

1. STATE VECTOR UPDATE, IF TRAJECTORY DEVIATION IS DUE TO ERRONEOUS ONBOARD NAVIGATION.
2. PRE-MECO ATO ABORT SELECTION, IF VARIABLE IY IS ENABLED.
3. ENGAGE CSS AND MANUALLY FLY AWAY FROM LIMIT LINES. MCC WILL PROVIDE YAW STEERING COMMANDS OVER AIR-TO-GROUND. FDO IS PRIME FOR DETERMINATION OF YAW STEERING COMMANDS. NOTE: THIS OPTION IS NO LONGER AVAILABLE AFTER A BFS ENGAGE.
4. PRE-MECO TAL OR RTLS ABORT SELECTION (SELECT HIGHEST APPLICABLE ABORT PRIORITY MODE).

NOTE: PRIORITY OF CSS AND TAL/RTLS SELECTION OVER BFS IN SECOND STAGE MAY BE WAIVED IF IT IS KNOWN THAT BFS WILL RECOVER AUTO GUIDANCE TO CORRECT TARGET CONDITIONS. ©[053096 PRCB-4001]

5. BFS ENGAGE. ©[053096 PRCB-4001]

NOTE: BFS ENGAGE WILL ONLY BE CONSIDERED IF IT IS KNOWN THAT IT WILL CORRECT THE DEVIATION AND IF MORE THAN ONE SSME IS RUNNING. SINGLE-SSME FLIGHT ON THE BFS IS NOT POSSIBLE, AND AUTO, THREE-SSME OUT CONTINGENCY LOGIC IS NOT AVAILABLE IN THE BFS.

6. MANUAL MECO: REFERENCE RULE {A4-259}, FLIGHT TERMINATION/MANUAL MECO ACTION. ©[081497-6306A]

FLIGHT RULES

SECTION 5 - BOOSTER

FAILURE DEFINITIONS

A5-1 **LOSS OF SRB THRUST VECTOR CONTROL (TVC)** @[012402-4987]

SRB TVC IS LOST WHEN THE HYDRAULIC SUPPLY PRESSURES OF BOTH HPU'S ON THE SAME SRB ARE 1000 PSIG OR LESS. @[041196-1874A]

The SRB TVC system has a lock-out style valve which will actuate to the lock position when the hydraulic supply pressure is 1000 to 600 psig. Two hydraulic power units (HPU's) are installed per SRB, and both can supply hydraulic power to the TVC actuators. Actuator source pressure is switched from the primary HPU to the secondary HPU when the hydraulic supply pressure on a single HPU reaches 2050 ±150 psig. This switchover is indicated by an Actuator Primary Pressure OK discrete value of False and it effectively loses one HPU. However, TVC is not lost until neither HPU can deliver hydraulic supply pressure of 1000 psig to the actuators. (Reference System Handbook Drawing 9.14 and USBI documents 10SPC-0055, rev B, section 4.2.2.10, and 10MNL-0045, Rev D). @[012402-4987]

Note: Above 1000 psig, the lock-out valve opens, and TVC is still available. @[041196-1875A]

A5-2 **SPACE SHUTTLE MAIN ENGINE OUT** @[121197-6472A]

PREMATURE ENGINE SHUTDOWN IS CAUSED BY AN ENGINE LIMIT EXCEEDED, DUAL CONTROLLER ELECTRONICS FAILURES, OR A COMBINATION OF A SINGLE CHANNEL LIMIT EXCEEDED AND A CONTROLLER ELECTRONIC FAILURE. THE CUES FOR DETERMINING AN ENGINE SHUTDOWN ARE DEFINED IN PARAGRAPHS A, B, C, AND D OF THIS RULE. THE SHUTDOWN SOFTWARE LIMITS ARE DEFINED IN PARAGRAPH E. THE AVIONIC FAILURE COMBINATIONS ARE DEFINED IN PARAGRAPH F.

ENGINE OUT DETERMINATION WILL BE BASED ON THE FOLLOWING CUES:

- A. ONBOARD (WITH VALID SSME DATA):
1. RED MAIN ENGINE STATUS LIGHT IS ILLUMINATED.
 2. PC < 30 PERCENT (METER)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

3. SSME FAIL L (C,R)

Two cues are required for calls that may cause an abort. The MPS dedicated display driver sequence in the flight software illuminates the red status light if the SSME is in the shutdown or post-shutdown phase. The SSME operations sequence in the flight software uses power level < 30 percent as the indication that the SSME has shut down. The 30 percent value represents a power level below which the engine cannot operate. The PASS SSME fail message is generated by the GAX when the engine fail flag is set by the SSME OPS sequence. The flag is set when either the engine status word shows shutdown or post shutdown phase, or a data path failure has occurred and the engine safing command flag has been set.

B. MCC (WITH VALID SSME DATA):

AT LEAST TWO OF THE FOLLOWING CUES ARE REQUIRED:

1. SSME FAILURE IDENTIFIER (FID) "013" INDICATING SSME SHUTDOWN FOR REDLINE VIOLATION.
2. SHUTDOWN OR POST-SHUTDOWN PHASE (REFLECTED IN ENGINE STATUS WORD).
3. PC < 900 PSIA.
4. SSME FAIL L (C,R)

Two cues are required for calls that may cause an abort. A FID 013 issued by the SSME controller represents an engine shutdown due to a redline exceedance. The redline that was exceeded is defined by the delimiter part of the FID. Shutdown and post-shutdown phases are set in the engine status word when the SSME controller commands shutdown. Pc of 900 psia corresponds to approximately 30 percent power level. The PASS SSME fail message is generated by the GAX when the engine fail flag is set by the SSME OPS sequence. The flag is set when either the engine status word shows shutdown or post shutdown phase, or a data path failure has occurred and the engine safing command flag has been set. ©[121197-6472A]

C. ONBOARD (WITH SSME DATA PATH FAILURE):

AT LEAST THREE OF THE FOLLOWING ARE REQUIRED:

1. G-LEVEL DECREASE (ON DEDICATED DISPLAY G-METER OR BFS CRT TRAJECTORY DISPLAY G-LINE).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

2. A HELIUM, DP/DT FAULT MESSAGE FOLLOWED BY CONSTANT ENGINE HELIUM TANK PRESSURE (IF NO PREVIOUS FAULT MESSAGE FOR A HELIUM LEAK).
3. MPS H₂ OUT P L (C,R)
4. MPS O₂ OUT T L (C,R)

During second stage when the first, second, and third engines shut down in sequence, the g-level decreases by 33, 50, and 100 percent, respectively. During first stage, the SRB thrust far exceeds the SSME thrust making it difficult to detect an engine shutdown based upon changes in vehicle acceleration. If the engine did not previously have a helium leak, the crew will get a helium DP/DT fault message, followed by constant helium tank pressure on the affected engine. If the tank pressure remains constant, no helium is being used and; therefore, the engine has shut down. In OI-22 and subs, the crew will get fault messages for both the GH₂ outlet pressure and GO₂ outlet temperature dropping below 1050 psia and 125 deg F, respectively. Because both of these parameters are channelized through the same OI MDM and powered from the same OI DSC, the two fault messages could be generated by a single MDM or DSC failure. For this reason, the crew must use three of the four cues when determining an engine out behind a data path failure. ©[020196-1812] ©[121197-6472A]

D. MCC (WITH SSME DATA PATH FAILURE):

AT LEAST TWO OF THE FOLLOWING CUES ARE REQUIRED:

1. A SUDDEN DROP IN ACCELERATION OR THRUST FACTOR AS DETERMINED FROM TELEMETRY DATA. (THRUST FACTOR AVAILABLE IN SECOND STAGE ONLY).
2. ORBITER GH₂ OUTLET PRESSURE < 800 (1050) PSIA OR ORBITER GO₂ OUTLET TEMPERATURE < 260 DEG (300 DEG) F.
3. A HELIUM DP/DT FAULT MESSAGE FOLLOWED BY CONSTANT ENGINE HELIUM TANK PRESSURE (IF NO PREVIOUS FAULT MESSAGE FOR A HELIUM LEAK).
4. A DROP IN SECOND STAGE PERFORMANCE AS DETERMINED BY THE ARD.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

Two cues are required for calls that may cause an abort. For an engine failure in second stage, an abrupt drop in vehicle acceleration will result. The GH_2 outlet pressure and GO_2 outlet temperature are orbiter parameters that can be used to determine the status of an engine. Both the GH_2 and GO_2 limits are set to correspond to an engine power level of approximately 30 percent. This is well below the power level that an engine can operate. Flight data from STS 51-F indicates the GO_2 outlet temperature was < 125 deg F for about 15 seconds post engine shutdown. The GO_2 outlet temperature did rise again post shutdown to a value of approximately 300 deg F. Since both orbiter parameters are channelized through the same OI MDM and powered from the same OI DSC, the two are grouped together as one engine out cue. If an engine did not previously have a helium leak, the crew will get a DP/DT fault message while the engine initiates shutdown purges. Once the helium purges have terminated, the engine will no longer use helium and; therefore, the helium tank pressure will remain constant. Thrust factor (FT FACTOR) is a second stage guidance downlisted parameter from the vehicle and is calculated by dividing the expected thrust by the calculated thrust. If an engine shuts down behind a data path failure, the thrust factor will drop to a value less than 1.0. If an engine fails in first stage, thrust factor is not available, but the second stage performance as determined by the ARD would reflect the loss in performance from the engine shutdown.

FLIGHT RULES

A5-2 SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

NOTES:

- [1] MUST EXCEED LIMIT OR FAIL REASONABLENESS FOR 60 MSEC.

A parameter must be over its redline or reasonableness limit for three consecutive 20 msec controller cycles before action is taken by the controller. This requirement prevents action from being taken on a data hit.

- [2] THE HPOTP SECONDARY SEAL PRESSURE REDLINE IS ONLY ACTIVE ON THE PHASE II SSME. THIS REDLINE IS NOT PRESENT ON THE BLOCK I SSME, BLOCK IIA SSME, OR THE BLOCK II SSME. @[032395-1765A] @[121197-6472A]
- [3] SHUTDOWN FOR AN OUT-OF-LIMIT CONDITION INITIATED BY MAIN ENGINE CONTROLLER IF LIMIT ENABLED. LIMIT INHIBIT/ENABLE OPERATIONS DEPENDENT ON THE POSITION OF THE MAIN ENGINE LIMIT SHUTDOWN SWITCH.

This indicates that, if the limit shutdown logic is enabled, then a redline violation will result in an SSME shutdown.

- [4] IF ALL SENSORS FAIL REASONABLENESS, THAT REDLINE IS DELETED. @[092195-1792B]

Redline monitoring is no longer performed because the redline sensors have failed.

- [5] THE HPOTP INTERMEDIATE SEAL PRESSURE LOWER REDLINE IS 170 PSIA ON THE PHASE II SSME AND IS 159 PSIA ON THE BLOCK I SSME, BLOCK IIA SSME, AND THE BLOCK II SSME. @[032395-1765A] @[020196-1812]
- [6] THE REDLINE UPPER LIMIT IS CALCULATED IN REAL TIME BY CONTROLLER SOFTWARE AND IS A FUNCTION OF ENGINE POWER LEVEL. THEREFORE, THE LIMITS AT 67, 100, 104, AND 109 PERCENT POWER LEVELS ARE APPROXIMATELY 2436, 3543, 3677, AND 3846 PSIA FOR A PHASE II SSME, 2447, 3559, 3694, AND 3862 PSIA FOR A BLOCK I SSME, AND 2243, 3254, 3392 (@104.5), AND 3530 PSIA FOR A BLOCK IIA SSME, RESPECTIVELY. THIS REDLINE HAS BEEN DELETED FOR THE BLOCK II SSME. @[111094-1732] @[092195-1792B] @[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-2 SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)**

The HPFTP coolant liner pressure varies with actual chamber pressure.

- [7] THIS REDLINE MAY BE REVISED ON A FLIGHT-BY-FLIGHT BASIS TO ENSURE COMPARABLE MARGIN ON CHANNEL A AND CHANNEL B BETWEEN THE PREDICTED NOMINAL VALUE AND THE REDLINE VALUE. IF A CHANNEL A TO B BIAS IS ADDED, THEN THIS BIAS IS CARRIED OVER INTO THE REASONABLENESS CALCULATIONS FOR THE INTERCHANNEL CHECKS. @[092195-1792B]

Some flight SSME HPFTP's may operate at a lower temperature. Engines with these turbopumps may have their channel A redline adjusted downward to provide the same 100 deg R difference between the main stage operating temperature and the redline as present on other HPFTP's. @[111094-1732]

- [8] THE INTRACHANNEL CHECK AND THE CHANNEL AVERAGE MUST BE WITHIN THE SPECIFIED LIMITS IN ORDER TO BE PROCESSED BY THE CONTROLLER'S SHUTDOWN LIMIT LOGIC. THESE REASONABLENESS CHECKS ARE IN ADDITION TO THE NORMAL SENSOR MONITORING PERFORMED FOR IGNITION CONFIRMED AND CONTROL LOOP PROCESSING QUALIFICATION.

The MCC Pc channels will be disqualified for control purposes for an intrachannel difference of greater than 75 psi. The MCC Pc redline logic incorporates two reasonableness criteria to ensure that only valid pressures will be used.

- [9] THE LOGIC FOR THE HPFT AND THE HPOT DISCHARGE TEMPERATURE WAS MODIFIED BY THE IMPLEMENTATION OF THE THERMOCOUPLES. THE THERMOCOUPLE MODIFICATION UTILIZES TWO SENSORS PER CHANNEL FOR A TOTAL OF FOUR SENSORS PER REDLINE. @[092195-1782B] @[092195-1782B]

The sensor processing logic was modified to accommodate the different failure modes for the thermocouple sensors (versus the previous resistive thermal devices-RTD's) and to handle the additional number of sensors. The additional sensors were added to increase reliability against sensor failures resulting in pad aborts, erroneous in-flight shutdown, or the loss of redline protection. @[121197-6472A]

- [10] THE HPFTP COOLANT LINER PRESSURE REDLINE IS ONLY AVAILABLE FOR THE PHASE II, BLOCK I, AND BLOCK IIA ENGINE TYPES. @[121197-6472A]

The Block II SSME uses a Pratt & Whitney HPFTP/AT which does not have a coolant liner.

- [11] A COLD JUNCTION REFERENCE TEMPERATURE (T_{CJ}) IS PROVIDED FOR EACH CONTROLLER CHANNEL TO PROCESS THE HOT GAS THERMOCOUPLE SENSOR DATA. THE T_{CJ} IS USED TO CALIBRATE THE TEMPERATURE MEASUREMENT INPUT. EACH CHANNEL HAS A SINGLE RTD T_{CJ} WHICH IS USED FOR BOTH THE HPOT AND HPFT TEMPERATURE MEASUREMENTS. IF ONE CHANNEL'S T_{CJ} IS DISQUALIFIED, THE OTHER CHANNEL'S T_{CJ} WILL BE USED FOR BOTH CHANNELS. IF BOTH T_{CJ} 'S ARE DISQUALIFIED, THE LAST QUALIFIED VALUE WILL BE USED FOR SENSOR PROCESSING.

Thermocouple measurements require a cold junction reference temperature to provide accurate readings. The controller and its software was modified to accommodate the addition of these two transducers, which are required for use with the thermocouples.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-2 SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)**

- a. *PARAMETERS - This table covers parameters which the SSME controller qualifies, monitors, and uses to shut down the engine.*
- b. *CONTROLLER SHUTDOWN PROCESSING - All qualified sensors must vote for shutdown for action to proceed. ©[092195-1792B]*
- c. *QUALIFICATION/REASONABLENESS TESTING - Qualification, also known as reasonableness testing, is required to qualify the sensors for application to shutdown logic. The values chosen screen out sensors with identified sensor problems. ©[121197-6472A]*
- d. *SHUTDOWN LIMITS - Redline parameters are monitored to assure that the engine is performing within safe operating conditions. Limits are set to guard against uncontained SSME damage. The limits are based upon test stand data, flight experience, and engineering analysis. The engine redline design criteria was defined by MSFC and approved by Level II.*
- e. *HPFTP COOLANT LINER PRESSURE ©[092195-1792B]*

Phase II, Block I, and Block IIA SSME's - The redline limit was selected to prevent buckling of the coolant liner and subsequent stalling of the HPFTP. This limit was derived from an uncontained failure of SSME 0108 during a ground test. The exhaust turnaround duct buckled, the HPFTP stalled, and the low pressure fuel duct ruptured. Based upon this incident and analysis, the buckling pressure has been determined to be 595 psid with the delta pressure being measured between the coolant liner cavity and the turnaround duct. The redline was set to protect for a delta pressure of 400 psi and has been verified by lab tests. The reasonableness limits of 4500 and 1800 psi were established because they bracket the sensor range.

- f. *HPFT TURBINE DISCHARGE TEMPERATURE ©[092195-1792B]*

The limit was derived from analysis and protects against stress rupture of the HPFT blades due to high temperature operation. This redline was developed following uncontained failures on engines 0204 and 2013 during ground testing. These failures were attributed to turbine blade failure which resulted in HPFTP seizure and low pressure fuel duct rupture. Subsequent analysis determined a 2160 deg R maximum turbine blade root temperature capability for 109 percent power level. This temperature equates to a 2060 deg R turbine exhaust temperature. The 1960 deg R limit provides a 100 deg R margin for the Phase II and Block I SSME's. The 1860 deg R limit provides a 200 deg R margin for the Block IIA and Block II SSME's. This reduction for the Block IIA and Block II SSME's still leaves satisfactory margin from nominal operating conditions to the redline, due to the reduced temperature environment facilitated by the large throat MCC (reference 8/15/97 Ascent/Entry Flight Techniques Panel). The channel A location on some HPFTP's may run cooler, thus necessitating a lower redline value (potentially as low as 1850 deg R for the Phase II and Block I or 1750 deg R for the Block IIA and Block II). ©[111094-1732] ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)

The upper reasonableness limit of 2650 deg R guards against open circuits and analog-to-digital (A/D) converter failures. The intrachannel and interchannel reasonableness limits are screens for internal short circuits. An absolute lower limit is not feasible since a short will result in an in-range failure signature. If only one sensor remains, only the open circuit failure mode is detectable.

