If a non-isolatable MPS helium leak exists in the supply of one of two running SSME's while performing an RTLS abort, the likelihood that the associated SSME will shut down early, prior to reaching single engine abort capability, increases significantly. The probability that the shut down requirements of the last SSME are violated at MECO also increases significantly. Both possibilities are further compounded on the RTLS case by predicted MECO times which may extend by as much as 3 minutes longer than the nominal uphill MECO. Furthermore, since the maximum SSME operating time is defined at liftoff by the prelaunch loading of MPS helium, the SSME burn time cannot be extended to alleviate these concerns. The only available option is to use a higher main engine power level in order to minimize the predicted MECO time.

Analysis by flight design indicates that using 109 percent throttles on an RTLS abort can decrease the MECO time by as much as 55 seconds, assuming 109 is maintained throughout the trajectory (reference Ascent Abort Panel briefing charts, 10/6/94, "RTLS MECO Time Reduction for MPS Helium Leaks"). The resulting decrease in predicted MECO time may be the difference between a crew bailout and an intact abort landing. However, it must be noted that the trade off of using 109 percent throttles during the RTLS flyback phase is that, the ET separation QBAR is decreased by approximately 1.5 psf with respect to the designed RTLS condition, and the ET separation MPS propellant residuals are increased by approximately 0.5 percent over the designed RTLS condition. Since manual throttles must be maintained until the initiation of powered pitch around in order to stay at 109 throttles during flyback, the GPC's will not perform mass control throttling (auto throttles required) and the resulting separation conditions are slightly off-nominal. These conditions are considered acceptable when compared to violations which may occur on an alternative contingency abort. @[050400-7195A]

FLIGHT RULES

A5-152

PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL] (CONTINUED)

To minimize violations of the designed QBAR and residual constraints for this case, SSME throttles will be returned to the AUTO position prior to powered pitch around initiation if the MCC determines that the abort can be completed without compromising the non-leaking helium supply of a running SSME while in auto throttles. This action allows the GPC's to perform mass control throttling during flyback, thereby controlling ET separation conditions. If the MCC cannot determine abort capability prior to powered pitch around initiation, then manual throttles at 109 percent are maintained until powered pitch around is complete. Although fine mass control will not be performed, returning to auto throttles after powered pitch around completion minimizes crew actions during the pitch around maneuver and allows the engines to remain at 109 percent power level until the fine count throttle command is received from guidance near MECO. ©[050400-7195A]

Flight design analysis indicates that for cases involving manual throttling after powered pitch around initiation, the ET separation QBAR and MPS residual violations are minimized when the 109 percent SSME throttle setting is used during flyback. For these cases, there are no LO₂ NPSP concerns since there are always MPS residuals in the ET, and significant NPSP violations only occur during LO₂ low level cutoff. Consequently, SSME shut down from the fine count throttle setting is a preferred, not a mandatory, condition. ©[050495-1753A] ©[050400-7195A]

Rules {A2-64}, MANUAL THROTTLE CRITERIA; {A4-53}, USE OF MAXIMUM THROTTLES; {A5-5}, SUSPECT ENGINE; {A5-103}, LIMIT SHUTDOWN CONTROL; and {A5-156}, ABORT PREFERENCE FOR SYSTEM FAILURES, reference this rule. ©[092195-1770A] ©[ED] ©[100997-6298]

FLIGHT RULES**A5-153****PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS**

A. IF ALLOWABLE HELIUM INTERCONNECTS, PER RULE {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], WILL NOT SATISFY ZERO-G SHUTDOWN REQUIREMENTS PER PARAGRAPH E, BUT WILL SATISFY SHUTDOWN REQUIREMENTS AT THE CUES BELOW, THE AFFECTED ENGINE WILL BE SHUT DOWN MANUALLY (PUSH-BUTTON ONLY IF POSSIBLE), AS FOLLOWS: @[090894-1676A]

1. MCC DECISION (PRIME)

a. NOMINAL/ATO/AOA

(1) THREE ENGINES ON: VI = 23 KFPS

(2) TWO ENGINES ON: VI = 24.5 KFPS

b. TAL

TWO OR THREE ENGINES ON VI = 22.5 KFPS

c. RTLS

TWO OR THREE ENGINES ON: ALPHA = -1 DEGREES
@[032395-1759A]

In this case, the engine will run with the helium system leak, but the helium supply pressure may not be able to support the zero-g shutdown requirements at MECO. The required helium supply pressure for a safe shutdown will depend upon the number of helium regulators operating, the helium leak rate, and type of shutdown (i.e., hydraulic or pneumatic). If the requirements for a pre-MECO hydraulic, pneumatic, or single regulator shutdown will be satisfied subsequent to the cues mentioned in paragraph C, manual action is taken to shut the engine down while still protecting shutdown requirements. The engine is shut down approximately 30 seconds before MECO at a velocity which equates to MECO minus 30 seconds. This gives guidance time to adjust to the late engine out and converge on the proper MECO targets. The only exception to this is the RTLS abort where the engine is shut down during powered pitch down (alpha equals -1 degree). @[032395-1759A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

The shutdown pushbutton is used for engine shutdown instead of the AC power switches in order to shut the engine down hydraulically. A pre-MECO hydraulic shutdown requires less helium than a pre-MECO pneumatic shutdown and also retains post-MECO LO₂ dump capability through the affected engine. It also avoids the zero fault tolerant pneumatic shutdown mode. ©[090894-1676A]

2. ONBOARD DECISION (NO COMMUNICATION) ©[090894-1676A]

- a. IF A NON-ISOLATABLE MPS HELIUM LEAK EXISTS, THE CREW WILL SHUT DOWN THE AFFECTED ENGINE AT THE APPROPRIATE BOUNDARY LISTED IN PARAGRAPH A1.

If a leak develops in an engine helium supply and the crew cannot communicate with the MCC, shutting the affected engine down early may prevent the violation of shutdown helium requirements on that engine. With no communication with the ground the crew has no way to tell when the helium requirements will be violated. The helium margin which exists in each supply at liftoff will very likely keep shutdown requirements from being violated at the cues listed.

- b. IF AN MPS HELIUM SYSTEM IS OPERATING ON A SINGLE REGULATOR, THE CREW CANNOT COMMUNICATE WITH THE MCC, AND THE HELIUM SYSTEM TANK PRESSURE ON THAT SUPPLY IS LESS THAN 2163 (2200) PSIA AT MECO-60 SECONDS, THE CREW WILL SHUT DOWN THE AFFECTED ENGINE AT THE APPROPRIATE CUE LISTED ABOVE IN PARAGRAPH A1. ©[110900-7239]

1963 psia is the minimum engine system tank pressure which will support MECO requirements while operating on a single regulator (ref. paragraph E). In this configuration, approximately 200 psia of helium (10 psia/3 sec x 60 sec) is used between the velocity cues mentioned in paragraph A1 and MECO. Therefore, if the affected engine tank pressure is less than 2163 psia (1963 psia + 200 psia) at MECO minus 1 minute, MECO shutdown requirements will not be satisfied and the engine is shut down pre-MECO. The crew shutdown cue of 2200 psia is derived by adding 20 psia instrumentation error and rounding up to the nearest hundred (1963 psia + 200 psia + 20 psia instrumentation error + 17 psia rounding = 2200 psia). ©[110900-7239]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

- B. IF AN ENGINE HELIUM SUPPLY DEVELOPS A LEAK WITHIN 60 SECONDS OF MECO, WITH OR WITHOUT COMMUNICATION WITH THE MCC, THE CREW WILL USE THE SHUTDOWN PUSHBUTTON TO SHUT DOWN THE AFFECTED ENGINE PRIOR TO MECO. ©[041196-1876]

When helium system leaks develop late in flight, sufficient time to evaluate MECO capability may not exist. Since pre-MECO engine shutdowns consume less helium than zero-g shutdowns, it is safer to shut the affected engine down prior to MECO. Shutting the engine down soon after a helium system leak occurs also gives guidance software time to converge on the correct MECO velocity targets.
©[090894-1676A]

- C. IF ENGINE AND PNEUMATIC HELIUM SYSTEMS INTERCONNECTS TO AN ENGINE WITH A LEAKING MPS HELIUM SUPPLY ARE INSUFFICIENT TO SUPPORT ENGINE SHUT DOWN AT THE CUES OUTLINED IN PARAGRAPH A1, ENGINE SHUTDOWN PRIOR TO THOSE CUES MUST BE ACCOMPLISHED IN THE FOLLOWING MANNER WHILE TWO OR THREE ENGINES ARE RUNNING: ©[090894-1676A] ©[ED]

1. IF NO RUNNING ENGINE SUPPLIES HAVE BEEN INTERCONNECTED:
 - a. THE LEAKING ENGINE WILL BE ALLOWED TO SHUT DOWN ON THE ENGINE HPOTP INTERMEDIATE SEAL (IMSL) PURGE REDLINE AS LONG AS THE ENGINE HYDRAULIC SYSTEM IS FUNCTIONAL AND THE SSME REDLINE LIMITS ARE ENABLED.

On the Phase II SSME, an HPOTP IMSL purge redline violation will always occur when the intermediate seal pressure falls below 170 psia. However, the minimum helium system/engine interface pressure required to prevent an HPOTP IMSL violation decreases over the duration of engine operation. As the turbine/pump shaft heats up, the intermediate seal gap becomes smaller. Consequently, lower interface pressures will keep the HPOTP IMSL purge pressure above 170 psia. If the helium system regulator outlet pressure at the start of shutdown is below the minimum helium system regulator outlet pressure, the resulting helium purge flow rates may be significantly reduced during the shutdown sequence. If two engine abort capability to a landing site exists, while three engines are running, or single engine abort capability to a landing site exists, while two engines are running, a leaking engine will be allowed to shut down on the HPOTP IMSL purge redline. Although minor engine erosion may occur during the shutdown sequence due to reduced helium pressure, the shutdown will be contained and engine run time is maximized. ©[050495-1767B]

On the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, an HPOTP IMSL purge redline violation will always occur when the intermediate seal pressure falls below 159 psia. The alternate HPOTP used on these engines has a true controlled gap IMSL package. Due to this feature, the minimum helium system/engine interface pressure required to prevent an HPOTP IMSL violation does not change over the duration of engine operation. ©[050495-1767B] ©[020196-1812] ©[121197-6472A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

- b. IF A HYDRAULIC SHUTDOWN CANNOT BE PERFORMED, MANUAL SHUTDOWN WILL BE PERFORMED AT THE MINIMUM REQUIRED PNEUMATIC SHUTDOWN HELIUM INTERFACE PRESSURE PER PARAGRAPH E1 OR E2 OF THIS RULE.

If hydraulic shutdown capability is lost for any reason, the pneumatic shutdown requirements must be manually protected in order to prevent a catastrophic shutdown from occurring. ©[090894-1676A] ©[100997-6298]

- 2. IF A RUNNING SSME WITH A NON-LEAKING HELIUM SUPPLY HAS BEEN INTERCONNECTED TO A RUNNING SSME WITH A LEAKING MPS HELIUM SUPPLY (ABORT GAP). ©[090894-1676A]

For this case, the desired single engine abort capability is unattainable. However, a contingency abort may still be performed. Getting as far down range as possible prior to MECO improves ET separation conditions and decreases orbiter pull-out loads; hence, both engines will be allowed to run as long as possible. Shutting the leaking engine down before the good engine may allow both engines to shut down in a contained manner, since the leaking engine will be shut down under g's and therefore consume less helium during the sequence.

- a. THE LEAKING ENGINE WILL BE SHUT DOWN AT AN HPOTP IMSL PURGE PRESSURE (ON ALL QUALIFIED SENSORS) OF:

PHASE II SSME: 40 PSIA

BLOCK I, IIA, AND II SSME: 60 PSIA

©[100997-6298] ©[121197-6472A]

Phase II SSME: Shutting down the engine with the leaking supply at an HPOTP IMSL pressure of 40 psia keeps that engine running as long as feasible (a positive barrier pressure exists as measured between the IMSL and SECONDARY SEAL cavities) while the vehicle is in an abort gap. 40 psia, as measured by the IMSL transducers, equates to approximately 25 psia in the IMSL cavity. The nominal pressure in the secondary seal cavity is 12 psia. This results in a pressure differential of 13 psia across the carbon seals. A similar barrier pressure margin exists across the carbon seal to the oxygen (pump side) drain. Allowing the engine with the leaking MPS helium supply to run to an IMSL pressure of 40 psia is a worst case scenario which assumes that the desired abort boundary has not been achieved, and that the turbopump seal packages are intact. ©[050495-1767B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

BLOCK I SSME, BLOCK IIA SSME, and BLOCK II SSME: Shutting down the engine with the leaking supply at an HPOTP IMSL pressure of 60 psia keeps that engine running as long as feasible (a positive barrier pressure exists between the IMSL and the O₂ and H₂ cavities) while the vehicle is in an abort gap. 60 psia, as measured by the IMSL transducers, equates to approximately 42 psia in the IMSL cavity. The nominal pressure in the O₂ cavity is 16 psia and the nominal pressure in the H₂ cavity is 25 psia. This results in a pressure differential of 26 and 17 psia across the carbon seals. Allowing the engine with the leaking MPS helium supply to run to an IMSL pressure of 60 psia is a worst case scenario which assumes that the desired abort boundary has not been achieved and that the engine seal packages are intact.

@[050495-1767B] @[020196-1812] @[100997-6298] @[121197-6472A]

- b. THE NON-LEAKING, RUNNING ENGINE WILL BE ALLOWED TO RUN UNTIL MECO OR 1150 PSIA, WHICHEVER COMES FIRST. IF A MANUAL SHUTDOWN IS REQUIRED, IT WILL BE WITH THE SHUT DOWN PUSHBUTTON ONLY. @[090894-1676A] @[100997-6298]

Although 1288 psia is the minimum helium system tank pressure which will support zero-g shut down of an engine with two good regulators and no helium system leak, the last engine will be allowed to run until the MPS supply pressure reaches the crew C&W limit of 1150 psia. Allowing the engine to run to 1150 psia provides a clear engine shutdown cue for the crew (C&W alarm at 1150) and also takes advantage of any instrumentation error/margin which may exist in the onboard measurement system and the ground predicted shut down requirements respectively. @[100997-6298]

Reference Rule {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], for interconnect procedures.

- D. IF AN MPS HELIUM SYSTEM IS OPERATING ON A SINGLE REGULATOR AND DOES NOT MEET THE ZERO-G SHUTDOWN REQUIREMENTS OF THE ASSOCIATED ENGINE AS PREDICTED BY THE MCC, THE ENGINE WILL BE SHUT DOWN PER PARAGRAPHS A OR C ABOVE, WHILE PROTECTING THE SINGLE REGULATOR SHUTDOWN REQUIREMENTS OF PARAGRAPH E.6 BELOW.

When an MPS helium system is operating on a single helium regulator, the supply may not meet the MECO (zero-g) shutdown requirements of the affected engine. If it is predicted that the MECO requirements, as stated in paragraph E.6 below, will be violated, the engine must be shut down early according to paragraphs A.1, C.1 or C.2 above. @[090894-1676A]

FLIGHT RULES

A5-153

PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM LEAKS (CONTINUED)

A lower system MPS helium leak is a leak downstream of the system regulators. The resulting leak rate should be constant. Lower system leaks are isolatable only when they occur between the regulator and the downstream check valve.

The zero-g line represents the minimum supply pressure to support a hydraulic or pneumatic shutdown at MECO (zero-g) with two system regulators, with or without a lower system MPS helium leak. This requirement is the ICD value of 630 psia interface pressure at shutdown plus 7 seconds (ref. SSME-to-Orbiter ICD 13M15000). The pneumatic shutdown line represents the minimum supply pressure to support a pre-MECO pneumatic shutdown with two system regulators, with or without a lower system leak. This requirement is based on an analytical value of 529 psia interface pressure at shutdown plus 7 seconds. The redline shutdown curve is the minimum supply pressure at which the HPOTP IMSL purge redline will be violated with one or two system regulators, with or without a lower system leak. For the Phase II SSME, this value is 518 psia interface pressure at shutdown and is based on an analysis and minimal test data (reference SODB data request R1-1507). For the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, this value is 576 psia interface pressure at shutdown and is based on SSME test 901-835 (reference SODB data request R1-1640). The minimum pressure which will support the expected shutdown mode and mass flow rate should always be protected. These curves include 20 psia instrumentation error. ©[090894-1676A] ©[020196-1812] ©[121197-6472A] ©[110900-7239]

FLIGHT RULES

A5-153

**PRE-MECO SHUT DOWN OF ENGINES DUE TO MPS HELIUM
LEAKS (CONTINUED)**

An MPS upper system helium leak is a leak upstream of the system regulators. The resulting leak rate should decay over time. Upper system leaks are isolatable only when they occur between the helium isolation valve and the downstream regulator.

The zero-g line represents the minimum supply pressure to support a hydraulic or pneumatic shutdown at MECO (zero-g) with two system regulators, with or without an upper system leak. This requirement is the ICD value of 630 psia interface pressure at shutdown plus 7 seconds (ref. SSME-to-Orbiter ICD 13M15000). The pneumatic shutdown line represents the minimum supply pressure to support a pre-MECO pneumatic shut down with two system regulators, with or without an upper system leak. This requirement is based on an analytical value of 529 psia interface pressure at shutdown plus 7 seconds. The redline shutdown curve is the minimum supply pressure at which the HPOTP IMSL purge redline will be violated with one or two system regulators, with or without an upper system leak. For the Phase II SSME, this value is 518 psia interface pressure at shutdown and is based on analysis and minimal test data (reference SODB data request R1-1507). For the BLOCK I SSME, BLOCK IIA SSME, and the BLOCK II SSME, this value is 576 psia interface pressure at shutdown and is based on SSME test 901-835 (reference SODB data request R1-1640). The minimum pressure which will support the expected shutdown mode and mass flow rate should always be protected. These curves include 20 psia instrumentation error. ©[050495-1767B] ©[121197-6472A] ©[110900-7239]

3. IF THE ENGINE CAN SHUT DOWN HYDRAULICALLY BUT HPOTP IMSL REDLINE SHUT DOWN CAPABILITY IS LOST FOR ANY REASON, A MANUAL SHUTDOWN MUST PROTECT THE MINIMUM INTERFACE PRESSURES FOR A PRE-MECO HYDRAULIC SHUT DOWN AS SHOWN ABOVE IN PARAGRAPH E. ©[090894-1676A]

If both HPOTP IMSL purge pressure transducers have failed or the redline limit software is not available for any reason, a redline engine shutdown will never occur. Manual action must be taken above the minimum hydraulic shutdown interface pressure.

4. IF A PNEUMATIC SHUT DOWN IS REQUIRED FOR ANY REASON, A MANUAL SHUT DOWN MUST PROTECT THE MINIMUM INTERFACE PRESSURES FOR A PRE-MECO PNEUMATIC SHUTDOWN PER PARAGRAPH E.

For all four SSME types (Phase II, BLOCK I, BLOCK IIA, and BLOCK II), it takes significantly more helium to support a pre-MECO pneumatic shutdown than it does to support a pre-MECO hydraulic shutdown. Consequently, pre-MECO pneumatic shutdown capability must be manually protected for all cases where hydraulic engine function has been lost or for which a pneumatic shutdown will occur. ©[050495-1767B] ©[121197-6472A]

@[050495-1767B] @[020196-1812] @[121197-6472A] @[110900-7239]

If the MPS supply system has an upper system leak, the pneumatic system will be interconnected to the engine as late in the flight as is practical, but above the minimum tank pressure required to support engine shutdown. After the interconnect is performed a determination is made as to whether or not the leak is an upper system leak or a tank leak. If the leak is found to be a tank leak, the pneumatic tank only numbers must be protected. The leak in the tank may deplete all of the engine system helium before the pneumatic tank and engine tank equalize in pressure. If this is the case, the pneumatic tank alone must support engine shutdown. @[090894-1676A]

- @[050495-1767B] @[020196-1812] @[121197-6472A] @[110900-7239]

The requirements for engine shutdown in the single regulator mode are represented by three distinct pressures. The single regulator must now flow two times nominal mass in order to meet shutdown requirements. A higher initial helium tank pressure is needed to meet this demand. @[050495-1767B] @[ED] @[100997-6298]

Rules {A5-5}, SUSPECT ENGINE; {A5-102}, AUTO/MANUAL SHUTDOWN; {A5-103}, LIMIT SHUTDOWN CONTROL; {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES; and {A5-152}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], reference this rule. @[121197-6482B] @[111298-6785A]

FLIGHT RULES

A5-154

LH₂ TANK PRESSURIZATION [CIL]

THE ET LH₂ TANK ULLAGE PRESSURE WILL BE MANUALLY CONTROLLED USING THE LH₂ ULLAGE PRESSURE SWITCH WHEN THE LH₂ ULLAGE PRESSURE IS < 27.7 (28.0) PSIA. THE PRESSURIZATION WILL BE CONTROLLED SO THAT THE ULLAGE PRESSURE DOES NOT EXCEED 35 (34.0) PSIA TO AVOID THE LOW CRACKING PRESSURE OF THE TANK VENT/RELIEF VALVE. ©[101096-4474A]

The pressurization flow control system consists of three tank ullage pressure sensors, signal conditioners for the orbiter flow control valve electronics, and three gaseous hydrogen flow control valves. Each ullage pressure sensor is wired to a signal conditioner which in turn controls the GH₂ pressurant flow from its respective engine. Each control system is single string; i.e., ullage pressure no. 1 feeds only the electronics for the center SSME, no. 2 to the left SSME, and no. 3 to the right SSME. The flow control valves are used to maintain the LH₂ tank ullage pressure between 32 and 34 psia. The signal conditioners use 33.0 psia as the set point for the ullage pressure. Failure of one flow control valve to the closed position (low flow) does not cause the ullage pressure to drop below 28.0 psia or violate the SSME NPSP ICD. However, the pressure cannot be maintained above 28.0 psia when two flow control valves fail closed. Additionally, failure of one flow control valve to the open position (high flow) does not cause the ullage pressure to rise to the LH₂ tank vent valve relief setting of 36 psia (reference December 22, 1995 PSIG and Rockwell action item 951208-02). ©[021199-6791A]

There are several failure modes associated with the LH₂ tank pressurization flow control system. This flight rule addresses the case of two ullage pressure sensors failed high (i.e., above the ullage pressure where the flow control valve is commanded closed) which will cause their respective flow control valves to remain closed. The remaining flow control system will not maintain the tank pressure. When the true tank pressure decays to 28.0 psia on the remaining good sensor, a class 3 BFS alert will be set. (The 28.0 psia value was reviewed and approved as DCR 3581A and DCR 3586 at the July 11, 1996 SASCB.) An LH₂ ullage pressure of 28.0 psia is the value at which manual action will be taken. This pressure includes crew response time and one sigma dispersions of the instrumentation error: 0.21 psia (reference Booster SCP 2.2.1). Additionally, this lower value of 28.0 psia protects the minimum ullage pressure to support the NPSP requirement of 27.7 (reference December 22, 1995 PSIG and Rockwell action item 951208-02, chart 1-18). In response to the alert, the crew will use the LH₂ ullage pressure switch to open the flow control valves by overriding the electronics on all flow control valves. The tank pressure should then increase. However, the pressure could go through the control band and reach the tank vent valve relief setting of 36 ? 1 psig. Therefore, the value of 34.0 psia was chosen as the value at which the crew would close the flow control valves before venting could occur. If venting occurs while the vehicle is in first stage, a fire could propagate along the side of the external tank (reference PRCB presentation February 10, 1987 and the 32nd PSIG). The high flow setting of the -1301 FCV's (70 percent instead of 100 percent used with the -0361) allows for manual action to be taken prior to staging. For this failure case, venting GH₂ is not a concern due to a gradual pressure recovery when the switch is placed in the high flow position during first stage (reference May 8, 1996 PSIG and action item-941005-03 Rev 3). ©[101096-4474A] ©[021199-6791A]

FLIGHT RULES

A5-154 LH2 TANK PRESSURIZATION [CIL] (CONTINUED)

Other failure modes of the GH₂ pressurization system include: a mechanical failure of two flow control valves, a flow restriction in either an SSME GH₂ repressurization path or in the main pressurization line, a hole in the side of the LH₂ tank or a vent valve not closed. However, the LH₂ ullage pressure switch cannot correct conditions caused by these failure modes. For these cases, all three ullage pressures could decay below 28.0 psia since the sensors are accurately reading the decaying tank pressure. If the pressure decay continues, the minimum NPSP of the engines will be violated. ©[101096-4474A] ©[021199-6791A]

Rules {A4-56H}, PERFORMANCE BOUNDARIES, and {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP, reference this rule. ©[071494-1646A]

A5-155 LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP ©[040899-6818A]

- A. MAIN ENGINE LIMIT SHUTDOWN SOFTWARE WILL BE MANUALLY ENABLED UPON RECOGNITION OF EITHER AN LH₂ ULLAGE LEAK OR FOR ANY ORBITER GH₂ PRESSURIZATION SYSTEM ANOMALY EXCEPT ONE GH₂ FLOW CONTROL VALVE FAILED CLOSED.

For LH₂ net positive suction pressure (NPSP) decaying below the ICD requirement, the engines will eventually violate their high pressure fuel turbopump (HPFTP) turbine discharge temperature (TDT) redlines. Low LH₂ NPSP causes the fuel turbopumps to cavitate, resulting in turbine overspeed and increased discharge temperatures. Cavitation is possible on all SSME's; therefore, the main engine limit shutdown software will be manually enabled to allow any number of engines to shut down for HPFT TDT redline exceedance.