©[092195-1792B] ©[121197-6472A]

g. **HPOT TURBINE DISCHARGE TEMPERATURE** ©[092195-1792B]

The upper redline limit was derived from analysis to protect the heat exchanger from overheating and rupturing leading to catastrophic failure. The limit of 1760 deg R provides a 100 deg margin (1860 deg R is based on meeting one mission life capability; i.e., until nominal predicted MECO) for the Phase II, and Block I SSME's. The 1660 deg R limit provides a 200 deg R margin for the Block IIA and Block II SSME's. This reduction for the Block IIA and Block II SSME's still leaves satisfactory margin from nominal operating conditions to the redline, due to the reduced temperature environment facilitated by the large throat MCC (reference 8/15/97 Ascent/Entry Flight Techniques Panel). The lower redline limit of 720 deg R provides protection against inadvertent deep throttling of the engine, which causes ice formation in the HPOT turbine, subsequent turbine imbalance, and potential catastrophic HPOTP failure. ©[121197-6472A]

The reasonableness limit of 2650 deg R guards against open circuits and A/D converter failures. The intrachannel and interchannel reasonableness limits are screens for internal short circuits. An absolute lower limit is not feasible since a short will result in an in-range failure signature. If only one sensor remains, only the open circuit failure mode is detectable. ©[121197-6472A]

h. **HPOTP SECONDARY SEAL PRESSURE**

PHASE II SSME - The redline limit was derived from analysis to prevent the LO₂ from the HPOTP pump combining with the hot fuel-rich turbine gas in the seal purge cavity. The redline protects against failures of the HPOTP primary or secondary turbine seals. The limit is set to ensure that the HPOTP intermediate seal cavity pressure is greater than the HPOTP secondary seal cavity pressure by 9 psi during main stage, with a minimum seal purge flow rate and a maximum seal gap. Both reasonableness tests provide protection against avionics failures of the pressure sensor system. ©[032395-1765A] ©[092195-1792B]

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME - Due to significant design changes in the alternate HPOTP seal package on these engines, this transducer and its redline have been eliminated. Rationale for this is the oxidizer and secondary H₂ drain pressure margins are large, and a secondary labyrinthine (lab) seal analysis at more than six times its maximum possible operating clearance showed helium barrier delta pressure is insensitive to lab seal clearance changes. ©[032395-1765A] ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-2

SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)i. *HPOTP INTERMEDIATE SEAL PRESSURE -*

PHASE II SSME - The redline limit was derived from analysis to prevent the LO₂ from the HPOTP pump combining with the hot fuel-rich turbine gas in the purge cavity. This redline guards against excessive seal wear or loss of helium purge by ensuring that the HPOTP intermediate seal cavity pressure is greater than the HPOTP secondary seal cavity pressure by 9 psi during main stage under the worst seal gap condition. Both reasonableness tests provide protection against avionics failures of the pressure sensor system. ©[032395-1765A] ©[092195-1792B] ©[121197-6472A]

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME - The redline limit was derived from analysis to prevent LO₂ from the alternate HPOTP pump combining in the purge cavity with H₂ from the fuel cooled roller and ball bearing package. This redline guards against excessive seal wear or loss of helium purge by ensuring that the HPOTP intermediate seal cavity pressure is greater than the HPOTP O₂ cavity and secondary H₂ cavity pressures by 10 psi during main stage under the worst seal gap condition. Both reasonableness tests provide protection against avionics failures of the pressure sensor system. ©[032395-1765A] ©[092195-1792B] ©[121197-6472A]

j. *MCC PC SENSOR AVERAGE - The redline was initially added to protect the engine against the type of failure seen on engine 2106, in which a burnthrough of the bellows section of the high pressure oxidizer turbopump turbine section occurred. This failure was caused by an oxidizer preburner failure and resulted in a bypass of hot gas flow from the turbine directly into the hot gas manifold which caused a massive drop in MCC Pc. The original redline limit of 400 psi below the commanded Pc was chosen based upon the amount of damage sustained by the engine 2106 high-pressure oxidizer turbopump at the time the engine was shut down by a facility redline. The MCC Pc redline was updated for STS-89 and subsequent flights to 200 psi below the commanded Pc during steady state operations, while retaining the 400 psi during throttling and when power level is less than or equal to 75 percent RPL. This update was based upon the amount of damage sustained by engine 0524 which experienced a nozzle failure and uncontained shutdown during test 901-933. ©[121197-6472A]*

The intrachannel reasonableness limit (|Bridge 1 - Bridge 2| ? 125 psi) protects against single-bridge failures. Due to hardware and software limitations in the controller for sampling sensor inputs, the delta value must be set large enough to account for differences in the actual MCC Pc if the actual MCC Pc is decreasing rapidly due to a real engine combustion problem. If the value is set too tight, the actual MCC Pc could drop greater than the reasonableness limit between sampling the bridge 1 and bridge 2 sensor measurements. A smaller value could allow one or both MCC Pc channels to be erroneously disqualified. If both channels are disqualified, the MCC Pc redline is disabled at a time it is most needed. The redline qualification limit was increased from 75 psi to 125 psi in response to the catastrophic failure of development SSME 0212 (test 904-44), during which the actual decay rate of the MCC Pc was 105 psi between input samples of the A1/A2 and B1/B2 Pc pairs. The channel average upper reasonableness limit protects against an off-scale high sensor pair or input electronics failure. The lower limit protects against a failed low sensor pair or input electronics failure. ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-2 SPACE SHUTTLE MAIN ENGINE OUT (CONTINUED)**

This matrix identifies failures which result in loss of controller redundancy and in premature engine shutdown. Shutdown caused by dual controller failures cannot be prevented even if the limit shutdown monitoring is inhibited. In these cases when the second failure occurs, the engine will immediately shut down via the controller's fail-safe pneumatic shutdown sequence. Shutdowns caused by redline violations can be inhibited manually by the limit shutdown monitoring switch or automatically by the GPC software after an engine out or data path failure.

Rules {A5-5}, SUSPECT ENGINE; {A5-6}, SSME REDLINE SENSOR FAILED; {A5-7}, SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN; {A5-8}, SPACE SHUTTLE MAIN ENGINE TYPES; {A5-110}, SSME PERFORMANCE DISPERSION; and {A5-111}, AC BUS SENSOR ELECTRONICS CONTROL [CIL], reference this rule. [121197-6482B] [121197-6472A] [111298-6785A] [ED]

A5-3 STUCK THROTTLE

FAILURE OF A MAIN ENGINE TO THROTTLE COULD BE CAUSED BY COMBINATIONS OF ENGINE AND AVIONICS FAILURES WHICH CAUSE THE ENGINE OPERATING MODE TO CHANGE TO ELECTRICAL OR HYDRAULIC LOCKUP, OR BY ORBITER AND MAIN ENGINE AVIONICS FAILURES CAUSING A COMMAND PATH FAILURE.

A. ELECTRICAL LOCKUP

THE ENGINE PROPELLANT VALVES ARE ACTIVELY CONTROLLED AT THEIR LAST COMMANDED POSITION THAT EXISTED PRIOR TO LOSS OF BOTH SENSOR CHANNELS OF EITHER THE LH₂ FLOWMETER TRANSDUCERS OR MAIN COMBUSTION CHAMBER PRESSURE TRANSDUCER PAIRS.

The SSME valves are controlled to their last commanded values to minimize mixture ratio excursions. Mixture ratio is a function of measured main combustion chamber pressure (Pc) and LH₂ flowrate. The mass flowrate is calculated from measured volumetric flowrate and calculated fuel density (as calculated from LPFT discharge pressure and temperature). Should the LPFT discharge pressure or temperature be disqualified, a "fixed" density value for the LH₂ density will be used. Should both channels of either the measured Pc or volumetric flowrate be disqualified, or a combination of loss of controller redundancy and a loss of the remaining channel's Pc or volumetric flowrate, the engine enters into the "electrical lockup" mode and all valves are maintained at their last commanded position until shutdown is commanded. If the controller implements the shutdown, it will be a hydraulic shutdown. If the crew must manually shut down the engine (ref. Rules {A5-108}, MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP, and {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES), the shutdown will be a hydraulic shutdown. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002. [030994-1614A] [ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-3

STUCK THROTTLE (CONTINUED)

B. HYDRAULIC LOCKUP

ALL FIVE ENGINE PROPELLANT VALVES ARE HYDRAULICALLY ISOLATED AT THEIR LAST POSITION WHEN BOTH CHANNELS OF SERVOACTUATORS HAVE BEEN DISQUALIFIED FOR ANY COMBINATION OF THE FOLLOWING FAILURES: ISSUANCE OF A SERVOACTUATOR ERROR INDICATION INTERRUPT (SEII), FAILURE OF THE DIGITAL-TO-ANALOG CONVERTER (DAC) TEST, FAILURE OF THE SERVOACTUATOR MODEL, OR LOSS OF CONTROLLER REDUNDANCY. THE SEII LIMIT IS 6 PERCENT FOR CHANNEL A AND 10 PERCENT FOR CHANNEL B.

Hydraulic isolation of the valves minimizes, but does not prevent, valve drift which could result in further deviations from nominal valve positions causing loss of performance and/or possible engine shutdown. One hydraulic system supplies hydraulic actuation to the five engine valves (a different hydraulic system for each engine). Each valve has a redundant servocontrol system. Channel A is normally controlling unless it has been disqualified. Channel A disqualification could be due to loss of channel A power, loss of channel A input or output electronics, failure of the SEII 6 percent test (expressed in terms of percent full range valve travel), failure of the output electronics (OE) DAC test, or failure of the channel A servoactuator model. The SEII test compares the actual valve position to the expected valve position based on an internal servoactuator model. The OE DAC test verifies that each DAC's output voltage level is equal to its last commanded value, and that the command decoder addresses the correct OE DAC by proper decoding of the four LSB's of the OE storage register. The servoactuator model/monitor test verifies proper operation of the hardware and software associated with SEII's. Channel B disqualifications could be due to the same type of failures listed for channel A, except channel B uses an SEII test limit of 10 percent error comparison instead of 6 percent to take into account the switchover transient from channel A to B. Should both channels be disqualified, the SSME enters into "hydraulic lockup." In this mode, the engine might experience loss of performance due to valve drift. If this occurs and a redline limit is exceeded, the engine will be pneumatically shut down. If a redline is not exceeded, then shutdown of the engine will be accomplished by engine pneumatics when a manual or commanded shut down occurs. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-3 STUCK THROTTLE (CONTINUED)

C. COMMAND PATH FAILURE

LOSS OF COMMAND CAPABILITY FROM THE GPC TO AN SSME ON AT LEAST TWO COMMAND CHANNELS. @[030994-1614A]

Without GPC commands, the SSME will not be able to accomplish the following functions: change throttle settings, inhibit/enable shutdown limits, respond to shutdown commands, or perform an LO₂ dump. Shutdown commands could be issued by guidance software, from a low level cutoff, or from a manual shutdown pushbutton. Each controller normally requires two of three valid command paths from the GPC's to control the SSME (start commands require three of three functional command paths). SSME controller software change RCN 4354 implemented in version OI-6 and subs added the capability for the engine to accept a shutdown enable/shutdown command pair on a single channel under special circumstances: an internal timer has expired (currently set at 512.86 seconds from engine start); limits have never been inhibited; the shutdown enable/shutdown command pair come in on the same channel, sequentially (with no other command in-between); and a valid command is not concurrently being received on the other two channels. Shutdown of the SSME without GPC control is accomplished by the removal of ac power to the controller. This action activates the fail-safe engine pneumatic system, shutting the engine down safely. A data path failure will also result from this action, requiring the crew to push the affected engine's shutdown pushbutton to inform guidance of an engine out and to safe the engine by closing the LH₂ and LO₂ prevalves. Reference Computer Program CEI, Block II, SSME Controller Operational Program, CP406R0002. @[030994-1614A]

A5-4 DATA PATH FAILURE

LOSS OF ALL PRIMARY AND SECONDARY DATA FROM THE SSME CONTROLLER TO GPC'S.

Since TREF, engine status word and average Pc values are present in both the primary and secondary data, the loss of both data types from the controller is required for the GPC to acknowledge a data path failure. This failure is identified by the GPC SSME SOP software. The loss of both data paths will prevent onboard and ground monitoring of all SSME data. (Ref. FSSR for SSME SOP).

FLIGHT RULES

A5-5

SUSPECT ENGINE

A SUSPECT ENGINE IS A RESULT OF ANY OF THE FOLLOWING FAILURE CONDITIONS:

- A. ALL QUALIFIED REDLINE SENSORS ON A PARAMETER SHIFT IN THE SAME DIRECTION, WITH AT LEAST ONE, BUT NOT ALL, QUALIFIED SENSORS VIOLATING THE REDLINE LIMIT(S). @[092195-1795]

If all redline sensors pass their reasonableness limits, at least one, but not all, are violating their redline limit(s) and all non-voting sensors have shifted toward their redline(s), the SSME can continue to operate but will shut down if the remaining qualified sensors exceed their shutdown limits. The fact that all qualified sensors have moved toward their redlines indicates that something is wrong with the engine and that shutdown could occur at any moment. Reference rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for reasonableness/qualification limits and redline limits. @[ED]

- B. ALL QUALIFIED SENSORS EXCEED THE LIMITS FOR A PARTICULAR REDLINE AFTER SHUTDOWN MONITORING IS INHIBITED.

If all qualified sensors exceed limits with the shutdown monitoring inhibited, the SSME is approaching the failure situation which the limits were designed to prevent. The redline will only remain inhibited as long as the vehicle is in an abort region gap. While the limits are inhibited, the engine may fail at any moment with uncontained engine damage and loss of vehicle and crew, since the shutdown limit protection is not available for this case. Reference rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for redline limits. Reference rule {A5-103}, LIMIT SHUTDOWN CONTROL, for re-enabling boundaries. @[092195-1795] @[ED]

- C. NONISOLATABLE MPS HELIUM LEAK

Using the MPS helium leak isolation procedure, the crew can determine if isolating a given leg will stop the leak. If the procedure does not stop the leak, it is nonisolatable and may result in SSME shutdown due to HPOT intermediate seal pressure dropping below the redline. The SSME with a helium leak is considered suspect since its leak rate could increase at any time and thus could cause the engine to shut down earlier than predicted by the MCC. Reference rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[032395-1766]

- D. LOW LH₂ NPSP

If LH₂ NPSP is low enough to require manual throttling or cause a TAL due to an LH₂ tank ullage leak or failed closed GH₂ flow control valves, at least one SSME may be approaching a redline limit shutdown due to high HPFTP turbine discharge temperatures. Reference rules {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-5 SUSPECT ENGINE (CONTINUED)**

- E. DRIFTING PERFORMANCE WITH ALL QUALIFIED CHANNELS OF ANY GIVEN REDLINE PARAMETER APPROACHING THEIR REDLINE LIMITS.

An engine in hydraulic lockup is expected to drift. This performance drift should elevate HPOTP turbine discharge temperatures which may eventually exceed the redline causing the engine to shutdown. Nozzle leaks and HPOTP efficiency loss cases may cause redline exceedance and subsequent shutdown due to violation of one of the turbine temperature redlines or the MCC Pc low redline. MCC Pc shifts and FFM shifts may cause a redline exceedance (probably one of the turbine temperatures) and subsequent shutdown. Electric lockups due to large FFM shifts can cause a redline exceedance (due to turbine temperatures or the MCC Pc redline). Reference rule {A5-2}, paragraph E, SPACE SHUTTLE MAIN ENGINE OUT, for redline limits. @[ED]

Rules {A4-56}, PERFORMANCE BOUNDARIES; and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES; reference this rule. @[092195-1770A] @[092195-1795]

A5-6 SSME REDLINE SENSOR FAILED

AN SSME REDLINE SENSOR WILL BE DECLARED FAILED PER THE FOLLOWING CRITERIA: @[092195-1794] @[121296-4624]

- A. AN SSME REDLINE SENSOR IS DECLARED FAILED IF IT WAS DISQUALIFIED BY THE SSME CONTROLLER DUE TO VIOLATION OF ITS REDLINE QUALIFICATION LIMIT DURING THE START PREP (PRELAUNCH), START, OR MAINSTAGE PHASE. IN ADDITION, AN MCC PC CHANNEL SHALL BE CONSIDERED FAILED IF IT HAS FAILED ITS CONTROL INTRACHANNEL QUALIFICATION LIMIT. @[111699-7096]

Once an SSME redline sensor has been disqualified, it can no longer be used by the SSME controller software for redline monitoring (reference rule {A5-2}, paragraph E, SPACE SHUTTLE MAIN ENGINE OUT, for qualification limits). Redline pressure sensors that fail during start prep (prelaunch) will generate a major component failure (MCF) and preclude launching. However, because of the quadruple redundancy scheme, a redline temperature sensor can fail during start prep (prelaunch) without generating an MCF and without an LCC violation. For the purpose of limits management, this is considered a failed sensor. (Ref. Rule {A5-103}, LIMIT SHUTDOWN CONTROL). @[111699-7096]

A failure of the MCC Pc control intrachannel qualification monitor (pressure delta between the two bridges exceeds 75 psia) is also indicative of a sensor failure, even though the Pc channel is still used for redline monitoring. The redline intrachannel qualification delta is larger (125 psia) to account for the case of a real engine failure dropping the Pc so quickly that the delta between bridges could exceed the 75 psia in the time it takes the controller to read in the two values. The control intrachannel check is included in the failure criteria because that channel could degrade at any time and violate the redline intrachannel check. @[111699-7096]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-6

SSME REDLINE SENSOR FAILED (CONTINUED)

The SSME controller performs a Pc reference (ref) check as part of the Pc control logic. The Pc ref logic evaluates the health of the Pc channel, as opposed to the individual sensors, by comparing the Pc channel averages to the reference Pc. It checks to see if the Pc channel average is greater than 75 psi from the reference Pc (200 psi when throttling or below 75 percent RPL). In order for sensors to cause this check to fail, both sensors would have to fail simultaneously and in the same direction. It is more likely that there is a channel failure causing the Pc ref limits to be violated, and thus this is not considered a failed sensor. If a channel fails the Pc discriminator logic check, it is considered a channel failure, not a sensor failure.

Rule {A5-7}, SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, references this rule. @[121296-4624] @[ED]

- B. AN HPOTP DISCHARGE PRESSURE SENSOR OR AN HPFTP DISCHARGE PRESSURE SENSOR SHALL BE CONSIDERED A FAILED REDLINE SENSOR IF IT WAS DISQUALIFIED BY THE SSME CONTROLLER DUE TO VIOLATION OF ITS QUALIFICATION LIMIT DURING THE START PREP (PRELAUNCH), START, OR MAINSTAGE PHASE.

NOTE: THE DISCHARGE PRESSURES DO NOT HAVE AN ASSOCIATED REDLINE BUT ARE ELECTRONICALLY THE SAME AS THE REDLINE PRESSURE SENSORS.

The HPOTP and HPFTP discharge pressure sensors are electronically the same as the redline pressure sensors and thus are operationally considered the same as a redline sensor. Qualification limits were added to these parameters when the Pc discriminator logic was introduced post STS-91 (ref. SSME Requirement Change Notices # 6503 & 6524). Once an HPOTP DP or HPFTP DP sensor is disqualified, it is no longer used in the controller's Pc discriminator logic. The first of these two sensors to fail will not generate an MCF and will not cause an LCC violation. Therefore, if this sensor fails in the start prep (prelaunch), start, or mainstage phase, it is considered failed for the purpose of limits management (ref. Rule {A5-103}, LIMIT SHUTDOWN CONTROL). Note: a second discharge pressure sensor failure in start prep (prelaunch) or start will post an MCF and will preclude launching. @[111699-7096]

- C. IF THE FLIGHT CONTROLLERS CAN POSITIVELY IDENTIFY THE SENSOR FAILURE MODE(S) AS BEING THE CAUSE OF AN ENGINE SHUTDOWN, THE AFFECTED SSME REDLINE SENSOR(S) WILL BE DECLARED FAILED.
@[092195-1794] @[111699-7096]

Rule {A5-103}, LIMIT SHUTDOWN CONTROL, references this rule.

FLIGHT RULES**A5-7****SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN** @[ED]

- A. AN SSME WILL BE DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE OF THE HPFTP COOLANT LINER PRESSURE TRANSDUCERS (PHASE II AND BLOCK I SSME ONLY), ONE OF THE HPOTP SECONDARY SEAL PRESSURES (PHASE II SSME ONLY), OR ONE OF THE HPOTP INTERMEDIATE SEAL PRESSURE TRANSDUCERS, IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING. @[121296-4624]

NOTE: AN SSME IS NOT DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE OF THE TWO SSME MCC PC CHANNELS IS DISQUALIFIED.

The HPFTP coolant liner pressure redline (Phase II and Block I SSME only), the secondary seal pressure redline (Phase II SSME only), and the intermediate seal pressure redline each have two pressure transducers per redline (single transducer per controller channel). Therefore, if one or more transducers are disqualified for either a controller failure (input electronics or power supply, reference Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT) or a sensor failure (reference Rule {A5-6}, SSME REDLINE SENSOR FAILED), causing any remaining pressure redline to have a single qualified transducer, the engine will be considered one redline sensor failure away from an erroneous shutdown. This definition is used by Rule {A5-103}, LIMIT SHUTDOWN CONTROL, but only after the criteria outlined there (e.g., at least one redline sensor has failed) has been met. @[121296-4624] @[ED]

No single main combustion chamber pressure (MCC Pc) transducer failure can cause an engine to shut down on the MCC Pc redline when only one channel remains. Engine shutdown is prevented because of the way the MCC Pc transducers are qualified (redline processing is performed on channel pairs). An MCC Pc channel must have a channel average between 1000 and 3500 psia, and the two transducers on the channel must be within 125 psia of each other, for the channel to be qualified to vote for shutdown, reference Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT. The channel is disqualified for redline processing if either of these conditions is not met. The redline is violated if all qualified channel averages are 400 psia less than reference Pc (defined by the SSME controller for a given SSME power level). If one of the Pc transducers drifts high, with only one channel remaining, the controller channel's two Pc sensors will be disqualified for thrust control processing. This disqualification will occur when the delta between the two channels reaches 75 psia. This will place the SSME in electrical lockup. Additionally, if the sensor continues to drift such that delta between the two sensors is 125 psia, the controller channel's Pc transducers will be disqualified for redline shutdown processing. This disqualification will occur prior to the 400 psia redline being violated. For cases where both transducers are on the remaining channel drift, (thermal isolator problem or lee jet/sense tube problem), the engine will continually rebalance in response to the drifting Pc. If the drift is severe enough, the engine may exceed the 400 psia engine redline. In either case, SSME redline limits should be reenabled as specified in Rule {A5-103}, LIMIT SHUTDOWN CONTROL. @[ED]

FLIGHT RULES

A5-7

SSME ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN (CONTINUED)

- B. AN SSME IS DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE HPOT TURBINE DISCHARGE TEMPERATURE (TDT) TRANSDUCER IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING.
- C. AN SSME IS NOT DECLARED ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN IF ONLY ONE HPFT TURBINE DISCHARGE TEMPERATURE TRANSDUCER IS QUALIFIED FOR REDLINE SHUTDOWN PROCESSING.

Once a sensor has been disqualified, it can no longer be used by the SSME controller software for redline monitoring. Reference Rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for information on qualification/reasonableness testing. There are known thermocouple failure modes that can cause a sensor to fail below the lower HPOT turbine discharge temperature redline, but above the qualification limit. Therefore, the HPOT turbine discharge temperature redline will be considered one redline sensor failure away from an erroneous shutdown if only one qualified HPOT turbine discharge temperature sensor is qualified. Because there is no lower HPFT turbine discharge temperature redline limit, an SSME is not declared one redline sensor failure away from an erroneous shutdown if only one qualified HPFT turbine discharge temperature transducer is qualified for shutdown. ©[121296-4624] ©[ED]

A failure causing one turbine discharge temperature to remain qualified, but vote for shutdown on the upper redline, can result in SSME shutdown - if there are three or less qualified transducers at the redline location. This can occur because the redline logic disqualifies the "lower" transducers. Reference Rule {A5-2E}, SPACE SHUTTLE MAIN ENGINE OUT, for information on qualification/reasonableness testing. The only known thermocouple failure mode, where the thermocouple fails in-qualification-range high while violating the upper redline limit, is a "smart" failure in the SSME controller thermocouple sensor signal conditioning pre-amp circuit. This failure mode has a very low probability of occurrence (reference the special Rocketdyne briefing on this topic to the Shuttle Program Manager on 11/9/95). The entire thermocouple turbine discharge temperature redline processing philosophy of disqualifying the "lower" transducer depends on this low probability. Since the redline processing philosophy does not protect for this case, this flight rule does not protect for this case either. ©[ED]

Rules {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT; {A5-6}, SSME REDLINE SENSOR FAILED; and {A5-103}, LIMIT SHUTDOWN CONTROL, reference this rule. ©[121296-4624] ©[ED]

SPACE SHUTTLE MAIN ENGINE TYPES @[ED]

	HPOTP	MCC	HPFTP
PHASE II	ROCKETDYNE	STANDARD	ROCKETDYNE
BLOCK I/IA	P&W	STANDARD	ROCKETDYNE
BLOCK IIA	P&W	LARGE THROAT	ROCKETDYNE
BLOCK II	P&W	LARGE THROAT	P&W

@[121197-6472A]

THERE ARE MANY HARDWARE DIFFERENCES ASSOCIATED WITH THE VARIOUS SSME TYPES. ONLY THE DIFFERENCES WITH SIGNIFICANT BOOSTER SYSTEMS FLIGHT CONTROLLER OPERATIONAL IMPACTS ARE LISTED HERE.

FROM THE BOOSTER SYSTEMS FLIGHT CONTROLLER'S PERSPECTIVE, THE BLOCK I AND THE BLOCK IA OPERATIONAL CHARACTERISTICS ARE IDENTICAL. FOR THE PURPOSES OF THE FLIGHT RULES, THE NOMENCLATURE 'BLOCK I' WILL BE USED FOR BOTH.

FOR BLOCK I/IIA/II: INCORPORATION OF THE PRATT AND WHITNEY (P&W) ALTERNATE HPOTP IN PLACE OF THE ROCKETDYNE BASELINE HPOTP ELIMINATES THE SECONDARY SEAL REDLINE AND LOWERS THE INTERMEDIATE SEAL REDLINE (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

FOR BLOCK IIA/II: INCORPORATION OF THE LARGE THROAT MCC IN PLACE OF THE STANDARD THROAT MCC REDUCES THE OVERALL OPERATING PRESSURES AND TEMPERATURES AT A GIVEN POWER LEVEL AND LOWERS THE HPOTP AND HPFTP TURBINE DISCHARGE TEMPERATURE REDLINES (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

FOR BLOCK II: INCORPORATION OF THE PRATT AND WHITNEY ALTERNATE HPFTP IN PLACE OF THE ROCKETDYNE BASELINE HPFTP ELIMINATES THE COOLANT LINER REDLINE (REF RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT).

DETAILS OF THESE CHANGES ARE COVERED IN BOOSTER SYSTEMS' CONSOLE TOOLS AND DOCUMENTATION.

Rule {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT, references this rule. @[121197-6472A]

FLIGHT RULES**A5-9****LH₂ ULLAGE LEAK** ©[ED]

WITH THREE SSME'S RUNNING AT MISSION POWER LEVEL, AN ET LH₂ ULLAGE LEAK IS CHARACTERIZED BY ALL OF THE FOLLOWING: ©[040899-6818A] ©[102501-4880A]

- A. LH₂ ULLAGE PRESSURE IS STEADILY DECAYING AND:
1. HAS DROPPED BELOW 32.6 (32.2) PSIA PRIOR TO AN MET OF 2 MINUTES 30 SECONDS, OR
 2. HAS DROPPED BELOW 31.0 (30.6) PSIA AFTER AN MET OF 2 MINUTES 30 SECONDS
- B. THE GH₂ 2-INCH DISCONNECT PRESSURE IS GREATER THAN 444 (414) PSIA.

The ET LH₂ ullage pressure is maintained by the three flow control valves (FCV's) in the orbiter GH₂ pressurization system. The set point for the GH₂ FCV signal conditioners is 33.0 psia. A 0.4 psi signal conditioner deadband encompassing the set point results in actual activation values as low as 32.6 psia or as high as 33.4 psia. A significant LH₂ ullage leak or an orbiter GH₂ pressurization system anomaly (reference Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP) will cause the LH₂ ullage pressure to drop below the set point for the GH₂ FCV signal conditioner. The orbiter GH₂ pressurization system will then respond by opening the three GH₂ FCV's in an attempt to increase ullage pressure. The FCV's have been shimmed, such that an open FCV provides 70 percent flow through the valve and 31 percent flow when the valve is commanded closed. These settings are also referred to as the 'high flow' and 'low flow' positions, respectively.

Data provided by Lockheed Martin/Michoud (reference PSIG telecon May 22, 2001) indicates that a GH₂ pressurization system operating at -3 sigma could cause the ullage pressure to decay to a minimum pressure of 31.0 psia (30.6 indicated when a 0.4 psi worst case transducer bias is included). To avoid erroneously declaring an ullage leak when the GH₂ pressurization system is functioning nominally, an ullage leak will not be declared unless the ullage pressure is decaying and has dropped below 32.6 (32.2) psia prior to an MET of 2 minutes 30 seconds or below 31.0 (30.6) psia after an MET of 2 minutes 30 seconds. These ullage pressures (during the specified time periods) are the lowest that could possibly occur for a nominally operating GH₂ pressurization system (reference PSIG telecon May 22, 2001). ©[102501-4880A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-9

LH₂ ULLAGE LEAK (CONTINUED)

It is important to establish the difference between an ullage leak and an orbiter GH₂ pressurization system anomaly since the required actions are different (reference Rule {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES). The 2-inch disconnect pressure cue is sufficient to distinguish between an ullage leak and an orbiter GH₂ pressurization system anomaly once the LH₂ ullage pressure has decayed below 32.6 (32.2) psia or 31.0 (30.6) psia (depending on the MET that it occurs) with all three GH₂ FCV's open. If the GH₂ 2-inch disconnect pressure is consistent with the expected value for three open FCV's (high flow position), then the LH₂ ullage pressure problem is determined to be the result of an LH₂ ullage leak. If the GH₂ 2-inch disconnect pressure is below that expected for three open FCV's, then the cause of the low ullage pressure is an orbiter GH₂ pressurization system anomaly. ©[102501-4880A]

A value for the 2-inch disconnect pressure was chosen at the lowest expected value for three flow control valves open and not less than the predicted value for one flow control valve failed closed (low flow position) to avoid erroneously calling an ullage leak. Data provided by BNA/Huntington Beach (reference PSIG telecon May 18, 2001), on all flights since the reshimming of the flow control valves (70 percent/31 percent), showed that the lowest 2-inch disconnect pressure seen to date for three flow control valves open at mission power level was 448 psia (on STS-99, 97, 100, and 106). These pressures were all for Block IIA cluster flights, which have shown to provide the least amount of ullage pressurization gas. Subtracting out a one sigma dispersion (4 psia) and a 3 percent instrumentation error (30 psia) yields a 2-inch disconnect pressure value of 414 psia. Analysis and data obtained from STS-104 (first flight of a single Block II engine) indicates a Block II SSME will provide the same amount of ullage pressurization gas as a Block IIA engine; therefore, the disconnect pressure of 444 (414) psia can be used to determine the presence of an ullage leak for any engine configuration of a Block IIA or Block II type SSME. The disconnect pressure cue is only valid at the mission power level with three SSME's running. ©[102501-4880A]

Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, references this rule. ©[040899-6818A]

FLIGHT RULES

A5-10

SIGNIFICANT ENGINE HELIUM SYSTEM LEAK [ED]

TANK PRESSURE DECAY RATE (DP/DT) > 20 PSIA OVER 3 SECONDS, OR AN INDICATED HELIUM USAGE WHICH IS GREATER THAN 0.055 LBM/SEC AFTER AN MET OF 1 MINUTE. [090894-1676A]

NOTE: DECAY RATE CORRESPONDS TO THE BFS DECAY RATE COMPUTATION AND THE INDICATED HELIUM USAGE IS BASED ON MCC MASS FLOW RATE COMPUTATIONS.

Tank pressure decay rate (DP/DT) > 20 psia/3 seconds is twice the nominal value of approximately 10 psia/3 seconds. This value takes into account normal data noise and the 10 psi data granularity and represents the minimum value usable to detect helium leaks on board the vehicle. In addition to the DP/DT computation, the MCC uses a mass flow rate computation (lbm/sec) in order to detect helium leaks. The maximum nominal mainstage usage for the engine HPOTP IMSL purge is 0.047 lbm/sec (ref. SSME-to-Orbiter ICD 13M15000). Usage above 0.047 lbm/sec is indicative of an off-nominal condition in the associated MPS helium system supply.

Small leaks which are above 0.047 lbm/sec and below the crew alarm criteria (approximately 0.087 lbm/sec) will not be isolated prior to an MET of 1 minute. Action to isolate small helium leaks is not taken within the first minute after liftoff because the ground computation requires 20 seconds of data after liftoff for proper initialization and because additional time is required by the MCC for leak evaluation. Also, a leak of this size which is isolated shortly after an MET of 1 minute will probably not violate the single regulator zero-g shutdown requirements. However, continued usage at this rate may significantly reduce the helium available to support engine shutdown at MECO.

Even though helium usage above 0.047 is off nominal, MCC action is only taken for leaks with a usage above 0.055 lbm/sec or greater. This number accounts for noise in the ground computation and protects nominal MECO helium requirements.

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule.
[090894-1676A]

FLIGHT RULES

A5-11 **SIGNIFICANT PNEUMATIC SYSTEM HELIUM LEAK** [ED]

ANY LEAK IN THE PNEUMATIC TANK SYSTEM OR PNEUMATIC ACCUMULATOR WHICH WILL ANNUNCIATE THE CREW SYSTEMS MANAGEMENT (SM) ALERT (PNEU TK P < 3800.0 PSIA) PRIOR TO MECO -30 SECONDS. [090894-1676A] [021199-6790]

An attempt is made to isolate leaks in the MPS pneumatic helium supply in order to conserve helium for LO₂ prevalve closure at MECO. Furthermore, if the leak is isolated, the pneumatic helium supply will be available to support the operation of a leaking MPS helium engine supply.

Isolation will only be performed if the leak is large enough to annunciate the crew SM Alert prior to MECO -30 seconds. [021199-6790]

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule. [090894-1676A]

A5-12 **INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE** [ED]

A PNEUMATIC ACCUMULATOR PRESSURE WHICH IS LESS THAN 700 PSIA. [090894-1676A]

Seven hundred psia is the minimum actuation pressure which will ensure proper LO₂ and LH₂ prevalve closure timing at MECO. Pressures of 400 to 500 psia will fully position the valves; however, timing requirements may not be satisfied (ref. SODB, Vol. ii, Section 4.3.1). Four of six test cases of three engine prevalve closures at an initial pressure of 400 psia were within the timing specification of 1.15 seconds maximum closing time. Of the two that violated requirements, one was 0.03 seconds slow and the other was 0.06 seconds slow (reference PSIG telecon charts, 5/19/93).

It is critical that the LO₂ prevalues close within timing constraints at MECO. LO₂ prevalve closure and the injection of helium into the pogo accumulator are used to maintain pressure on the engine high pressure oxidizer turbopump, preventing pump cavitation during the shutdown sequence.

Rule {A5-151}, PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL], references this rule. [090894-1676A]

FLIGHT RULES**A5-13****MPS DUMPS AND VACUUM INERTING DEFINITIONS** @[092701-4867A] @[ED]**A. MPS DUMP**

A PRESSURIZED MPS LO₂ AND UNPRESSURIZED LH₂ DUMP PERFORMED IN MM 104 FOR NOMINAL, ATO, AND AOA MISSIONS THAT IS NORMALLY AUTOMATIC AT MECO + 2 MINUTES, BUT CAN BE STARTED OR DELAYED MANUALLY. @[092195-1791]

B. MPS GH₂ INERT @[092195-1791]

A MANUAL INERTING OF GH₂ THROUGH THE PRESS LINE VENT VALVE PERFORMED AFTER THE MPS POWERDOWN AND ISOLATION PROCEDURE FOR NOMINAL, ATO, AND AOA MISSIONS. @[111094-1719]

C. FIRST AUTOMATED VACUUM INERT @[092195-1791]

AN AUTOMATIC INERTING OF THE LH₂ AND LO₂ FEEDLINE SYSTEMS THROUGH THE LH₂ BACKUP DUMP VALVES AND THE LO₂ FILL/DRAIN VALVES RESPECTIVELY. THIS INERT IS PERFORMED AFTER THE MPS DUMP FOR NOMINAL, ATO, AND AOA MISSIONS AT MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) AND CAN ALSO BE PERFORMED MANUALLY.

D. MANUAL VACUUM INERT @[092195-1791]

A MANUAL INERTING OF THE LH₂ OR LO₂ FEEDLINE SYSTEM WHICH IS PERFORMED DUE TO INEFFICIENT AUTOMATED VACUUM INERT(S). THE MANUAL VACUUM INERT IS PERFORMED ANY TIME AFTER MPS DUMP START + 22 MINUTES (APPROXIMATELY MECO + 24 MINUTES) SUCH THAT THE AUTOMATED COMMANDS AND THE CREW'S SWITCH THROWS WILL NOT COINCIDE. THE LO₂ FEEDLINE SYSTEM IS MANUALLY INERTED THROUGH THE LO₂ FILL/DRAIN VALVES. THE LH₂ FEEDLINE SYSTEM IS MANUALLY INERTED THROUGH EITHER THE LH₂ BACKUP DUMP VALVES OR THROUGH THE LH₂ FILL/DRAIN VALVES.