- B. ORBITER GH₂ PRESSURIZATION SYSTEM ANOMALY

IF ULLAGE PRESSURE IS STEADILY DECAYING BELOW THE CONTROL BAND AND IS NOT THE RESULT OF AN ULLAGE LEAK (PER RULE {A5-9}, LH₂ ULLAGE LEAK), THE ENGINES WILL BE MANUALLY THROTTLED PER THE STEPS GIVEN BELOW. THE MANUAL THROTTLE STEPS WILL BE BASED ON THE SETTINGS LISTED IN THE TABLE BELOW WHEN THE LH₂ NPSP DROPS BELOW 3.5 PSI OR THE HPFTP TDT'S INCREASE TO WITHIN 75 DEG R OF THEIR REDLINES. TO PREVENT THE VEHICLE ACCELERATION FROM EXCEEDING 3.0 G'S AFTER MANUAL THROTTLING IS INVOKED, THE CREW WILL MANUALLY THROTTLE BACK TO MAINTAIN 3.0 G'S. ©[ED] ©[040899-6818A] ©[031500-7181A] ©[ED]

FLIGHT RULES

A5-155

LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH2 NPSP (CONTINUED)

ONCE INITIATED, MANUAL THROTTLES WILL BE MAINTAINED UNTIL MECO. A MANUAL MECO WILL BE REQUIRED.

A GH₂ pressurization system anomaly could be caused by either multiple flow control valves failed closed or a plugged GH₂ pressurization leg. Coverage of the highly unlikely GH₂ plugged pressurization leg failure mode is a result of PRCB Directive S050270DP, "Main Propulsion System (MPS) Critical Items List (CIL) Submittal Waiver Request," November 9, 1998. ©[040899-6818A]

Underspeeds resulting from two GH₂ flow control valves failed closed or a plugged GH₂ pressurization leg for specific engine configurations, or three GH₂ flow control valves failed closed in all cases, will potentially result in loss of crew and vehicle due to either early engine shutdowns (due to LH₂ NPSP) or ET structural failure. Manually throttling to a lower throttle setting increases the supplied NPSP by lowering LH₂ pressure losses across the LH₂ manifolds and lines and also reduces the SSME NPSP requirement for engine operation. The combination of higher supplied NPSP and reduced NPSP requirement enables continued engine operation. Once initiated, manual throttles are maintained until MECO in order to prevent the auto throttle up to the mission power level that would occur following an SSME failure. Since the NPSP drops with this throttle up, maintaining manual throttles protects against the potential loss of additional SSME(s). ©[051500-7181A]

The severity of the LH₂ NPSP loss is not only dependent upon the GH₂ pressurization system failure mode but also upon the engine configuration and power level for a particular mission. Analysis shows that two GH₂ flow control valves failed closed on a nominal, ATO, or AOA mission using three Block I or Phase II SSME's at 104 percent will not result in a LH₂ NPSP degradation which requires throttling (reference February 19, 1997 PSIG, Action Item 970205-01). Analysis also shows that missions using specific combinations of Block I and Block II SSME's may require throttling if two flow control valves are failed closed. Further analysis suggests that throttling may be expected for those missions using three Block IIA/II SSME's if two flow control valves are failed closed or one of the SSME's pressurization legs becomes plugged such that there is 0 percent flow from that leg.

A GH₂ pressurization leg refers to the series of hardware in the GH₂ pressurization line that carries flow from each SSME's LPFTP turbine outlet to the 2-inch pressurization line that provides ullage pressure to the ET LH₂ tank. Each engine contains a check valve, a filter, and a flow control valve (reference SSSH 10-12). The hardware in these lines could potentially fail closed or, in the most extreme case, become plugged by contamination. ©[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-155

LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP (CONTINUED)

There are three possible scenarios resulting in a plugged GH₂ pressurization system leg. The first scenario involves the filter upstream of the flow control valve becoming plugged, resulting in 0 percent flow to the associated valve. The second and third scenarios are an obstruction, or mechanical failure, of the check valve upstream of the flow control valve or an obstruction of the flow control valve itself. This would result in 0 percent flow being provided from that engine to the 2-inch pressurization line. Since flow from all three pressurization legs is required to maintain ullage pressure above 32.6 psia, all three flow control valves will be commanded open as the system attempts to maintain pressure in the ET LH₂ tank. However, since flow in a single leg is obstructed, ullage pressure will steadily decay below the control band as the fuel volume in the ET LH₂ tank decreases. ©[040899-6818A]

The value of 3.5 psi for the LH₂ NPSP was chosen as the primary cue to avoid LH₂ NPSP regions where severe cavitation occurs and HPFTP turbine temperatures increase exponentially. The HPFTP is expected to run to a LH₂ NPSP of 1.0 to 2.0 psi before cavitation becomes critical. The ground LH₂ NPSP computation assumes a 3 sigma worst case LH₂ inlet temperature of 37.2 deg R from liftoff until MECO. The use of this worst case temperature provides for 2 sigma protection (i.e., a 0.8 psi bias) in the ground NPSP computation. The ground computation uncertainties are a result of measurement inaccuracies in ullage pressure, head pressure, frictional losses, and vapor pressure used in the derivation of NPSP. On average, the actual vehicle NPSP will be 0.8 psi higher than the NPSP value displayed by the MCC ground computation. HPFTP TDT's were selected as a backup cue in case an HPFTP starts to severely cavitate at a higher LH₂ NPSP value than expected. Both temperature limits (channels A and B) are calculated by subtracting 75 deg R from the redlines. Larger margins from the redline may overlap the nominal operating temperature range and provide false cues for action (ref. PSIG Flight Rule Reviews on 2/25/88, 3/23/88, and 11/17/93). ©[071494-1646A]

The cue of 3.0 g's of acceleration was selected to ensure protection of vehicle acceleration limits (3.0 g). Various vehicle configurations or GH₂ pressurization system failure modes may or may not result in exceedance of vehicle acceleration limits. However, if a 3.0 g acceleration limit is used as an auto or manual throttling cue for all cases, vehicle structural limits are protected at all times. Reference Rule {A2-61}, Q-BAR/G-CONTROL. Three-g is not used as a cue for the first manual throttle step since leaving throttles in auto will throttle at 3.0 g's. Once manual throttles are taken for an NPSP or HPFTP TDT cue, throttles will remain in manual and 3.0 g's will be protected in addition to the NPSP and HPFTP TDT cues. The shuttle crews are trained that after selecting manual throttles, if the vehicle acceleration exceeds 3.0 g's, they will need to manually throttle to maintain 3.0 g's. ©[031500-7181A]

Throttling in three steps was selected to minimize crew/MCC impact and workload. The steps approximately divide the action equally into thirds. The first step, 95 percent, was originally chosen to avoid the Rocketdyne HPFTP impeller resonance region (i.e., 88 to 92 percent). This is no longer a concern as a result of a redesign of the impeller. The throttle setting of 95 percent was retained for training simplicity. The second step, 80 percent, is midway between the first step and the minimum power level. The last step, 67 percent, is the minimum power level and further commanded power reduction is not possible. ©[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-155 LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP (CONTINUED)

C. LH₂ ULLAGE LEAK @[040899-6818A]

MANUAL THROTTLES WILL BE SELECTED IMMEDIATELY FOLLOWED BY A TAL ABORT TO THE MOST IN-PLANE SITE (GO TAL SITE OR ACLS). AFTER TAL SELECTION, THE THROTTLES WILL BE RETURNED TO AUTO.

Throttling for low LH₂ NPSP due to an LH₂ ullage leak (reference Rule {A5-9}, LH₂ ULLAGE LEAK), or an open LH₂ vent/relief valve, delivers less ullage pressurization gas causing LH₂ NPSP to decay faster than keeping the engines at 104 percent. @[ED]

GPC software automatically throttles the engines down if TAL is selected above an I-loaded inertial velocity. To prevent the software from throttling the engines down when there is an LH₂ ullage leak, manual throttles are selected prior to selecting TAL. Once TAL is selected, the throttles will be returned to AUTO where they will stay at 104 percent until 3 g's are reached. Three-g throttling may cause engine shutdowns, but this is an accepted risk to avoid vehicle structural damage. @[071494-1646A]

Since there is no way to accurately predict when engine shutdown will occur for this case, it is important to reach multiple engine-out capability and an acceptable MECO as soon as possible. The earliest multi-engine out abort site, either ACLS or TAL, will always be the preferred one for this case (reference rule {A4-56}, PERFORMANCE BOUNDARIES).

The main engine limit shutdown software will be manually enabled upon recognition of this failure to protect against multiple engine shutdowns without limits enabled.

Rules {A2-64}, MANUAL THROTTLE CRITERIA; {A2-61}, Q-BAR/G-CONTROL; {A2-301}, CONTINGENCY ACTION SUMMARY; {A4-56}, PERFORMANCE BOUNDARIES; {A4-59}, MANUAL THROTTLE SELECTION; {A5-9}, LH₂ ULLAGE LEAK; {A5-103}, LIMIT SHUTDOWN CONTROL; {A5-154}, LH₂ TANK PRESSURIZATION [CIL]; and {A5-156}, ABORT PREFERENCE FOR SYSTEMS FAILURES, reference this rule. @[092195-1770A] @[040899-6818A] @[ED]

FLIGHT RULES

A5-156

ABORT PREFERENCE FOR SYSTEMS FAILURES

A. LH₂ ULLAGE LEAK @[040899-6818A]

IF LOW LH₂ NPSP OCCURS DUE TO AN EXTERNAL TANK LH₂ ULLAGE LEAK, A TAL ABORT WILL BE PERFORMED TO A TAL OR ACLS BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY. @[ED]

B. GH₂ PRESSURIZATION SYSTEM ANOMALIES

IF THE LOW LH₂ NPSP OCCURS DUE TO THREE GH₂ FLOW CONTROL VALVES FAILED CLOSED, A TAL ABORT WILL BE PERFORMED TO A TAL OR ACLS BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY. THIS IS THE ONLY GH₂ PRESSURIZATION SYSTEM ANOMALY FOR WHICH AN ABORT WILL BE PERFORMED. REFERENCE RULE {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP.

A TAL abort is preferred over RTLS because TAL MECO conditions are satisfied sooner than RTLS MECO conditions. If an LH₂ ullage leak occurs, throttling will not be performed for low LH₂ NPSP (see rationale for Rule {A5-155C}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP). Once an ullage leak occurs, it is possible for the leak to worsen. In this case, the NPSP may deteriorate much faster than the failed closed flow control valve case. There is no method to predict when engine shutdown will occur. It is important to reach multiple engine-out capability and MECO conditions as soon as possible. The earliest MECO conditions and multiple engine-out capabilities are available during a TAL abort or an abort to an ACLS. If an intact abort is not performed, the risk of a bailout or other contingency condition will increase. @[021199-6791A]

An abort will not be performed for two flow control valves failed closed or for a plugged GH₂ pressurization system leg. The flow control valves are normally open valves (must be powered closed). The close power will cycle the valves as required to satisfy the ullage pressure control band (reference Rule {A5-154}, LH₂ TANK PRESSURIZATION [CIL]). It is assumed that the failure will occur during power cycling. With two valves failed closed, the third valve will not be power-cycled. Therefore, the third valve will remain open (unpowered) and nominal MECO conditions may be achieved by implementing Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. For a plugged GH₂ pressurization leg, the other two flow control valves will operate and nominal MECO conditions may be achieved by implementing Rule {A5-155}, LIMIT SHUTDOWN CONTROL AND MANUAL THROTTLING FOR LOW LH₂ NPSP. If three flow control valves are failed closed, a TAL abort will be selected. @[040899-6818A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-156

ABORT PREFERENCE FOR SYSTEMS FAILURES (CONTINUED)

C. ENGINE-TO-ENGINE HELIUM INTERCONNECT

A TAL ABORT TO EITHER A TAL OR ACLS, BASED ON WHICHEVER PROVIDES THE EARLIEST MULTIPLE ENGINE-OUT CAPABILITY, WILL BE PERFORMED IF THE HELIUM SYSTEM FROM A RUNNING ENGINE IS INTERCONNECTED TO A LEAKING ENGINE HELIUM SUPPLY IN ORDER TO ACHIEVE INTACT ABORT CAPABILITY (REF. RULE {A5-152B}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL]) ©[090894-1676A]

Because of the severity of the helium leak which requires the implementation of Rule {A5-152B}, PRE-MECO MPS HELIUM SYSTEM INTERCONNECTS [CIL], adequate helium may not be available to support three-engine operation to nominal MECO. In this case, it is possible that a non-leaking engine as well as the leaking engine could shut down due to inadequate helium. Therefore, it is important to reach multiple engine-out capability and MECO conditions as soon as possible. This will be accomplished by performing a TAL abort or an abort to an ACLS. ©[090894-1676A] ©[021199-6791A]

Rule {A5-9}, LH₂ ULLAGE LEAK, references this rule. ©[040899-6818A] ©[ED]

FLIGHT RULES

A5-157**ET LOW LEVEL CUTOFF SENSOR FAILED DRY**

THE FAILURE TO THE DRY STATE OF THREE OR MORE ET PROPELLANT LOW LEVEL SENSORS ON THE SAME TANK WILL REQUIRE A TAL ABORT TO BE PERFORMED (TO A TAL, OR ACLS IF NO TAL SITE IS AVAILABLE) IF UPHILL CAPABILITY DOES NOT EXIST (REF. RULE {A4-56H}.1, PERFORMANCE BOUNDARIES). A PREFLIGHT EVALUATION WILL BE REQUIRED TO DETERMINE UPHILL CAPABILITY FOR THIS FAILURE. ©[021397-4824]

NOTE: THREE OR MORE "DRY" INDICATIONS WILL CAUSE PREMATURE MECO IF THE LOW LEVEL ARM COMMAND IS PRESENT PRIOR TO REACHING THE REQUIRED MECO TARGET. TWO SENSORS INDICATING "DRY" WILL NOT REQUIRE AN ABORT.

Propellant low level shutdown software is provided to protect the vehicle from an uncontrolled engine failure which would be caused by the depletion of either LO₂ or LH₂ propellant to a running engine. The software logic requires two qualified sensors to indicate dry after the arming mass is reached in order to start the low level timer and issue the MECO command. On the first pass after the arming mass is reached, the software will disable one dry low level sensor. On the next pass, the software will command MECO if two other low level sensors on the same tank are failed dry. Therefore, three sensors dry when the arming mass is reached will result in an early MECO which may require a TAL or ACLS abort. The failure of two sensors will not cause a premature MECO when the arming mass is reached, since one will be disabled. The crew will be required to abort TAL (or ACLS if no TAL site is available) on some performance-critical missions (as determined by flight design) to prevent a MECO from occurring in a region where no abort capability exists. ©[021397-4824]

Rule {A2-301}, Note 31, CONTINGENCY ACTION SUMMARY, references this rule.

A5-158 THROUGH A5-200 RULES ARE RESERVED

FLIGHT RULES

MPS MANAGEMENT: POST-MECO

A5-201 MPS DUMP INHIBIT [CIL] @[020196-1813A]

A. INSIGHT INTO ENGINE INLET CONDITIONS AVAILABLE:

IF A PROPELLANT LEAK IS DETECTED PRE-MECO ON ANY ENGINE WHICH SHUTS DOWN (MANUAL OR CONTROLLER INITIATED) PRIOR TO MECO, IT WILL BE ISOLATED FROM DUMPING IMMEDIATELY FOLLOWING MECO. THIS DUMP INHIBIT DECISION WILL BE BASED ON THE FOLLOWING:

1. LO₂ INLET PRESSURE < 40 PSIA,

FOR A DUMP INHIBIT OF THE LO₂ SYSTEM, AN EARLY APU SHUTDOWN WILL BE REQUIRED FOR TAL AND RTLS ABORTS (REFERENCE FLIGHT RULE {A16-205A}, EARLY APU SHUTDOWN).
@[020196-1813A]

2. LH₂ INLET PRESSURE < 30 PSIA.

FOR A DUMP INHIBIT OF THE LH₂ SYSTEM, AN EMERGENCY POWERDOWN/MODE V EGRESS WILL BE REQUIRED FOR TAL AND RTLS ABORTS (REFERENCE FLIGHT RULES {A16-12B}.2, EMERGENCY POWERDOWN). AN EARLY APU SHUTDOWN WILL OCCUR AS A RESULT OF THE EMERGENCY POWERDOWN. @[020196-1813A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-201

MPS DUMP INHIBIT [CIL] (CONTINUED)

For nominal, RTLS, TAL, ATO, and AOA missions, the dump inhibit will be performed immediately post-MECO on the affected SSME if insight into the engine inlet conditions is available and the above criteria are met. The dump inhibit is performed by manually closing the associated pre valve and powering down that engine's controller. To minimize dump and vacuum inert impacts, only the associated pre valve will be closed on the side which was determined to be leaking. The engine controller is powered off to close the bleed and hydraulic valves. These actions will prevent excessive leakage of propellant into the aft compartment during the MPS propellant dump, thereby minimizing a potentially hazardous condition in the aft compartment (reference the PSIG Flight Rule Review of 2/25/88). Causes for early shutdown include redline limit shutdown, multiple loss of controller avionics, and manual shutdown for a MPS helium leak, a hydraulic or electrical lockup, or a command path failure. Since flight data indicates that the pump inlet pressures drop below the above limits after MECO, an engine propellant leak cannot be detected if a low level cutoff occurs. The low pressure fuel pump discharge pressure can be used as a backup to the LH₂ inlet pressure and would also use 30 psia as the dump inhibit criterion. If a breach of one or more of the LH₂ propellant lines has occurred, the possibility exists of uncontained/uncontrolled LH₂ propellant in the aft, which constitutes a flammability and explosion hazard on a RTLS or TAL abort. This condition requires the most expeditious powerdown of the vehicle (emergency powerdown) and crew egress (Mode V) possible. An LO₂ leak is not considered as hazardous as an LH₂ leak and therefore does not require an emergency powerdown and Mode V egress. However, both kinds of leaks do warrant an early APU shutdown after an RTLS or TAL abort in order to eliminate an ignition source in a hydrogen or oxygen enriched environment. These postlanding actions are not required after a nominal, ATO, or AOA mission since no uncontained residuals will remain in the aft compartment at the time of landing.

Rules {A16-12B}.2, EMERGENCY POWERDOWN, and {A16-205A}, EARLY APU SHUTDOWN, reference this rule. ©[020196-1813A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-201

MPS DUMP INHIBIT [CIL] (CONTINUED)

B. INSIGHT INTO ENGINE INLET CONDITIONS UNAVAILABLE:

1. NOM/ATO/AOA:

FOR ANY ENGINE WHICH SHUTS DOWN (MANUAL OR CONTROLLER INITIATED) PRIOR TO MECO, THE MPS DUMP INHIBIT WILL BE PERFORMED IMMEDIATELY POST-MECO ON THE PROPELLANT SYSTEM(S) ON WHICH INSIGHT HAD BEEN LOST. THIS ACTION WILL BE TAKEN ON A TIME PERMITTING BASIS TO MINIMIZE POTENTIAL LEAKAGE. THE LPFP DISCHARGE PRESSURE CAN BE USED AS A BACKUP CUE TO ASSESS LH2 INLET CONDITIONS.

Loss of insight into the inlet pressures (and the LPFP discharge pressure for the fuel side) results in the inability to assess the inlet conditions. Therefore, the dump will be inhibited for any engine shut down prior to MECO for the nominal case, an ATO, or an AOA if the inlet condition(s) cannot be assessed (at the time of shutdown) due to avionics failures since a contained shutdown cannot be guaranteed. In the case where there was no leakage, any residuals trapped in the engine by the dump inhibit procedure will have time to bleed out prior to landing.

2. TAL/RTLS:

THE MPS DUMP INHIBIT WILL NOT BE PERFORMED.

Due to the extremely low probability of a noncatastrophic, uncontained shutdown, and the additional failure to lose insight, the cases of survivable shutdowns with leakage hidden due to loss of insight on a TAL and RTLS will not be covered. If the MPS dump is inhibited for the RTLS and TAL cases due to loss of insight and no leakage existed, it would induce an unnecessary risk of trapped LH₂ residuals (approximately 26 lbs. LH₂ on a RTLS and approximately 8 lbs. LH₂ on a TAL abort, at touchdown). These amounts of LH₂ are enough to cause a venting concern for the convoy and preclude normal convoy operations and would require as a minimum an expedited powerdown and Mode V egress per Rule {A16-11F}, EXPEDITED POWERDOWN. However, if leakage was assumed, an emergency powerdown and Mode V egress would be performed per paragraph A of this rule. ©[020196-1813A]

FLIGHT RULES

A5-202

ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL]

A. NOMINAL

IF AN ET/ORBITER 17-INCH DISCONNECT VALVE IS NOT VERIFIED CLOSED, ET SEPARATION WILL BE DELAYED UNTIL MECO PLUS 6 MINUTES TO ALLOW THRUST DECAY FROM THE OPEN VALVE AND THUS PREVENT RECONTACT BETWEEN THE ET AND ORBITER. THE MPS PROPELLANT DUMP WILL BE AUTOMATICALLY PERFORMED DURING THE WAIT PERIOD. FOR AN UNDERSPEED AT MECO WHICH REQUIRES THE OMS-1 BURN TO BE PERFORMED PRIOR TO MECO PLUS 6 MINUTES, ET SEPARATION WILL BE PERFORMED AT OMS-1 TIG MINUS 1 MINUTE 30 SECONDS OR IMMEDIATELY IF REQUIRED, AND THE MPS DUMP WILL BE MANUALLY DELAYED UNTIL AFTER SEPARATION. @[030994-1618B]

BOTTOM-SUN WILL BE REQUIRED FOR THERMAL CONDITIONING (REFERENCE RULE {A10-243}, ET UMBILICAL DOOR CLOSURE DELAY FOR DISCONNECT VALVE FAILURE [CIL]). @[021199-6795A]

B. RTLS/TAL

ET SEPARATION IS AUTOMATIC FOR 17-INCH DISCONNECT VALVE FAILURE.

The ET separation sequence software in the GPC's will inhibit ET separation automatically if it does not receive at least one of the two close position indications from each of the orbiter 17-inch disconnect valves. The closed position indicators may not show closed for real valve failures or loss of insight. This prevents a recontact problem which could occur between the ET and the orbiter after separation due to the large venting force (>10,000 lbf) of the open 17-inch valve (reference SODB, volume 1, section 3.4.3.1).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-202

ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL] (CONTINUED)

The crew will perform a manual separation 6 minutes after the nominal separation time. This waiting period allows the tank and the Orbiter manifold to vent to a level where the venting force < 1800 lbf, which is considered safe for separation (reference SODB, volume 1, section 3.4.3.1). For underspeeds at MECO, which require an OMS-1 to be performed prior to MECO plus 6 minutes, ET separation has to be performed 1 minute 30 seconds prior to OMS-1 ignition. The 1 minute 30 second time was selected to ensure that the crew had sufficient time to prepare for the OMS-1 ignition (reference SODB, volume 1, section 3.4.3.1). The MPS dump will be manually delayed by placing the MPS Propellant Dump Sequence Switch in the STOP position if the separation time would occur during the scheduled MPS dump. The switch is taken back to the GPC position after the ET SEP -Z translation to allow the automated MPS dump to commence. The MPS dump is delayed since performing the MPS dump during ET separation is not a certified separation mode. Time criticality during an RTLS and TAL aborts necessitates an automatic ET separation for OI-22 and subsequent software. The RTLS ET separation software allows 6 seconds of venting. Recontact damage will be risked on an RTLS to avoid rapid degradation of ET separation conditions and possible loss of control. The TAL ET separation software allows 15 seconds of venting to avoid recontact while minimizing the time to OPS 3 transition. TAL aborts incorporate an I-loaded software timer expiration (MSID V97U9717C) to sequence automatic ET separation while RTLS aborts use a hardcoded software constant for separation.

The LO₂ MPS manifold repressurization valves are not commanded open after a 17-inch LO₂ disconnect failure to prevent excessive loss of helium during the MPS dump. The LH₂ MPS manifold repressurization valves are not opened during this timeframe.

Rule {A10-243}, ET UMBILICAL DOOR CLOSURE DELAY FOR DISCONNECT VALVE FAILURE [CIL], references this rule. ©[021199-6795A]

FLIGHT RULES

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]

A. AN MPS PROPELLANT MANIFOLD OVERPRESSURE CONDITION (> 312 (249) PSIA FOR LO_2 OR > 66 (60) PSIA FOR LH_2) WILL BE RELIEVED BY THE FOLLOWING METHODS:

1. PRE-MPS DUMP

THE MPS DUMP WILL AUTOMATICALLY BE STARTED IMMEDIATELY IF THE LH_2 MANIFOLD PRESSURE IS BETWEEN 60 AND 90 PSIA AND NOT COMMFAULTED. @[092701-4867A]

2. POST-MPS DUMP, PRE-FIRST AUTOMATED VACUUM INERT

THE LH_2 OUTBOARD FILL/DRAIN AND TOPPING VALVES WILL AUTOMATICALLY OPEN IF:

- a. THE LH_2 MANIFOLD PRESSURE IS BETWEEN 60 AND 90 PSIA AND NOT COMMFAULTED AND
- b. THE LH_2 BACKUP DUMP VALVES SWITCH WAS NOT TAKEN TO OPEN.