SRB SYSTEMS MANAGEMENT

@[021694-ED]

A5-51 **LOSS OF SRB THRUST VECTOR CONTROL (TVC)** @[012402-4987]

FOR THE LOSS OF TVC ON ONE SRB, THE FLIGHT WILL BE CONTINUED UNTIL LOSS OF VEHICLE CONTROL.

The loss of two Hydraulic Power Units (HPU's) on one SRB results in no TVC control on that SRB. This may result in loss of control depending on nozzle position. There is no manual control available; therefore, there is no crew action that can be taken. @[012402-4987]

A5-52 THROUGH A5-100 RULES ARE RESERVED

FLIGHT RULES

SSME SYSTEMS MANAGEMENT

A5-101 ABORT CUE REQUIREMENT

ANY ENGINE CONDITION THAT CAUSES AN ABORT DECISION WILL BE CONFIRMED USING TWO CUES.

Two cues are required so that a single instrumentation failure will not cause an erroneous abort decision.

A5-102 AUTO/MANUAL SHUTDOWN

MANUAL SHUTDOWN OF AN ENGINE WILL NOT BE ATTEMPTED IF AUTOMATIC LIMIT SHUTDOWN CAPABILITY IS ENABLED AND AN ENGINE IS APPROACHING A SHUTDOWN LIMIT. AN EXCEPTION TO THIS RULE IS WHEN EXCESSIVE HELIUM LEAKAGE REQUIRES A MANUAL ENGINE SHUTDOWN AS DISCUSSED IN RULE {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[032395-1766]

The automatic limit shutdown system was designed to prevent a catastrophic failure of an engine. Due to response times and the complexity of the SSME, the ground and crew will not try to interfere with this system.

A5-103 LIMIT SHUTDOWN CONTROL

A. PREMATURE MAIN ENGINE SHUTDOWN @[121296-4625]

THE MAIN ENGINE LIMIT SHUTDOWN CONTROL CAPABILITY WILL BE MANAGED AS FOLLOWS: @[121296-4625] @[111298-6785A]

1. INHIBITED AT ONE ENGINE-OUT

GPC AUTOMATICALLY COMMANDS INHIBIT TO THE REMAINING TWO ENGINES.

The main engine limit shutdown switch is a three-position switch: ENABLE, AUTO, and INHIBIT. At lift-off, the switch is in the AUTO position, and the limit shutdown control logic is enabled on all three engines. After one engine-out occurs, the main engine limit shutdown control capability on the two remaining engines is automatically inhibited. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

2. WITH ONE ENGINE OUT AND BFS NOT ENGAGED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" THEN "AUTO." REENABLING WILL BE BASED UPON THE FOLLOWING CONDITIONS:
 - a. THE CREW WILL MANUALLY REENABLE THE LIMITS AS SOON AS POSSIBLE FOLLOWING THE ENGINE OUT. @[111298-6785A]

The reenabling of the main engine limit shutdown software is required to regain, as soon as possible, the engine redline shutdown protection in the event of a second engine failure. The reenabling of the main engine limit shutdown software will be accomplished by taking the main engine limit shutdown switch to ENABLE then to AUTO. This allows one of the running engines to shut down due to a limit violation while automatically inhibiting the main engine limit shutdown control capability on the one remaining engine. Single-engine flight control capability would then take the vehicle to MECO.

The philosophy of when to reenable the main engine limit shutdown software attempts to balance the risk of an engine failing catastrophically while the limits are inhibited against the risk associated with a two engine-out contingency abort.

A meeting was held with the Shuttle Program Manager on September 10, 1998, to discuss the risks. Insufficient data is available to perform a risk trade since 1) The likelihood of an SSME running safely above a redline limit is unknown, and 2) The likelihood of surviving a contingency abort and the associated ET separation, flight control, thermal, crew bailout, and rescue is also unknown. The two engine-out contingency abort risks were accepted over running an SSME with limits inhibited. The risk of running an SSME with limits inhibited was accepted over the three engine-out contingency abort. Based on this philosophy, the main engine limit shutdown software will remain enabled (or reenabled) for one engine-out cases and inhibited for all two engine-out cases. @[121296-4625] @[111298-6785A]

The September 15 and November 18, 1987, and June 2, 1995, Ascent/Entry Flight Techniques panels reviewed the failure history of the redline sensors and came to the conclusion that the engine redline sensors are reliable and should, in general, be trusted to not cause an inadvertent shutdown.

- b. IF THE MCC DETERMINES ONE OF THE REDLINE SENSORS IS FAILED AND:

THIS RULE CONTINUED ON NEXT PAGE

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

- (1) EITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED UNTIL THE FOLLOWING BOUNDARY IS REACHED AND THEN REENABLED: @[121296-4625] @[111298-6785A]

RTLS - SINGLE ENGINE RTLS BOUNDARY

TAL, AOA, ATO, NOM - SINGLE ENGINE LIMITS BOUNDARY FOR A PRIME TAL SITE OR OTHER AUGMENTED TAL/CONTINGENCY SITE IF WEATHER OR LANDING AIDS PERMIT (REFERENCE RULE {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). IF WEATHER AND/OR LANDING AIDS DO NOT PERMIT, REENABLE AT SINGLE ENGINE PRESS. @[092195-1793]

- (2) NEITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, REENABLE THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE AS SOON AS POSSIBLE.

The MCC is responsible for evaluating sensor failures since the flight crew has no visibility into the sensor health. Software flags issued by the onboard main engine controller sensor reasonableness software or previously observed failure modes would be used by the MCC as criteria to say that a sensor had failed. If, previous to the first engine shutdown, a sensor failure were detected and then the engine shut down based on the remaining redline sensor, that second failure would not be counted as a sensor failure unless the flight controllers could positively identify the sensor failure mode. A subsequent sensor failure on another running engine would have to occur before two sensor failures could be counted. This type of situation occurred on STS 51-F. All sensor failures on STS 51-F were detected by the onboard main engine sensor reasonableness software. This software also informed the flight controllers of the failures via the downlisted failure identifier data words. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-103****LIMIT SHUTDOWN CONTROL (CONTINUED)**

The main engine limit shutdown software will be enabled at an appropriate boundary with one sensor failure on one of the three engines, because one sensor failure does not indicate a trend for a generic failure of the sensors. If either of the remaining two engines is one sensor failure away from an erroneous shutdown, limits will remain inhibited until an abort boundary is reached. The limits will be reenabled when an abort boundary (as defined in Rule {A4-56}, PERFORMANCE BOUNDARIES) is reached such that a single-engine abort can be accomplished to the desired site. On an RTLS, this abort boundary is Single Engine RTLS (which is designated by the "two-out red on the TRAJ display" call). If neither of the remaining engines is one sensor failure away from an erroneous shutdown, limits can be reenabled as soon as possible. This allows the redlines to provide the earliest protection against a real engine hardware failure. @[111298-6785A]

On a TAL, AOA, ATO, or nominal profile, this abort boundary is Single Engine Limits if weather or landing aids permit. Otherwise, the limits will be reenabled at Single Engine Press (ref. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). With one sensor failure and either of the remaining engines one sensor failure away from shutting down erroneously, the risk of an engine shutdown due to another sensor failure is higher than that due to an actual engine failure if the limits were reenabled. Because of this increased risk of an engine shutdown caused by sensor failures, the exposure to bailout is not acceptable unless the next sensor failure will not cause an erroneous shutdown. For these reasons, the limits are inhibited until the single engine limits boundary to minimize the need for a contingency abort and crew bailout. @[121296-4625]

- c. IF THE MCC DETERMINES TWO OR MORE OF THE SAME TYPE (TEMPERATURE OR PRESSURE) ENGINE REDLINE SENSORS HAVE FAILED AND:
- (1) EITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED THROUGH MECO.
 - (2) NEITHER OF THE REMAINING ENGINES IS ONE REDLINE SENSOR FAILURE AWAY FROM AN ERRONEOUS SHUTDOWN, REENABLE THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE AS SOON AS POSSIBLE:

The shutdown sensors on the same redline will be suspected of having a generic problem if more than one sensor fails (two or more sensors failed on the same type of redline). If either remaining engine is one sensor failure away from an erroneous shutdown, limits will remain inhibited through MECO in order to prevent the next sensor failure from shutting down a good engine. The two failures could occur on one or more engines including the failed engine. If neither engine is one sensor failure away from an erroneous shutdown, then limits are reenabled as soon as possible. This allows the earliest possible protection by the redline sensors against a real engine hardware failure. @[121296-4625] @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

3. WITH ONE ENGINE OUT AND BFS ENGAGED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED THROUGH MECO BY THE BFS AUTOMATIC COMMAND. @[121296-4625] @[111298-6785A]

The main engine limit shutdown control will be inhibited on two remaining engines if the BFS is engaged. The BFS does not have single-engine flight control software and therefore cannot control the vehicle with two engines shut down. If the engine shuts down after the BFS is engaged, the BFS will automatically command inhibit to the remaining engines. If the engine shuts down while on the PASS, limits subsequently reenabled, and then BFS engaged, the BFS will again automatically command inhibit to the remaining engines since the BFS reevaluates and responds to engine out status when engaged.

4. WITH TWO ENGINES OUT, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN INHIBITED THROUGH MECO.

Since three engine-out contingency aborts contain "black zones" and are more severe than the two-engine contingency aborts, limits will remain inhibited on the last running engine.

Rules {A2-6}, LANDING SITE WEATHER CRITERIA [HC]; {A2-55}, USE OF LOW-ENERGY GUIDANCE; and {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL, reference this rule. @[120894-1663]

B. STUCK THROTTLE IN THE THRUST BUCKET

IF A STUCK THROTTLE CONDITION OCCURS DURING MAX Q THROTTLING SUCH THAT THE POWER LEVEL IS LESS THAN THE NOMINAL FLIGHT POWER LEVEL, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN ENABLED.

When an engine experiences a stuck throttle in the thrust bucket, performance may be reduced sufficiently that an abort gap may occur between RTLS capability and any downrange abort capability. Uphill capability may also be lost. Main engine limit shutdown software remains enabled to allow for the stuck engine to shut down if it exceeds redline limits. In the case of a hydraulic lock-up, valve drift may occur resulting in potential redline limit exceedance; therefore, the main engine limit shutdown software remains enabled. It has been accepted that the loss of a good engine could result in a 1 and 2/3 RTLS contingency abort.

- C. WITH ONE ENGINE OUT AND ONE OF THE REMAINING ENGINES HAS A NON-ISOLATABLE MPS HELIUM LEAK, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED BASED ON THE FOLLOWING: @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

1. PRIOR TO THE SINGLE ENGINE LIMITS (TAL ABORT) OR SINGLE ENGINE RTLS (RTLS ABORT) BOUNDARY: @[111298-6785A]

WHEN THE PNEUMATIC HELIUM AND/OR FAILED ENGINE'S MPS HELIUM TANK PRESSURE REACHES 1150 PSIA FOLLOWING THE INTERCONNECT TO THE LEAKING SYSTEM'S HELIUM OR WHEN BOTH LEAKING ENGINE'S HELIUM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA

2. OTHERWISE, NO ACTION REQUIRED.

IF THE SINGLE ENGINE LIMITS (TAL ABORT) OR SINGLE ENGINE RTLS (RTLS ABORT) BOUNDARY IS REACHED WITHOUT INTERCONNECTING TO THE NON-LEAKING, RUNNING ENGINE'S HELIUM, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED.

IF HELIUM FROM THE NON-LEAKING, RUNNING ENGINE IS REQUIRED TO SUPPORT THE LEAKING ENGINE'S OPERATION (REF. RULE {A5-152}, PRE MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]), THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN INHIBITED THROUGH MECO. @[090894-1676A] @[121296-4625]

For the case of two engines running (one with a non-isolatable MPS helium leak), the main engine limit shutdown software will be reenabled by the crew per paragraph A.2.a. If the leaking engine cannot support the SE Limits or SE RTLS boundary with an interconnect from pneumatic and/or the failed engine's helium, the leaking engine will be allowed to operate below the HPOTP IMSL redline to avoid a two engine-out contingency abort (per Rules {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], and {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS). To operate below the redline, limits must be inhibited. The MCC will call for the main engine limit shutdown switch to "inhibit" when the pneumatic helium and/or failed engine's helium tank pressure reaches 1150 psia following the interconnect to the leaking system or when the leaking system's regulator pressures are below 715 (679) psia. The 1150 psia tank pressure cue was selected as the operational cue corresponding to the crew's MPS helium tank pressure C&W (not the pneumatic helium tank pressure C&W) while ensuring that the HPOTP IMSL redline limit is not exceeded prior to inhibiting the limits. It also minimizes the amount of time that the remaining engines are exposed to main engine limits being inhibited. The 715 (679) psia regulator pressure cue was selected as a backup cue for large MPS helium leaks to ensure that the HPOTP IMSL redline limit is not exceeded before main engine shutdown limits are inhibited. The main engine limit shutdown software will be reenabled upon reaching the first single engine abort landing site capability, which is either SE Limits or SE RTLS (ref. AEFTP #107, 11/4/93), if an interconnect from a running engine has not been performed. This represents the earliest time after which an attempt can be made to reach a landing site with a good engine out. @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-103****LIMIT SHUTDOWN CONTROL (CONTINUED)**

The main engine limit shutdown software will remain inhibited if the non-leaking, running engine's helium has been interconnected to a leaking engine (no three engine-out abort capability). Keeping limits inhibited in this configuration will allow the main engine with the leaking MPS helium supply to continue to operate below the normal HPOTP IMSL redline. Running the engine below the normal redline is an acceptable risk while the vehicle is in an abort gap since the only alternative is an early MECO and the loss of the vehicle and crew. @[121296-4625] @[111298-6785A]

Reference Rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS. @[090894-1676A]

- D. IF FLOW CONTROL VALVE FAILURES OR AN ULLAGE GAS LEAK CAUSE A LOW LH₂ NPSP CONDITION, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" PER FLIGHT RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. @[121296-4625]

Reference Rule and rationale {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP.

- E. IF A DATA PATH FAILURE OCCURS ON AN ENGINE THAT IS CONFIRMED RUNNING, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED PER FLIGHT RULE {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

Reference Rule and rationale {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

- F. IF A GPC SET SPLIT OCCURS AND THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE ON TWO ENGINES IS AUTOMATICALLY INHIBITED, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED.

In a set split condition, two GPC's will not see data from one of the engines and will automatically inhibit the main engine limit shutdown software on the other two engines. If limits are reenabled by taking the main engine limit shutdown switch to ENABLE then AUTO, the limits would be automatically inhibited on the next cycle. Therefore, the main engine limit shutdown switch will only be taken to ENABLE. Reference Rule and rationale {A5-104}, DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

- G. FOR LOSS OF TVC CONTROL ON AN OPERATING MAIN ENGINE, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED (THREE ENGINES RUNNING) UNTIL TWO-ENGINE TAL CAPABILITY IS ACHIEVED OR, ON AN RTLS, UNTIL AFTER POWERED PITCH-AROUND (PPA) IS COMPLETE.

The risk of running an engine with the main engine limits inhibited is accepted over the risk of loss of control during the RTLS powered pitch around (PPA) as a result of a gimbaling engine failure. If a main engine has lost TVC capability, the failure of a gimbaling engine could result in a loss of control, even if single-engine roll control (SERC) is active. Since an RTLS trajectory is much more demanding than an uphill or TAL case from a control standpoint, avoiding an RTLS abort is highly desirable. Additionally, if the loss of TVC is due to hydraulic system failures, the engines in hydraulic lockup could fail due to valve drift, so a trajectory that provides the earliest possible single-engine capability is desirable. If a three-engine RTLS is performed, the main engine limit shutdown software will be inhibited until after PPA, since a loss of control is very possible if PPA is attempted with one gimbaling and one nongimbaling engine. @[121296-4625] @[111298-6785A]

Reference rule {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.

- H. DURING A THREE ENGINE RTLS ABORT, TIME PERMITTING, THE MAIN ENGINE LIMIT SHUTDOWN SWITCH WILL BE TOGGLED TO INHIBIT, ENABLE, AND BACK TO AUTO. THIS ACTION WILL BE DELAYED AS LONG AS POSSIBLE, BUT MUST BE COMPLETED PRIOR TO AN MET OF 8 MINUTES. @[121296-4625] @[111298-6785A]

A GPC or manual toggle of the main engine limit shutdown software to inhibit will be required on a three engine RTLS abort due to the incorporation of single command channel shutdown logic in the main engine controller software. The intent of this is to protect the vehicle and crew from exposure to a latent orbiter/main engine command path failure at MECO (catastrophic). This is accomplished by reducing the normal 2 of 3 shutdown command channel agreement criteria to 1 of 3 shutdown command channel acceptance processing. The software, which is invoked after a mission specific timer has expired, will allow acceptance and execution of the following two sequential commands, shutdown-enable followed by a shutdown command on a single command channel. Should a limit's inhibit command be processed and accepted by the controller prior to the execution of the single command channel logic, single command channel processing will no longer be performed. The mission specific timer is calculated by subtracting 5.5 seconds (3 sigma dispersion) from the predicted MECO time referenced to SSME start. That is, the predicted MECO time in MET plus the time from the last SSME start (6.36 seconds) minus 3 sigma dispersion (5.5 seconds). @[091098-6710A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-103

LIMIT SHUTDOWN CONTROL (CONTINUED)

Toggling of the main engine limit shutdown switch on a three engine RTLS is performed in order to preclude the possibility of losing all main engines due to a failed-to-sync GPC after the controller timer has expired. Normally, exposure to this condition is either minimized (to approximately 5 seconds) by projected MECO times on the order of 511 seconds on uphill missions and TAL aborts, or eliminated by a main engine out (the GPC's command inhibit on the remaining engines and the single command channel shutdown processing is disabled). However, the time of exposure to a three engine out condition may be significant (120 seconds) on a systems RTLS abort. This exposure results from the extended main engine burntime (MECO at approximately 630 seconds MET) and the absence of an engine-out limits inhibit command. Consequently, the main engine limit shutdown software will be manually toggled to inhibit in order to minimize exposure to a failed-to-sync GPC. This action will be delayed as long as possible in order to retain main engine shutdown capability, and to possibly eliminate an unnecessary action, should a main engine out occur prior to the expiration of the controller timer. The cue of 8 minutes provides margin prior to expiration of the timer. ©[090894-1679A] ©[121296-4625] ©[091098-6710A]

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

WITH A DATA PATH FAILURE AND THE ENGINE CONFIRMED ON BY THE MCC, THE MAIN ENGINE LIMIT SHUTDOWN CONTROL CAPABILITY WILL BE MANAGED IN THE FOLLOWING MANNER: @[121296-4594A]

A data path failure occurs when the GPC's (PASS or BFS) either do not see the main engine time reference word (TREF) updating or when the two main engine identification words (ID words 1 & 2) are not one's complements. If this occurs in the controlling GPC's, the controlling GPC's will automatically inhibit the main engine limit shutdown software on the other two main engines. However, the GPC software will not inhibit the limits on the engine with the data path failure. This response occurs because the GPC's assume the engine has failed behind the data path failure.

A. BFS NOT ENGAGED:

1. THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE REENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" THEN "AUTO".

Once the MCC confirms that the engine with the data path failure is running, the crew will remove the inhibits by manually placing the main engine limit shutdown switch to ENABLE, then AUTO. This switch movement causes the main engine limit shutdown software to be reenabled on all running engines.

2. FOR AN ENGINE OUT: @[111298-6785A]
 - a. IF THE ENGINE THAT SHUT DOWN WAS THE ONE THAT HAD THE DATA PATH FAILURE, THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL REMAIN ENABLED.

If the engine that shuts down is the engine with the data path failure, the GPC's will not automatically inhibit the main engine limit shutdown software. The main engine limit shutdown software will remain enabled to allow for a second engine out (ref Rule {A5-103}, LIMIT SHUTDOWN CONTROL).

@[121296-4594A] @[111298-6785A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

- b. IF THE ENGINE THAT SHUT DOWN WAS NOT THE ONE WITH THE DATA PATH FAILURE, THE PASS WILL AUTOMATICALLY INHIBIT LIMITS. LIMITS WILL REMAIN INHIBITED UNTIL MECO.
 @[121296-4594A] @[111298-6785A]

If the engine that shuts down did not have the data path failure, the limit shutdown control capability of the two remaining engines will automatically be inhibited by the PASS GPC's. In this case, however, the limits will remain inhibited until MECO. The reason is that, if the limits were reenabled and the remaining engine with the good data path exceeds a redline and shuts down, MECO confirmed conditions would be satisfied by having two engines with main combustion chamber pressure less than 30 percent power level and one engine with a data path failure. MECO command would be sent, resulting in the shutdown of the engine with the data path failure. This early MECO could result in an unacceptable underspeed. @[121296-4594A]

B. BFS ENGAGED:

1. THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE ENABLED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "ENABLE" (UNLESS THE BFS AUTOMATICALLY REENABLED LIMITS UPON BFS ENGAGE). @[111298-6785A]

If the data path failure occurs before BFS engage, when the BFS is engaged, all data path failure flags are reset in the BFS software. The BFS immediately attempts to establish communication with the engines. However, if this is not successful a data path failure is annunciated on that engine. At this point, the BFS software automatically inhibits the main engine limit shutdown software on the other two engines. If the data path failure occurs after BFS engage, the BFS will inhibit limits on the other two engines. Once the MCC confirms the engine with the data path failure is running, the crew will remove the inhibits by manually placing the main engine limit shutdown switch to ENABLE to prevent running the engines for the remainder of the flight with limits inhibited. The BFS main engine limit shutdown switch logic does not work the same way it does in the PASS (in the BFS, ENABLE/AUTO will cause the limits to go back to inhibit).

The BFS will automatically reenables limits if the data path failure is recovered when the BFS is engaged.
 @[121296-4594A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-104

DATA PATH FAIL/ENGINE-ON LIMIT SHUTDOWN CONTROL

2. FOR A SUBSEQUENT ENGINE OUT: @[121296-4594A]

THE MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE INHIBITED BY PLACING THE MAIN ENGINE LIMIT SHUTDOWN SWITCH TO "INHIBIT" (UNLESS THE BFS AUTOMATICALLY INHIBITED LIMITS AT ENGINE OUT). LIMITS WILL REMAIN INHIBITED UNTIL MECO.

If the BFS has been engaged, a subsequent engine shutdown will require the limits to be inhibited because BFS does not have single engine roll control logic (ref Rule {A5-103}, LIMIT SHUTDOWN CONTROL). BFS will automatically inhibit limits if the engine that shut down did not have a previous data path failure, had a data path failure at shutdown, or had a previous data path failure prior to BFS engage but was recovered upon BFS engage. Limits will have to be manually inhibited by taking the main engine limit shutdown switch to INHIBIT if the engine that shut down had a non-recovered data path failure prior to shutdown.

Rules {A5-102}, AUTO/MANUAL SHUTDOWN, {A5-103}, LIMIT SHUTDOWN CONTROL, and {A5-113}, MANUAL MECO/MECO CONFIRMED, reference this rule. @[121296-4594A]

FLIGHT RULES

A5-105

DATA PATH FAIL/ENGINE-OUT ACTION

IF THE MCC CONFIRMS THAT AN ENGINE WITH A DATA PATH FAILURE HAS SHUT DOWN, THAT ENGINE'S SHUTDOWN pb WILL BE PUSHED TO MODE THE GUIDANCE AND FLIGHT CONTROL LOGIC AND TO CLOSE THE ASSOCIATED PREVALVES.

SHOULD THE SAFING FUNCTION OF THE pb BE INOPERATIVE DUE TO SHUTDOWN pb OR CONTROL BUS PROBLEMS, THE APPROPRIATE MDM PER THE TABLE BELOW WILL BE POWER CYCLED FOR 1 SECOND TO ALLOW THE pb TO OPERATE. THE POWER CYCLED MDM MAY BE REGAINED VIA AN I/O RESET POST SAFING. @[021397-4823]

<u>S/D pb CONTACT</u>	<u>CONTROL BUS</u>	<u>MDM</u>
CTR A	AB1	FF1
CTR B	BC1	FF2 @[111699-7140]
LEFT A	BC2	FF2
LEFT B	CA2	FF3
RT A	CA3	FF3
RT B	BC3	FF4

The GPC guidance software will not know an engine has shut down prematurely if the data path from that engine has also failed. Pushing the corresponding shutdown pb will set the safing command in the GPC for that engine. When the safing command is set, the SSME OPS sequence will close the prevalves and set the engine fail flag for that engine. Closing the prevalves is essential to isolate the failed engine if the engine failure caused damage to the engine propellant supply lines. There is a potential for a fire or propellant loss with the prevalves open. The engine fail flag is used by the ascent guidance software to mode the guidance and targeting functions to correspond to the number of SSME's that are operating. This is required for proper control of the vehicle.

If the two contacts on the shutdown pb disagree, the safing command will not be set. A contact disagreement can be caused by a failure of a contact, the loss of the fuse to a contact, or the loss of the control bus providing power to a contact. Power cycling the MDM associated with that contact will cause the failed contact to be comm faulted; this will allow the safing command to be set when the pb is pushed. For FF 1, 2 or 3, the power cycle must be of approximately 1 second in duration before moding guidance. This is to ensure that the MDM is off long enough to be comm faulted, yet repowered quickly to avoid caging the associated IMU. The comm faulted MDM can be recovered with an I/O reset after the appropriate shutdown pb is pushed and guidance has been moded. @[021397-4823]

FLIGHT RULES

A5-106

MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES

MANUAL SHUTDOWN OF AN AFFECTED ENGINE WILL BE PERFORMED PRIOR TO OR AT MECO FOR THE FOLLOWING COMMAND AND/OR DATA PATH FAILURE CASES:

A. COMMAND PATH FAILURE.

1. NOMINAL/ATO/AOA:

- a. THREE ENGINES ON - SHUT DOWN AT VI = 23K FPS USING THE AC POWER SWITCHES AND SHUTDOWN PB.
- b. TWO ENGINES ON - SHUT DOWN AT VI = 24.5K FPS USING THE AC POWER SWITCHES AND SHUTDOWN PB.
- c. MCC CONFIRMS COMMAND PATH FAILURE BY NO THROTTLING OF AFFECTED ENGINE WHEN THE ENGINES ARE COMMANDED TO THROTTLE.

2. RTLS:

TWO OR THREE ENGINES ON - SHUT DOWN DURING POWERED PITCHDOWN AT ALPHA = -1 USING THE AC POWER SWITCHES AND SHUTDOWN PB. @[032395-1759]

3. TAL:

TWO OR THREE ENGINES ON - SHUT DOWN AT VI = 22.5K FPS USING AC POWER SWITCHES AND SHUTDOWN PB.

In the case of a command path failure, the only way to shut down an engine is with the engine ac power switches. Shutting down with the ac power switches also creates a data path failure. Therefore, the shutdown pushbutton is pushed to tell guidance that an engine is out. The engine is shut down approximately 30 seconds before MECO to prevent depleting LO₂ through an SSME and causing uncontained engine damage. A velocity which equates to MECO minus 30 seconds also gives guidance time to compensate for late engine out and converge to the proper MECO targets. The only exception is an RTLS where the engine is shut down during powered pitchdown at alpha = -1 degrees. On a three- or two-engine abort RTLS, if an engine is shut down at TGO ? 60 seconds, guidance will not mode to the target set corresponding to the remaining number of engines. @[032395-1759A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-106

MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES (CONTINUED)

The cue of alpha = -1 degree (approx MECO-5 sec) was chosen to allow SSME shutdown to begin prior to predicted MECO while the LO₂ is still under G's from the other engine(s). This alleviates LO₂ net positive suction pressure concerns for the high pressure oxidizer turbopump (HPOTP). Alpha = -1 degree also protects for 1-sigma aerodynamic dispersions. Although sizable transients can be expected subsequent to engine shutdown, flight control has been demonstrated to null these transients prior to ET separation (in some cases ET separation inhibits of approximately 1 second will occur, reference AEFTP #87 and #122 minutes). On a three-engine press-to-MECO case, MECO minus 30 seconds occurs at a VI = 23 kfps. On a two-engine press-to-MECO case, MECO minus 30 seconds occurs at a VI = 24.5 kfps. On a TAL abort, MECO minus 30 seconds occurs at a VI = 22.5 kfps. ©[032395-1759A]

B. DATA PATH FAILURE

1. MCC DECISION (PRIME)

NOMINAL/ATO/AOA/TAL/RTL5 :

- a. NO ACTION REQUIRED.
- b. MCC CONFIRMS COMMAND PATH OPERATIONAL BY GH₂ OUTLET PRESSURE COMPARISON TO POWER LEVEL COMMAND.

2. ONBOARD DECISION (NO COMMUNICATION).

NOMINAL/ATO/AOA/TAL/RTL5 :

CREW ACTION SAME AS FOR COMMAND PATH FAILURE.

For a data path failure, the engine will accept throttling and MECO commands so that no action is required. The crew cannot tell the difference between a data path failure and a command/data path failure. The two failures that caused the data path failure may also have caused a command path failure (i.e., two controller interface adapters (CIA's), or a CIA and a multiplexer interface adapter (MIA) in the EIU). Unless the command capability is verified by the MCC, the crew will assume a command and data path failure and will take the same action as a command path failure. The MCC can verify the command path status by observing that the GH₂ outlet pressure changes with the throttle command. If an engine throttles down when commanded, its command path is operational.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-106 MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES
(CONTINUED)

C. COMMAND AND DATA PATH FAILURE.

1. MCC DECISION (PRIME)

NOMINAL/ATO/AOA/TAL/RTLS:

- a. ACTION SAME AS COMMAND PATH FAIL
- b. MCC CONFIRMS CASE BY NO CHANGE IN GH2 OUTLET PRESSURE ON THE AFFECTED ENGINE WHEN ENGINE COMMANDED TO THROTTLE.

2. ONBOARD DECISION (NO COMMUNICATION)

NOMINAL/ATO/AOA/TAL/RTLS:

CREW ACTION SAME AS FOR COMMAND PATH FAILURE.

The loss of an EIU or the loss of an MIA and a CIA or the loss of two CIA's will cause a data path failure and a command path failure on the same engine.

This is a very serious failure mode because this failure will close the LO₂ prevalues on an operating engine if preventative action is not taken. A water-hammer effect could occur which would rupture the LO₂ feedline and result in uncontained engine damage and loss of vehicle. At MECO, the GPC logic assumes an engine with a data path failure does not have a command path loss (i.e., the GPC assumes the engine accepted and complied with the shutdown command); therefore, the prevalues are commanded closed. To prevent this catastrophic shutdown of the engine at MECO, the engine ac power switches must be used to shut down the engine before MECO is commanded. The ac power switches will shut down the engine; the pushbutton is then pressed to mode guidance.

Rules {A2-59D}, BFS ENGAGE CRITERIA; {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES); {A5-110}, SSME PERFORMANCE DISPERSION; {A5-107}, MANUAL SHUTDOWN FOR SUSPECT COMMAND PATH FAILURES; {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS; and {A7-9}, REDUNDANT SET SPLIT, reference this rule. ©[032395-1766] ©[061296-6147A] ©[ED]

FLIGHT RULES

A5-107

MANUAL SHUTDOWN FOR SUSPECT COMMAND PATH FAILURES

AN ENGINE WITH SUSPECT COMMAND CAPABILITY FOR SHUTDOWN WILL BE MANUALLY SHUT DOWN PRIOR TO MECO USING THE SAME CUES LISTED FOR A COMMAND PATH FAILURE IN FLIGHT RULE {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES.

If a transient failure observed during powered flight results in the temporary loss of a command channel, the respective command channel will be considered suspect since the failure could return at any time. If another avionics failure and a reoccurrence of the previously observed transient failure results in a command path failure (per Rule {A5-3}, STUCK THROTTLE), the command capability of this engine will be considered suspect even if the engine reacts to the 3g throttle back command. Therefore, this engine will be shut down pre-MECO per Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURE. The engines have single command channel shutdown logic that allows the engine to shut down by accepting shutdown commands on only one out of three command channels. Operationally, this logic is only relied upon for late, unexpected failures. ©[111501-4939]

One example of a transient failure is an EIU power-on-reset failure. A power-on-reset failure causes the temporary loss of a single power supply in an EIU. Since the EIU MIA ports 1 and 3 are on the same power source (MIA ports 2 and 4 are on another), this failure will cause the temporary loss of command and data transfer capability on two MIA ports (ground data only shows the status of MIA ports 1 and 4; therefore, MIA ports 3 and 2 are assumed bypassed with ports 1 and 4, respectively). After this failure has occurred, the command transfer capability will be regained automatically while the data transfer capability will be regained via an I/O Reset. The following scenario is an example of the concern that this failure raises: If an engine has a command channel B failure and a power-on-reset failure on MIA ports 1 and 3, the engine will be considered to have suspect command capability even if the engine responds to throttle commands and will be shut down pre-MECO. ©[111501-4939]

FLIGHT RULES**A5-108****MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP**

AN SSME IN HYDRAULIC OR ELECTRICAL LOCKUP MAY HAVE TO BE MANUALLY SHUT DOWN TO PREVENT A VIOLATION OF THE ENGINE LO₂ NPSP REQUIREMENTS NEAR MECO. MANUAL SHUTDOWN WILL BE REQUIRED UNDER THE FOLLOWING CONDITIONS FOR ANY ENGINE LOCKED UP ABOVE THE MINIMUM POWER LEVEL (KMIN). @[061297-6171] @[090999-7052A]

A. NOMINAL/ATO: @[ED]

1. THREE ENGINES ON:

a. ONE STUCK THROTTLE - SHUT DOWN THE AFFECTED ENGINE AT VI = 23K FPS USING THE SHUTDOWN PB.

b. TWO STUCK THROTTLES - (REF. RULE {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES), AND RULE {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES). @[ED]

2. TWO ENGINES ON - NO ACTION REQUIRED.

B. RTLS AND TAL - NO ACTION REQUIRED.

Manual shutdown of an engine in hydraulic or electrical lockup is only required for a three-engine nominal or ATO mission. The three-engine LO₂ low level cutoff delay timer (as defined by the I-load NOM_LO2_LOW_LVL_TIME_DELAY_L - currently 0.358 seconds) is designed for three engines shutting down from the minimum power level (as defined by the I-load KMIN - currently 67 percent power level). If one engine is stuck above the minimum power level, the LO₂ net positive suction pressure (NPSP) and post shutdown LO₂ mass requirements may be violated. Therefore, an LO₂ depletion cutoff at power levels greater than that accounted for by the low level timers could cause high pressure oxidizer pump overspeed resulting in a potentially catastrophic engine shutdown. Given the potentially catastrophic nature of the shutdown and given that an LO₂ low level cutoff cannot always be predicted (reference the STS-93 unpredicted LO₂ low level cutoff which was caused primarily by an SSME nozzle leak which was smaller than the minimum criteria of Rule {A5-110}, SSME PERFORMANCE DISPERSION, and therefore not modeled in the Abort Region Determinator (ARD)), it was decided to accept the operational impacts of always shutting down a locked up engine when three engines are on as opposed to relying on the ARD to make a real-time performance evaluation (reference Ascent Flight Techniques Panel Meeting #160, August 27, 1999). These impacts include up to 60 feet per second of lost performance and a planar error at MECO of up to 10 feet per second (some planar error is inevitable for these cases even if the stuck engine is not shut down).

@[090999-7052A] @[092701-4819A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-108

MANUAL SHUTDOWN FOR HYDRAULIC OR ELECTRICAL LOCKUP (CONTINUED)

Analysis performed without dispersions indicates the LO₂ residual mass requirement is satisfied for an engine stuck at up to 76 percent power level (reference PSIG telecon, August 25, 1999). However, to protect for dispersions in the analytically derived LO₂ mass requirement, to protect for potential uncertainties in the engine power level prediction at shutdown, to maximize the NPSP and LO₂ residual mass provided, and to provide operational simplicity, a manual engine shutdown is performed for any engine stuck greater than the minimum power level. By shutting down the stuck engine prior to MECO, the two remaining engines will throttle to 91 percent power level for fine count. The low level cutoff delay timer for the two-engine on case is zero, thereby maximizing the NPSP and LO₂ residual mass for two engines shutting down from 91 percent. @[061297-6171] @[090999-7052A]

For the two-engine-on case with stuck throttles at any power level, the technical community determined that the NPSP would not be severely violated and the minimum post shutdown LO₂ mass requirements would be satisfied. Therefore, no action was required (reference the 24th PSIG in November 1983 and Ascent Flight Techniques on May 21, 1984). For an RTLS or TAL abort, the LO₂ residuals should be sufficient enough to prevent an LO₂ low level shutdown.