THE LH_2 OUTBOARD FILL/DRAIN AND TOPPING VALVES WILL AUTOMATICALLY CLOSE AT MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES). IF THE OUTBOARD FILL/DRAIN DOES NOT CLOSE, THE SOFTWARE WILL COMMAND THE LH_2 INBOARD FILL/DRAIN VALVE CLOSED. @[111094-1730A] @[021199-6792B]

3. POST-FIRST AUTOMATED VACUUM INERT @[092701-4867A]

THE AFFECTED LO_2 OR LH_2 OUTBOARD FILL/DRAIN VALVE WILL BE MANUALLY OPENED IMMEDIATELY. THIS VALVE WILL BE CLOSED AFTER THE SYSTEM HAS BEEN INERTED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

Because of the characteristics of the LO₂ system, it is highly unlikely that a real overpressure condition will occur without multiple (> 2) system failures prior to the start of the MPS dump (nominally at MECO + 2 minutes). Therefore, no crew action is taken for LO₂ manifold pressure above C&W (249 psia). Heat soak back will vaporize any fluid propellants, increasing the pressure in the lines. On the LO₂ side, the pressure can be relieved by either the MPS dump or vacuum inerting. On the LH₂ side, the pressure can be relieved by MPS dump, vacuum inerting, or opening the LH₂ backup dump valves in OPS 1. An automatic MPS dump will be performed to avoid reaching proof pressure (66 psig) if the software limit (greater than 60 psia and less than 90 psia) is reached before the scheduled MPS dump occurs. If the LH₂ manifold pressure C&W limit of 65 psia is reached, the crew will open the LH₂ backup dump valves and both LH₂ inboard and outboard fill/drain valves per the Ascent Pocket Checklist procedure. If the LH₂ manifold pressure is between 60 and 90 psia after the MPS dump terminates but prior to the first automated vacuum inert start (dump start + 17 minutes, approximately MECO + 19 minutes) and the LH₂ backup dump valves switch on panel R2 was not taken to OPEN, an automated contingency LH₂ vacuum inert will be started by the software and relieve the pressure. This contingency inert will be performed by opening the LH₂ topping and LH₂ outboard fill/drain valves (the LH₂ inboard fill/drain valve remains open following the MPS dump). If the LH₂ manifold pressure is between 60 and 90 psia after the MPS dump terminates but prior to the first automated vacuum inert start and the LH₂ backup dump valves switch on panel R2 was taken to OPEN, an automated contingency LH₂ vacuum inert will not be started by the software because manual action has already been taken. ©[092701-4867A]

If either the LO₂ or LH₂ C&W limit is reached after the first automated vacuum inert, the affected LO₂ or LH₂ outboard fill/drain valve will be opened manually to relieve the pressure. Only the outboards are opened since the inboards should already be open. This is only performed for true high pressure in the affected manifold and not for instrumentation failures. Procedures in the Orbit Pocket Checklist have the crew open all the fill/drain valves since the crew does not have time to determine which system has the overpressure condition. The LO₂ manifold pressure C&W limit (249 psia) is approximately midway between the relief (190 psig) and proof (312 psig) pressures (ref. SODB, volume I, section 4.3). The LH₂ manifold pressure C&W limit (65 psia) is set to avoid having system delays in starting the MPS dump allow the LH₂ manifold pressure to exceed the C&W limit. Rule {A5-205C}, NOMINAL, AOA, AND ATO MPS DUMP FAILURES, references this rule. ©[111094-1730A] ©[021199-6792B] ©[092701-4867A] ©[ED]

FLIGHT RULES

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

- B. IF THE LH₂ RELIEF ISOLATION VALVE FAILS CLOSED POST-MECO AND ANY OMS BURN TIG IS PRIOR TO THE START OF THE FIRST AUTOMATED VACUUM INERT AT MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) : ©[021199-6792B] ©[090999-7035] ©[092701-4867A]
1. THE LH₂ BACKUP DUMP VALVES WILL BE MANUALLY OPENED PRIOR TO THE OMS BURN. THE LH₂ BACKUP DUMP VALVES WILL AUTOMATICALLY CLOSE AT THE COMPLETION OF THE FIRST AUTOMATED VACUUM INERT AT MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES).
 2. THE AUTOMATED LH₂ MANIFOLD REPRESSURIZATION FOLLOWING THE SECOND AUTOMATED VACUUM INERT WILL BE MANUALLY INHIBITED BY TAKING THE LH₂ MANIFOLD PRESS SWITCH TO CLOSE PRIOR TO THE MM 106 TRANSITION. THE LH₂ MANIFOLD PRESS SWITCH WILL BE TAKEN TO GPC AFTER THE MM 106 TRANSITION + 3 MINUTES.

If the LH₂ relief isolation valve does not open, the LH₂ manifold cannot be relieved through the relief valve. The nominal pressure buildup post-MECO is not expected to reach the manifold relief setting with a nominal MPS dump and nominal vacuum inerts. If the manifold pressure builds up greater than 60 psia, the software will automatically start the MPS dump or an automated contingency LH₂ vacuum inert (through the LH₂ fill/drain valves) to relieve the pressure. The LH₂ backup dump valves will be manually opened if an OMS burn is expected to occur prior to the nominal first automated vacuum inert start time of MPS dump start + 17 minutes (approximately MECO + 19 minutes). The OMS burn will increase the sublimation of the LH₂ residuals, resulting in a pressure buildup that may reach the relief setting. Although the software will automatically provide pressure relief if needed, the LH₂ backup dump valves are opened to prevent the pressure rise from nearing the proof pressure of the manifold (66 psig). The valves will be left open until the end of the first automated vacuum inert when they will automatically close. The second automated vacuum inert will be allowed to proceed normally except for the LH₂ manifold repressurization. The repressurization is manually inhibited by taking the LH₂ manifold press switch to close because there is no manifold relief capability. This will be performed prior to the MM 106 transition because the second automated vacuum inert and subsequent manifold repressurization will initiate at the MM 106 transition. The LH₂ manifold press switch will be taken to GPC after the MM 106 transition + 3 minutes (corresponding to the completion of the second automated vacuum inert and subsequent manifold repressurization) in order to avoid powering the valve until it is nominally checked in the Deorbit Prep timeframe. ©[092701-4867A]

A5-203

MPS PROPELLANT MANIFOLD OVERPRESSURE [CIL]
(CONTINUED)

- C. IF AUTOMATIC LH₂ VENT, DUMP, AND RELIEF CAPABILITY IS LOST AS A RESULT OF DUAL GPC/FA MDM FAILURES (GPC'S/FA MDM'S 1 AND 3, 1 AND 4, OR 3 AND 4), THE CREW WILL MANUALLY OPEN THE LH₂ FEEDLINE RELIEF ISOLATION VALVE IMMEDIATELY POST-MECO.
@[090999-7035]

Certain dual GPC/FA MDM failure combinations occurring during ascent will prevent the LH₂ relief isolation valve as well as the LH₂ backup dump valves and LH₂ fill/drain valves from opening after MECO. Without a relief path, the LH₂ manifold pressure will rapidly rise to a dangerous pressure level in seconds. During the STS-1 flight, where the LH₂ backup dump valves were not commanded open at 11.4 seconds after MECO as they are now, the LH₂ manifold pressure went from 34 psia before 17-inch disconnect closure to 50 psia within 15 seconds and subsequently relieved until the start of the MPS dump. The LH₂ manifold burst pressure is 83 psig. The crew can manually open the LH₂ feedline relief isolation valve with a single switch throw on panel R4. Pressure rise on the LO₂ side is not a major concern as a result of the slower pressure rise rate, higher manifold burst pressure, and the available leak path through the SSME oxidizer pump seal packages. For any dual GPC/FA MDM failures, the onboard procedure has the crew take both the LO₂ and LH₂ feedline relief isolation valve switches to open for procedural simplicity. @[030994-1618B] @[021199-6792B] @[092701-4867A]

FLIGHT RULES

A5-204

MANUAL MPS DUMP @[092701-4867A]

THE MPS DUMP WILL BE MANUALLY DELAYED BY TAKING THE MPS DUMP SEQUENCE SWITCH TO "STOP" UNTIL AFTER ET SEPARATION FOR THE FOLLOWING FAILURE CASES IN ORDER TO AVOID PERFORMING THE MPS DUMP DURING ET SEPARATION:

- A. AFT RCS LEAK.
- B. FORWARD RCS LEAK.
- C. MPS FEEDLINE DISCONNECT FAILURE(S) WITH AN OMS-1 TIG PRIOR TO MECO + 6 MINUTES. @[090999-7035]

To prevent orbiter recontact with the ET, the MPS dump is delayed until after ET separation for RCS leaks and the feedline disconnect failure(s). With an RCS leak, the potential exists for the MPS dump forces to overwhelm the reduced RCS control authority during ET separation; therefore, the MPS dump is delayed until after separation by taking the MPS dump sequence switch to stop. With a feedline disconnect failure and an OMS-1 TIG prior to MECO + 6 minutes, the MPS dump is delayed per Rule {A5-202}, ET SEPARATION INHIBIT FOR 17-INCH DISCONNECT FAILURE [CIL], to prevent dump forces from interfering with the separation sequence (dump and vent forces could cause recontact). Analysis certifying the MPS dump during ET separation (SSEIG minutes, April 26, 1999) is not valid in these cases because the analysis assumed 1) the only RCS jets that are failed are those affected by a GPC 4 failure, and 2) the MPS dump can occur no earlier than 1.4 seconds after ET structural separation. @[090999-7035] @[092701-4867A] @[ED]

Taking the MPS dump sequence switch to stop for an ET toggle switch failure along with an LH2 manifold pressure transducer bias between 60 and 90 psia is not covered per the direction of the PRCB (PRCBD # S050270EF) on July 1, 1999. Since the most likely time that the ET toggle switch failure (FMEA/CIL's 05-6-2237-02 and 05-6-2237-03) can occur is post MECO, the crew would not have time to inhibit the MPS dump prior to MECO + 20 seconds (dump start time for the LH2 transducer failure). The PRCB also considered the combination of these two failures to be too unlikely to be specifically covered by crew procedures or by the Flight Rules. Rule {A5-205}, NOMINAL, AOA, AND ATO MPS DUMP FAILURES, references this rule. @[090999-7035] @[092701-4867A] @[ED]

FLIGHT RULES

A5-205

NOMINAL, AOA, AND ATO MPS T DUMP FAILURES

@[092701-4867A] @[ED]

- A. MPS DUMP SWITCH FAILURE - IF THE MPS DUMP SEQUENCE SWITCH IS NEEDED TO DELAY THE MPS DUMP AND IS UNAVAILABLE DUE TO A CONTROL BUS FAILURE, THE AFFECTED CONTACT WILL BE COMM FAULTED BY POWER CYCLING THE APPROPRIATE MDM PER THE TABLE BELOW. @[021397-4825]

<u>SW CONTACT</u>	<u>CONTROL BUS</u>	<u>MDM</u>
A	AB3	FF1
B	BC3	FF2

The MPS dump sequence switch can no longer be used to manually control the dump if the switch fails redundancy management. The MPS dump sequence switch is only used to delay the automated MPS dump until after ET separation for an aft RCS leak, a forward RCS leak, or an ET separation inhibit due to feedline disconnect failures with an OMS-1 TIG prior to MECO + 6 minutes per Rule {A5-204}, MANUAL MPS DUMP. If the MPS dump sequence switch is needed to delay the MPS dump and one of the contacts is failed due to loss of either control bus AB3 or BC3, the affected contact could be taken out of the switch RM logic by power cycling either MDM FF1 or FF2. @[111094-1720B] @[021397-4825] @[092701-4867A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-205

**NOMINAL, AOA, AND ATO MPS T DUMP FAILURES
(CONTINUED)**

- B. LH2 DUMP FAILURES - AN LH2 DUMP WILL BE PERFORMED BY MANUALLY OPENING THE LH2 BACKUP DUMP VALVES PRIOR TO THE END OF THE MPS DUMP FOR THE FAILURE TO OPEN EITHER THE LH2 INBOARD OR OUTBOARD FILL/DRAIN VALVE. THE LH2 BACKUP DUMP VALVES WILL BE MANUALLY CLOSED BETWEEN MECO + 7 MINUTES AND MECO + 10 MINUTES BY TAKING THE LH2 BACKUP DUMP VALVE SWITCH TO CLOSE THEN GPC. OTHERWISE, THE LH2 MANIFOLD REPRESSURIZATION FOLLOWING THE SECOND AUTOMATED VACUUM INERT WILL BE MANUALLY INHIBITED BY TAKING THE LH2 MANIFOLD PRESS SWITCH TO CLOSE PRIOR TO THE MM 106 TRANSITION. THE LH2 MANIFOLD PRESS SWITCH WILL BE TAKEN TO GPC AFTER THE MM 106 TRANSITION + 3 MINUTES. ©[092701-4867A]

The LH₂ portion of the MPS dump is a 120-second unpressurized dump through the LH₂ fill/drain valves, the LH₂ topping valve, and the LH₂ backup dump valves. If the LH₂ outboard fill/drain valve fails closed prior to the start of the MPS dump, approximately 57 lbm of hydrogen will remain at the end of the MPS dump. If the LH₂ inboard valve fails closed, approximately 6 lbm of hydrogen will remain. For these cases, the LH₂ backup dump valves will be taken to the open position prior to the end of the MPS dump. This will allow all but approximately 5 lbm of hydrogen to be vented off before the LH₂ backup dump valves are manually closed.

If no other crew action is taken, the LH₂ backup dump valves will remain open until the termination of the first automated vacuum inert (dump start + 19 minutes, approximately MECO + 21 minutes). At the termination of the first automated vacuum inert, the LH₂ backup dump valves will automatically close until the start of the second automated vacuum inert at the MM 106 transition. At the termination of the second automated vacuum inert, all but 0.24 lbm of hydrogen will be vented. This amount of hydrogen residual is sufficiently high to cause concern regarding the automatic manifold press checkout because the manifold pressure is expected to reach approximately 41 psia which is high enough to open the LH₂ feedline relief valve. In order to avoid opening the LH₂ feedline relief valve (the vent port is located near the vertical stabilizer), the automatic manifold press checkout will be manually inhibited by taking the LH₂ manifold press switch to close. This will be performed prior to the MM 106 transition because the second automated vacuum inert and subsequent manifold repressurization will initiate at the MM 106 transition. The LH₂ manifold press switch will be taken to GPC after the MM 106 transition + 3 minutes (corresponding to the completion of the second automated vacuum inert and subsequent manifold repressurization) in order to avoid powering the valve until it is nominally checked in the Deorbit Prep timeframe. ©[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-205

NOMINAL, AOA, AND ATO MPS T DUMP FAILURES (CONTINUED)

If the crew closes the LH₂ backup dump valves between MECO + 6 minutes, 40 seconds and MECO + 10 minutes, (prior to the start of the first automated vacuum inert), the hydrogen residuals following the second automated vacuum inert will be between 0.09 lbm and 0.10 lbm, respectively. For simplicity, the crew action to take the LH₂ backup dump valve switch to close then GPC will be performed between MECO + 7 minutes and MECO + 10 minutes. It is believed that these residuals are insufficient to cause hydrogen to relieve on orbit. All residuals are based on Boeing IL SHA0-01-014 / SI-01-044 dated February 19, 2001. ©[092701-4867A]

Manual control of the LH₂ backup dump valves is only available in OPS 1. If the hydrogen residuals were not properly inerted in OPS 1, the manifold pressure may rise above the 83 psig burst pressure of the manifold. This scenario would require the crew to pro to OPS 303 (via OPS 301) in order for the software to automatically open the LH₂ backup dump valves. Once the manifold pressure returns to normal, the vehicle may be transitioned back to OPS 2. For this reason, the hydrogen residuals are managed in OPS 1 via the LH₂ backup dump valve switch.

Currently, no ops code exists to open the LH₂ backup dump valves via real-time command (RTC), and due to the fact that the pressure will rise from the max relief setting to the burst pressure in a relatively short amount of time (approximately 1.0 hour), the decision was made not to pursue a GPC memory read/write (GMEM). In the case of an AOA, the manifold pressure should not reach burst pressure prior to the OPS 303 transition. ©[111094-1720B]

- C. LO₂ DUMP FAILURES - AN INCOMPLETE LO₂ DUMP MAY REQUIRE A MANUAL LO₂ VACUUM INERT TO BE PERFORMED PER RULE {A5-206}, MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA).
©[111094-1730A] ©[021397-4825]

The LO₂ is dumped through the SSME main oxidizer valves. There is no secondary dump path available during the MPS dump. However, after MPS dump termination, residuals will vent through the engine high pressure oxidizer pump seals, and the relief system will protect the manifold from overpressurization. ©[092701-4867A]

FLIGHT RULES

A5-206

MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA)

- A. FOR NOMINAL/ATO MISSIONS, A MANUAL LO₂ VACUUM INERTING MAY BE PERFORMED BY THE CREW IF THE LO₂ MANIFOLD PRESSURE IS GREATER THAN 30 PSIA AFTER THE SCHEDULED TERMINATION OF THE FIRST AUTOMATED VACUUM INERT. MANUAL LO₂ VACUUM INERTING WILL NOT BE PERFORMED UNTIL THE LO₂ MANIFOLD PRESSURE VENTS BELOW 30 PSIA. @[111094-1718A] @[092701-4867A]

LO₂ vacuum inerting can be delayed because the LO₂ prevalues remain open after the MPS dump which allows the pressure to vent through the engine high-pressure oxidizer pump seals. After the pressure decays below 30 psia, the software or crew can then perform vacuum inerting without any vehicle control problems. The software can only perform the automated LO₂ vacuum inert between MPS dump start +17 minutes (approximately MECO + 19 minutes) and MPS dump start + 19 minutes (approximately MECO + 21 minutes).

For a nominal and ATO mission, there should be sufficient time to allow the pressure to decay and then perform the LO₂ vacuum inert if required. The manual vacuum inert may not be necessary depending on the effectiveness of the pressure relief through the engine high-pressure oxidizer pump seals. On an AOA, there may not be sufficient time to vent below 30 psia, however, no action would be required because the LO₂ manifold will be inerted automatically in MM 304 by the MPS entry dump sequence.

LO₂ manifold pressure will be less than 30 psia if the MPS dump was performed successfully. However, if two or three engine main oxidizer valves were not able to open for the MPS dump, the residual oxidizer could result in a manifold pressure greater than 30 psia. Opening the LO₂ fill/drain valves when the manifold pressure is greater than 30 psia will cause the vehicle to roll significantly as was experienced during an MPS dump detailed test objective on STS 51-D. The roll was due to the oxidizer flow force at the LO₂ outboard fill/drain valve and flow impingement on the wing.

- B. FOR A BCE STRING 2C FAILURE, A MANUAL LO₂ VACUUM INERT WILL BE PERFORMED AFTER MPS DUMP START + 22 MINUTES (APPROXIMATELY MECO + 24 MINUTES) IF THE LO₂ MANIFOLD PRESSURE IS CONFIRMED TO BE LESS THAN 30 PSIA.

The loss of BCE STRING 2C commfaults the LO₂ manifold pressure sensor. The MPS dump sequence will not perform the LO₂ portion of the first automated vacuum inert if the manifold pressure sensor is commfaulted. Any LO₂ inlet pressure sensor can be used by the MCC as a backup to the LO₂ manifold pressure if the corresponding LO₂ prevalue is open. The crew's manifold pressure meter on panel F7 should also be available to determine the LO₂ manifold pressure. The BCE STRING X procedure in the Ascent Pocket Checklist directs the crew to perform the MPS vacuum inert procedure for the STRING 2C failure. @[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-206

MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA) (CONTINUED)

- C. ON A SYSTEMS AOA, A MANUAL VACUUM INERT MAY BE REQUIRED IF OPS 3 IS ENTERED PRIOR TO INITIATION OF THE FIRST AUTOMATED VACUUM INERT. @[092701-4867A]

On a systems AOA, there may not be sufficient time for the software to initiate the first automated vacuum inert and the crew must manually perform the vacuum inert to insure no residuals, since no entry dump/inert will be performed.

- D. MANUAL LH₂ VACUUM INERTING WILL BE PERFORMED BY MANUALLY OPENING THE LH₂ INBOARD AND OUTBOARD FILL/DRAIN VALVES FOR THE FAILURE TO OPEN THE LH₂ BACKUP DUMP VALVES. THE FIRST MANUAL VACUUM INERT WILL BE PERFORMED AS CLOSE TO THE AUTOMATIC SEQUENCE AS POSSIBLE, BETWEEN MPS DUMP START + 17 MINUTES (APPROXIMATELY MECO + 19 MINUTES) AND MPS DUMP START + 19 MINUTES (APPROXIMATELY MECO + 21 MINUTES). THE SECOND MANUAL VACUUM INERT WILL BE PERFORMED POST OMS-2 AND PRIOR TO THE MM 106 TRANSITION. @[092195-1791]

If either of the LH₂ backup dump valves do not open during the MPS dump or automated vacuum inert(s), the system will be manually inerted using the LH₂ fill/drain valves in order to minimize residuals in the LH₂ manifold. The first manual vacuum inert will be performed as close to the automatic sequence timing as possible (to minimize hydrogen residuals). The second manual vacuum inert will be performed prior to the MM 106 transition in order to allow the automatic manifold press checkout and to minimize hydrogen residuals. By performing the manual vacuum inert(s), the hydrogen residuals will be sufficiently low to allow for the automatic manifold press checkout. The MCC will direct the crew to perform the manual vacuum inerting procedure in the Ascent Pocket Checklist for both vacuum inerts. @[ED] @[092701-4867A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-206 MANUAL VACUUM INERTING REQUIREMENTS (NOMINAL, ATO, AOA) (CONTINUED)

E. IF A MANUAL VACUUM INERTING IS REQUIRED, THE MCC WILL REQUEST, WHENEVER POSSIBLE, THAT THE CREW PERFORM THE PROCEDURE ON THE AFFECTED SYSTEM(S) ONLY LO₂/LH₂. IF POSSIBLE, THE MER MPS ENGINEER WILL BE CONSULTED PRIOR TO SCHEDULING A MANUAL VACUUM INERT. @[111094-1718A] @[092701-4867A]

Although several crew LO₂/LH₂ vacuum inerting procedures are integrated in order to cover single failure cases which affects both systems, it is preferable that the procedures be performed on only the affected system(s) whenever possible. Performing the manual vacuum inert for only the affected system will minimize cycling of the MPS fill/drain valves and should, consequently, maximize the useful life of the MPS hardware. @[111094-1718A] @[ED]

Vacuum inerting will be repeated if propellants are believed to remain in the manifolds. Because there are several potential causes for propellant residuals, because of the significant technical resources available to the MER MPS engineer, and because it is likely that there will be a significant period of time to discuss the situation, the Booster Flight Control Team will consult with the MER MPS engineer if at all possible. Based on reviews of Boeing IL SHA0-01-014 / SI-01-044 dated February 19, 2001, LH₂ manifold pressures above 40 psia will be considered high enough to perform a manual vacuum inert of the LH₂ manifold. @[092701-4867A]

A5-207 LH₂ PRESSURIZATION VENT CONTROL

AFTER THE ET/ORBITER UMBILICAL DOOR IS CLOSED, THE LH₂ PRESSURIZATION LINE VENT WILL NOT BE OPENED TO AVOID VENTING LH₂ INTO THE UMBILICAL CAVITY. @[021199-6793]

Damage to the door or cavity may occur if the LH₂ pressurization line vent is opened while line pressure is high and the vent door is closed (ref. SODB, volume I, section 3.4.3.1-6).

FLIGHT RULES**A5-208****POST-MECO AND ENTRY HELIUM ISOLATION** ©[ED]

- A. MPS ENGINE OR PNEUMATIC HELIUM REGULATOR PRESSURE > 800 (810) PSIA AND THE: ©[021199-6787B]
1. VENT DOORS CLOSED: CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE ASAP.
 2. VENT DOORS OPEN: CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE AS TIME PERMITS.

Analysis indicates an MPS helium regulator failed open can cause an overpressurization of the aft compartment in approximately 17 seconds if the vent doors are closed. This overpressurization will not result in a loss of the vehicle. However, the safety factor for the 1307 Bulkhead will be reduced to 1.31 during entry and structural damage will likely occur which will require the vehicle to be taken out of service for thorough inspection and refurbishment as necessary (reference Rockwell International Analysis PCIN R76186, July 15, 1988).

Crew action is required above 800 psig when the relief valve begins to flow helium into the aft compartment. Since any action will be taken where the ambient pressure is near zero psia, 800 psia will be equivalent to 800 psig. Crew caution and warning is set to 810 psia for the MPS helium regulator pressures. 810 psia is sufficiently close to 805 psia (the relief valve cracking pressure of 800 psig plus 5 psia for transducer accuracy) that action can be taken at the crew caution and warning cue while still maintaining adequate margin to 850 psig where the relief valve goes full open.

With the vent doors open, no action is required. The vent doors close on a TAL at ET SEP command. During an RTLS, the vent doors close at the MM 602 transition. During the nominal or ATO entry, the vent doors close at the transition to MM 304. During an AOA, the vent doors are manually closed just prior to the MM 304 transition. For all of these entry profiles, the vent doors open at Mach 2.4.

Entry MPS helium regulator shifts are most likely to occur during periods of high flow demand such as when the MPS helium isolation valves open at the transition to MM 303 or when the MPS helium blowdown valves open at Mach 5.3. For simplicity, the crew procedure for MPS helium regulator shifts call for the immediate isolation of the associated MPS helium isolation valve(s) on entry prior to Mach 2.4. After Mach 2.4, MCC may direct the crew to close the associated MPS helium regulator valves, time permitting. Training in the nominal helium leak isolation procedure will allow the crew to react to the caution and warning system in less than 15 seconds. ©[021199-6787B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-208

POST-MECO AND ENTRY HELIUM ISOLATION (CONTINUED)

- B. FOR ALL OTHER POST-MECO AND ENTRY HELIUM OR PNEUMATIC SYSTEM LEAKS, THE SYSTEM WILL BE ISOLATED AS TIME PERMITS. POST-ISOLATION, AN ATTEMPT WILL BE MADE TO MANUALLY RECONFIGURE THE MPS HELIUM SYSTEM TO SUPPORT THE ENTRY PURGE IF TIME PERMITS. @[021199-6787B]

If a leak occurs on an engine or pneumatic helium system, the affected system will be isolated as time permits. Helium is required for manifold pressurization during the MPS dump and entry, for valve actuation, and for the entry aft compartment purge. Since the crew has no insight into the configuration of the MPS helium system interconnect valves, it is likely that the crew will need assistance from MCC in order to isolate any post-MECO helium leak. These procedures may be complicated and will be performed as time permits.

For nominal missions, if a leak occurs prior to the MPS dump, the leak may be isolated and the helium system subsequently reconfigured to support the MPS dump. On entry, if time permits after the leak is isolated, the helium system may be manually reconfigured to support the entry purge. The entry purge is highly desirable for the nominal end of mission but is considered mandatory during aborts. If a hazardous gas leak is evident in the aft compartment or OMS pods, the entry purge will be required. Also, contamination may be ingested into the evacuated MPS manifolds if the helium pressurization is not performed. The contamination in the lines would require cleaning before the next flight which would increase the vehicle's turnaround time.