Shutdown of an engine in either a hydraulic or electric lockup will be performed by shutdown pushbutton only. The shutdown pushbutton method for manual shutdown of an engine in either hydraulic or electric lockup minimizes the exposure to the unnecessary risk of a pneumatic shutdown in the case of the electrically locked-up engine and simplifies crew procedures in the case of the hydraulically locked-up engine. @[090999-7052A]

FLIGHT RULES

A5-109 MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES)

A. THREE ENGINES RUNNING:

1. NOMINAL/ATO - MANUALLY SHUT DOWN ONE ENGINE AT V_T ? 23K FPS.
2. TAL - MANUALLY SHUT DOWN ONE ENGINE AT V_T ? 22.5K FPS. ENABLE MANUAL THROTTLES PRIOR TO ABORT SELECTION TO MAINTAIN NOMINAL POWER LEVEL. @[082593-1464C]
3. RTLS - BEFORE SELECTING RTLS, MANUAL THROTTLES WILL BE ENABLED AND MINIMUM THROTTLES SELECTED. AT LEAST 10 SECONDS OF MINIMUM THROTTLE LEVEL IS DESIRED PRIOR TO RTLS SELECTION. AUTO THROTTLES WILL BE RESELECTED ANYTIME PRIOR TO POWERED PITCH-AROUND (PPA). IF BOTH ENGINES WITH STUCK THROTTLES ARE AT MORE THAN 85 PERCENT, MANUALLY SHUT DOWN ONE ENGINE 2 MINUTES PRIOR TO MECO. @[082593-1464C]

SHUTDOWN PRIORITY: (1) COMMAND PATH FAIL, (2) HYDRAULIC LOCKUP, (3) ELECTRICAL LOCKUP

B. TWO ENGINES RUNNING - NO ACTION REQUIRED.

For dual command path failures, reference Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES. For dual hydraulic failures, ref. Rule {A8-61}, SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES.

If two of three operating engines have stuck throttles, manual shutdown of an engine will be required to prevent violation of the 3.5g acceleration limit. This limit cannot be violated with only two engines operating. Also, this limit cannot be violated on a three-engine RTLS if at least one of the stuck throttles is less than or equal to 85 percent. Above 85 percent, shutting down an engine 2 minutes prior to MECO ensures that it will not be violated. @[110900-7242]

For all RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of an early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection. @[082593-1464C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-109

MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES) (CONTINUED)

For TAL, it is undesirable to throttle down the good engine due to the guidance transients which may occur and the fact that little time would be gained to perform the abort dump. Therefore, manual throttles will be selected to prevent an automatic throttledown when TAL is declared. This action is not required if TAL is declared early enough that automatic throttling will not occur at abort selection. However, since there is no disadvantage to selecting manual throttles for this short period of time, manual throttles will always be selected for consistency. AUTO throttles will be reselected after TAL is declared. ©[082593-1464C]

Shutdown priorities are established to protect against the maximum risk. Command path failure means the engine will not automatically shut down at MECO, which is catastrophic. Hydraulic lockup means shutdown requires the nonredundant pneumatic system. Electric lockup results in a nominal shutdown.

Shutdown will be performed on the command path failed engine using the ac power switches and shutdown pushbutton. Shutdown of an engine in either a hydraulic or electric lockup will be performed by shutdown pushbutton only. The shutdown pushbutton method for manual shutdown of an engine in either hydraulic or electric lockup minimizes the exposure to the unnecessary risk of a pneumatic shutdown in the case of the electrically locked-up engine and simplifies crew procedures in the case of the hydraulically locked-up engine.

Rule {A2-301}, Note 8, CONTINGENCY ACTION SUMMARY, and {A4-59}, MANUAL THROTTLE SELECTION, reference this rule. ©[092195-1770A]

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION @[070899-6819]

- A. SHOULD AN SSME PERFORMANCE DISPERSION ARISE, THE ABORT REGION DETERMINATOR (ARD) PROGRAM IN THE MCC WILL BE ADJUSTED ASAP WITH THE FOLLOWING INFORMATION: @[070899-6819]
1. AFFECTED SSME CAUSING THE PERFORMANCE DISPERSION
 2. TIME OF OCCURRENCE
 3. MODE AND LEVEL OF THE PERFORMANCE DISPERSION CONDITION INCLUDING INSTANTANEOUS PERFORMANCE INFORMATION.

The SSME performance dispersion rule defines the failures and the minimum criteria which must be met prior to updating the ARD with an SSME performance case. The Booster Main Engine Tables quantify each of the performance cases and include the minimum criteria for calling the performance cases. These tables are generated using the SSME Power Balance Model data provided by Rocketdyne in response to a Shuttle Operational Data Book (SODB) Request. The Engine Status Word (ESW), MCC Pc, HPOT/HPFT discharge temperatures, LPFP discharge temperature, OPOV/FPOV position, and/or HPOP/HPFP discharge pressures are the primary cues used for determining performance cases. Updates to the ARD consist of changes in power level (thrust), specific impulse (Isp), and mixture ratio (MR). The ARD uses these SSME performance parameters to predict abort mode capabilities real time. A change in any of these parameters could affect the abort boundaries significantly.

- B. AN SSME PERFORMANCE EVALUATION CAN ONLY BE MADE WHEN THE SSME COMMANDED POWER LEVEL IS KNOWN AND THE SSME IS IN A STEADY-STATE CONDITION. QUANTIFIABLE PERFORMANCE DISPERSIONS ARE AS FOLLOWS:
1. SINGLE MCC PC CHANNEL SHIFT HIGH OR LOW WILL BE CALLED IF THE DELTA BETWEEN MCC PC CHANNEL A AND MCC PC CHANNEL B IS ? 50 PSI:
 - a. FOR PC SHIFT HIGH ACTUAL LOW, THE LOWEST MCC PC CHANNEL WILL BE USED FOR PERFORMANCE EVALUATION.
 - b. FOR PC SHIFT LOW ACTUAL HIGH, THE HIGHEST MCC PC CHANNEL WILL BE USED FOR PERFORMANCE EVALUATION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

- c. FOR A SINGLE MCC PC CHANNEL SHIFT, THE AFFECTED MAIN ENGINE CONTROLLER CHANNEL WILL BE POWER CYCLED FOR 1 SECOND BY THE CREW IF AN ATO CANNOT BE ACHIEVED. THIS PROCEDURE WILL NOT BE IMPLEMENTED IF IT WILL CAUSE AN SSME SHUTDOWN OR NOT CORRECT THE PERFORMANCE DISPERSION AS DEFINED BELOW: @[061297-6147A] @[070899-6819]
- (1) LIMIT EXCEEDED ON ANY REMAINING SHUTDOWN SENSOR(S) ON OTHER CHANNEL SO THAT IT CAUSES ENGINE SHUTDOWN.
 - (2) LOSS OF OTHER CHANNEL'S DCU, INPUT ELECTRONICS, OR OUTPUT ELECTRONICS (CAUSES SSME SHUTDOWN). @[070899-6819]
 - (3) WHEN IN ELECTRICAL LOCKUP OR WHEN CHANNEL POWER CYCLE CAUSES ELECTRICAL LOCKUP. @[061297-6147A]
 - (4) WHEN IN HYDRAULIC LOCKUP OR WHEN CHANNEL POWER CYCLE CAUSES HYDRAULIC LOCKUP. @[061297-6147A]

NOTE: IT IS ACCEPTABLE TO CAUSE A MOMENTARY OR PERMANENT SSME COMMAND PATH FAILURE, BECAUSE THE SSME CAN STILL REBALANCE TO CORRECT FOR THE PERFORMANCE CASE. @[061297-6147A]

The SSME thrust is controlled using the MCC Pc channel average. A single MCC Pc channel erroneously shifting high or low will cause the SSME to shift in the opposite direction in an attempt to rebalance the SSME. That is, for an MCC Pc channel shift high case, the SSME will actually shift low. The good MCC Pc channel will shift in the direction of the actual SSME shift causing a delta between the two MCC Pc channels. The good MCC Pc channel will be used for performance evaluation. A difference of 50 psi between the two MCC Pc channels is the minimum detectable single MCC Pc channel shift, and it equates to an actual MCC Pc error of 25 psi (level 1, MCC Pc Shift Tables).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

A shifted MCC Pc channel can so adversely impact SSME performance that an ATO cannot be achieved. For such a case, the Booster will call for the controller channel with the malfunctioning MCC Pc channel to be power cycled for 1 second. Booster must be ready to identify the channel and switch to be cycled by the crew. The controller channel that has been power cycled will remain available for command and data transfer, but the controller IE (sensor data to the controller) and OE (control to the valve servo-actuators and servo-switches) on that channel will be disqualified. Disqualification of a shifted Pc sensor's IE will restore engine operation to nominal thrust and mixture ratio conditions. This action should not be taken if it will cause engine shutdown or not correct the performance dispersion. Cases that would cause engine shutdown consist of redline shutdown sensor(s) violating redline limits on the remaining channel or loss of the remaining channel's DCU, IE, or OE. Reference {Rule A5-2}, SPACE SHUTTLE MAIN ENGINE OUT, paragraphs E and F. If the SSME is in electrical or hydraulic lockup or when channel power cycle causes electric or hydraulic lockup, disqualifying the faulty sensor (channel) will not correct the dispersion since the engine valves cannot be repositioned. It is acceptable to create a momentary or permanent command path failure because it is not necessary for the controller to have good GPC commands in order for the SSME to rebalance. However, command path failures are unlikely since the SSME command channel is expected to be regained once the controller power is turned back on. If a command path failure does occur, the affected SSME must be shut down prior to MECO based on the cues listed in Flight Rule {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES. @[070899-6819]

2. A DUAL MCC PC CHANNEL SHIFT HIGH OR LOW CASE WILL BE CALLED WHEN THE MCC PC ERROR IS ≥ 37.5 PSI. A MINIMUM MCC PC ERROR OF 37.5 PSI IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL THREE TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPOP DISCHARGE PRESSURE, AND HPFP DISCHARGE PRESSURE) EXCEED THE LEVEL 1.5 CRITERIA PER THE MCC PC SHIFT TABLES. A DELTA BETWEEN THE MCC PC CHANNELS MAY OR MAY NOT BE PRESENT. @[070899-6819]

Actual MCC Pc error can also result from shifts in both the MCC Pc channels (shifting by the same or different amounts) or a shift in one MCC Pc channel with the other channel previously disqualified; this is defined as a dual MCC Pc channel shift. For this case, the actual SSME MCC Pc error will be determined using the HPOT discharge temperature, HPOP discharge pressure, and HPFP discharge pressure. A dual MCC Pc channel shift will be assessed when all three of these telemetry parameter deltas exceed the minimum criteria (SSME MCC Pc error ≥ 37.5 psi) listed in the Booster Main Engine Tables (approved at the A/EFTP No. 152 on September 18, 1998). Both the single and the dual MCC Pc channel shift cases will use the same MCC Pc Shift Tables for the ARD updates, and the level in both cases will be based on the actual MCC Pc error. For a dual MCC Pc shift case, waiting for MCC Pc error of 37.5 psi (level 1.5) protects against erroneously calling the case due to prediction sigmas, and it reliably differentiates this case from other cases that have similar SSME temperature and pressure movements.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

3. LPFT DISCHARGE TEMPERATURE SHIFT CASE WILL BE CALLED WHEN THE LPFT DISCHARGE TEMPERATURE SENSOR SHIFTS LOW? 2 DEG R.

A shift in LPFT discharge temperature sensor will cause an error in the fuel density calculation. This error in fuel density will propagate into an error in the mixture ratio calculation. The SSME controller will then attempt to return the calculated mixture ratio to the nominal value by adjusting the SSME valves causing an off-nominal engine performance dispersion. A performance adjustment to the ARD will only be made for a shift low of the LPFT discharge temperature sensor because the LPFT discharge temperature cannot realistically get colder. The minimum detectable error is 2 deg R to cover instrumentation accuracy, run to run variations, and to ensure sufficient change in the SSME parameters for failure identification.

4. ELECTRICAL LOCKUP WILL BE CALLED WHEN THE ENGINE STATUS WORD (ESW) INDICATES THAT THE SSME IS IN ELECTRICAL LOCKUP.
- a. IF THE MCC PC OR THE LH₂ FLOWMETER SENSORS SHIFT PRIOR TO ELECTRICAL LOCKUP AND IF THE SSME IS LOCKED UP AT THE MISSION POWER LEVEL, AN ARD ADJUSTMENT WILL BE MADE USING THE MCC PC SHIFT TABLES OR LH₂ FLOWMETER SHIFT TABLES. @[070899-6819]
- b. IF THERE IS NO QUANTIFIABLE SHIFT IN THE MCC PC OR THE LH₂ FLOWMETER SENSORS PRIOR TO ELECTRICAL LOCKUP, AN ARD ADJUSTMENT WILL BE MADE USING THE BACKUP ELECTRICAL LOCKUP TABLES. @[070899-6819]

An electrical lockup will be called when the ESW mode indicates that the SSME is in electrical lockup. Electrical lockup is caused by disqualification of both channels of either the MCC Pc or the LH₂ flowmeter sensors (reference Flight Rule {A5-3}, STUCK THROTTLE). If the MCC Pc or LH₂ flowmeter sensor shift caused an SSME to rebalance prior to disqualification, an ARD adjustment will be made using the MCC Pc shift tables or the LH₂ flowmeter shift tables. If there is no quantifiable shift in the SSME performance prior to an electrical lockup, then an ARD adjustment will be made using the backup electrical lockup table.

The fuel flow meter and Pc shift tables are only valid at the mission power level. For electrical lockups that do not occur at the mission power level, the backup electrical lockup tables are used. The backup electrical lockup tables adjust thrust, Isp and MR for LO₂ inlet pressure at the time of the lockup.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

5. AN LH₂ FLOWMETER SHIFT HIGH OR LOW WILL BE CALLED WHEN THE FUEL FLOW ERROR IS ? 450 GPM. A MINIMUM FUEL FLOW ERROR OF 450 GPM IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL FOUR TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPOP DISCHARGE PRESSURE, HPFP DISCHARGE PRESSURE, AND FPOV POSITION) EXCEED THE LEVEL 1 CRITERIA.

The SSME mixture ratio is controlled using the measured volumetric flowrate from the LH₂ flowmeter. A shift in the LH₂ flowmeter will cause the SSME controller to calculate incorrect values for LH₂ mass flowrate, propagating into a mixture ratio error. The controller will then attempt to return the calculated mixture ratio to the nominal value by adjusting the SSME valves. This will cause the real thrust, Isp, and MR to be off-nominal. A flowmeter shift low will cause the controller to increase LH₂ flow, "shift low actual high," causing the real mixture ratio to be low. A LH₂ flowmeter shift high will cause the controller to decrease the LH₂ flow, "shift high actual low," causing the real mixture ratio to be high. The LH₂ flowmeter shift case will be assessed only when all four telemetry parameter deltas (HPOT discharge temperature, HPOP discharge pressure, HPFP discharge pressure, and FPOV position) exceed the level 1 criteria (SSME fuel flow error ? 450 GPM) listed in the Booster Main Engine Tables. The OPOV position cue was replaced by the HPFP discharge pressure cue after the Block I SSME's were introduced into the fleet - due to OPOV position oscillations (reference PSIG Action No. 940112-D01.

6. HYDRAULIC LOCKUP WILL BE DECLARED WHEN THE HYDRAULIC SUPPLY PRESSURE DROPS BELOW 1500 PSIA OR WHEN THE ESW INDICATES HYDRAULIC LOCKUP. THE INSTANTANEOUS AND DRIFT PERFORMANCE WILL BE COMPUTED IN REAL-TIME, AND THE ARD WILL BE ADJUSTED ACCORDINGLY. @[070899-6819]

The SSME propellant valves will not properly actuate with the hydraulic supply pressure below 1500 psia and will begin to drift due to flow torque effects. As the SSME propellant valves drift and as the SSME controller also attempts to adjust the valves to account for vehicle acceleration/inlet pressure effects, the SSME controller will disqualify both servo-actuators and mode the SSME into hydraulic lockup as indicated by the ESW. The SSME controller can also mode the SSME into hydraulic lockup for reasons other than loss of hydraulic supply pressure (reference Flight Rule {A5-3}, STUCK THROTTLE). For either case, the ARD will be updated with an instantaneous thrust, Isp and MR. If the performance is changing with time due to valve drift, the mainstage performance during lockup will be calculated real time via an algorithm in the Booster Operational Support Software. Once the drift performance can be quantified, the drift level and the drift time used in these calculations will be passed to the Trajectory Officer for ARD update. The drift rate is assumed to be linear (based on SSME test stand data). Ground testing of hydraulic lockup has shown that significant valve drift can occur on an engine in hydraulic lockup. Design changes to the SSME valve actuators have been incorporated to minimize valve drift in case of hydraulic lockup. @[070899-6819]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-110

SSME PERFORMANCE DISPERSION (CONTINUED)

7. PRE-THRUST LIMITING NOZZLE LEAK WILL BE CALLED AT LEAK RATES \geq 7 LBM/SEC. A MINIMUM LEAK RATE OF 7 LBM/SEC IS DEFINED BY THE BOOSTER MAIN ENGINE TABLES WHEN ALL FOUR TELEMETRY PARAMETER DELTAS (HPOT DISCHARGE TEMPERATURE, HPFT DISCHARGE TEMPERATURE, HPFP DISCHARGE PRESSURE, AND OPOV POSITION) EXCEED THE LEVEL 1 CRITERIA.

Leakage from the nozzle tubes is the most likely source of a fuel leak based upon SSME experience, but Booster will call any fuel leak downstream of the fuel flowmeter a nozzle leak. During a nozzle leak, fuel is lost overboard causing a decrease in thrust, and the SSME will command the OPOV open in an attempt to maintain a constant SSME thrust. As the leak rate gets larger, the OPOV will continue to open causing the actual SSME mixture ratio and thrust to increase. When the maximum OPOV command limit is exceeded, the SSME will enter a mode called thrust limiting where the OPOV will no longer be commanded to open further. If the leak rate continues to increase after thrust limiting, the actual SSME mixture ratio and thrust will start to decrease. Due to the difference in performance parameter trends for pre-thrust limiting and post-thrust limiting nozzle leaks, the Booster Main Engine Tables considers them separate performance cases for the ARD update. ©[070899-6819]

Pre-thrust limiting nozzle leaks will be assessed for an ARD update only when all four telemetry parameter deltas (HPOT discharge temperature, HPFT discharge temperature, HPFP discharge pressure, and OPOV position) exceed the level 1 criteria (fuel leak rate \geq 7 lbm/sec) listed in the Booster Main Engine Tables (approved at the A/EFTP # 152 on September 18, 1998). The minimum criteria protects against erroneously calling the case due to prediction sigmas, and it reliably differentiates this case from other cases that have similar SSME temperature, pressure, and valve movements. In the case of pre-thrust limiting nozzle leaks, the level 1 criteria for OPOV position delta (approximately 3 percent) is large enough to prevent the Block I SSME OPOV position oscillation (approximately 1 percent) from erroneously exceeding the minimum cue during nominal operations. The approximately 1 percent OPOV oscillation is only present on Block I SSME and not on Phase II/Block IIA/Block II SSME's. ©[070899-6819]

8. POST-THRUST LIMITING NOZZLE LEAKS WILL BE CALLED WITH THRUST LIMITING FLAG SET.
9. AN HPOT EFFICIENCY LOSS WILL BE CALLED WITH THRUST LIMITING FLAG SET.