During an RTLS abort, post-MECO isolation may not be performed. Because of the limited flight duration and the crew workload, there may not be adequate time to reconfigure the MPS helium system to support the entry purge.

- C. IF ALL CAUTION AND WARNING IS LOST FOR ANY MPS HELIUM REGULATOR PRESSURE TRANSDUCER(S):
1. NOMINAL/ATO:
 - a. PRIOR TO MACH 2.4: MCC WILL HAVE THE CREW CLOSE THE ASSOCIATED MPS HELIUM ISOLATION VALVE(S).
 - b. AFTER MACH 2.4: NO ACTION REQUIRED. @[021199-6787B]
 2. AOA/TAL/RTLS: NO ACTION REQUIRED. @[021199-6787B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-208

POST-MECO AND ENTRY HELIUM ISOLATION (CONTINUED)

Without hardware or software caution and warning, it is unlikely that MCC could diagnose an MPS helium regulator failed open and tell the crew to close the associated MPS helium isolation valve before the aft compartment is overpressurized (17 seconds). For a nominal or ATO entry, if hardware and software caution and warning is unavailable, the crew will preemptively close the associated MPS helium isolation valve(s). Caution and warning may be lost due to the loss (or bias) of the MPS helium regulator pressure transducer, loss of the associated OI DSC or OI MDM, or loss of the BFS.

After the vent doors open at Mach 2.4, the overpressurization of the aft compartment is no longer a concern and preemptively closing the MPS helium isolation valve(s) to protect for a potential MPS helium regulator failed open is not required. Preemptive helium isolation is also not required on the AOA, TAL, or RTL entry. Protecting for the additional, unrelated failure of an MPS helium regulator following the loss of caution and warning will not be performed because of the relatively short exposure period and high crew workload during aborts.

Preemptive closure of MPS helium isolation valves for the loss of caution and warning will require an MCC call except for a failure of the BFS GPC. The BFS FAIL crew procedure in the Entry Pocket Checklist and Ascent/Entry Systems Procedures directs the crew to close the MPS helium B isolation valves and the pneumatic helium isolation valves since caution and warning for these pressure transducers is only available in the BFS. This procedure does not differentiate between a nominal and abort entry profiles. ©[021199-6787B]

FLIGHT RULES

A5-209

ENTRY MPS HELIUM PURGE/MANIFOLD PRESSURIZATION

©[022802-5080] ©[ED]

THE ENTRY MPS HELIUM PURGE AND MANIFOLD PRESSURIZATION FUNCTIONS ARE HIGHLY DESIRABLE TO PURGE THE AFT COMPARTMENT OF ANY HAZARDOUS FLUID BUILDUP AND TO PREVENT AIR INGESTION INTO THE MPS LO₂ AND LH₂ MANIFOLDS. IF THIS FUNCTION IS LOST, THEN THE FOLLOWING ATTEMPTS WILL BE MADE, TIME PERMITTING, TO RECOVER THEM:

A. NOMINAL/AOA:

EFFORTS TO RECOVER THE ENTRY MPS HELIUM PURGE AND LO₂ AND LH₂ MANIFOLD PRESSURIZATION WILL ONLY BE ATTEMPTED IF IT WILL NOT IMPACT CRITICAL CAPABILITY IN OTHER ORBITER SYSTEMS. FOR CRITICAL POWER/COOLING CASES (I.E., LOSS OF TWO FUEL CELLS OR TWO FREON LOOPS), THE ENTRY PURGE AND MANIFOLD PRESSURIZATION WILL BE INHIBITED PER CREW PROCEDURES.

B. RTLS/TAL:

1. FOR THE ENTRY MPS HELIUM PURGE, RECOVERY EFFORTS WILL ONLY BE ATTEMPTED IF IT WILL NOT IMPACT CRITICAL CAPABILITY IN OTHER ORBITER SYSTEMS.
2. FOR THE MPS LH₂ MANIFOLD PRESSURIZATION, IF THE SITUATION PERMITS, THE FUNCTION WILL BE RECOVERED (BY A SWITCH THROW, PORT MODE, OR RESTRING) IN ORDER TO AVOID INGESTION OF AIR INTO THE LH₂ MANIFOLD.

NOTE: FAILURE TO PRESSURIZE THE LH₂ MANIFOLD WITH MPS HELIUM REQUIRES AN EXPEDITED POWERDOWN AND MODE V EGRESS PER RULE {A16-11F}, EXPEDITED POWERDOWN.
©[022802-5080]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A5-209

ENTRY MPS HELIUM PURGE/MANIFOLD PRESSURIZATION (CONTINUED)

The MPS entry helium purge is used to purge the aft compartment of hazardous fluids (e.g., LH₂, LO₂, N₂H₄, NH₃, or hydraulic oil) during entry. For nominal and AOA entries, hazardous MPS propellants will have had time to be fully inerted as part of the MPS dump sequence; and therefore, the importance of the purge is low. On RTLS and TAL entries, residual MPS propellants may be present, thereby increasing the importance of the purge. If the presence of hazardous fluids is suspected due to system leaks or failures, the purge may help to reduce the potential for combustion by reducing the hazardous fluid concentrations in the aft compartment. The effectiveness of the MPS entry purge is unknown; therefore, critical capability in other Shuttle systems should not be traded off to regain the purge. At the Ascent Entry Flight Techniques Panel Meeting (AEFTP #168 on 10/27/00), it was decided that if it was deemed appropriate by the flight control team to regain the purge, a temporary port mode (to latch the purge valve commands) could be attempted, but a restring was determined to not be warranted due to the unknown effectiveness of the purge. The decision to port mode will depend upon the specific flight phase and failure scenario present in the orbiter as established in Flight Rule {A2-5}, PORT MODING/RESTRINGING GUIDELINES. ©[022802-5080]

It is desirable to pressurize the MPS propellant manifold during entry because failure to do so will result in the ingestion of air into the MPS propellant lines requiring additional turnaround time to clean the contaminated manifolds. Also, loss of the LH₂ manifold pressurization on RTLS and TAL aborts will result in the creation of an explosive mixture in the LH₂ manifold as air is ingested and mixes with the hydrogen residuals. This scenario will require an expedited powerdown per Flight Rule {A16-11}, EXPEDITED POWERDOWN. At the AEFTP Meeting (AEFTP #168 on 10/27/00), it was decided that the recovery technique for the loss of LH₂ manifold pressurization could be a switch throw, temporary port mode (to latch the LH₂ manifold pressurization commands), or restring. In general, a switch throw will be attempted before a port mode, which will be attempted before a restring; however, the recovery technique used will depend upon the specific flight phase and failure scenario present in the orbiter as established in Flight Rule {A2-5}, PORT MODING/RESTRINGING GUIDELINES. The importance of the LO₂ manifold pressurization function is insufficient to justify recovery actions during an RTLS or TAL entry (contamination/reflight issue).

To accomplish a safe entry on a nominal or AOA entry with the loss of two Freon loops or the loss of two fuel cells, critical power and cooling capability must be conserved via power reductions in all orbiter systems. MPS valves that are normally closed valves will be positioned to the CLOSE position in order to conserve power (as documented in the Orbit Pocket Checklist, Entry Pocket Checklist, Contingency Deorbit Prep, and Systems AOA Procedures Flight Data File). This reconfiguration will save approximately 218.4 watts. ©[022802-5080]

FLIGHT RULES

A5-210

ENTRY MPS PROPELLANT DUMP FAILURES [CIL]

@[020196-1813A]

A. NOMINAL/ATO: @[110900-7240]

NO ACTION IS REQUIRED.

During nominal/ATO missions, automatic software or crew procedures will insure dumping and/or inerting of the LO₂ and LH₂ residuals prior to entry. A complete LH₂ dump can be done if either the LH₂ backup dump valves or LH₂ fill/drain valves are open. A complete LO₂ dump can be done if two or three SSME's perform LO₂ dumps, or if the LO₂ fill/drain valves are both open (reference Rockwell Internal Letter no. 287-104-87-004, dated January 8, 1987). The LH₂ backup dump valves are the only dump path opened during the nominal/ATO entry MPS dump sequence, and no action is required in the event that these valves do not open.

B. AOA/TAL:

IN MM 304, IF GPC/MDM FAILURES CAUSE ALL LH₂ DUMP PATHS TO BE LOST (INCLUDING THE LH₂ BACKUP DUMP VALVES), THE AFFECTED LH₂ FILL/DRAIN VALVE(S) WILL BE MANUALLY OPENED. IF THE SOFTWARE CANNOT CLOSE THE LH₂ OUTBOARD FILL/DRAIN OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES, THE LH₂ OUTBOARD FILL/DRAIN VALVE WILL BE MANUALLY CLOSED AT A RELATIVE VELOCITY (V_{REL}) OF 5300 FT/SEC.

In the LH₂ system, there are single GPC/MDM failures which result in the loss of GPC control of the LH₂ fill/drain valves and the LH₂ topping valve. In these cases, the affected LH₂ fill/drain valve(s) will be manually opened on a TAL only if the LH₂ backup dump valves are not open. Sufficient time exists to dump LH₂ residuals through the backup LH₂ valves for AOA or TAL aborts, leaving approximately 3 lbs of hydrogen residuals (per Rockwell International internal letter 287-100-94-164, dated August 9, 1994). There are also combinations of GPC/MDM failures which result in the loss of all LH₂ dump paths. On a TAL abort, the crew will manually open the affected LH₂ fill/drain valve(s). The LH₂ backup dump valves cannot be manually opened in these cases because the switch is software driven and only read in OPS 1. The LH₂ outboard fill/drain valve will be closed in order to preserve helium for the aft compartment purge and to prevent the combination of atmospheric O₂ with the residual LH₂ in the manifold. The velocity cue used to close the LH₂ outboard fill/drain valve represents the nominal closing time and corresponds to an altitude at which possible ignition of residual LH₂ can occur.

FLIGHT RULES

A5-210

ENTRY MPS PROPELLANT DUMP FAILURES [CIL]
(CONTINUED)

C. RTLS: @[110900-7240]

IN MM 602, IF GPC/MDM FAILURES CAUSE THE LH₂ OUTBOARD FILL/DRAIN DUMP PATH TO BE LOST (DUE TO A FAILURE OF THE LH₂ OUTBOARD FILL/DRAIN, OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES), THE AFFECTED LH₂ FILL/DRAIN VALVE(S) WILL BE MANUALLY OPENED. IF THE SOFTWARE CANNOT CLOSE EITHER THE LH₂ OUTBOARD FILL/DRAIN VALVE OR THE LH₂ INBOARD FILL/DRAIN AND TOPPING VALVES, THE LH₂ OUTBOARD FILL/DRAIN VALVE WILL BE CLOSED AT A V_{REL} OF 3800 FT/SEC.

NOTE: AN EXPEDITED POWERDOWN/MODE V EGRESS WILL BE REQUIRED IF A DUMP PATH THROUGH THE LH₂ OUTBOARD FILL/DRAIN VALVE CANNOT BE ACQUIRED (REFERENCE RULE {A16-11F}, EXPEDITED POWERDOWN). @[020196-1813A]

In the LH₂ system, there are GPC/MDM failures which result in the loss of GPC control of the LH₂ fill/drain valves and the LH₂ topping valve. The failure of the LH₂ outboard fill/drain valve will result in an incomplete LH₂ dump on RTLS aborts. Analysis has shown that approximately 40.8 pounds of LH₂ residuals will remain in the MPS LH₂ manifold if the only LH₂ dump path is through the backup LH₂ valves (reference Rockwell internal letter 287-100-04-164, dated August 9, 1994). Venting LH₂ residuals will preclude normal convoy operations (reference rule {A16-11F}, EXPEDITED POWERDOWN). In order to avoid this ground hazard, the affected LH₂ fill/drain valve(s) will be opened. The LH₂ outboard fill/drain valve will be closed in order to preserve helium for the aft compartment purge and to prevent the combination of atmospheric O₂ with the residual LH₂ in the manifold. The velocity cue used to close the LH₂ outboard fill/drain valve represents the nominal closing time and corresponds to an altitude at which possible ignition of residual LH₂ can occur.

FLIGHT RULES

SECTION 6 - PROPULSION

FAILURE DEFINITIONS

A6-1 **OMS/RCS HELIUM TANK**

AN OMS AND/OR HELIUM TANK IS CONSIDERED LOST IF:

- A. OMS PRESSURE < 390 (640) PSIA, RCS PRESSURE < 400 (456) PSIA.

The fail limit is defined as a low helium tank pressure such that the regulated outlet pressure is insufficient to maintain the propellant tank pressure within normal operating range.

The OMS fail limit is 390 psia. At that helium pressure a single engine flow rate will result in lower than nominal propellant tank pressures (below 250 psia). Off-nominal testing has shown that under a single engine flow rate the helium tank pressure decreased to 180 psia before a chamber pressure of 80 percent was reached. However, the 390 psia limit guarantees nominal regulator performance (390 psia corresponds to the regulator spec inlet pressure). Reference SODB constraint 4.3.3.2.1.e.1 for the 390 psia limit.

The RCS fail limit is 400 psia. At this helium pressure a four-jet flow rate will result in lower than nominal propellant tank pressures (below 245 psia). Reference SODB constraint 4.3.2.3.3-f.2 for the 400 psia limit.

- B. ALL PRESSURIZATION PATHS CLOSED.

If both valves or regulators are failed closed, no passageway exists for He to pressurize the propellant tank. Therefore, the He tank is effectively lost.

A6-2 **OMS PROPELLANT TANK (OXIDIZER OR FUEL)**

AN OMS PROPELLANT TANK IS CONSIDERED LOST IF:

- A. PREBURN - FUEL INLET PRESSURE < 208 (216) OR OXIDIZER INLET PRESSURE < 143 (151) OR BOTH FUEL AND OXIDIZER INLET PRESSURE < 158 (166) PSIA OR PROPELLANT QUANTITY? 3 PERCENT.

A low fuel inlet pressure (< 208) preburn will result in reduced fuel flow at the OMS engine during the burn. The fuel is used as a coolant for the engine combustion chamber, and with reduced flow, the cooling jacket temperature will increase. At ignition, a low fuel inlet pressure (208 psia) will result in the violation of the onboard OMS fuel injector temperature fault detection annunciation (FDA) limit (260 deg F). Within approximately 10 to 20 seconds, the injector temperatures will increase to a dangerous level causing possible chamber wall burn through. Consequently, for confirmed low fuel inlet pressure as defined in the Flight Rules, the affected propellant feed system will be considered failed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-2

OMS PROPELLANT TANK (OXIDIZER OR FUEL) (CONTINUED)

A low oxidizer pressure less than normal but > 143 psia preburn will cause the engine to burn cooler than normal (fuel rich mixture ratio results in a cooler burn). However, with oxidizer inlet pressure < 143 psia, the chamber pressure violates the FDA limit of 80 percent and may cause unstable combustion and chamber wall hot spots. Therefore, this engine should not be started to prevent possible chamber wall burn through.

When both of the oxidizer and fuel inlet pressures are low (i.e., operating in a blowdown condition), the OMS engines can be burned until the inlet pressures reach 158 psia because the mixture ratio remains fairly constant. Although the chamber FDA limit is violated, the engine can be safely operated until both the oxidizer and fuel inlet pressures decrease below the 158 psia value, the chamber pressure decreases below 72 percent, or the fuel injector temperature reaches 260 deg F.

The OMS propellant tank is also considered failed (unusable) when propellant quantities are < 3 percent. This is to prevent the propellant tank from reaching depletion levels during a burn and ingesting helium into the OMS engine. The ingestion of helium into the OMS engine could result in unstable operation. For a propellant-critical situation, the engine can be operated until tank depletion without risk of uncontained engine damage. The 3 percent quantity is derived as follows: 2.3 percent trapped propellant in the tank plus > 0.7 percent gauge error (0.7 percent gauge error only applies for total quantities less than 5.0 percent). The 3 percent value should be utilized only during the burn while monitoring the OMS hardware quantity gauging system.

B. ALL ASSOCIATED TANK ISOLATION VALVES FAILED CLOSED.

Restriction of a propellant path from the propellant tanks to the OMS engine is an effective loss of the propellant tank.

C. PROPELLANT TEMPERATURE < 40 DEG (44 DEG) F OR > 100 DEG (96 DEG) F.

The engine design specification is 40 deg to 100 deg F propellant. These temperatures define an envelope for which it is known to be safe to start and operate the OMS engine. Engine testing has been limited to this temperature range and engine performance is unknown beyond this range. High propellant (fuel) temperature may result in propellant boiling in the cooling jacket causing unknown performance. It is also believed that low propellant temperatures could cause large Pc spikes at engine start. (Reference SODB, volume I, paragraph 4.3.3.D.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-2

OMS PROPELLANT TANK (OXIDIZER OR FUEL)
(CONTINUED)

D. RESTRICTION IN OXIDIZER FEED SYSTEM: PC < 76 (80) PERCENT, OMS RM ENGINE SELECT DOWN ARROW ("?") ON MANEUVER EXECUTE DISPLAY (POST-MECO ONLY), AND OXIDIZER INLET PRESSURE < 128 (136) PSIA.

An oxidizer restriction may cause Pc and total vehicle acceleration to decrease below the OMS RM limit triggering the down arrow. The oxidizer feed restriction can be confirmed, during the burn, with a low oxidizer inlet pressure which corresponds to the Pc limit of 80 percent. (Reference SODB paragraph 3.4.3.3-11a for minimum Pc, and SODB request response R921 for inlet pressure verification.)

E. RESTRICTION IN FUEL FEED SYSTEM: OMS FUEL INJECTOR TEMPERATURE > 260 DEG (260 DEG) F* AND FUEL INLET PRESSURE LESS THAN OR EQUAL TO THE LOWER FAIL LIMIT.

* NORMAL OPERATING TEMPERATURE PLUS INSTRUMENTATION ACCURACY WILL NOT MEET FAILURE LIMIT.

116	203 (211)
117	193 (201)

@[110900-7250]

The fuel flow through the engine cooling jacket may be reduced by a fuel restriction, causing hot spots in the combustion chamber. Without proper engine cooling, the probability exists for an engine burn through, creating a hazard to the surrounding structure and pod. In addition, a restriction in the fuel feed line system would result in an oxidizer rich mixture ratio with a higher combustion temperature. SODB data indicates a need for engine specific fuel inlet pressures as cues for OMS propellant tank failures. Instrumentation inaccuracy of 8 psi must be protected to adequately protect the OMS engine. SODB, volume III (CAUTION: SODB, volume III, contains engineering estimates for non-nominal performance evaluation. Data may not be supported by test.), table 4.3.3 contains engine-specific data and should be used to determine tank failure limits.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-2

OMS PROPELLANT TANK (OXIDIZER OR FUEL) (CONTINUED)

A 260 deg F fuel injector temperature at the cooling jacket outlet clearly identifies an off-nominal situation, yet is sufficiently removed from the failure limit to allow time for crew action. The low fuel inlet pressure indicates that the restriction is upstream of the transducer. A restriction large enough to result in a decreased fuel inlet pressure and high fuel injector temperature beyond the defined limits results in the failure of the propellant tank to support further OMS/RCS activities.

Rule {A6-256}, OMS/RCS HEATER PERFORMANCE MONITORING, references this rule.

F. OXIDIZER AND FUEL BOTH IN BLOWDOWN (LOSS OF HE TANK), OMS RM ENGINE SELECT DOWN ARROW ("?") ON MANEUVER EXECUTE DISPLAY AND PC < 68 (72) PERCENT.

Test results have determined that with both the oxidizer and fuel tanks in blowdown, the OMS engines can be safely operated below the 80 percent Pc alarm with an acceptable propellant mixture ratio. When Pc drops below 68 percent, unstable combustion occurs. (Reference SODB, paragraph 3.4.3.3-11b.)

G. PROPELLANT LEAK UPSTREAM OF BALL VALVES, PC < 76 (80) PERCENT AND OMS RM ENGINE SELECT DOWN ARROW ("?") ON MANEUVER EXECUTE DISPLAY.

A propellant leak large enough to cause low Pc and decayed acceleration during an OMS engine burn, as indicated by a down arrow, identifies an OMS propellant system failure. Even though the leak may be isolated, the engine and associated propellant system cannot be used since the leak would affect crossfeed (ref. SODB, paragraph 3.4.3.3-11a).

FLIGHT RULES

A6-3

OMS ENGINE

AN OMS ENGINE IS CONSIDERED LOST IF:

- A. AN ENGINE BALL VALVE POSITION < 47 (70) PERCENT THAT RESULTS IN AN ENGINE PC < 76 (80) PERCENT AND AN OMS DOWN ARROW (") ON THE MANEUVER EXECUTE DISPLAY.

OMS engine Pc must be > 76 (80) percent (100 psia) when not in ullage blowdown (reference SODB, volume I, paragraph 3.4.3.3) or Pc must be > 68 (72) percent (90 psia) in ullage blowdown (reference SODB, volume I, paragraph 3.4.3.3) to ensure safe engine operation. A ball valve position of 47 percent causes sufficient blockage of propellant flow to result in an engine Pc = 76 percent (100 psia). Although ball valve position > 47 percent results in safe engine operation, a conservative 70 percent (ref. SODB, volume I, paragraph 3.4.3.3) is required to clearly identify ball valves not in a normal position. This ball valve failure confirms that the problem is an engine failure and not a propellant tank failure.

- B. OMS ENGINE FEEDLINE TEMPERATURE < 30 DEG (38 DEG) F OR > 125 DEG (117 DEG) F.

Test data have demonstrated that engine starts are acceptable with propellant temperatures at these limits as long as the bulk propellant tank temperature is within limits. Operation with bulk propellant outside of these limits is untested and uncertified. Problems that would probably be encountered are rough combustion, insufficient cooling, and excessive high chamber pressure which could overstress the engine chamber. (Reference SODB, paragraph 4.3.3.4.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-3 OMS ENGINE (CONTINUED)

C. FUEL RESTRICTION: OMS FUEL INJECTOR TEMPERATURE > 260 DEG (260 DEG) F* AND FUEL INLET PRESSURE GREATER THAN OR EQUAL TO THE UPPER FAIL LIMIT.

* NORMAL OPERATING TEMPERATURE PLUS INSTRUMENTATION ACCURACY WILL NOT MEET FAILURE LIMIT.

ENGINE SERIAL #	FU IN P UPPER FAIL LIMIT (PSI)
101	230 (222)
105	235 (227)
106	228 (220)
107	227 (219)
108	238 (230)
109	238 (230)
110	234 (226)
111	232 (224)
113	228 (220)
114	229 (221)
115	233 (225)
116	233 (225)
117	225 (217)

©[110900-7251]

Fuel is used to cool the OMS engine combustion chamber. The fuel injector temperature is measured after the fuel has passed through the regenerative cooling jacket. Normally this temperature is 220 deg F during a burn. The 260 deg limit was selected to positively identify that the engine was operating in an anomalous manner. At all temperatures below 260 deg F, engine operation is safe. However, as the fuel injector temperature exceeds this limit, combustion chamber wall burn through becomes increasingly likely. Since chamber pressure is largely unaffected by the loss of cooling, only fuel inlet pressure can confirm that a fuel restriction exists. A higher-than-normal fuel inlet pressure is indicative of a restriction in the fuel flow downstream of the engine ball valves. SODB data indicates a need for engine-specific fuel inlet pressures as a secondary cue for OMS engine failure. Instrumentation inaccuracy of 8 psi must be protected to prevent the crew concluding fuel injector temperature transducer failure when an OMS engine failure has occurred.

SODB, volume III, table 4.3.3 (CAUTION: SODB volume III contains engineering estimates for non-nominal performance evaluation. Data may not be supported by test.) contains engine-specific data and should be used to determine engine failure limits.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A6-3****OMS ENGINE (CONTINUED)**

- D. PROPELLANT LEAK DOWNSTREAM OF BALL VALVES, PC < 76 (80) PERCENT, AND OMS RM ENGINE SELECT DOWN ARROW (∇) ON MANEUVER EXECUTE DISPLAY OR FUEL INJECTION TEMP > 260 DEG F.

A propellant leak large enough to cause low Pc and decayed acceleration, as indicated by the down arrow or fuel injector temperature high, during a burn results in the loss of the affected engine. (Reference SODB, volume I, paragraphs 3.4.3.3 and 3.4.4.3.)

- E. PREVIOUS FUEL OR OXIDIZER DEPLETION CUTOFF.

Although WSTF tests with a fuel depletion cutoff did not damage an OMS engine, there is significant risk that engine damage may occur during shutdown. This is due to the loss of engine cooling when fuel no longer passes through the cooling jacket around the combustion chamber. Uncontained damage did not occur during WSTF tests but zero-g effects are unknown.

It is not desirable to reuse an OMS engine following an oxidizer depletion cutoff. A period of time is required for oxidizer from a different propellant source to reach the engine during the first engine start following oxidizer depletion cutoff. During this time, unburned fuel accumulates in the combustion chamber because of the very low vapor pressure of monomethylhydrazine. When the oxidizer reaches the injector, extremely rough combustion will result. Uncontained engine damage could result.

There have not been any tests to verify reuse of an engine which has experienced a previous oxidizer or fuel depletion cutoff.

Reference: SODB 3.4.3.3. Rule {A6-106}, OMS ENGINE BURN TO DEPLETION, references this rule.

- F. PRE-MECO PC ? 76 (80) PERCENT CONFIRMED BY ENGINE BALL VALVE POSITION < 47 (70) PERCENT OR OXIDIZER INLET PRESSURE > 235 (227) PSIA.

The crew will get a class 2 alarm at Pc < 76 (80) percent, but there is no MNVR EXEC display or ENG SEL down arrow pre-MECO to indicate loss of acceleration. Therefore, oxidizer inlet pressure or ball valve position is checked for an additional indication of an engine failure. The rationale used for paragraphs A and C (CAUTION: SODB, volume III, contains engineering estimates for non-nominal evaluation. Data may not be supported by test.) applies here also. (Reference SODB, volume I, 3.4.3.3, table 3.4.3.3 and SODB request response R921.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-3 OMS ENGINE (CONTINUED)

G. OXIDIZER RESTRICTION: PC < 76 (80) PERCENT, OMS RM ENGINE SELECT DOWN ARROW ("?") ON MANEUVER EXEC DISPLAY, AND OXIDIZER INLET PRESSURE > 235 (227) PSIA.