An ARD update will be made for a post-thrust limiting nozzle leak or HPOT efficiency loss case only when the SSME has entered the thrust-limiting mode. Subsequent to thrust limiting, the two cases are differentiated by using the HPOT discharge temperature. The HPOT discharge temperature will rise in both of the thrust limiting cases, but the delta value is much greater in the case of a nozzle leak. In order to differentiate between the two cases, the HPOT discharge temperature delta cue was developed as the breakover value for each of these cases. The HPOT efficiency loss will not result in off-nominal SSME operation prior to thrust limiting; therefore, it is only assessed after thrust limiting is initiated.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A5-110****SSME PERFORMANCE DISPERSION (CONTINUED)**

The SSME Project Office acknowledges that there are "Overall Call Uncertainties" associated with each of the off-nominal SSME performance cases. Uncertainties exist in mixture ratio, power level, and Isp values. Subsequent to the quantification of an off-nominal performance case, mixture ratio, power level, and Isp are passed to the Flight Dynamics Officer and are used to update the ARD. The uncertainties associated with each of these parameters, for each of the performance cases, are documented in MSFC letter EE21/095-016 (Review of Booster Real-time Software (BRTS) Algorithm's, D. R. Goslin to B. R. Stone, March 17, 1995). On February 6, 1996, the Integration Control Board (ICB) made the decision not to protect these uncertainties (ICB Item WACMO0167, Booster Console Uncertainty on ARD Performance). Therefore, ARD Flight Propellant Reserve (FPR) will not reflect these uncertainties.

©[041196 1877]

Rules {A4-61}, THRUST LIMITING, HYDRAULIC, OR ELECTRICAL LOCKUP; {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT; {A5-3}, STUCK THROTTLE; and {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES reference this rule. ©[061297-6147A] ©[ED]©[070899-6819]

A5-111**AC BUS SENSOR ELECTRONICS CONTROL [CIL]**

THE ORBITER AC BUS SENSOR ELECTRONICS POWER SWITCH WILL BE PLACED TO "OFF" FOR THE FOLLOWING ENGINE FAILURE CASES:

- A. ENGINE OUT (REF. RULE {A9-152}, AC BUS SENSORS SWITCH MANAGEMENT) ©[121296-4624]
- B. LOSS OF SSME CONTROLLER REDUNDANCY (REF. RULE {A5-2}, SPACE SHUTTLE MAIN ENGINE OUT) ©[ED]
- C. ALL QUALIFIED REDLINE SENSORS ON A SINGLE REDLINE, ON A SINGLE CHANNEL, VOTING FOR SHUTDOWN. ©[121296-4624]

There are single point failures in the ac bus sensor electronics that can cause loss of a single phase of an ac bus which powers the SSME controllers. After an engine failure or electrical/avionics failures that leave an engine one failure away from shutdown, the bus overvoltage protection is less important than keeping an engine running. Therefore, the sensor monitoring electronics power is terminated by moving three switches (AC BUS SNSR) on panel R1 to OFF.

FLIGHT RULES

A5-112

MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN

MANUAL THROTTLING TO THE MINIMUM SSME POWER LEVEL WILL BE PERFORMED TO PROTECT MECO LO₂ NPSP REQUIREMENTS WHEN LO₂ LOW-LEVEL CUTOFF IS PREDICTED TO OCCUR BEFORE FINE COUNT THROTTLEDOWN. MANUAL THROTTLING TO THE MINIMUM POWER LEVEL WILL BE PERFORMED WHEN THE ONBOARD PROPELLANT REMAINING COMPUTATION REACHES 2 PERCENT, AND THE MCC FLIGHT DYNAMICS OFFICER (FDO) IS PREDICTING A VELOCITY UNDERSPEED AT MECO WHICH IS GREATER THAN THE FOLLOWING: @[071494-1645] @[121296-4630B]

- A. TWO OR THREE ENGINES ON: 500 FT/SEC
- B. ONE ENGINE ON: 250 FT/SEC

THE CREW WILL PERFORM SSME THROTTLEBACK FOR THE ONE ENGINE-ON CASE EXCEPT FOR CERTAIN CONTINGENCY ABORT CASES (AS DOCUMENTED ON THE CONTINGENCY ABORT CUE CARDS IN THE ASCENT CHECKLIST FLIGHT DATA FILE) OR UNLESS INSTRUCTED TO DO OTHERWISE BY THE MCC. @[071494-1645] @[121296-4630B]

If FDO is predicting a low-level cutoff prior to the guidance software issuing the fine count command (ref. rationale of Rule {A4-59G}, MANUAL THROTTLE SELECTION), the engines will shut down at an unsafe power level. This will cause the LO₂ NPSP to be well below the required value, possibly causing uncontained engine damage at shutdown. For two or three engine-on cases, analysis indicates that the vehicle acceleration near MECO will be sufficient to prevent SSME shutdown prior to fine count as long as the predicted underspeed (based on 2 sigma MPS propellant protection) is no greater than 500 ft/sec. Because of low vehicle acceleration, analysis of the single engine-on case indicates that SSME requirements will not be violated as long as the predicted underspeed (based on 2 sigma MPS propellant protection) at MECO is less than 250 ft/sec. The two/three engine-on case assumes a vehicle mass of 379,000 lbs at MECO minus 10 seconds and the one engine-on case assumes 368,000 lbs (the difference is based on the additional 11,000 lbs MPS propellant needed for the two engine-on case, which will also protect the three engine-on case). Both cases assume that the thrust provided by a single engine at 104 percent is 488,800 lbf. The 500 ft/sec and 250 ft/sec cues are derived from using the $F = M \cdot A$ equation, as well as those used by the fine count throttle logic in the guidance software (reference NASA memorandum DF6-94-08, dated 5/11/94). If the predicted underspeed is greater than allowed for either case, manual throttling will be performed to the minimum power level, thereby reducing the NPSP requirements prior to reaching a low-level cutoff condition. The minimum throttle level was selected because it provides the best LO₂ NPSP shutdown conditions. The throttledown cue of 2 percent propellant remaining was selected to allow sufficient time to perform the manual throttling while minimizing any performance impact.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-112

MANUAL THROTTLEDOWN FOR LO2 NPSP PROTECTION AT SHUTDOWN (CONTINUED)

Analysis (reference Ascent/Entry Flight Techniques Panel #91, 7/17/92) shows that most of the error in the onboard propellant remaining computation occurs on the two-engine-out press-to-MECO abort when no OMS dump is performed. Engine performance problems also contribute to the propellant remaining error. The worst case engine problem is low specific impulse (Isp). Worst-on-worst analysis with two engines out simultaneously at the press-to-MECO boundary and the third engine running with an Isp which is 10 seconds below nominal shows that the 2 percent cue still provides sufficient time to throttle the engine down before low-level cutoff occurs. ©[071494-1645]

After throttledown, the crew will be prepared to perform a manual MECO at the desired MECO velocity should it be reached prior to the low-level cutoff.

The crew will not always throttleback for the one engine-on case. For certain contingency aborts, the software determines and performs fine count throttles (throttleback) as required for MECO. No manual throttles are required in these cases as documented on the contingency abort cue cards in the ascent checklist flight data file. ©[121296-4630B]

Rule {A2-64}, MANUAL THROTTLE CRITERIA, references this rule.

FLIGHT RULES

A5-113

MANUAL MECO/MECO CONFIRMED @[110900-7230A]

A. PERFORMING MANUAL MECO

MANUAL MECO IS PERFORMED BY PRESSING ALL THREE MAIN ENGINE SHUTDOWN PUSHBUTTONS SIMULTANEOUSLY. IF FAILURE(S) CAUSE THE MAIN ENGINE SHUTDOWN PUSHBUTTONS TO NOT COMMAND MECO, THEN THE MANUAL MECO WILL BE PERFORMED VIA THE ALTERNATE METHODS FOR SETTING THE MECO CONFIRMED FLAG OUTLINED IN PARAGRAPH B.

If required, manual MECO is usually performed by pressing the three SSME shutdown pushbuttons simultaneously. The crews are trained to perform manual MECO using all three pushbuttons rather than just the pushbuttons of running engines because pushing all three pushbuttons protects against certain failure scenarios without creating any additional risk. However, under certain conditions, pressing all three pushbuttons will not command MECO. If a failed contact (i.e., due to control bus or bad contact) on any pushbutton cannot be comm-faulted prior to MECO or if both contacts have either failed or are comm-faulted, MECO will not be commanded when all three pushbuttons are pushed. These failures will result in two engines being shut down while the engine associated with the bad pushbutton will continue to run. If such a failure is recognized prior to MECO and manual MECO is required, the crew will be instructed to command MECO by setting the MECO confirmed flag via the appropriate alternate method outlined in paragraph B.

Performing a manual MECO on any trajectory is very time critical, and it must be recognized ahead of time if the three pushbuttons will not work so that alternate methods may be employed at the required moment.

B. SETTING THE MECO CONFIRMED FLAG

THE THREE MAIN ENGINE SHUTDOWN PUSHBUTTONS WILL BE PUSHED POST MECO FOR MULTIPLE COMMAND/DATA PATH FAILURE CASES TO SET THE MECO CONFIRMED FLAG. IF THE MECO CONFIRMED FLAG WILL NOT BE SET WHEN THE SHUTDOWN PUSHBUTTONS ARE PRESSED, IT WILL BE OBTAINED VIA THE FOLLOWING ALTERNATE METHODS:

1. NOMINAL/ATO/TAL: MANUALLY PROCEEDING TO OPS 104
2. RTLS: PERFORMING A FAST SEP FROM THE EXTERNAL TANK
@[110900-7230A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-113

MANUAL MECO/MECO CONFIRMED (CONTINUED)

The SSME operations sequence will set the MECO confirmed flag for chamber pressure less than 30 percent on all three engines or a data path failure on one engine and the chamber pressure less than 30 percent on the other two engines. If two engines experience a data path failure, the software will never pass this check and MECO confirmed flag will not be set. To work around this problem, the crew can push the three shutdown pushbuttons after MECO to set the MECO confirmed flag. Prior to OI-22, all three SSME pushbuttons had to be pressed simultaneously in order to set the MECO confirmed flag in the BFS. In OI-22 and subsequent, the SSME pushbuttons can be pressed individually to set the MECO confirmed flag (CR# 89203A). The MECO confirmed flag must be set to start the ET separation sequence. ©[110900-7230A]

In the event that multiple avionics failures or a failed pushbutton contact has disabled a shutdown pushbutton, alternate methods of setting the MECO confirmed flag must be performed. On nominal ATO and TAL trajectories, the MECO confirmed flag can be set by manually keying in OPS 104 PRO. Since the OPS 104 transition is not legal on an RTLS trajectory, the MECO confirmed flag must be set by performing a fast sep from the external tank. A fast sep is performed by taking the ET SEPARATION switch to MAN and pressing the ET SEPARATION pushbutton. In PASS, fast sep logic is only supported in major modes 102, 601, or in major mode 103 when the Second SSME Fail Confirm flag had been set. BFS only supports fast sep logic in major mode 102. ©[110900-7230A]

The above steps are taken post MECO because setting the MECO confirmed flag at or before MECO causes MECO to be commanded. On uphill and TAL trajectories, setting the MECO confirmed flag to allow the ET separation sequence to proceed is not particularly time critical so the three pushbuttons can be tried first before other methods. However, setting MECO confirmed on an RTLS trajectory is very time critical. In time critical situations, it must be recognized ahead of time if the three pushbuttons will not work so that alternate methods may be employed at the required moment. ©[110900-7230A]

FLIGHT RULES

A5-114 **SSME HYDRAULIC REPRESSURIZATION/POSTLANDING SSME REPOSITIONING**

A. ON-ORBIT/ENTRY-1 DAY REPRESSURIZATION

APPLICATION OF MPS HELIUM TO SSME VALVE ACTUATORS IS NOT REQUIRED DURING HYDRAULIC REPRESSURIZATION AND SSME REPOSITIONING WHEN THE TVC ACTUATORS DRIFT OUT OF POSITION PER FLIGHT RULE {A8-106}, TVC-SSME STOW/ACTUATOR FLUID FILL (REPRESSURIZATION).

B. ENTRY/POSTLANDING REPOSITIONING

MPS HELIUM WILL BE PROVIDED TO THE ENGINES DURING HYDRAULIC REPRESSURIZATION AND SSME REPOSITIONING. THIS ENSURES THAT ENGINE VALVES DO NOT DRIFT OPEN. HOWEVER, LACK OF HELIUM IS NOT A CONSTRAINT AGAINST PERFORMING EITHER PROCEDURE.

Hydraulic pressure is applied to the TVC actuators to prevent SSME movement during on-orbit, entry, and postlanding operations. Maintaining helium pressure on the closed side of the engine valves will keep the valves from opening when hydraulic pressure is applied to the TVC actuators. Keeping the valves closed prevents engine contamination during entry and postlanding. On-orbit SSME contamination is unlikely; therefore, the application of helium for on-orbit TVC drift is not required. This will also reduce MPS helium regulator cycles.

A5-115 THROUGH A5-150 RULES ARE RESERVED

FLIGHT RULES

MPS MANAGEMENT: PRELAUNCH THROUGH MECO

A5-151 PRE-MECO MPS HELIUM SYSTEM LEAK ISOLATION [CIL]

- A. MPS ENGINE SYSTEM HELIUM LEAK ISOLATION WILL BE PERFORMED FOR ANY SIGNIFICANT LEAK (PER RULE {A5-10}, SIGNIFICANT ENGINE HELIUM SYSTEM LEAK) AS LONG AS THE ATTEMPT TO ISOLATE THE LEAK WILL NOT CAUSE THE ENGINE TO SHUT DOWN. @[090894-1676A] @[ED]

If an MPS engine helium system experiences a helium leak the crew will perform a helium leak isolation procedure. However, since certain power bus failures will result in helium leg A isolation valves failing closed (MNA, APC4 or ALC1; MNB, APC5 or ALC2; or MNC, APC6 or ALC3 failure will close the center, left, or right SSME isolation valve, respectively), the crew must be reminded not to attempt leak isolation for these cases. The closing of the leg B isolation valve will stop helium flow to the engine and cause an SSME redline limit shutdown due to low HPOTP intermediate seal (IMSL) purge pressure. The shutdown may cause engine damage since both regulator isolation valves are closed. No helium will be available for SSME IMSL purging during the shutdown sequence.

- B. AN ATTEMPT WILL BE MADE TO ISOLATE ANY SIGNIFICANT PNEUMATIC SYSTEM LEAK (REF. RULE {A5-11}, SIGNIFICANT PNEUMATIC SYSTEM HELIUM LEAK). @[ED]

A significant pneumatic system helium leak could result in insufficient pressure for prevalve actuation at MECO. The LO₂ prevalves are required to close at MECO in order to maintain pressure at the HPOTP pump inlet. This prevents pump cavitation and overspeed which could result in uncontained SSME damage. An attempt is made to isolate the pneumatic helium supply so the remaining helium can be used to pressurize the pneumatic accumulator and support prevalve closure at MECO.

- C. IF AN MPS PNEUMATIC HELIUM SYSTEM LEAK/ISOLATION CAUSES INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE (REF. RULE {A5-12}, INSUFFICIENT PNEUMATIC HELIUM ACCUMULATOR PRESSURE), THE SYSTEM WILL BE RECONFIGURED AT MECO-30 SECONDS. @[ED]

Seven hundred psia in the pneumatic accumulator is the minimum non-resupplied pressure which will close all the LO₂ prevalves within timing constraints at MECO. If the pneumatic helium supply has been isolated due to a leak or is used to support the mainstage operation of an engine with a helium leak, the pneumatic accumulator pressure may fall below 700 psia. Should the accumulator pressure fall below 700 psia for any reason, the pneumatic helium isolation valves, the left engine helium crossover valve and, if necessary, the engine interconnect valves, will be reconfigured to repressurize it. This will be accomplished at MECO minus 30 seconds and ensures that 700 psia is available in the pneumatic accumulator until the start of prevalve closure at MECO.

Note: Taking the interconnect out-open to open on an engine when the pneumatic tank is depleted will not cause a large enough flow transient to cause the engine to shut down (documented by RI Downey internal letter number 287-100-93-259, dated 11/09/93). @[090894-1676A]

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]

- A. TO SUSTAIN THE OPERATION OF AN ENGINE WITH AN MPS HELIUM LEAK, FOR SINGLE REGULATOR OPERATION, OR FOR EXTENDED BURN TIME, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AT THE FOLLOWING CUES: ©[090894-1676A] ©[050400-7195A]

If a helium leak develops and the decay rate is such that the engine will not meet zero-g shutdown requirements or will cause an early shutdown, the helium system of an engine and/or the pneumatic helium system will be interconnected to that engine's system. This action may allow the engine to meet the zero-g shutdown requirements and will maintain engine operation as long as possible. Similar action is taken if the leak has been isolated and the system will not meet shutdown requirements.