The engine can also fail if the oxidizer injector is restricted, which causes the upstream oxidizer inlet pressure to increase. Operating at this low oxidizer inlet pressure will result in an engine failure indicated by low Pc and acceleration. (Reference SODB, volume I, paragraph 3.4.3.3. A request has been submitted for inlet pressure verification.)

H. OMS BALL VALVE POSITION > 0 PERCENT (FAILED OPEN RANGE LOWER LIMIT) AND < 47 (70) PERCENT POSTBURN AND INSTRUMENTATION FAILURE CANNOT BE POSITIVELY IDENTIFIED.

ENGINE SERIAL #	OMS BALL VALVE FAILED OPEN RANGE LOWER LIMIT	
	BV1 %	BV2 %
101	6	5
105	3	5
106	4	6
107	6	6
108	4	5
109	4	6
110	3	4
111	6	3
113	4	4
114	5	3
115	3	3
116	2	4
117	5	4

@[110900-7251] @[1112102-ED]

For failure definition purposes, the OMS ball valves are considered a functionally integral part of the OMS engine. OMS ball valve position indicators are single-point instrumentation on the series ball valves. To distinguish an instrumentation failure from a hardware failure, it is necessary to examine the time-ordered history of the anomaly.

The normal position of the ball valves when not operating is 0 percent open (decimals of percent open are rounded). If the ball valves are failed to < 47 percent, the affected OMS Pc will be < 80 percent which is the level at which the engine is considered failed. (Refer to rationale of Rule {A6-108}, OMS BALL VALVE FAILURE MANAGEMENT.) The position indicators have an instrumentation accuracy of 5 percent.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-3

OMS ENGINE (CONTINUED)

In order to avoid declaring an engine failed due to instrumentation accuracy effects, the ball valve will be considered closed if the indicated position is less than or equal to 5 percent. The failed open range lower limits listed in the above table are based on this value of 5 percent, plus an engine-specific error. This additional error is caused by the generic scale and generic bias factor used to convert the voltage measured by the hardware to a percent open. These generic factors are used for all engines and vary slightly from the individual scale and bias factors associated with each engine. For example, the value of 4 percent shown for ball valve 1 of engine 109 is the result of adding the scale and bias factor error of -1 percent to the instrumentation error of 5 percent. When that ball valve is closed, it should indicate within the range of -6 to 4 percent.

Note that flow through the valve begins at 10 percent. If the failed open range lower limit is exceeded, then the valve is failed open and a flow path through that valve may exist. Since there are two ball valves in series, should any single ball valve be open > 10 percent postburn, the other ball valve in that series will prevent propellant leakage into the engine proper.

If an instrumentation failure cannot be positively identified, the engine is considered failed. The affected engine will be used for deorbit only, and then, only if the other engine is failed. If the ball valve position is more than 47 percent open, an acceptable OMS Pc will be obtained during any subsequent engine operation. (Reference SODB, volume I, paragraph 3.4.3.3-17, and Flight Rules {A6-3A}, OMS ENGINE, and {A6-108}, OMS BALL VALVE FAILURE MANAGEMENT.)

I. OMS GN₂ SYSTEM FAILURE (REF. RULE {A6-5}, OMS N₂ ACCUMULATOR).

Reference Rule {A6-5}, OMS N₂ ACCUMULATOR, for rationale. Rules {A6-106}, OMS ENGINE BURN TO DEPLETION; and {A6-108}, OMS BALL VALVE FAILURE MANAGEMENT, reference this rule.

FLIGHT RULES

A6-4 OMS N2 TANK

AN OMS N₂ TANK IS CONSIDERED LOST IF:

- A. PRESSURE < 309 (469) PSIA (NO PURGE AVAILABLE).

An OMS N₂ tank failure is defined as insufficient GN₂ pressure to allow a nominal engine start with no purge and a subsequent accumulator only start with the GN₂ tank isolation valve closed. A GN₂ tank pressure of 309 psia (283 psi for an accumulator start and 26 psi for a nominal no purge start) will provide sufficient pressure to accomplish this requirement with a 100 percent ball valve opening on both burns. (Reference SODB, volume I, paragraph 3.4.3.3.14.)

- B. REGULATOR FAILED CLOSED.
- C. FAILED CLOSED CHECK VALVES.
- D. OMS ENGINE PRESSURE VALVE FAILED CLOSED.

Any one of these conditions has isolated the tank from the ball valve rack assembly, effectively failing the tank. Rule {A6-55}, OMS N₂ TANK FAILURE MANAGEMENT, references this rule.

A6-5 OMS N2 ACCUMULATOR

THE OMS N₂ SYSTEM IS CONSIDERED LOST IF:

INSUFFICIENT N₂ REGULATOR PRESSURE TO OPERATE ENGINE BALL VALVES:

- A. N₂ REGULATOR PRESSURE < 283 (299) PSIA WITH ENGINE PRESSURE VALVE CLOSED.
- B. N₂ REGULATOR PRESSURE < 244 (260) PSIA WITH ENGINE PRESSURE VALVE OPEN (ASSUMES N₂ TANK PRESSURE EQUAL TO N₂ REGULATOR PRESSURE)

An OME is considered failed if ball valves cannot be guaranteed to fully open. The engine can be used in a contingency if ball valves can be guaranteed to open > 90 percent. With the engine pressurization valve closed, the pressure below the valve must be above 283 psia to move the ball valve rack assembly. With the pressurization valve open, allowing the large tank volume to pressurize the accumulator, the ball valve rack will only require 244 psi. (Both the regulator pressure and tank pressure must be above 244 psia.) Performance drops off drastically at lower N₂ or accumulator pressures. Instrumentation accuracy is 16 psi on the accumulator pressure. (Reference SODB, volume I, table 4.3.3-3.)

Rules {A6-3I}, OMS ENGINE; {A6-51}, OMS FAILURE MANAGEMENT [CIL]; {A6-55}, OMS N₂ TANK FAILURE MANAGEMENT; and {A6-56}, OMS N₂ REGULATOR FAILURE MANAGEMENT, reference this rule.

FLIGHT RULES

A6-6

OMS/RCS CROSSFEED LINE

THE OMS/RCS CROSSFEED LINE IS CONSIDERED LOST IF:

- A. OMS/RCS CROSSFEED TEMPERATURE < 40 DEG (48 DEG) F OR > 125 DEG (117 DEG) F.

It takes approximately 10 seconds from ignition to reach thermal equilibrium in an OMS engine and regenerative cooling jacket. A crossfed OME will use the propellant from the feedlines and all of the propellant in the crossfeed lines during this thermal startup phase. It takes approximately 6 seconds to burn the feedline and crossfeed line propellant through an OME. ©[092701-4850]

The OME starts with propellant below 30 deg F or OME steady state operation with propellant below 40 deg F may result in rough combustion and excessive high chamber pressure which could overstress the engine chamber. Propellant temperatures below 40 deg F may also affect structural components such as service couplings and transducer fittings. Below 30 deg F, there is a concern that the oxidizer may freeze, rupturing or blocking propellant lines. RCS jet operation with propellant below 40 deg F may result in rough combustion. For RCS crossfeed during entry, the lower limit is 68 deg (70 deg) F to protect against ZOT's (refer to Flight Rule {A6-258}, ARCS BULK PROPELLANT TEMPERATURE MANAGEMENT).

OME startup with propellant above 125 deg F reduces engine cooling effectiveness, resulting in violation of injector temperature limits. Localized "hot spots" of propellant may develop in stagnant crossfeed lines. This is caused by non-uniformity's in line heater installation coupled with non-synchronous heater cycling. Hot spots can be tracked and confirmed during periods of interconnect. Hot spots less than 125 deg F are acceptable for OME and RCS steady state operation. Refer to SODB table 3.4.3.3.

- B. NO FLOW PATH EXISTS.

The OMS/RCS crossfeed lines are considered failed when no flow path exists. Dual valve failure or a line leak could result in a flow path loss.

- C. CROSSFEED LINE PRESSURE IS < 15 (49) PSI OXIDIZER OR < 1 (35) PSIA FUEL (AS INDICATED BY RCS MANIFOLD PRESSURES) AS A RESULT OF PROPELLANT LEAKAGE.

Pressure less than 49 psia oxidizer or 35 psia fuel as a result of propellant leakage is cause to declare the crossfeed line failed. A known leaking line resulting in violation of the above limits will not be repressed unless staged repress techniques increase pressures to within acceptable limits. The OMS crossfeed line pressure will be checked via RCS manifold pressures until additional pressure transducers are installed. Any attempt to repressurize the leaking line risks structural damage as a result of excessive surge pressures.

For a crossfeed pressure less than the above limit as a result of thermal affects, the crossfeed line may be repressed according to the Flight Rules restrictions.

FLIGHT RULES

A6-7

RCS PROPELLANT TANK (OXIDIZER OR FUEL)

AN RCS PROPELLANT TANK IS CONSIDERED LOST IF:

A. PRESSURE IS < 185 (190) PSIA.

To maintain primary jet inlet pressures greater than 175 psia, the tank pressure must remain above 185 psia. With lower than normal inlet pressures (< 175), the chamber pressure during a firing becomes significantly higher than the inlet pressure. This results in a high frequency "chug" or combustion instability which causes hot spots on the chamber wall and in extreme cases may cause the chamber wall to fail. Reference SODB 3.4.3.2.10.a.

The vernier jets have a lower but undefined operational limit where the lower pressure can lead to the accumulation of carbon deposits in the chamber pressure tube. Blockage of the Pc tube may result in false fail-off jet indications.

B. ARCS:

1. ARCS (ENTRY ONLY) AND FRCS: PROPELLANT QUANTITY
? 0 PERCENT.

Propellant gauge quantity reflects usable propellant. Trapped propellant and gauge error are not included in the gauge quantity. For the FRCS, the gauge error propellant is available for contingency operations to 1.5 percent below a gauge reading of 0 percent (ref. Rule {A6-357}, FORWARD RCS CONTINGENCY PROPELLANT AVAILABLE).

2. ARCS ON ORBIT: PROPELLANT QUANTITY ? 20 PERCENT.

The on-orbit aft RCS tank failure limit is based upon the on-orbit expulsion efficiency of the RCS tank (78 percent of the design tank volume; ref. SODB 4.3.2.2.1.f.2). The on-orbit expulsion efficiency of the RCS is significantly less than the entry expulsion efficiency because the aft RCS tanks were designed to operate most efficiently during entry g-loading. Propellant can be expelled on orbit to 16 percent PVT gauge quantity (provided PVT gauging is perfectly accurate). Protecting for gauge error (50 lbs OX, 34 lbs FU), the minimum quantity on orbit becomes 20 percent. The 20 percent of propellant will be available for control during entry (post EI: $g > 0.05$), since expulsion efficiency during this period increases to 96.5 percent of the design tank volume.

C. ASSOCIATED TANK ISOLATION VALVES FAILED CLOSED.

No passageway exists for propellant to flow from the tank to the jets, effectively failing the tank.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-7 **RCS PROPELLANT TANK (OXIDIZER OR FUEL)**
(CONTINUED)

D. ARCS PROPELLANT TEMPERATURE IS < 50 DEG (52 DEG) F OR > 100 DEG (98 DEG) F.

The concern with violating the upper limit is that the oxidizer viscosity and adhesion to the acquisition screens allows a lower pressure to pull helium into the lower compartment and then to the jets. Violating the lower limit increases the restriction of fuel flow in the channels. During high flow demands, the large delta pressure across the screens occurs near the tank outlet. This large delta pressure breaks down the screen and pulls helium into the lower compartment. (Reference SODB, volume I, table 3.4.3.2.)

E. FRCS PROPELLANT TEMPERATURE < 40 DEG (42 DEG) F OR > 100 DEG (98 DEG) F.

Tank certification constraint (reference SODB, volume I, table 3.4.3.2).

F. PROPELLANT ACQUISITION DEVICE BREAKDOWN.

Confirmed evidence of propellant acquisition device breakdown will be cause to declare that RCS tank failed. Multiple jet fail-offs on the same feed system (e.g., multiple LRCS jet fail-offs while feeding from the LRCS) are the indication that a breakdown has occurred in either the screens or bulkhead of the RCS tank. Helium ingestion resulting from the tank failure may be cleared using propellant from either the good RCS feed system or the OMS. The tank will not be used except as a last resort during entry. Rule {A6-305}, AFT RCS REDLINES, references this rule.

FLIGHT RULES

A6-8

RCS THRUSTER

AN RCS THRUSTER IS CONSIDERED LOST IF:

A. FAILED ON - FIRES IN ABSENCE OF GPC "ON" COMMAND.

A thruster is "failed-on" when it fires in the absence of an "ON" command from the GPC. This failure will occur if the injector valve power (driver output) from the RJD fails high or if both the oxidizer and fuel thruster valves fail open. The failure is detected by RCS RM when an RJD output discrete is present with the absence of the GPC jet command B for three consecutive cycles. The failure is confirmed on the ground via the analog chamber pressure (Pc) and/or vehicle rates, and propellant consumption.

The BFS fail-on jet is detected by RM when the affected jet Pc discrete is present (> 36 psia) with no GPC command B for three consecutive cycles and fuel manifold valve open discrete indicates true.

B. FAILED OFF - DOES NOT FIRE IN PRESENCE OF GPC "ON" COMMAND.

A thruster is "failed-off" when the jet does not fire in the presence of an "ON" command from the GPC. This failure will occur when the RJD output discrete fails low (which can be caused by any of a number of upstream failures) or one of the thruster valves fails closed. The failure is detected by RCS RM when the Pc discrete is zero (indicating Pc < 26 psia as sensed by the RJD electronics) in the presence of a GPC command B for three consecutive cycles. The failure is confirmed on the ground via analog Pc, RJD output discrete, jet injector temperature, or vehicle rates.

C. FAILED LEAK - LOSS OF PROPELLANT THROUGH THRUSTER VALVE AS CONFIRMED BY PRIMARY OXIDIZER INJECTOR TEMPERATURE < 30 DEG F OR FUEL INJECTOR TEMPERATURE < 20 DEG F; OPS 2 VERNIER INJECTOR TEMPERATURE (OXIDIZER OR FUEL) < 130 DEG F.

A jet is "failed-leak" if either injector valve (oxidizer or fuel) fails to close completely or if propellant leaks through a deformed or damaged thruster valve seal. Seal leakage is the most common form of jet leak. The failure is detected both on the ground and by RCS RM when either injector temperature falls below RCS RM limits for three consecutive cycles. The RM limits are established as specified in the SODB. The failure is confirmed on the ground via the injector temperature signature or RCS quantity telemetry. The vernier injector temperatures are assumed to track together; therefore, action will be taken when the first of either fuel or oxidizer is < 130 deg F.

During entry, residual fuel may be held against the injector on the primary upfiring jets by gravity. This is why the fuel limit is lower than the oxidizer limit. Vernier jet injector temperature sensors are located on a large mass of metal which acts as a heat source. Because of the location, these sensors respond more slowly to leaks than do the primary jet sensors. The vernier leak limit is set to accommodate these conditions.

FLIGHT RULES

A6-9

RCS JET HEATER

AN RCS JET HEATER IS CONSIDERED LOST IF:

- A. PRIMARY THRUSTER - BOTH OXIDIZER AND FUEL INJECTOR TEMPERATURES DECREASE TOGETHER TO BELOW 50 DEG (55 DEG) F.

Normal heater operations will keep the jets above 60 deg F. In the event of a jet heater failure, the colder temperatures may result in shrinkage of the injector valve seats causing jet leakage. To prevent seat shrinkage, the jet should be kept above 50 deg F; and to prevent RM from deselecting the jet, the temperatures should be kept above the thermal leak limit (fuel > 20 deg F, oxidizer > 30 deg F). The jets may be warmed by hot-firing the jets for at least 2 seconds (firing a cold jet less than 2 seconds may cause the jet to leak). Reference SODB, volume I, paragraph 3.4.3.2.13.a.

B. VERNIER THRUSTERS:

1. INADEQUATE JET HEATER OPERATION - THRUSTER HAS NOT BEEN FIRED IN AT LEAST 1.5 HOURS AND BOTH OXIDIZER AND FUEL INJECTOR TEMPERATURES DROP BELOW 130 DEG F AND DECREASE FROM 130 DEG TO 90 DEG F AT A RATE OF LESS THAN 15 DEG F PER HOUR WITH NO INCREASE IN THE JET CHAMBER PRESSURE.
2. HEATER FAILED OFF - BOTH OXIDIZER AND FUEL INJECTOR TEMPERATURES DROP BELOW 130 DEG F AND DECREASE FROM 130 DEG TO 90 DEG F AT A RATE OF LESS THAN 2 DEG F PER MINUTE WITH NO INCREASE IN THE JET CHAMBER PRESSURE.

Normal operating temperatures for vernier jets are above 140 deg F. However, some attitudes (e.g., gravity gradient) which do not require vernier jet firings may allow a vernier jet to cool to below 130 deg F, even without a heater failure, because the heaters are undersized. For inadequate jet heater operation or a failed vernier heater, the vernier minimum injector temperature can be reduced from 130 deg to 90 deg F if the conditions set forth in this rule are met. Failure to meet these conditions indicates a vernier jet leak. Cooler temperatures are less likely to cause the verniers to leak than the primaries because of the conical valve seat design. The 90 deg F coldsoak limit will prevent seal shrinkage which would result in propellant leakage. It is possible that a slow temperature decay rate is due to a leak that is contained within the vernier thrust chamber. If the chamber pressure increases, it is probable that the vernier has leaked, the jet throat has frozen closed, and the leak has continued. In this case, firing the affected thruster may cause damage in the pod.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-9**RCS JET HEATER (CONTINUED)**

Vernier jet injector temperatures less than 130 deg F indicate either inadequate heater operation, a heater failure, or an injector leak. Inadequate heater operation or a heater failure will allow both fuel and oxidizer temperatures to decay together. Jet injector leaks will cause the injector temps to decay much faster than for a heater failure. Also, the leaking injector temperature (oxidizer or fuel) will decay further than the nonleaking injector temperature. However, an instrumentation contact resistance may cause false readings greater than 15 deg F delta oxidizer and fuel temperatures masking any 5 deg F or greater delta created by a leak. Therefore, delta temperature cannot be used to distinguish leaks from heater failures. Reference Rule {A6-158}, RCS LEAKING JET MANAGEMENT; and SODB, volume I, paragraph 3.4.3.2.13.b.

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

OMS He TANK LEAK/FAIL ©[072398-6518A]

A. ONE OMS HELIUM TANK LEAK PRIOR TO OMS-2:

STD:

Since pre-MECO ATO dumps may be required for ascent performance (i.e., to avoid TAL), the dump will be continued whenever possible.

If the leak rate cannot support OMS-1 TELP to a quantity sufficient to protect the OMS propellant landing weight constraint (EOM quantity < 22 percent per OMS tank), a pre-MECO OMS dump to maximum blowdown will be performed.

Utilizing the dump software to increase the OMS blowdown available prior to helium tank failure results in the capability to achieve an ATO orbit with steep deorbit and nominal CG's versus an ATO orbit with shallow deorbit and 1.9 Y CG using forward RCS and aft RCS propellant to quantity-1 supplement (no dump and He tank fails pre-OMS-1). Mission Control Center (MCC) is prime to recommend the pre-MECO dump based on a leak rate evaluation and time to MECO.

If no pre-MECO dump is performed or the dump is terminated early and the affected He tank can support nominal OMS-1 TETP, then nominal OMS-1 will be performed, TELP, in order to maximize blowdown available prior to He tank fail. The OMS BURN MONITOR cue card, He P LOW will be utilized by the crew for the burn. Since not enough time is available to reconfigure TELP prior to ignition, the burn will be initiated TETP, then reconfigured to a TELP burn. The burn will be continued TELP until He tank fail or maximum blowdown. At that time, the crew will reconfigure to TEGP for the remainder of the burn. If no pre-MECO dump to maximum blowdown is performed or the dump is terminated early and the affected He tank cannot support OMS-1, go to single He tank fail prior to OMS-1. An ATO orbit can still be achieved. ©[072398-6518A]

If the leak rate indicates the helium tank will support nominal OMS-1 TELP to a quantity sufficient to protect the OMS propellant tank landing weight constraint (22 percent), OMS-1 will be performed TELP until He tank fail or until maximum blowdown has been achieved. If maximum blowdown is achieved, no additional OMS propellant is trapped onboard, and therefore allows the EOM quantity < 22 percent. If the amount of He required to support OMS-1 TELP to a quantity sufficient to protect the landing weight constraint is less than the amount of He required for the entire OMS-1 TELP, protecting the landing weight constraint rather than the entire OMS-1 TELP increases the chances of allowing nominal OMS-1 to be performed, and decreases the requirement for the pre-MECO dump to maximum blowdown.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

Using the leaking He tank for OMS-1 rather than dumping pre-MECO has two advantages:

- a. No pre-MECO crew actions required.
- b. Using the delta V for OMS-1 rather than dumping pre-MECO results in a net gain of delta V.

In the case where the He required to support OMS-1 TELP to a quantity sufficient to protect the landing weight constraint is more than the amount of He required for the entire OMS-1 TELP, the landing weight must still be protected.

If full blowdown has been achieved post-OMS-1, OMS-2 will be performed TEGP. If not in full blowdown post-OMS-1 and the leak rate indicates the tank will support OMS-2 TETP, the burn will be performed TELP. The OMS BURN MONITOR cue card He P LOW will be utilized by the crew for the burn. The burn will be initiated TELP until He tank fail or maximum blowdown is achieved. At that time, the crew will reconfigure to TEGP for the remainder of the burn. If the leak rate will not support OMS-2 TETP, a dump will be performed TELP ASAP post-OMS-1. Again, the dump will be continued until He tank fail or maximum blowdown is achieved. ©[072398-6518A]

If a pre-MECO ATO dump is required and the leak rate will support nominal OMS-1 TELP to a quantity sufficient to support the landing weight constraint (22 percent), the ATO dump should be performed. Since ATO targets will be used, a dump TELP to maximum blowdown or He tank fail will be performed ASAP post-MECO.

DIRECT:

If performing a pre-MECO OMS assist/ATO dump will increase available blowdown, the dump will be continued whenever possible.

If the leak rate indicates the He tank will support nominal OMS-2 TELP to a quantity sufficient to protect the OMS tank landing weight constraint (22 percent), perform nominal OMS-2 TELP until affected pod maximum blowdown or He tank fail. If the He tank is not failed and the pod is not in full blowdown post-OMS-2, a dump will be performed postburn in order to maximize blowdown in the affected pod. If performing an earlier pre- or post-MECO dump will result in a net increase in delta V available for the mission, then consideration may be given to doing so, crew workload permitting. It is possible a nominal mission can be achieved without violating Y CG limits or landing weight constraints. ©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

If the leak rate cannot support OMS-2 TELP, however, a dump must be performed in order to maximize blowdown prior to He tank fail. If the leak rate will support a post-MECO dump TELP to a quantity sufficient to protect the OMS landing weight constraint (22 percent), perform same until He tank fail or maximum blowdown is achieved. A "post-MECO dump" implies the leak rate should support a dump to at least 49 percent at MET 15:00 minutes. 49 percent remaining provides enough ullage in the tank to use the tank in blowdown mode to 22 percent. 49 percent applies to engine no. 106 only. The quantity is, of course, engine specific and may vary ± 2 percent. The leak rate is extrapolated to MET 15:00 minutes. Fifteen minutes was chosen in order to provide the crew sufficient time to set up and complete the dump. The dump should be started ASAP post-MECO and should continue until He tank fail or maximum blowdown is achieved. Dumping post-MECO is generally preferred because it precludes any pre-MECO crew action. Still, if performing the dump pre-MECO will result in a net increase in delta V available, and if crew workload permits, consideration may be given to doing so. ©[072398-6518A]

Cutoff at minimum Hp which requires the least total delta V for the insertion and deorbit burns and ensures orbital lifetime at least two orbits beyond the first day PLS.

(Ref. Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS.) ©[ED]

If the leak rate will not support a post-MECO dump TELP to a quantity sufficient to protect the OMS tank landing weight constraint, a pre-MECO dump to maximum blowdown should be performed. For this case, the pre-MECO dump increases the OMS blowdown capability prior to He tank fail, thus resulting in a net increase in delta V available.

B. ONE OMS HELIUM TANK LEAK POST-OMS-2:**STD/DIRECT:**

Full blowdown may exist post OMS-2. If full blowdown does not exist, nominal orbit activities and/or an OMS burn may be used to maximize blowdown (ref. Rule {A6-201}, OMS/RCS LEAKING HE TANK BURN).

C. ONE OMS HELIUM TANK FAILURE PRIOR TO OMS-1:**STD:**

If a He tank fail occurs prior to OMS-1, only blowdown delta V is available in that system (approximately 15 fps for a full OMS load). Pre-flight analysis, based on OMS load and mass properties, determines the resulting abort mode capability on a flight specific basis.

If a pre-MECO OMS assist or ATO dump is required, the dump will be terminated in order to prevent exceeding the Y CG limit. ©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

DIRECT: ©[072398-6518A]

If an OMS assist or ATO OMS dump is required and an OMS He tank failure has occurred, the OMS assist or ATO OMS dump must be terminated. If the dump is completed, the Y CG will considerably exceed the limit.

If a He tank fail occurs prior to OMS-2, blowdown delta V is available in that system (approximately 15 fps for a full OMS load). Pre-flight analysis, based on OMS load and mass properties, determines the resulting abort mode capability on a flight specific basis.

D. ONE OMS HELIUM TANK FAILURE BETWEEN OMS-1 AND OMS-2.

OMS-2 is cut off at minimum Hp in order to assess available delta V to achieve steep deorbit and an acceptable orbit altitude.

E. ONE OMS HELIUM TANK FAILURE POST-OMS-2:

STD/DIRECT:

Full blowdown may exist post-OMS-2. OMS redlines must be assessed to determine whether all orbit activities can be accomplished.

F. TWO OMS HELIUM TANKS LEAKING/FAILED PRIOR TO OMS-1:

STD:

If both He leak rates will support OMS-1 and OMS-2, nominal OMS-1, -2 will be performed TETP

If both He tanks will not support OMS-1 and OMS-1, 2, the abort dump software will be utilized to increase the OMS blowdown prior to He tank fail. MCC is prime to recommend the pre-MECO dump based on an evaluation of both the leak rate and time to MECO. Performing the pre-MECO dump may result in the capability to achieve an ATO orbit with steep deorbit and nominal CG's versus aborting pre-MECO. ©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

If either He tank fails or a partial dump is performed, insufficient delta V may exist to achieve an ATO shallow or AOA steep. In this case, an abort will be performed according to the abort priorities (reference Rule {A2-52A}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES) TAL, if prior to last TAL boundary. After TAL boundary, TAL to an ACLS. If failures occur post-MECO, utilize optimum AOA shallow targets (minimum delta V requirement) if sufficient OMS blowdown plus ARCS to the PRESS QTY is available. If sufficient delta V is not available, a TAL to an ACLS/ELS is required.
 ©[072398-6518A]

DIRECT:

If pre-MECO OMS dump is required, continue dump TETP. For OMS assist/ATO dumps, when at maximum blowdown or He tank pressure < 640 psi, reconfigure dump to SEGP until remaining system at maximum blowdown or He tank pressure < 640 psi.

If both OMS He tanks are leaking, the abort dump software will be utilized to increase the OMS blowdown prior to He tank fail. MCC is prime to recommend the pre-MECO dump based on an evaluation of both the leak rate and time to MECO. Performing the pre-MECO dump may result in the capability to achieve an ATO orbit with steep deorbit and nominal CG's versus aborting pre-MECO.

If either He tank fails or a partial dump is performed, insufficient delta V may exist to achieve an ATO shallow or AOA steep. In this case, an abort will be performed according to the abort priorities (reference Rule {A2-52A}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES). TAL, if prior to last TAL boundary. After TAL boundary and pre-MECO, TAL to an ALCS. Post-MECO, AOA-shallow will be performed if sufficient delta V is available. OMS blowdown delta V with aft RCS supplement to AFT PRESS QTY will be used. If insufficient delta V is available for an AOA shallow, a TAL to an ACLS/ELS must be performed.

If uphill capability available (due to OMS load or pre-MECO dump) and either He tank pressure will be < 640 psi post-OMS-2, perform OMS-2 SESP. This will preserve the remaining system for deorbit. Determination of which system to use for OMS-2 is situation dependent. In general, if one He system will support through OMS-2, that system should be used. This will preserve the engine for a second start without violating OMS engine start box constraints (ref SODB Vol III, Para. 4.3.3.14). Target consideration for OMS-2 should include post-burn start box, cg and tank landing weight constraints.

If both He leak rates will support OMS-2, nominal OMS-2 will be performed TETP. Note: Nominally, maximum blowdown will not exist post-OMS-2, thus an additional dump may be required post-OMS 2.
 ©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

G. TWO OMS HELIUM TANKS FAILED BETWEEN OMS-1 AND OMS-2: @[072398-6518A]

STD:

Insufficient delta V exists to continue nominal ascent. Enough delta V may exist in the OMS pods supplemented with RCS to deorbit steep from minimum Hp. If steep targets cannot be met, shallow deorbit will be performed. Rationale in paragraph F also applies to this scenario.

H. TWO OMS HELIUM TANKS FAILED POST-OMS-2:

STD/DIRECT:

If maximum blowdown exists post-OMS-2, some portion of the mission may be supported. If maximum blowdown does not exist, shallow deorbit may be required with RCS supplement. OMS redlines must be assessed to determine whether orbit activities can be accomplished.

OMS HELIUM LEG LEAK

I. ONE OMS HELIUM LEG LEAK:

STD/DIRECT:

The intent of this rule is to maximize the blowdown available in the affected system with as few represses as possible. Each time the helium isolation valves are opened to repress the leaking leg, there is a possibility that the sudden increase in pressure in that leg will completely fracture the helium line, causing total loss of that helium tank. After OMS-1 and/or -2, the affected system should be at or below maximum blowdown. If the leak occurs on orbit, orbit activities would be used to bring the remaining propellant quantity down to maximum blowdown. However, if interconnect operations are used towards this end, only that blowdown capability predicted to be available at the next PLS TIG can be included in the planning for that deorbit. This is to avoid relying on a repressurization from the leaking helium leg to meet the deorbit redlines.

J. TWO OMS HELIUM LEG LEAKS: @[072398-6518A]

Same as single leak rationale.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)OMS GN₂ TANK -LEAK/FAIL ©[072398-6518A]K. ONE OMS GN₂ TANK LEAK/FAIL:

STD/DIRECT:

As long as the GN₂ tank can support an engine burn without affecting the accumulator pressure and subsequent one start capability, the affected OMS engine is available. GN₂ tank failures do not impact abort dumps since only one start is required for the OMS dump. If the GN₂ tank has failed, the OMS assist or ATO dump should be performed SEGP to save the last start for OMS or deorbit.

L. TWO OMS GN₂ TANK LEAKING/FAILED:

STD/DIRECT:

GN₂ tank failures do not impact abort dumps since only one start is required for the OMS dump. An OMS assist or ATO dump is canceled to reserve the OMS starts for OMS-1 and deorbit. ©[072398-6518A]

As long as the GN₂ tank can support an engine burn without affecting the accumulator pressure and subsequent one start capability, the affected OMS engine is available. If both OMS GN₂ tanks are failed prior to the scheduled burn, use one of the remaining OMS starts for OMS-1 and save the other start for the deorbit burn. After a safe orbit has been achieved, a tail-Sun attitude may be selected to warm up the OMS accumulator in an attempt to gain another OMS start (N₂ REG P > 299 is sufficient N₂ to operate engine ball valves).

Previous rules specified performing OMS-1 4+X for this case. The rule was changed to perform OMS-1 using one of the two remaining starts for the following reasons:

- a. *Provides redundancy (downmode from OMS to 4+X). If burn initially performed 4+X and a +X jet failure occurs, the remaining jets may not have the capability to perform uphill OMS-1 due to lack of thrust.*
- b. *Depending on the OMS-1 delta V, 4+X thrust may be insufficient to accomplish the burn (large underspeed cases).*
- c. *Saves propellant.*
- d. *Have the capability to change attitude while on orbit to warm up OMS GN₂ accumulator and increase the pressure to greater than 299 psi (299 allows one additional start).*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)OMS GN₂ ACCUMULATOR LEAK ©[072398-6518A]M. ONE OMS GN₂ ACCUMULATOR LEAK:

STD/DIRECT:

WSTF testing has shown that, if a GN₂ leak occurs through the purge valves at a rate of ? 14 psia/sec with the engine press valve closed (? 5 psia/sec with P valve open), sufficient cooling will be provided to the affected OMS engine and chamber wall burn through will not occur. As a result, the affected OMS engine can be used, but only for OMS-1 and deorbit. In addition, the GN₂ accumulator pressure must be > 260 psia preburn (ref. {A6-5}, OMS N₂ ACCUMULATOR). The engine will not be used for OMS-2 and on-orbit burns to preclude increasing the leak rate each time the purge valves are used and to preserve GN₂ for the deorbit burn. ©[ED] ©[ED]

Note that the WSTF data indicated a leak rate of 14 psia/sec through the purge valves will not significantly affect engine startup, operation, or shutdown. However, leak rates > 14 psia/sec were not tested due to concerns that the GN₂ tank did contain enough supply to support larger leak rates for an appreciable (deorbit-sized) OMS burn. There are also concerns of engine cooling at higher leak rates; however, no data or analysis exists to validate these concerns.

If the engine will not support the entire deorbit burn SETP, then it is not considered a valid deorbit downmode (ref Annex Flight Rule, OMS/RCS DOWNMODING CRITERIA) and RCS steep deorbit must be redlined. Otherwise, if RCS steep deorbit is not redlined and the good OMS engine fails during the deorbit burn, the burn cannot be completed SETP and RCS 4+X steep deorbit capability would not exist. In addition, if the leak rate increases, RCS steep deorbit must be redlined since there is no way to guarantee that the rate will not increase again and exceed 14 psia/sec. ©[ED]

If RCS steep deorbit must be redlined, nominal OMS-1 and OMS-2 will be performed only if sufficient OMS and RCS propellant margin is available to cover RCS deorbit from the nominal orbit. Propellant trade-offs as defined in Rule {A2-108}, CONSUMABLES MANAGEMENT, must also be considered when calculating the redline. If sufficient margin does not exist to cover RCS deorbit to steep targets, perform delayed ATO OMS-1 and OMS-2. Raise orbit within redlines. These calculations are performed preflight and are based on nominal MECO delta V's obtained from FDO's prior to flight. ©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A6-51****OMS FAILURE MANAGEMENT [CIL] (CONTINUED)**

If the leak rate cannot support the deorbit burn leaking engine, two pods from an $HP \geq$ safe HP, then a two OMS engines to one OMS engine downmode will not be available to complete the burn should the good engine fail. For this case, the leaking engine will experience a GN_2 depletion shutdown, and a subsequent downmode to RCS will be required. To avoid a GN_2 depletion shutdown (which carries a risk of unstable combustion), it is prudent in this case to not use the leaking engine for deorbit but instead to plan the burn SETP using the non-leaking engine. This not only provides a valid downmode to RCS for a subsequent engine failure but allows the use of existing procedures (one OME burn card, etc.). Attempting TETP downmode to RCS is not recommended due to the complications associated with real-time modification of procedures and downmode cues. ©[072398-6518A]

If the leak rate will support SETP from greater than safe H_p , then the engine may be used for deorbit with the condition that if the good engine fails above safe H_p but prior to having SETP completion, the burn must be stopped. ©[072398-6518A]

(Ref. SODB, Volume I, Paragraph 3.4.3.3-15.) ©[ED]

N. TWO OMS GN_2 ACCUMULATOR LEAKS**OMS 1/2 AND DIRECT:**

Delayed ATO targets are chosen for two GN_2 accumulator leaks in order to preserve the remaining GN_2 for the deorbit burn. The orbit may be raised using RCS jets within redlines. Sufficient GN_2 to complete the deorbit burn single engine must be available in each OMS pod in order to raise the orbit.

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)OMS PROPELLANT TANK LEAK/FAIL ©[072398-6518A]

O. ONE OMS PROPELLANT TANK LEAK/FAIL PRIOR TO END OF OMS-2:

STD:

Since pre-MECO ATO dumps may be required for ascent performance, the ATO dump should be continued SELP to avoid a TAL abort. The dump will burn a portion of the leaking propellant which prevents this propellant from being trapped onboard. Dumping the leaking propellant provides more ullage in the good tank of the affected pod. The ullage is required to allow mixed crossfeed. FDO must analyze the amount of propellant dumped during the ATO dump to determine whether an AOA or an ATO abort is feasible. The amount of delta V remaining (limited by the leak, quantity of propellant dumped, and Y CG) must quickly be calculated to determine whether sufficient delta V is available to perform delayed ATO OMS-1, -2 and deorbit shallow. RCS supplement should be considered (ref. Rules {A2-52}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES; and {A2-53}, FORWARD RCS USAGE GUIDELINES). If an AOA or ATO orbit cannot be achieved, a TAL abort must be performed.

Since delayed ATO targets require less delta V than nominal OMS-1, delayed ATO targets are used. OMS-1 is performed TETP for the following reasons: (1) cannot perform burn SELP because OMS-1 is a critical burn and redundancy is required, (2) cannot perform burn TELP because bad propellant WILL NOT be fed into a good system, (3) cannot perform burn entirely out of the good pod since it is desirable to use as much leaking propellant as possible. Post-delayed ATO OMS-1, the leaking pod should be dumped to depletion. Dumping the leaking pod prevents this propellant from being trapped onboard. As a result, more delta V is available from the good OMS pod without a Y CG impact. Post-delayed ATO OMS-1 Ha and Hp are usually high enough to provide sufficient stay capability to preclude a requirement for OMS-2 (assuming nominal MECO). Since a propellant leak may cool the pod to where an orbit 3 deorbit is not feasible, a safe orbit altitude which allows a 48-hour stay capability to sublimate leaked propellant may be required. If the pod thermal environment indicates freeze-up may occur and the current orbit does not provide 48-hour stay capability, raise orbit with FRCS. Deorbit using mixed crossfeed if required and available with RCS supplement.

If the tank fails at OMS-1 ignition, complete the burn SEGP. Deorbit using mixed crossfeed (if available and required).

Note that consideration may be given to executing the deorbit burn using mixed crossfeed if doing so will optimize overall performance and vehicle health (CG impacts, tank landing constraints, etc.).

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

DIRECT: ©[072398-6518A]

For cases where the amount of OMS delta V available from the non-leaking side, supplemented with RCS delta V above the Aft Press Quantity, is insufficient to protect a Press-to-Orbit (ref. Rule {A2-52}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES) which includes AOA Steep and ATO to Min Hp with FPLS or FD2 deorbit to shallow targets (ref. Rule {A4-56}, PERFORMANCE BOUNDARIES), a TAL abort must be declared. This case will typically occur for those missions that have the combination of a small OMS load, large ballast requirements, and large delta V requirements for the described scenario. Analysis must be performed post-dump to determine whether the trapped propellant on the leaking side might be able to offset any aft RCS ballast requirements.

Since pre-MECO ATO dumps may be required for ascent performance, the ATO dump should be continued SELP to avoid a TAL abort. The dump will burn a portion of the leaking propellant which prevents this propellant from being trapped onboard. Dumping the leaking propellant provides more ullage in the good tank of the affected pod. The ullage is required to allow mixed crossfeed. FDO must analyze the amount of propellant dumped during the ATO dump to determine whether an AOA or an ATO abort is feasible. The amount of delta V remaining (limited by the leak, quantity of propellant dumped, and Y CG) must quickly be calculated to determine whether sufficient delta V is available to perform delayed ATO OMS-1, -2 and deorbit shallow. Forward and aft RCS supplement to aft quantity-1 should be considered. If an AOA Steep or ATO orbit cannot be performed, a TAL abort must be performed.

Direct insertion ascent implies that an OMS-1 burn is nominally not performed. Since OMS-2 is not performed until approximately 43 minutes into the flight, the leaking propellant will be dumped ASAP post-MECO. Dumping the propellant prevents the weight of the propellant from being trapped onboard. As a result, all of the propellant in the good pod can be used without a Y CG impact. In addition, dumping the propellant reduces the likelihood of freezing the entire pod.

Since no propellant will be available for use in the leaking pod, OMS-2 will be performed SEGP. Cut off at minimum Hp which requires the least total delta V for the insertion and deorbit burns and ensures orbital lifetime at least two orbits beyond the first day PLS (ref. Annex Flight Rule, TRAJECTORY AND GUIDANCE PARAMETERS). Deorbit first day PLS if the leaking pod thermal environment allows. Most likely, pod thermal will indicate that an orbit 3 deorbit is not feasible. ©[ED]

If tank fail occurs prior to post-MECO dump or at OMS-2 ignition (all propellant trapped onboard), steep day 2 deorbit targets may be accomplished with RCS supplement and Y CG within limits.

Note that consideration may be given to executing the deorbit burn using mixed crossfeed if doing so will optimize overall performance and vehicle health (CG impacts, tank landing constraints, etc.).

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

P. ONE OMS PROPELLANT TANK LEAK POST-OMS-2: ©[072398-6518A]

STD/DIRECT:

A perigee adjust or out-of-plane burn is performed immediately in accordance with Flight Rule {A4-104}, OMS LEAK/PERIGEE ADJUST. Propellant should be dumped to depletion (? on crew display) in order to reduce the amount of propellant leaked into the pod and to minimize the amount of propellant that is trapped onboard.

Q. ONE OMS PROPELLANT TANK FAIL POST-OMS-2:

STD/DIRECT:

For a propellant tank failure during the deorbit burn, the deorbit burn must be terminated if the perigee is above a value calculated by FDO that will allow completion of the OMS burn. If above this PRPLT FAIL Hp, insufficient delta V remains in the OMS and RCS to complete the planned deorbit burn.

R. TWO OMS PROPELLANT TANKS LEAKING/FAILED:

STD:

For two OMS leaks in the same pod, treat as a single leak/fail realizing mixed crossfeed is not an option, see paragraphs O, P, and Q rationale.

For two OMS leaks on different sides, abort according to the abort priorities (ref. Flight Rule {A2-52A}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES). TAL, if prior to last TAL boundary. After TAL boundary and pre-MECO, a TAL to an ALCS will be performed. If the leaks occur post-MECO, perform optimum AOA OMS-1 shallow OMS-2. Use mixed crossfeed if available in order to keep the Y CG within limits. Aft RCS supplement to AFT PRESS QTY should also be used.

Note that consideration may be given to executing the deorbit burn using mixed crossfeed if doing so will optimize overall performance and vehicle health (CG impacts, tank landing constraints, etc.).
©[072398-6518A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

If two OMS leaks occur, different propellants and different sides, an ATO will not be attempted. Previously, delayed ATO was attempted if either leak rate supported delayed ATO OMS-1. A delayed ATO is not an option for the two leaks-different propellants and different sides. Consider the following scenarios:

- a. *Two OMS leaks, different propellant, different sides, and one leak rate supports delayed ATO OMS-1; delayed ATO OMS-2 is performed with RCS. 160 fps is required to satisfy shallow targets. No OMS delta V is available, however, since one pod was not used for OMS-1. As a result, no blowdown is available for mixed crossfeed deorbit from this pod. 44 fps RCS delta V was used for OMS-2. Therefore, only 57 fps RCS delta V remains. AS A RESULT, IF ONE LEAK RATE SUPPORTS DELAYED ATO OMS-1, THE DELAYED ATO IS NOT A VIABLE OPTION.*
- b. *Two OMS leaks, different propellant, different sides, and both leak rates support delayed ATO OMS-1; delayed ATO OMS-2 is performed with RCS. 160 fps is required to satisfy shallow targets. Only 70 fps is available in the OMS (limited by the amount of blowdown available in the good tanks for mixed crossfeed). 44 fps RCS delta V was used for OMS-2. Therefore, only 57 fps RCS delta V remains. The total delta V available is 127 fps, not enough to satisfy the 160 fps required for shallow deorbit. AS A RESULT, IF BOTH LEAK RATES SUPPORT DELAYED ATO OMS-1, THE DELAYED ATO IS STILL NOT A VIABLE OPTION.*
- c. *Two OMS leaks, different propellant, different sides, and both leak rates support nominal OMS-1; OMS-2 cutoff at 100 nm is performed with RCS. 130 fps is required to satisfy shallow targets. Only 90 fps is available in the OMS (limited by the amount of blowdown available in the good tanks for mixed crossfeed). 88 fps RCS delta V was used for OMS-2. Therefore, only 13 fps RCS delta V remains. The total delta V available is 103 fps, not enough to satisfy the 130 fps required for shallow deorbit. AS A RESULT, IF BOTH LEAK RATES SUPPORT NOMINAL OMS-1, NOMINAL OMS-1, OMS-2 CUTOFF AT 100 NM IS NOT A VIABLE OPTION.*

For two OMS leaks same propellant, the earliest abort option will be chosen since no OMS mixed crossfeed is available.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)**DIRECT:**

For two OMS leaks in the same pod, treat as a single leak/fail realizing mixed crossfeed is not an option, see paragraphs O, P, and Q rationale.

For two OMS leaks on different sides, abort according to the abort priorities (reference Rule {A2-52A}, ASCENT MODE PRIORITIES FOR PERFORMANCE CASES). TAL, if prior to last TAL boundary. After TAL boundary and pre-MECO, TAL to an ACLS. If the leaks occur post-MECO, an AOA must be performed. AOA delta V costs vary according to MECO Ha. As a result, RCS supplement may or may not be required. Again, mixed crossfeed will be used if required and available in order to maintain Y CG within limits. ®[072398-6518A]

Similar to the standard insertion case, an ATO will not be considered for the two leak case. Again, with two OMS leaks, insufficient blowdown delta V exist post-OMS-2 for a shallow deorbit.

OMS INLET LINE LEAK

S. ONE OMS INLET LINE LEAK PRIOR TO OMS-2: ®[072398-6518A]

STD:

Post-MECO, the leak will be secured to minimize propellant leakage into the pod. Since delayed ATO targets require less delta V than nominal OMS-1 with cutoff at $H_p = 100$, a delayed ATO OMS-1 is performed. OMS-1 is performed TETP for the following reasons: (1) should not perform SELP because OMS-1 is a critical burn and redundancy is required, (2) cannot perform burn TELP because bad propellant WILL NOT be fed into a good system, (3) do not perform burn SEGP since it is desirable to use as much propellant from the leaking system as possible. Post-delayed ATO OMS-1 Ha and Hp are usually high enough to provide sufficient stay capability to preclude a requirement for OMS-2 (assuming nominal MECO). Since a propellant leak may cool the pod to a point where a rev. 3 deorbit is not possible, an orbit altitude which allows 48-hour stay capability for propellant sublimation may be required. If the pod thermal environment indicates freeze-up may occur and the current orbit does not provide 48-hour stay capability, raise orbit with FRCS. In order to minimize repress cycles on the inlet line, a dump will be performed only if necessary to satisfy Orbiter CG envelope or OMS tank landing weight constraint. Deorbit using mixed crossfeed if required and available with forward and aft RCS supplement. Note that consideration may be given to executing the deorbit burn using mixed crossfeed if doing so will optimize overall performance and vehicle health (CG impacts, tank landing constraints, etc.).

If the inlet line repress fails at OMS-1, perform OMS-1 SEGP. Propellant tank fail rules now apply (see paragraphs O and Q).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)

DIRECT:

If the delta V available supports continuing to MECO, Post-MECO, the leak will be secured to minimize propellant leakage into the pod. Direct insertion implies that an OMS-1 is nominally not performed. To avoid a repress of the inlet line, OMS-2 is performed SEGP cutoff at minimum Hp. As in the OMS 1/2 case, a dump will be performed only if necessary to satisfy the Orbiter CG envelope or the OMS tank landing weight constraint. Deorbit using mixed crossfeed if required with forward and aft RCS supplement.

Note that consideration may be given to executing the deorbit burn using mixed crossfeed if doing so will optimize overall performance and vehicle health (CG impacts, tank landing constraints, etc.).

If the inlet line repress fails, propellant tank fail rules apply (see paragraphs O and Q). ©[072398-6518A]

T. ONE OMS INLET LINE LEAK POST OMS-2: ©[072398-6518A]

STD/DIRECT:

A perigee adjust burn is performed at the next opportunity to lower Orbiter altitude using the leaking propellant. Rule {A6-203}, OMS LEAKING INLET LINE PERIGEE ADJUST BURN, provides additional guidelines on the scheduling of the perigee adjust burn. If propellant remains after the perigee adjust burn, an out-of-plane dump may be performed if required to satisfy the Orbiter CG envelope or the OMS tank landing.

U. TWO OMS INLET LINES LEAKING:

STD:

For two OMS inlet line leaks in the same pod, treat as a single leak. Mixed crossfeed is not an option (see paragraphs S and T).

For two OMS inlet line leaks, different sides same propellant, an ATO will not be attempted since mixed crossfeed is not an option. Pre-MECO, the leaks will be treated as tank leaks. Post-MECO, optimum AOA targets will be used to minimize OMS propellant requirements. Attempt AOA OMS-1 and OMS-2 TETP.

For two OMS inlet line leaks, different sides different propellants, an ATO will be attempted since 4+X mixed crossfeed is available. A delayed ATO OMS-1 will be performed. Deorbit 4+X mixed crossfeed with aft RCS supplement to aft quantity-1.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-51

OMS FAILURE MANAGEMENT [CIL] (CONTINUED)**DIRECT:**

For two OMS inlet line leaks in the same pod, treat as a single leak. Mixed crossfeed is not an option (see paragraphs S and T).

For two OMS inlet line leaks, different sides, same propellant, an ATO will not be attempted since mixed crossfeed is not an option. The leaks will be secured post-MECO to minimize leakage into the pod and an AOA OMS-2 TETP will be attempted with RCS supplement if required.

For two OMS inlet line leaks, different sides, different propellant, an ATO will be attempted since 4+X mixed crossfeed is available. The leaks will be secured post-MECO to minimize leakage into the pod and an OMS-2 cutoff at minimum Hp will be performed. Deorbit 4+X mixed crossfeed with RCS supplement if required. ©[072398-6518A]

OMS ENGINE FAILURE:

V. **ONE OMS ENGINE FAILURE:** ©[072398-6518A]

STD/DIRECT:

If sufficient OMS and RCS propellant margin is available to redline RCS steep deorbit from the nominal orbit, then nominal OMS-1 and OMS-2 will be performed. Propellant trade-offs as defined in Rule {A2-108}, CONSUMABLES MANAGEMENT, must also be considered when calculating the redline. If sufficient margin does not exist to cover RCS deorbit to steep targets, perform delayed ATO OMS-1 and OMS-2. If the failure occurs during OMS-1, nominal OMS-1 must be completed. Perform OMS-2 cutoff at minimum Hp. Raise orbit within redlines.

These calculations are performed preflight and based on nominal MECO delta V's obtained from FDO's prior to flight.

W. **TWO OMS ENGINES FAILED:**

STD/DIRECT:

RCS +X is the last option for translation after both OMS engines have failed. RCS 4+X uses more OMS propellant than the OMS engines for an equivalent delta V due to Isp differences. Therefore, an ATO to minimum Hp is performed to minimize the delta V requirements. Deorbit is scheduled first day or next PLS opportunity because the next failure results in the loss of deorbit capability. ©[072398-6518A]

RCS FAILURE MANAGEMENT (CONTINUED)

FAILURE DEFINITION

FRCS HE TANK LEAK/FAIL:

- HE TANK LEAK IF PRESSURE > 456 PSI AND DECREASING ABNORMALLY.
- HE TANK FAIL IF PRESSURE < 456 PSI.
- FULL BLOWDOWN IF PROPELLANT TANK QUANTITY < 23 PERCENT.