A tank pressure of 920 psia (900 psia required + 20 psia instrumentation error) is the minimum value, including instrumentation error, which will support the normal operating range of the helium system regulators. The difference between the actual requirement, 920 psia, and the C&W value, 1150 psia, results from a change in the estimated instrumentation error of the helium tank pressure transducers as a result of vehicle specific calibration curves. With calibration curve coefficients unique to each helium tank pressure transducer, the accuracy of each reading is 0.15 percent. An accuracy of 0.15 percent over the 5000 psia transducer range equates to an error of 7.5 psia. To account for any potential degradation in accuracy (e.g., transducer replacements where the new transducer is less accurate or calibration equipment changes), one PCM count (10 psia) was added to the 7.5 psia error. This new instrumentation error of 17.5 psia was then rounded to the nearest PCM count resulting in 20 psia instrumentation error used by the MCC and incorporated into crew procedures. The interconnect cues shown in the subsequent paragraphs are used as a guideline to ensure sufficient helium to sustain SSME operation with a helium leak. It is important to note that the interconnect must be performed above the minimum tank pressure required to support the shutdown mode. That is, the interconnect must be performed at a higher tank pressure for a pneumatic shutdown than for a pre-MECO redline shutdown due to helium depletion because the pneumatic shutdown requires more helium. The tank pressure of 920 is quoted as the "no later than" cue in order to provide the absolute minimum tank pressure above which the interconnect must be performed. Since there is not one tank pressure interconnect to satisfy all cases (leak types, shutdown mode, leak size, etc.), the C&W cue of 1150 is sufficient for the crew to use in no-comm cases. The change in calculated instrumentation error did not warrant a change to the onboard software or hardware caution and warning. ©[050495-1767B] ©[100997-6298] ©[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

Since the helium tank and regulator pressure requirements were derived using vehicle specific calibration curves, it must be noted that the onboard readings will vary between the BFS GNC SYS SUMM 1 display and the OMS/MPS MEDS display / MCDS MPS meter. The BFS GNC SYS SUMM 1 data is based on vehicle specific calibration curve coefficients; whereas due to system limitations, the OMS/MPS MEDS display and the MCDS MPS meter data are based on generic calibration curve coefficients. When the MCC calls for an interconnect or SSME shutdown based on a helium tank or regulator pressure, it is understood that the crew will use the data available on the BFS GNC SYS SUMM 1 display. This understanding was accepted by CB, DT, and DA8 (reference AEFTP #152, September 18, 1998). ©[110900-7239]

Dropping helium system regulator outlet pressure is also used to detect potential SSME HPOTP intermediate seal (IMSL) purge pressure violations. If both helium regulators have been in steady state operation between 715 psia and 785 psia outlet pressure, a sudden decrease in outlet pressure may be indicative of a system failure. Action is taken as soon as both regulator outlet pressures fall below 715 (679) psia in an attempt to prevent the engine from shutting down. Six hundred and seventy nine psia was derived from the minimum normal regulator outlet pressure, 715 psia, minus 36 psia instrumentation error prior to OI-26B. For OI-26B and subsequent flights, the instrumentation error was reduced to 5 psia. However, the Caution and Warning limit remains at 679 psia because the change to 5 psia would result in a Caution and Warning value very close to the nominal control band of the regulator (regulator is psig, instrumentation is psia) and was not considered worth the effort in updating Caution and Warning. With regard to helium system leaks, a regulator outlet pressure below 715 psia does not indicate that the regulator is malfunctioning. Low outlet pressures are indicative of helium system leaks which result in high helium mass flow rates or supply tank depletion resulting in low inlet pressures to the system regulators. Taking action at 679 psia not only prevents premature helium system interconnecting, but also gives some assurance that another helium system can be interconnected to the leaking supply before the engine interface pressure reaches the expected shutdown value of 518 psia for the Phase II SSME, or 576 psia for the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME (reference SODB data requests R1-1507 and R1-1640, respectively) even with the reduction in instrumentation error with OI-26B. ©[050495-1767B] ©[020196-1812] ©[121197-6472A] ©[050400-7195A] ©[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

1. FOR A NON-ISOLATABLE UPPER SYSTEM LEAK: @[050400-7195A]
 - a. WITH THREE ENGINES ON, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS LATE AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B] @[110900-7239]

When a non-isolatable upper system leak occurs, it is best to perform helium interconnects as close to the minimum shutdown requirement as possible. If the interconnect is performed too early and the system leak is a tank leak, helium in the leaking tank will no longer be used to support engine operation and will therefore be wasted.

- b. WITH LESS THAN THREE ENGINES ON, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL BUT ABOVE THE CUES GIVEN IN PARAGRAPH A.1.a.

When a non-isolatable upper system leak occurs after an engine has shut down, helium interconnects can be performed as soon as practical. An upper system leak could be either a leak in the engine's helium tank or an upper system leak above the helium regulators. If the leak is an upper system leak, then interconnecting as soon as practical does not waste any helium. If the leak is in the tank, interconnecting as soon as practical will result in the helium from the leaking tank being wasted. However, a good interconnect from a previously shutdown engine will provide a nominal feed rate to the engine with the tank leak and will allow it to support a zero-g shutdown. Interconnecting early not only allows the reconfiguration to take place while the crew is in a low g environment, but also allows for an earlier assessment of the shut down requirements of the leaking engine. @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

2. FOR A NON-ISOLATABLE LOWER SYSTEM LEAK, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B] @[050400-7195A] @[110900-7239]

For non-isolatable lower system leaks, helium interconnects can be performed immediately after leak identification, but must be performed above the minimum tank pressure needed to support engine shutdown. A leak below the regulator will have the same mass flow rate after the interconnect that it had prior to the interconnect. Interconnecting early allows the reconfiguration to take place while the crew is in a low g environment.

3. FOR A NON ISOLATABLE LEAK THAT REQUIRES INTERCONNECTING THE HELIUM SYSTEM OF A NON-LEAKING RUNNING ENGINE, THE INTERCONNECT WILL BE PERFORMED WHEN THE TANK PRESSURES ON ALL PREVIOUSLY INTERCONNECTED SYSTEMS REACH 500 PSIA OR THE AFFECTED SSME HPOTP IMSL PRESSURE REACHES 70 PSIA.

If the leaking engine supply, the previously shut down engine supply, and the pneumatic supply are insufficient to obtain single engine abort capability to a landing site, interconnecting is also allowed, within certain limits, from the remaining engine which has a good MPS helium supply in an attempt to regain landing site abort capability per paragraph B.2.a. Because an attempt is being made to avoid a contingency abort due to insufficient MPS helium, the interconnect from a non leaking running SSME helium supply to an engine with a leaking helium supply will be performed as late as is reasonably possible. The interconnect will be performed once the leaking system reaches 500 psia (500 psia is a generic tank pressure which, with SSME limits inhibited, should ensure that crossover margin is maintained in the SSME HPOT IMSL package) or an HPOTP IMSL pressure of 70 psia (70 psia provides 10 psia interconnect margin against the Block I/IIA/II SSME limit of 60 psia in rule {A5-153C}.2.a, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS). An interconnect cue of 500 psia in the tank or 70 psia in the IMSL package should also prevent the SSME HPOT IMSL pressure from decaying below 60 psia while the SSME is operating. @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

**PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)**

4. FOR SINGLE REGULATOR OPERATION OF THE MPS HELIUM SYSTEM, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM TANK PRESSURE REQUIRED TO SUPPORT THE SINGLE REGULATOR SHUTDOWN MODE PER RULE {A5-153}, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920) OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050495-1767B] @[050400-7195A] @[110900-7239]

If a helium system is operating on a single regulator, due to an isolated leak or any other system failure, the resulting mass flow rate of helium through the system is nominal. Therefore, helium system interconnects may be accomplished as soon as convenient. When operating on a single regulator, all shut down modes must protect for single regulator operation. A single regulator providing helium flow to an engine must flow the equivalent helium of two operating regulators. Higher pressures must be maintained at the regulator inlet in order to ensure that shutdown pressure and mass flow rate requirements are satisfied.

5. FOR AN ENGINE REQUIRING EXTENDED ENGINE BURN TIME, HELIUM SYSTEM INTERCONNECTS WILL BE PERFORMED AS SOON AS PRACTICAL, BUT ABOVE THE MINIMUM ENGINE TANK PRESSURE REQUIRED TO SUPPORT THE ENGINE SHUTDOWN MODE PER THE HELIUM CURVES FOR A NON-ISOLATABLE LOWER SYSTEM LEAK WITH NOMINAL FLOW RATE GIVEN IN RULE {A5-153E}.1, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS, AND NO LATER THAN 900 PSIA (920 PSIA) TANK PRESSURE ON THE AFFECTED ENGINE OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[110900-7239]

If the predicted MECO time is extended due to low ascent performance or an abort requirement such that interconnecting is necessary to meet shutdown requirements, the pneumatic system and the helium system of any failed engine can be interconnected to a running engine as soon as practical. The minimum tank pressure which will support a zero-g shut down of an engine with two good regulators and no helium leak is given in the helium curves for a non-isolatable lower system leak with nominal flow rate in rule {A5-153E}.1, PRE-MECO SHUTDOWN OF ENGINES DUE TO MPS HELIUM LEAKS. Since an engine with extended burn time has a constant helium usage, the curve for an engine with a non-isolatable lower system helium leak is used to define the minimum zero-g requirement.
@[090894-1676A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

6. IN THE NO-COMM CASE, THE CREW WILL PERFORM HELIUM SYSTEM INTERCONNECTS AT A SYSTEM PRESSURE OF 1150 PSIA OR WHEN BOTH HELIUM SYSTEM REGULATOR PRESSURES ARE BELOW 715 (679) PSIA. @[050400-7195A]

In the loss of comm case, crew action is taken at 1150 psia. 1150 psia is the C&W limit. The alarms and tones annunciated at 1150 psia are a good reminder to the crew that action needs to be taken. If the tank pressure reaches this value and continues to fall, the engine HPOTP IMSL purge redline limit may be violated. Action is taken at 1150 psia to preclude an early engine out situation while making as much use of available helium as possible. The engine IMSL seal limit should not be violated until the pressure decays below approximately 518 psia at the engine interface for the Phase II SSME (ref. SODB Vol. 3, Section 4.3.1) or 576 psia at the engine interface for the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME (ref. SSME test 901-835 and the 09-13-95 PSIG). @[050495-1767B] @[020196-1812] @[100997-6298] @[121197-6472A] @[110900-7239]

- B. IF THE INTERCONNECT CUES IN PARAGRAPH A ARE MET, THE INTERCONNECT OF THE PNEUMATIC HELIUM SYSTEM OR THE HELIUM SYSTEM OF ANOTHER ENGINE WILL BE PERFORMED PER THE FOLLOWING CONDITIONS: @[090894-1676A] @[100997-6298]

If an engine helium supply is depleting due to a leak, or helium shut down requirements are not met due to extended burn times or single regulator operation, interconnecting other helium systems will be allowed in some situations to sustain the operation of an engine.

1. WITH THREE ENGINES ON:

ONLY THE PNEUMATIC HELIUM SYSTEM WILL BE INTERCONNECTED AND THE ENTIRE SYSTEM WILL BE USED IF REQUIRED.

The entire pneumatic helium system will be used to sustain the operation of an engine, since sufficient helium margin should be available in the other two helium systems and the pneumatic accumulator to satisfy the zero-g requirements for pre-valve actuation, SSME pogo system post-charge, shutdown and entry environmental purges, and entry MPS manifold pressurization. @[090894-1676A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

**PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)**

2. WITH TWO ENGINES ON: @[050400-7195A]
- a. INTERCONNECTING THE PNEUMATIC HELIUM SYSTEM AND THE HELIUM SYSTEM OF THE PREVIOUSLY SHUT DOWN ENGINE WILL BE PERFORMED.

For the two engine on case, interconnecting is allowed from the previously shut down engine and the pneumatic system. This will not only maximize the leaking engine run time but may also re-establish zero-g shutdown capability. @[110900-7239]

- b. INTERCONNECTING THE HELIUM SYSTEM OF THE NON-LEAKING RUNNING ENGINE WILL BE PERFORMED BY TAKING THE INTERCONNECT VALVE OF THE NON-LEAKING RUNNING ENGINE TO OUT OPEN FOR 15 SECONDS (ONE TIME ONLY) AND THEN BACK TO THE GPC POSITION IF ALL OF THE FOLLOWING CONDITIONS ARE SATISFIED:
- (1) THE INTERCONNECTS PER PARAGRAPH B.2.a WILL NOT ALLOW THE LEAKING ENGINE TO SUPPORT SINGLE ENGINE ABORT CAPABILITY TO A LANDING SITE (SINGLE ENGINE LIMITS OR SINGLE ENGINE RTLS BOUNDARY), AND
- (2) THE TOTAL FLOWRATE OF THE LEAKING SYSTEM HAS NEVER BEEN GREATER THAN 0.30 LBM/SEC.

Margin in the non-leaking, running SSME MPS helium supply will be used to support the operation of another SSME with a leaking supply. Interconnecting in this case will result in one MPS helium supply supporting two SSME's, one at an off-nominal flowrate. Consequently, the interconnect of a running supply will only be performed if the total flowrate of the leaking supply has never been greater than 0.30 lbm/sec. The 0.30 lbm/sec total flowrate requirement is a generic value which will provide at least 15 seconds, and at most 1.5 minutes, of additional runtime for the SSME with the leaking supply. Total flow rates above 0.30 lbm/sec make it extremely likely that either a second SSME will fail prior to reaching a certified abort boundary, or that helium available to the last SSME will be depleted to a level which is below MECO requirements. By not interconnecting for large leaks, three SSME out contingency aborts are avoided and a crew survival path is maintained by two SSME out abort coverage. @[100997-6298] @[121197-6472A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

Numerous assumptions had to be made in order to cover this case with a generic rule. All the variables were assigned generic values and discussed at Ascent Entry Flight Techniques #135 on October 18, 1996. The assumptions were as follows. The maximum allowable flowrate of the leaking system was derived for the RTLS abort case since three out black zones occur at a later MET than on a TAL. The first SSME shuts down at liftoff and a non isolatable lower system leak develops on one of the remaining engines at the same time. There is a total of 134 pounds of helium available from both the leaking engine and the one that shut down. Of an initial 13 pounds of helium in the pneumatic system, 10 are available to support the leaker. Single engine operation of the last engine must be maintained, while preserving the zero g shutdown helium requirement, until an RTLS MECO time of 10:45 MET, which assumes 109 SSME throttles. Given this MECO time, there are 14 excess pounds of helium available from the running engine to support the leaking helium supply, resulting in a total of 158 pounds of helium available for the leaking engine. Assuming 2 1/2 minutes is the maximum run time needed for single engine completion of an RTLS contingency abort, the leaking engine must support a run time of 8:15 MET (MECO time minus 2 minutes 30 seconds). Assuming that 8 pounds of helium are required to support the shutdown of the leaking engine, the remaining 150 pounds would support the engine's operation until 8:15 MET as long as the leak rate is not greater than 0.30 lbm/sec. AEFTP was also made aware that a real-time or non-real-time redefinition of any of these variables might result in an outcome which varies from current predictions. However, in any case it is agreed that helium from the last SSME should be interconnected to a leaking supply in an attempt to reach a runway, as long as three SSME out black zones are protected. @[100997-6298]

The running, non-leaking SSME supply will only be interconnected for 15 seconds. This will keep the SSME running while the pneumatic system is repressurized. The interconnect action also increases the likelihood that the last running SSME with a non-leaking MPS helium supply will retain sufficient helium in its supply to support guided MECO once the second SSME with a leaking MPS helium supply shuts down. @[121197-6472A] @[050400-7195A]

The interconnect is broken by taking the interconnect switch of the engine with the non-leaking helium system to the GPC position. If the leaking helium supply has been depleted due to a tank leak, or an upper system leak exists, breaking the interconnects in this manner allows the pneumatic system to remain interconnected to the engine with a leaking helium supply in order to support its shutdown. @[100997-6298]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

3. WITH ONE ENGINE ON: @[050400-7195A]

INTERCONNECTING THE PNEUMATIC HELIUM SYSTEM AND THE HELIUM SYSTEMS OF ALL PREVIOUSLY SHUT-DOWN ENGINES WILL BE PERFORMED.

- C. THROTTLE MANAGEMENT FOR TWO ENGINES ON WITH A NON-ISOLATABLE MPS HELIUM LEAK IN ONE OF THE RUNNING SSMEs WILL BE PERFORMED PER THE FOLLOWING: @[050495-1753A] @[100997-6298]

With three engines on, there are no regions where a subsequent engine out will not allow the remaining engines to perform an abort to a landing site. Therefore, 109 percent SSME throttles are not required for that case.

1. NOMINAL/ATO:

109 PERCENT SSME THROTTLES IS NOT REQUIRED FOR THESE CASES.

The only region where an abort cannot be performed to a landing site with the leaking engine out usually occurs between the PRESS-TO-ATO boundary and the SINGLE ENGINE LIMITS boundary. Since the time between these boundaries is less than 1.5 minutes, it is extremely unlikely that an interconnect from a running engine to a running engine will be required. Consequently, the maximum time spent at 109 throttles (at most 1.5 minutes) will not significantly reduce the predicted MECO time. @[050495-1753A] @[050400-7195A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)

2. TAL:

THE SSME'S WILL BE IMMEDIATELY THROTTLED TO 109 PERCENT POWER LEVEL AFTER THE ISOLATION PROCEDURE IS COMPLETED AND MPS HELIUM LEAK IS DETERMINED TO BE NON-ISOLATABLE. IF SINGLE ENGINE TAL 104 ABORT CAPABILITY IS ACHIEVED OR IS PREDICTED TO BE ACHIEVED WITHOUT INTERCONNECTING A RUNNING ENGINE SUPPLY, SSME THROTTLES MAY BE RETURNED TO 104 PERCENT POWER LEVEL. @[100997-6298] @[050400-7195A]

For this case, the additional risk associated with operating the main engines at 109 power level is acceptable in order to provide the crew and vehicle a chance to reach a runway (i.e., SE LIMITS). Commanding the engines to 109 percent power level, while the vehicle is in an abort gap with a helium leak on one of two running SSME supplies, maximizes the use of the remaining helium by reducing the time required to achieve abort capability to a landing site. Furthermore, the increased power level does not increase helium usage in the engine HPOTP IMSL purge package (usage remains unchanged from 67-109 percent power level) and should have no negative effect on the size of the leak in the MPS helium system. Operationally, the increased internal engine pressures and temperatures at 109 percent do increase the likelihood of having an SSME failure (ref. AEFTP #108 charts, 12/17/93). However, because the run time remaining on the last engine to MECO cannot be determined (its helium supply was compromised), the main engines will remain at 109 percent power level until fine count is reached and the software throttles back the engines, the crew initiates manual throttles at the 2 percent propellant remaining in the ET cue (reference rule {A5-112}, MANUAL THROTTLEDOWN FOR LO₂ NPSP PROTECTION AT SHUTDOWN,), or until the manual MECO (reference rule {A5-153}, PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS). @[090894-1676A] @[ED]

If single engine TAL 104 abort capability is achieved, or is predicted to be achieved, after throttling the SSME's to 109 percent power level and without interconnecting a running, non-leaking SSME helium supply, sufficient helium will be available in the non-leaking MPS helium system to complete a single engine abort at 104 or 109 percent power level and eliminate the possibility of having to return to 109 percent power level should the engine with the helium leak shut down prior to single engine TAL 104. Additionally, since the time between the single engine limits and single engine TAL 104 boundaries is short, it advisable to leave the throttles at 109 percent to preclude additional work for the crew should an engine fail in this region. Single engine TAL 104 is when the Flight Dynamics Officer determines that 109 percent power level is no longer required for single engine abort completion. Per the rationale above, it is desirable that the SSME throttle setting be returned to 104 percent whenever possible. @[ED] @[050495-1767B] @[050400-7195A]

FLIGHT RULES

A5-152

**PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]
(CONTINUED)**

3. RTLS:

THE SSME'S WILL BE IMMEDIATELY MANUALLY THROTTLED TO 109 PERCENT POWER LEVEL AFTER THE ISOLATION PROCEDURE IS COMPLETED AND THE MPS HELIUM LEAK IS DETERMINED TO BE NON-ISOLATABLE. IF IT IS DETERMINED BY THE MCC THAT THE ABORT CAN BE COMPLETED WITHOUT COMPROMISING THE NON-LEAKING SUPPLY OF A RUNNING SSME, MAIN ENGINE THROTTLES WILL BE RETURNED TO AUTO PRIOR TO POWERED PITCH AROUND INITIATION. OTHERWISE, AUTO SSME THROTTLES WILL BE RESELECTED AT THE COMPLETION OF POWERED PITCH AROUND.