ACTION SUMMARY

- A. ONE OR TWO HE SYSTEM LEAK PRIOR TO OMS-2:
1. PRE-MECO SECURE, RATE DAMP WITH ARCS.
 2. USE FRCS FOR ET SEPARATION, CANCEL +X TRANSLATION.
 3. USE UNTIL HE FAILED, THEN SECURE FRCS [1].
 4. USE RCS PROPELLANT CONSERVATION TECHNIQUES.
- B. ONE OR TWO LEAK POST-OMS-2:
1. PERFORM -X TRANSLATION OR FRCS DUMP TO ACHIEVE MAXIMUM BLOWDOWN UNTIL HE TANK FAIL.
 2. DESELECT FRCS JETS [1] UNLESS REQUIRED FOR HIGH PRIORITY ACTIVITIES.
 3. USE RCS PROPELLANT CONSERVATION TECHNIQUES.
 4. RESELECT FRCS JETS PRIOR TO DEORBIT.
 5. SECURE FRCS WHEN PROPELLANT TANK PRESSURE ? 190 PSI.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)

- C. ONE OR TWO FAIL PRIOR TO OMS-2:
1. PRE-MECO SECURE, RATE DAMP WITH ARCS.
 2. USE FRCS FOR ET SEPARATION, CANCEL +X TRANSLATION.
 3. POST-ET SEPARATION, SECURE FRCS [1]
 4. USE RCS PROPELLANT CONSERVATION TECHNIQUES.
- D. ONE OR TWO FAIL POST-OMS-2:
1. DESELECT FRCS JETS [1] UNLESS REQUIRED FOR HIGH PRIORITY ACTIVITIES.
 2. USE RCS PROPELLANT CONSERVATION TECHNIQUES.
 3. RESELECT FRCS JETS PRIOR TO DEORBIT.
 4. SECURE FRCS WHEN PROPELLANT TANK PRESSURE ? 190 PSI.

FRCS is critical for ET separation. Since very little blowdown capability exists at launch, the mated coast rate damping is performed using the ARCS maximizing the FRCS capability for ET separation. The MCC can determine if the helium tank will support a nominal mated coast/ET separation and will advise crew to open FRCS pre-MECO (maximizing blowdown) if the capability exists; otherwise the crew will perform mated coast with the ARCS. Once the helium tank has failed, the FRCS capability is drastically reduced. Therefore, propellant conservation techniques must be utilized to stretch mission duration. Sufficient blowdown capability is available to perform a successful ET separation.

Post-OMS-2, time is available to attempt a maximum blowdown burn to maximize FRCS capability for high priority on-orbit activities which require FRCS, in the entry preparation and deorbit burn timeframes.

The full blowdown quantity of 23 percent assumes use of the propellant tank to a pressure of 190 psi. (Reference SODB 4.3.2.1.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)**FAILURE DEFINITION****FRCS PROPELLANT TANK LEAK/FAIL:**

- PROPELLANT TANK LEAK IF QUANTITY DECREASE ABNORMAL.
- PROPELLANT TANK FAIL IF QUANTITY ? 0 PERCENT OR PRESSURE ? 190 PSI.

ACTION SUMMARY

E. ONE OR TWO LEAK:

1. SECURE, IF LEAK RATE CAN SUPPORT MATED COAST/ET SEPARATION, USE FRCS FOR MATED COAST AND ET SEPARATION. OTHERWISE, RATE DAMP WITH ARCS.
2. USE FRCS FOR ET SEPARATION. CANCEL +X TRANSLATION.
3. PERFORM FRCS DUMP TO DEPLETION, THEN SECURE FRCS [1].
4. USE RCS PROPELLANT CONSERVATION TECHNIQUES.

NOTE: IF THE LEAK RATE RESULTS IN A QTY < 52 PERCENT AT MECO, AND MECO CONDITIONS EXIST WHICH PROVIDE A DELAYED ET SEP CAPABILITY WITHOUT IMPACTING ORBITER PERFORMANCE (N/A RTLS, TAL), PERFORM DELAYED ET SEP (MECO + 6 MINUTES).

This rule allows using the FRCS to 0 percent versus performing a NO FRCS ET SEP by optimizing FRCS capability for ET SEP. The A/E FTP #48, 9/9/88, judged the risk of using the FRCS for ET SEP (when the computed quantity at MECO is < 52 percent) to be lower than the uncertified NO FRCS ET SEP procedure. Delaying ET SEP (MECO + 6 minutes) provides additional time to allow possible FRCS screen rewetting to occur. Rewetting the screens may prevent jet fail off's due to helium ingestion. If an RTLS, TAL, or underspeed conditions exist at MECO, an on-time ET SEP will be performed.

Same as paragraph A except apply propellant tank and perform FRCS dump to depletion. Dumping propellant overboard versus allowing propellant to leak into the FRCS module minimizes on-orbit cool down or postlanding fire hazard.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)

F. ONE OR TWO FAIL:

1. SECURE [1], RATE DAMP WITH ARCS.
2. PERFORM NO JET ET SEPARATION, CANCEL +X TRANSLATION.
3. USE RCS PROPELLANT CONSERVATION TECHNIQUES.

Loss of the FRCS for ET separation requires the use of a special technique to separate from the external tank.

FAILURE DEFINITION

ARCS HE TANK LEAK/FAIL:

- HE TANK LEAK IF PRESSURE > 456 PSI AND DECREASING ABNORMALLY.
- HE TANK FAIL IF PRESSURE < 456 PSI.
- FULL BLOWDOWN IF PROPELLANT TANK QUANTITY < 24 PERCENT.

ACTION SUMMARY

G. ONE LEAK/FAIL PRIOR TO OMS-2:

1. RATE DAMP AND ET SEPARATION IN NORMAL CONFIGURATION, CANCEL +X TRANSLATION.
2. WHEN HE TANK PRESSURE < 456 PSI PRE/DURING OMS-1 CROSSFEED FROM GOOD SIDE. POST-OMS-1, INTERCONNECT FROM OMS.
3. NOMINAL DEORBIT [2].
4. PRE-EI, CROSSFEED FROM GOOD SIDE.

The full blowdown quantity of 24 percent assumes use of the propellant tank to a pressure of 190 psi. (Reference SODB 4.3.2.1.)

Use mated coast/ET separation to increase the blowdown capability if the helium tank has not yet failed. If helium tank has failed, good pod RCS can be used for ET separation. However, the RCS entry redline has been violated due to loss of RCS in affected pod. Use OMS interconnect capability to conserve the remaining RCS for entry at the next PLS opportunity. Stay in interconnect configuration through OMS-2 and the deorbit burn.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)

H. ONE LEAK/FAIL POST-OMS-2:

1. INTERCONNECT FROM OMS.
2. IF LEAKAGE CANNOT SUPPORT NEXT PLS OPPORTUNITY, CROSSFEED FROM LEAKING RCS AND PERFORM +X TRANSLATION TO MAXIMUM BLOWDOWN. WHEN HE TANK FAILED OR MAXIMUM BLOWDOWN, INTERCONNECT FROM OMS THROUGH THE DEORBIT BURN. CROSSFEED FROM GOOD RCS FOR ENTRY.
3. IF LEAK CAN SUPPORT NEXT PLS, PRIOR TO DEORBIT, RECONFIGURE ARCS TO NORMAL FEED. IF HE TANK PRESSURE < 456 PSI, CROSSFEED FROM GOOD SIDE FOR ENTRY.
4. NOMINAL DEORBIT [2] [3].

Interconnect to OMS is required to enable MCC to establish a reliable leak rate. Once leak rate is determined, then the decision to perform a maximum blowdown burn or wait to the next PLS opportunity can be made. Regardless of the decision, stay in interconnect configuration to conserve RCS propellant in the good pod. Save affected pod blowdown for entry preparation and deorbit.

I. TWO LEAK/FAIL:

1. IF ON SAME SIDE, TREAT AS SINGLE LEAK/FAIL. SEE PARAGRAPHS G AND H.
2. IF LEAKING, CONTINUE TO USE TO MAXIMIZE ULLAGE UNTIL HE TANK FAILED.
3. IF SAME PROPELLANT, UPHILL ABORT [4].
4. IF DIFFERENT PROPELLANT, INTERCONNECT FROM OMS TO SAVE RCS ULLAGE. NOMINAL DEORBIT [2] [3], USE MIXED CROSSFEED FOR ENTRY.

Same as paragraph H. If same propellant in different pods, mixed crossfeed cannot be utilized to support entry.

With the OI-8 NO YAW JET software, a certified entry from a Q-bar = 20 to touchdown is now available. With this capability, previous abort calls for dual RCS He/propellant tank fail/leak can be avoided if control can be guaranteed through a Q-bar = 20. OMS interconnect is utilized from MECO until prior to EI for attitude control to minimize RCS propellant requirements.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52**RCS FAILURE MANAGEMENT (CONTINUED)**

The two He tank fail same propellant TAL abort case was eliminated. Sufficient blowdown is available to supply propellant requirements for EI to a $Q\text{-bar} = 20$ (available blowdown = 160 lb; required from EI to $Q\text{-bar} = 20$? 127 lb (based on review of GNC entry data)). An uphill abort cutting off at minimum H_p , which requires the least delta V for the insertion and deorbit burns and ensures orbital lifetime at least two orbits beyond the first day PLS, is selected to maximize the amount of OMS remaining to protect for interconnect operations post-deorbit burn. OMS remaining post-deorbit burn must be ? 10.3 percent (SODB 3.4.3.3.7.C) plus any expected usage.

The action is the same for one or both helium tanks leaking as for two He tanks failed. The rationale deals with the time to maximize blowdown in the leaking system(s). The time from MECO until a $Q\text{-bar} = 20$ on a TAL is 374 seconds (6.25 minutes) where if applied to a normal ascent would allow time to increase blowdown capability.

Two propellant tanks failed same propellant does not allow any type of certified entry. Since no control can be guaranteed, the most prudent action is the one that allows the most time and the most benign environment. By pressing uphill, time is gained to allow complex procedure and/or software changes to take place to help provide control until a $Q\text{-bar} = 20$ (i.e., DAP or procedure changes that will allow forward RCS control in pitch and yaw). A delayed ATO is selected to maximize the amount of OMS remaining to protect for interconnect operations post-deorbit burn.

For the cases of one propellant tank fail and the other leaking or both leaking same propellant yields a more complex case. If one pod contains 75 percent or more, ET separation can be performed in a timely and safe manner. The leak rate after ET separation must still support $Q\text{-bar} = 20$ to guarantee control until NO YAW JET can be engaged. If the leak rate supports TAL, the proper course of action is to abort TAL. If the leak rate does not support TAL, this case becomes the same as two propellant tanks failed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)

FAILURE DEFINITION

ARCS PROPELLANT TANK LEAK/FAIL:

- PROPELLANT TANK LEAK IF QUANTITY DECREASE ABNORMAL.
- PROPELLANT TANK FAILURE IF QUANTITY < 0 PERCENT OR PRESSURE < 190 PSI.
- NOMINAL OR ABORT ET SEPARATION: PROPELLANT TANK FAILURE IF QUANTITY < 75 PERCENT.

ACTION SUMMARY

J. ONE LEAK/FAIL:

1. PRE/DURING OMS-1, IF FAILED, CROSSFEED FROM GOOD RCS FOR ET SEP, CANCEL +X TRANSLATION.
2. POST-OMS-1, IF FAILED, INTERCONNECT FROM OMS.
3. PERFORM NOMINAL OMS-1 AND OMS-2.
4. PERFORM PERIGEE ADJUST OR OUT-OF-PLANE BURN IMMEDIATELY.
5. NOMINAL DEORBIT [2] [3].
6. IF FAILED, PRE-EI, CROSSFEED FROM GOOD RCS.

Crossfeed from good RCS to guarantee ET separation is accomplished. Then interconnect from OMS to conserve good pod RCS propellants. There is no reduction in the OMS delta V capability so a nominal ascent can be completed. However, deorbit will occur at the next PLS opportunity due to the violation of the RCS entry redline.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-52

RCS FAILURE MANAGEMENT (CONTINUED)

K. TWO LEAK/FAIL:

1. IF ON SAME SIDE, TREAT AS SINGLE FAILURE, SEE PARAGRAPH J.
2. INTERCONNECT FROM OMS, CANCEL +X TRANSLATION. POST-EI, FEED FROM RCS.
3. IF SAME PROPELLANT, SELECT RETURN, PRIORITY:
 - TAL/LATE TAL (IF LEAK RATE SUPPORTS ET SEPARATION AND ENTRY TO A Q-BAR = 20).
 - AOA (IF POST-MECO AND LEAK RATE SUPPORTS AN ENTRY TO A Q-BAR = 20).
 - ELS (IF LEAK RATE SUPPORTS AN ENTRY TO A Q-BAR = 20 CONSISTENT WITH RULE {A2-205}, EMERGENCY DEORBIT).
 - UPHILL ABORT [4].
4. IF DIFFERENT PROPELLANT, INTERCONNECT FROM OMS TO RCS TO SAVE RCS PROPELLANT. NOMINAL ENTRY [3]. USE MIXED CROSSFEED FOR ENTRY.

The rationale is the same as that for paragraphs I and J.

FLIGHT RULES

A6-53

OMS HELIUM INGESTION

FOR HELIUM INGESTION INTO THE OMS PROPELLANT TANK AFT COMPARTMENT AS REFLECTED IN AN OMS PROPELLANT TANK AFT QUANTITY DECREASE OF > 1.0 PERCENT FOR ANY SINGLE BURN WHEN OMS TANK QUANTITY > 45 PERCENT, OMS/RCS INTERCONNECT FROM THAT POD WILL NOT BE PERFORMED EXCEPT FOR DEORBIT.

The OMS bulkhead screen should not allow more than 1 percent of helium gas to enter the aft compartment for a single OMS burn. Experience to date has shown little or no gas transfer. A decrease in the aft quantity gauge > 1 percent during a burn when the propellant level covers the bulkhead screen indicates screen breakdown has occurred and further use of that tank without propellant settling burns is prohibited.

OMS tank propellant quantity less than 45 percent, RCS interconnect propellant usage may result in a decrease in OMS aft quantity (the forward compartment propellant may not be in contact with the bulkhead screen). With OMS propellant quantity less than 30 percent, there is no propellant remaining in the forward compartment and all usage will come from the aft compartment. In these cases, a decrease in the aft compartment quantity is not indicative of a screen failure. (Reference SODB, volume I, paragraph 3.4.3.3.)

FLIGHT RULES

A6-54

OMS PROPELLANT FAIL FEED CONSTRAINTS [CIL]

THE OMS CROSSFEED OR INTERCONNECT MODE WILL NOT BE USED TO FEED FROM A FAILED OR A SUSPECTED FAILED OMS PROPELLANT TANK AS LONG AS SHALLOW TARGETS, TANK LANDING WEIGHT CONSTRAINTS, AND CG LIMITS ARE PRESERVED. IF ANY OF THE ABOVE CONSTRAINTS ARE VIOLATED, THE INTERCONNECT MODE MAY BE USED TO ATTEMPT AN RCS +X PERIGEE ADJUST.

- A. ABOVE MINIMUM SAFE PERIGEE (SAFE HP), THE INTERCONNECT MODE MAY BE USED TO ATTEMPT AN RCS +X PERIGEE ADJUST. @[072398-6692A]

The only case of propellant blockage to date (STS-1) demonstrated that the screens present in the system are adequate to prevent migration of contaminants. STS-1 data showed that 50 percent of the OMS oxidizer inlet filter was blocked by contaminants with small traces downstream. The blockage may allow flow rate sufficient to support a +X translation while not supporting an OMS flow rate (+X OX=3.9 lb/sec and FU=2.4 lb/sec compared to OMS OX=12 lb/sec and FU=7.2 lb/sec, reference SODB tables 4.3.2-1 and 4.3.3-1 for flow rates). Troubleshooting can be performed by interconnecting to the L(R) RCS 1/2 leg. The OMS propellant might be able to support an RCS flow rate, thus avoiding an undesirable entry, (OMS propellant fail is not protected and can mean a shallow deorbit and no-yaw jet entry). For propellant contamination in the OMS to reach the RCS jets, it must pass through seven screens (two on each ac-motor valve and one at the inlet to the jet). This rule will also allow determination of a leak downstream of the ball valves that would appear as a propellant fail.

CIL retention rationale (FMEA 03-3-4002-1) addresses the case of propellant filter screens blocked by contamination. However, the conclusion of the March 9, 1995, PRCB was that by the time of the deorbit burn, the system has proved itself free of contaminants. Even so, propellant lines may be frozen by a small, undetected leak (ref. AEFTP #141, August 15, 1997), resulting in a propellant fail condition. For any OMS propellant fail (actual or suspected) above minimum safe perigee (safe hp), the CIL requirement is to stop the burn and troubleshoot the problem via interconnect. @[072398-6692A]

FLIGHT RULES

A6-54

OMS PROPELLANT FAIL FEED CONSTRAINTS [CIL] (CONTINUED)

- B. BELOW MINIMUM SAFE PERIGEE (SAFE HP), OMS CROSSFEED MAY BE ATTEMPTED FROM THE FAILED SYSTEM AFTER THE GOOD SYSTEM USABLE PROPELLANT HAS BEEN USED. ©[072398-6692A]

Once below safe Hp, the deorbit burn must be completed. The best immediate response is to terminate propellant wasting, ensuring the delta V from the remaining OMS is utilized efficiently. Still, because OMS propellant fail is not protected (Ref. All Flights Rule {A6-303B}, OMS REDLINES [CIL]), attempting completion of the deorbit burn using only the remaining systems (Good OMS + Aft RCS + Fwd RCS) will most likely violate one or more of the constraints listed above. It is prudent, therefore, to attempt a crossfeed from the failed system but only when the good system is nearly empty (i.e., 4 percent quantity remaining.) In that way, if the crossfeed is unsuccessful, almost no delta V has been lost in the attempt. However, if the failure proves not to have been a propellant failure, or if the blockage is below the crossfeed tee, the crossfeed will be successful and the deorbit burn can be completed normally. RCS interconnect to the failed system below minimum safe perigee should not be attempted since, should the interconnect not succeed, there is not sufficient time available to execute the necessary recovery procedures (staged manifold repress, failed jet recovery, etc.). ©[072398-6692A]

A6-55

OMS N₂ TANK FAILURE MANAGEMENT

FOR A FAILED OMS N₂ TANK, THE ASSOCIATED ENGINE WILL NOT BE USED UNTIL THE DEORBIT BURN IN ORDER TO CONSERVE THE FINAL ENGINE RESTART. IF N₂ REGULATOR PRESSURE > 366 (382) PSIA, TWO STARTS ARE POSSIBLE.

With an N₂ tank failure, a minimum of one OMS start remains in the accumulator. This start will be saved for the final engine burn in order to maintain OMS engine redundancy while on orbit. If the accumulator pressure is sufficient to support two OMS burns (N₂ regulator pressure > 366 (382) psi, 83 psi for the first start (no purge), and 283 psi for the last start and 16 psi instrumentation), the engine may be burned if subsequent failures dictate. A pressure of 366 (382) assumes that sufficient time is allowed between burns to allow the N₂ tank to return to equilibrium. Both burns will be 100 percent ball valves open. (Ref. Rules {A6-4}, OMS N₂ TANK; {A6-5}, OMS N₂ ACCUMULATOR; and {A6-56}, OMS N₂ REGULATOR FAILURE MANAGEMENT.) (Reference SODB, volume I, paragraph 3.4.3.3.15 and 4.3.3.1.d.)

FLIGHT RULES

A6-56**OMS N₂ REGULATOR FAILURE MANAGEMENT**

AN OMS ENGINE WITH INSUFFICIENT OMS N₂ ACCUMULATOR PRESSURE (N₂ REG PRESS < 283 (299) PSIA) TO OPEN BOTH BALL VALVES FULLY WILL NOT BE USED UNLESS THE OTHER ENGINE HAS FAILED AND THEN ONLY FOR THE DEORBIT BURN. IF THE OTHER OMS ENGINE HAS FAILED, N₂ ACCUMULATOR PRESSURE ON THE REMAINING OME MUST SUPPORT 90 PERCENT BALL VALVE OPENING (N₂ REG PRESS > 270 (270) PSIA).

Lower than 100 percent ball valve opening will result in off-nominal start characteristics. The risk of using an engine with < 100 percent ball valve opening is only acceptable if it is the last OME available for the deorbit burn. If an OMS engine has failed and the other will support 90 percent opening (N₂ Reg P > 270 (270) psia), then the risk versus risk tradeoff is between 90 percent OME ball valve opening (no regulator pressure instrumentation) and RCS deorbit. The 90 percent OME is preferable in this case. If the last remaining OME can only support < 90 percent, then an RCS deorbit must be performed since performance drops off drastically at lower N₂ or accumulator pressures. At 228 psia with pressurization valves open (246 psia if closed), the ball valves only open to 70 percent with greater than 1/2 second transition time. Engine starting characteristics are unacceptable with this slow opening time. Reference Rules {A6-5}, OMS N₂ ACCUMULATOR; and {A6-55}, OMS N₂ TANK FAILURE MANAGEMENT. (Reference SODB, volume I, 3.4.3.3.14, and volume III, table 4.3.3.)

FLIGHT RULES

A6-57

AFT RCS PROPELLANT TANK FAIL/HELIUM INGESTION

A. MATRIX:

PRE-MECO TANK QUANTITY (PERCENT)	RTL5	ASCENT	ORBIT	ENTRY
QTY >75	? NOM ET SEP	? NOM ET SEP	? NOM ORBIT OPS	? NOM ENTRY
QTY <75	? XFEED FROM GOOD RCS FOR ET SEP ? AFFECTED POD AVAIL FOR GRTL5 IF REQ'D	? XFEED FROM GOOD RCS FOR ET SEP ? POST-OMS-1 INTERCONNECT FROM OMS	? PRIMARY JETS: INTERCONNECT FROM OMS OR XFEED FROM GOOD RCS ? VERNIER JETS: NOM ORBIT OPS	? AFFECTED POD AVAIL POST-EI

B. RULES:

1. AN RCS TANK WILL BE CONSIDERED FAILED FOR ET SEPARATION IF PRE-MECO TANK QUANTITY < 75 PERCENT. ET SEPARATION WILL BE PERFORMED IN CROSSFEED FROM GOOD RCS.

An analysis has been completed based upon the RCS tank redesign (addition of abort helium diffusers and deletion of abort ducts) and recertification of the ARCS tanks. The analysis has shown that a gauge quantity of less than 75 percent prior to MECO results in a gas "short" to the lower compartment (L/C) and large quantities of gas will transfer to the L/C prior to the start of mated coast external tank separation (MC/ET SEP). Usage from tanks in this condition should be avoided during MC/ET SEP by crossfeeding from the good side to prevent possible jet fail because of helium ingestions. Reference SODB, volume I, paragraph 3.4.3.2-14.c.

2. AN RCS TANK SUSPECTED TO HAVE INGESTED HE:
 - a. CAN BE USED DURING ENTRY (POST-EI) WITH NO RESTRICTIONS OTHER THAN TO ACCOUNT FOR INCREASED TANK RESIDUALS (LOSS OF PROPELLANT PRIOR TO MECO WILL INCREASE TANK RESIDUALS BY 11 PERCENT).

The additional gas that transfers to the L/C will impact the tank entry expulsion efficiency by as much as 11 percent. However, during entry the gravitational force will hold the propellant over the tank outlet preventing helium ingestion and allowing use of the tank.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-57

AFT RCS PROPELLANT TANK FAIL/HELIUM INGESTION (CONTINUED)

- b. CAN BE USED FOR VERNIER JET OPERATIONS.
- c. WILL NOT BE USED FOR PRIMARY JET ORBIT OPERATIONS.

Since the vernier jets do not result in an excessive delta pressure across the RCS bulkhead screens to cause screen breakdown, verniers may be used for on-orbit operations. Rule {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEM FAILURES [CIL], references this rule.

A6-58

RCS REGULATOR FAILURE TROUBLESHOOTING

THE FORWARD AND AFT RCS WILL NOT BE OPERATED IN BLOWDOWN MODE TO TROUBLESHOOT A REGULATOR PATH IF A REDUNDANT PRESSURE PATH EXISTS.

There will be no troubleshooting for an RCS regulator flow path unless additional failures restrict the remaining flow path. Crew actions and flight impact are independent of the failure mode determined by troubleshooting the system. It is not prudent to expose the system to off-nominal operating conditions during troubleshooting when no real procedural advantage can be realized.

FLIGHT RULES

A6-59

LOSS OF AFT RCS LEAK DETECTION

RCS CROSSFEED OR OMS/RCS INTERCONNECT WILL BE UTILIZED DURING CREW SLEEP PERIODS FOR THE LOSS OF SINGLE ARCS POD LEAK DETECTION CAPABILITY.

During crew sleep periods, by crossfeeding or interconnecting to a good system (RCS or OMS respectively), use of the system with no leak detection capability available can be avoided and the feeding system leak detection capability can be utilized.

Because of SMS limitations and inability to model thermal effects, training in propellant leak detection has typically been limited to annunciation of pressure decays with no associated temperature decrease. For small leaks, we feel that temperature will be our only indication. For large leaks, cooling will certainly accompany the pressure decay. Therefore, with the existing temperature sensors and associated FDA, we believe the primary means for leak detection will be thermal monitoring.

The philosophy to terminate interconnect prior to crew sleep was changed prior to STS 41-B because of newly identified crossfeed line surge pressure concerns and the desire to minimize the number of times the interconnect mode was established. In addition, a better understanding of the pod thermal effects as a result of propellant leakage resulted in an increased confidence that small leaks would be more readily detectable through thermal indications rather than the standard pressure decay (reference APU HYDRAZINE LEAK ON STS 41-A). Consequently, we feel that maintaining interconnect operations during sleep periods can be accomplished safely while at the same time maintaining an adequate leak detection capability with associated crew FDA.

During crew-awake periods, the RCS propellant tank pressure FDA may be used to provide leak detection by isolating the helium tank and forcing the RCS to operate in a blowdown mode. This allows propellant to be used from the degraded system while still providing leak detection capability. Also, because the RCS has much less ullage than the OMS, less propellant would be leaked prior to annunciation when operating with the RCS in blowdown than when interconnected from the OMS.

FLIGHT RULES

A6-60

RCS MANIFOLD CLOSURE CRITERIA

RCS MANIFOLDS MAY BE CLOSED FOR THE FOLLOWING CONDITIONS:

RCS manifolds are nominally open. Manifolds that have been closed may cause complications if they are reopened after the manifold pressure significantly decreases due to a temperature change or a leak. A high pressure spike will be transmitted through the manifold when the manifold valve is reopened. If the pressure spikes are large enough, thruster valve bounce may occur resulting in propellant leakage.

Therefore, the manifolds are only cycled for the following identified cases.

** Note: There is no concern with vernier manifold pressure spikes and no concern with rupturing the primary manifold bellows. (Some test data indicate primary thruster valves may only bounce if helium gas is in the injector valve.)*

A. SYSTEM LEAK TROUBLESHOOTING.

Current leak isolation procedures require manifold isolation valves to be closed. In the event of a manifold leak, the manifold valve must be closed to prevent any further leakage. If the leak was not in the manifold, the manifold valve can be reopened with no damage to the failed system.

B. ISOLATION OF RM INDICATED FAILED-ON JET (FOR VERIFIED FAILED ON JET, MANIFOLD WILL NOT BE OPENED).

For an RCS jet failed on, the associated manifold valve must be closed to prevent excessive propellant usage and attitude control problems.

For false fail-on indications, the manifold can be reopened. MCC should then consult Rule {A6-156}, RCS RM LOSS MANAGEMENT.

For real fail-on jets the manifold will be evacuated when closed. If the failure has been cleared and the affected manifold is required to be GO for on-orbit operations, a GMEM procedure is available to repressurize the evacuated manifold. Consult Rule {A6-61}, RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL].

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-60

RCS MANIFOLD CLOSURE CRITERIA (CONTINUED)

- C. ISOLATION OF RM INDICATED LEAKING JET.
1. IF DIVERGENCE OCCURS BETWEEN OXIDIZER AND FUEL QUANTITIES.
 2. IF CORRESPONDING NONLEAKING INJECTOR TEMPERATURE DROPS BELOW 40 DEG F.
 3. IF INJECTOR TEMPERATURES AND CHAMBER PRESSURE SIGNATURES INDICATE BOTH INJECTOR VALVES ARE LEAKING.
 4. IF LEAK RATE IS OF THE MAGNITUDE THAT RESULTS IN PLUGGING OF THE CHAMBER THROAT AS INDICATED BY CHAMBER PRESSURE AND INJECTOR TEMPERATURES.

Normally no action is taken if a jet should fail leak. The injector valves are pressure assisted by design. Maintaining system pressure on the valve provides the best seal possible at the injector valve seat which may help seal the leak. Also, it is undesirable to close the manifold isolation valve because of the loss of additional RCS jets on that manifold (RCS RM declares the jets unavailable if manifold isolation valves are closed). If the manifold isolation valve were to be closed, the isolated manifold pressure would quickly decrease because of the leak.

The manifold isolation valve shall be closed if any of the following conditions are met:

- a. *To isolate the leaking jet from the system should a divergence be detected between the oxidizer and fuel quantities.*
- b. *To prevent ZOTS from occurring if both injector valves should start leaking. Due to the evaporative cooling effect of the initial propellant leak, the temperature of the nonleaking engine valve will tend to decrease. Should the second propellant valve begin to leak due to cold temperature, the resulting dual propellant leak can have very undesirable effects, such as valve ZOT. The minimum temperature reached by the nonleaking valve is primarily a function of the leak rate of the leaking valve. Thus, for a leaking jet, the nonleaking valve/injector temperature differential cannot be determined. The 40 deg F limit represents best engineering judgment for the minimum acceptable injector temperature for the nonleaking valve. ©[091098-6708]*
- c. *To prevent off-nominal combustion in the chamber due to both valves leaking, as evidenced by injector temperature and chamber pressure. ©[091098-6708]*
- d. *To prevent second valve leakage due to initial valve leakage causing blockage of the chamber throat. Blockage of the chamber throat will cause pressure to build up on the outside portion of the seal of the nonleaking valve, thus reducing its sealing force.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-60

RCS MANIFOLD CLOSURE CRITERIA (CONTINUED)

D. SYSTEM SECURING AS A RESULT OF POWERDOWNS.

Orbiter failures resulting in powerdown of electrical buses may cause the loss of RCS jet heaters and/or jet injector temperatures. Loss of the jet heaters will allow the jets to cool and the injector valve Teflon seals to shrink. When injector temperatures reach approximately 47 deg F, leakage may occur preventing future use of the jet (ref. Rule {A6-257}, RCS JET TEMPERATURE MANAGEMENT). Special hot fire procedures could be utilized to warm the jets but may be impractical because of the numerous jets affected. The manifold valves can be closed reducing propellant leakage into the jet.
@[091098-6708]

E. UNRECOVERABLE LOSS OF:

1. COMMAND PATH TO ALL JETS ON A MANIFOLD.
2. ELECTRICAL POWER (BOTH REDUNDANT SOURCES) TO A REACTION JET DRIVER (RJD).
3. RJD FUNCTION TO ALL ITS ASSOCIATED JETS.

These three cases lose all jets on a single manifold. No additional jets can be lost because of the manifold closure. Thus no additional capability is lost and the manifold will remain closed to protect against leaks or jet failures.

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL]

A. RCS MANIFOLD REPRESSURIZATION MANAGEMENT:

1. GENERAL:

- a. MANIFOLDS WILL BE REPRESSURIZED DIRECTLY FROM THE TANK VOLUME USING THE MANIFOLD ISOLATION VALVE ANYTIME BOTH THE MANIFOLD PRESSURES > 130 PSIA.

Tests conducted at WSTF revealed that when repressurization of a manifold was attempted with an initial manifold pressure < 50 psia and the tank pressure approximately 245 psia, the thruster valves bounced, leaking propellant into the combustion chamber. The uncontrolled leaking of oxidizer or fuel into the chamber can lead to oxidizer/fuel detonation in the injector passage (ZOT's). The concern is that the fuel will stay in the oxidizer injector passages and will not vaporize prior to the oxidizer reaching the jet (vapor pressure: oxidizer = 15 psi; fuel = 0 psi). Consequently, combustion will take place in the injector instead of the chamber, leading to thruster valve damage and propellant leaks. Based on these concerns and the test results, it was agreed in flight techniques to use special procedures (stage repress) if time permits for repressurization of manifolds where both the oxidizer and fuel manifold pressure < 130 psia (130 = 50 pressure + 50 pad + 30 instrumentation). Repress via the manifold isolation valve will be performed only if mandatory for attitude control during time-critical phases. There is no restriction against repressing manifolds if the manifold pressure > 130 psia.

- b. SIMULTANEOUS REPRESSURIZATION OF MORE THAN ONE SET (OXIDIZER AND FUEL) OF EVACUATED MANIFOLDS FROM AN RCS TANK IS NOT ALLOWED.

Simultaneous repressurization of evacuated manifolds is not allowed. Two evacuated manifolds repressed at WSTF resulted in an RCS tank bulkhead delta pressure > 7.0 psid (spec limit = 3.7 psid). This could result in damage to the bulkhead, resulting in broken screens, helium gas ingestion into the jets, jet failure, and subsequent loss of the tank.

- c. VERNIER MANIFOLDS WILL BE REPRESSURIZED USING THE MANIFOLD ISOLATION VALVE IF THE VERNIER JETS ARE OTHERWISE AVAILABLE FOR NORMAL ON-ORBIT OPERATIONS.

There is no constraint against repressing a vernier manifold. The vernier thruster valves are solenoid, not pilot operated, and do not bounce when subjected to large pressure spikes. The vernier alignment bellows spec limit was exceeded during repress tests at WSTF, but resulted in no damage. As long as the vernier jet capability is not precluded by another system failure, vernier manifolds will be repressed as required.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION
[CIL] (CONTINUED)

- d. LEAKING LINES WILL NOT BE REPRESSURIZED UNLESS MANDATORY FOR VEHICLE CONTROL.

The risks associated with leaking propellant into an OMS pod or forward RCS module do not warrant feeding a leak if the flow path is not mandatory to maintain vehicle control. Leaking lines should not be repressed to gain redundancy. The corrosive effects of oxidizer (N₂O₄), along with structural integrity (bulkhead delta P) concerns and toxicity, make it undesirable to feed an OX leak unless mandatory. The fire, explosive, and toxicity hazards of the fuel (mmH) make it undesirable to feed a fuel leak unless mandatory. Leakage of either propellant in a vacuum environment may cause freezing of other pod components resulting in loss of additional propulsion capability.

2. INDIVIDUAL OXIDIZER OR FUEL MANIFOLD PRESSURE < 130 PSIA:

MANIFOLDS WILL BE REPRESSURIZED DIRECTLY FROM THE TANK USING THE MANIFOLD ISOLATION VALVE EXCEPT IF CAUSED BY A JET FAIL LEAK OR PROPELLANT LEAK. MANIFOLD(S) WILL BE REPRESSURIZED IF REQUIRED FOR ET SEPARATION OR ENTRY CONTROL.

ANYTIME IF MANDATORY TO MAINTAIN ATTITUDE CONTROL.

Repressing a manifold where an individual oxidizer or fuel manifold pressure < 130 psia and the other pressure > 130 psia is allowed using the manifold isolation valve. For this case, the expected valve bounce will only occur on the affected propellant manifold, leaking only oxidizer or fuel into the chamber. The presence of one propellant does not represent a ZOT risk if the propellant sublimates and clears the chamber before further jet use. Oxidizer will clear the chamber in approximately 10 seconds while fuel takes 1 to 2 minutes.

Manifolds will not be repressed on orbit if the manifold pressure decay was caused by a propellant leak. Repressing the manifold may increase the leak rate. For jet leaks, manifolds may be repressed in an attempt to put pressure on the injector valve, possibly sealing the leak. These manifolds can be repressed during entry if mandatory for control.

3. BOTH OXIDIZER AND FUEL MANIFOLD PRESSURE < 130 PSIA:

- a. AN EVACUATED MANIFOLD CAUSED BY A JET FAIL-ON WILL NOT BE REPRESSURIZED UNLESS THE FAILURE HAS BEEN CLEARED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION
[CIL] (CONTINUED)

b. MANIFOLDS WILL BE REPRESSURIZED DIRECTLY FROM THE TANK USING THE MANIFOLD ISOLATION VALVE:

- (1) ANYTIME IF MANDATORY TO MAINTAIN ATTITUDE CONTROL.
- (2) DURING NOMINAL/RTLS ASCENT IF REQUIRED FOR ET SEPARATION. (SEE RULE {A8-55}, ET SEPARATION RCS REQUIREMENTS.)

NOTE: MANIFOLDS WILL NOT BE REPRESSED TO REGAIN REDUNDANCY. MULTIPLE MANIFOLDS WILL BE REPRESSED IF REQUIRED FOR ET SEPARATION OR ENTRY CONTROL.

c. INADVERTENT EVACUATED MANIFOLDS WILL BE REPRESSURIZED ON ORBIT USING A READ/WRITE PROCEDURE IF REQUIRED TO BE GO TO STAY ON ORBIT.

d. A STAGED REPRESSURIZATION PROCEDURE WILL BE USED ON ORBIT TO REPRESSURIZE MANIFOLDS AT VAPOR PRESSURE (LIQUID IN LINES).

A staged repressurization or read/write procedure will be used on orbit to repressurize desired manifolds where both the oxidizer and fuel manifold pressures are < 130 psia. The staged repressurization procedure is only effective if liquid exists in the lines and will not work for an evacuated manifold. The manifold is repressurized using the line volume between the tank isolation valves and the manifold isolation valves until a manifold pressure > 130 psia is achieved. (If the manifold pressure is not above vapor pressure after the first cycle of the staged repressurization procedure, the manifold may be partially evacuated and the staged repressurization procedure will not work.) Repressurization directly from the tank is acceptable after manifold pressures are > 130 psia. The read/write procedure allows the inadvertent evacuated manifold to be repressurized on orbit without the risk of a ZOT occurring. The GMEM procedure consists of opening the oxidizer tank isolation valve prior to the fuel isolation valve, allowing the oxidizer to sublime before the fuel arrives at the jet. These procedures will not be attempted in time-critical phases. Deorbit preparation OPS 3 transition has been baselined as the point at which these special procedures will no longer be utilized. The manifold isolation valve will be used to repressurize a manifold directly from the tank volume during time-critical phases. Confirmed jet fail-on evacuated manifolds will not be repressurized due to excessive propellant consumption and the possibility of further jet and RCS propellant tank damage. However, jet fail-on evacuated manifolds will be repressurized if the failures have been cleared (no driver out command with the RJD power on). The inadvertent evacuated manifold repressurized actions should be used in this case.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL] (CONTINUED)

B. OMS/RCS CROSSFEED LINE REPRESSURIZATION MANAGEMENT [CIL]:

	FUEL PRESSURE					
	> 130 PSIA		< 130 PSIA AND > 35 PSIA		< 35 PSIA	
OXID PRESSURE > 130 PSIA	[1]		[1]		[3]	[4]
OXID PRESSURE < 130 PSIA AND > 49 PSIA	[1]		[2]	[5]	[4]	[6]
OXID PRESSURE < 49 PSIA	[3]	[4]	[4]	[6]	[4]	[6]

NOTES:

- [1] NOMINAL OPERATIONS ALLOWED.
- [2] CROSSFEED LINE AVAILABLE FOR INTERCONNECT/CROSSFEED OPERATIONS SUBJECT TO RCS MANIFOLD REPRESS CONSTRAINTS.
- [3] REPRESSURIZATION OF RCS MANIFOLDS ALLOWED FROM THE RCS USING THE MANIFOLD ISOLATION VALVES ONE MANIFOLD AT A TIME. (REF. PARAGRAPH A.)
- [4] REPRESSURIZATION OF CROSSFEED NOT ALLOWED UNLESS CRITICAL FOR CREW SAFETY.
- [5] REPRESSURIZATION OF RCS MANIFOLDS ALLOWED USING RCS OR OMS STAGED REPRESSURIZATION PROCEDURE. (REF. PARAGRAPH A.)
- [6] REPRESSURIZATION OF RCS MANIFOLDS ALLOWED USING RCS STAGED REPRESSURIZATION PROCEDURES ONLY. (REF. PARAGRAPH A.)

1. RCS MANIFOLD PRESSURES WILL BE USED ON ORBIT TO DETERMINE THE GO/NO-GO STATUS OF THE CROSSFEED LINE PRIOR TO REPRESSURIZATION DIRECTLY FROM THE PROPELLANT TANK.

All 10 manifolds are used because analysis indicates if the crossfeed pressure were at a minimum because of thermal cycles, the pressure contained in the volume of 10 manifolds is sufficient to bring the crossfeed pressure up to within acceptable limits without a special staged repressurization procedure. There are pressure transducers on the crossfeed lines; however, when the lines are isolated, thermal cycles cause the pressures of the hydraulically locked-up lines to cycle significantly. The crossfeed line pressure transducers have a large instrumentation error (34 psia); and, when the lines are isolated, the fuel line pressure frequently indicates below the sum of the vapor pressure (1 psia) and the instrumentation error. The RCS manifold pressures are, therefore, used as a pressure check at the time of interconnect or crossfeed. Note that when the RCS manifolds are opened to the crossfeed lines, the RCS tank isolation and OMS crossfeed valves are closed, alleviating the concern of a pressure surge from a large pressurant source and ullage. An average pressure of all oxidizer manifolds will be used as the oxidizer crossfeed line pressure for evaluation. An average will also be used for the fuel crossfeed line pressure. Instrumentation bias must also be considered prior to averaging the pressures.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION
[CIL] (CONTINUED)

- a. OXIDIZER OR FUEL MANIFOLD PRESSURES < 15 (49) PSIA OXIDIZER OR < 1 (35) PSIA FUEL. THE CROSSFEED LINE WILL BE CONSIDERED FAILED FOR FURTHER ON-ORBIT OPERATIONS UNLESS CRITICAL FOR CREW SAFETY. DEORBIT WILL BE SCHEDULED AT THE NEXT PLS.

If the oxidizer pressure is < 49 psia and/or the fuel pressures < 35 psia, repress of the OMS crossfeed line from a high pressure tank is not allowed. A staged repressurization may be attempted to increase the crossfeed pressures to within acceptable limits. If the staged repressurization is unsuccessful, the crossfeed line will be declared failed. The pressure limits are based on an instrumentation error of 34 psia and vapor pressure of 15 psia for the oxidizer and one for the fuel. WSTF tests have verified that repressurizing a crossfeed line at pressures less than propellant vapor pressure is known to create unacceptable large surge pressures and must be avoided if possible. (Reference SODB 3.4.3.3.17.)

Flight Rules require two methods of deorbit capability to be go past the next PLS. Because of the crossfeed line failure, there will be no downmode capability for an OMS engine failure during the deorbit burn. (Reference Rule {A6-358}, VIOLATION OF MISSION COMPLETION REDLINES MATRIX.)

- b. OXIDIZER AND FUEL MANIFOLD PRESSURES > 15 (49) PSIA OXIDIZER OR > 1 (35) PSIA FUEL. THE CROSSFEED LINE IS AVAILABLE FOR INTERCONNECT/CROSSFEED OPERATIONS SUBJECT TO RCS MANIFOLD REPRESSURIZATION CONSTRAINTS. (REF. PARAGRAPH A.)

For crossfeed pressures > 49 psia oxidizer or > 35 psia fuel, there are no crossfeed line constraints. However, the RCS manifolds require a staged repressurization when both propellants are < 130 psia. The staged repressurization procedure will prevent surge pressures from bouncing the jet injector valves and causing a ZOT. An OMS staged repressurization procedure exists that allows the repressurization of all 10 RCS manifolds simultaneously rather than one at a time. (Ref. paragraph A.)

2. THE OMS CROSSFEED LINE WILL BE USED INDEPENDENT OF THE CROSSFEED LINE PRESSURE FOR MANEUVERS CRITICAL FOR CREW SAFETY, ABORT PROPELLANT DUMPS, OR IF REQUIRED, TO MAINTAIN ATTITUDE CONTROL.

Any interconnect or crossfeed required for crew safety will be executed without regard to the crossfeed line pressure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-61

RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL] (CONTINUED)

3. THE OMS CROSSFEED LINE WILL NOT BE USED TO SUPPORT MISSION SUCCESS ACTIVITIES (CROSSFEED/INTERCONNECT) UNTIL AN ACCEPTABLE CROSSFEED LINE PRESSURE HAS BEEN VERIFIED.

The OMS crossfeed line will not be used to support mission success activities (crossfeed/interconnect) until a satisfactory pressure check has been performed. This includes on-orbit crossfeed burns (planned or as a result of an engine failure). The risk of structural damage as a result of excessive surge pressures (i.e., no crossfeed pressure check) will only be accepted if the crossfeed is required to maintain crew safety.

Rules {A2-54B.3}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]; and {A6-60}, RCS MANIFOLD CLOSURE CRITERIA, reference this rule.

A6-62

OMS/RCS CONTINUOUS VALVE POWER MANAGEMENT

WHEN DETECTED, CONTINUOUS POWER TO AN OMS/RCS AC MOTOR VALVE WILL BE REMOVED ACCORDING TO THE FOLLOWING GUIDELINES:

- A. BY PLACING THE APPROPRIATE SWITCH IN GPC, OR
- B. IF "A" IS UNSUCCESSFUL AND CONTINUOUS POWER OCCURRED DURING A NONCRITICAL RECONFIGURATION PERIOD, BY PULLING THE APPROPRIATE AMC POD BUS CIRCUIT BREAKERS.

CIRCUIT BREAKERS PULLED UNDER "B":

1. WILL BE RESET DURING CRITICAL RECONFIGURATION PERIODS.
2. MAY BE RESET IF VALVE MOVEMENT IS REQUIRED.

A CRITICAL RECONFIGURATION PERIOD IS DEFINED AS MM 102 TO 105, MM 302 THROUGH THE OPS 9 TRANSITION, RENDEZVOUS, OR ORBIT BURNS REQUIRING A NON-STRAIGHTFEED DOWNMODE.

Continuous power is detectable only through ground monitoring of MCA logic status discrettes. A reading of "0" for an unexpected length of time indicates the presence of a continuous power situation. Analysis indicates that continuous power on a valve in conjunction with a fuel leak through the valve bellows may result in auto-decomposition of mmH. Since bellows leaks are not detectable in flight, removing power minimizes the potential hazard. Tests to date have not yet resulted in auto-decomposition of mmH. Therefore, during critical reconfiguration periods where immediate OMS/ RCS valve movement is required, the circuit breakers will be reset. Use of the switch to remove power is preferred over pulling the circuit breakers, since it affects only a single valve. Pulling of the AMC pod bus circuit breakers affects only OMS/RCS valve functions.

FLIGHT RULES

A6-63**RCS BFS PVT INIT PRELAUNCH CRITERIA**

RCS PVT INIT TMBU WILL BE UPLINKED PREFLIGHT IF THE I-LOADED WEIGHT OF THE INITIAL (WHI) RCS QUANTITIES DIFFER FROM THE ACTUAL LOADED RCS QUANTITIES BY GREATER THAN 3 PERCENT (HIGHER OR LOWER). ALL RCS QUANTITIES WILL BE CORRECTED WHEN AN UPLINK IS REQUIRED FOR ONE OR MORE QUANTITIES OUT OF LIMITS.

I-loaded WHI's, which are used to calculate the RCS usable quantities, are based on standard temperatures, pressures, and propellant loadings. Changes in temperatures, pressures, forward RCS propellant off-loading, off-nominal helium loads (still within LCC limits), and transducer biases or failures can affect the quantity readings. With these conditions present, it is possible to get false leak messages or degraded leak detection due to incorrect quantity readings. Preflight RCS PVT INIT TMBU's are sent to the BFS computer to update the BFS quantity gauging WHI constants. The updated constants reflect the actual temperatures, pressures, and propellant loadings in the RCS systems and adjust and finely tune the RCS quantity readings. The 3 percent uplink criteria was developed to minimize preflight uplinks (PVT INIT) and still provide reasonable leak detection protection. Currently, leak alarms are annunciated when the delta between the oxidizer and fuel quantities is 9.5 percent. With the 3 percent criteria a leak alarm will not be annunciated until a 12.5 percent oxidizer/fuel delta (169 lb oxidizer or 106 lb fuel). On orbit both the PASS (OPS 2) and BFS (OPS 3) RCS WHI constants will be updated via TMBU/UPLINK to reflect the actual usable RCS quantities remaining.

If an uplink is required prelaunch to correct quantities that differ from actual by 3 percent, WHI's will be uplinked to correct all RCS quantities. Once a prelaunch TMBU is required, the risk of building and sending the TMBU is not dependent on the number of constants being updated.

A6-64 THROUGH A6-100 RULES ARE RESERVED

FLIGHT RULES

OMS ENGINE MANAGEMENT

A6-101

OMS ENGINE BELL MOVEMENT DURING ASCENT

- A. FOR OMS TVC MOVEMENT CONFIRMED BY TWO SOURCES DURING THE HIGH QBAR REGION (REF. RULE {A8-53C}, OMS TVC LOSS), THE AFFECTED OMS ENGINE WILL BE CONSIDERED FAILED FOR ALL PURPOSES INCLUDING ABORT PROPELLANT DUMPS. THE OMS ENGINE SWITCH WILL BE IMMEDIATELY MODDED TO THE "OFF" POSITION TO PRECLUDE ANY SUBSEQUENT FIRING. @[11298-6733]
- B. FOR TVC MOVEMENT SUSPECTED DURING THE HIGH Q-BAR REGION BUT NOT CONFIRMED DUE TO MOVEMENT INDICATED BY ONLY ONE SOURCE, THE AFFECTED OMS ENGINE WILL BE CONSIDERED FAILED FOR ATO, OMS ASSIST, AND ON-ORBIT BURNS PENDING FURTHER TROUBLESHOOTING. THE OMS ENGINE SWITCH WILL BE PLACED IN THE "OFF" POSITION PRIOR TO OMS ASSIST OR FOLLOWING MECO.

PRE-MECO, THE ENGINE WILL BE USED FOR RTLS, TAL, AND CONTINGENCY DUMPS. POST-MECO, THE ENGINE WILL ONLY BE USED IN CONTINGENCY CASES IF REQUIRED FOR ORBITER OR CREW SAFETY, NOT FOR MISSION SUCCESS. @[11298-6733]

The consequences of using an OMS engine which has suffered engine bell damage due to aerodynamic forces can be severe (reference System Briefs "OMS Gimbal Position Constraints During Ascent Max G"). Clearly, such an engine should be disabled ASAP. Further note that since some abort propellant dumps and OMS Assist start both OMS engines immediately, the OMS engine switch must be in the OFF position prior to abort selection to prevent the engine from firing. Therefore, for confirmed thrust vector control (TVC) movement during the high Q-bar region of ascent, the engine will be considered failed (including OMS Assist, OMS-1, OMS-2, and abort dumps). @[11298-6733]

However, the consequences of performing an abort dump without using an OMS engine are not risk free. During RTLS, TAL, and contingency aborts, the resultant vehicle CG (both X and Y) may be unacceptable for flight control, the total vehicle weight may be significantly above the design factor of safety for g forces around the HAC or for touchdown, and the OMS propellant tank may be significantly above the constraint for both the g forces around the HAC and landing. For all these cases possible loss of vehicle could occur.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-101 OMS ENGINE BELL MOVEMENT DURING ASCENT (CONTINUED) ©[ED]

Additionally, there are other cases, extreme MECO underspeeds or loss of other OMS engine and RCS capability, where the results would be catastrophic if the affected engine were not used.

Therefore, if the TVC movement during the high Q-bar region cannot be confirmed with two sources, the engine bell will be considered failed for OMS Assist, ATO, and On-orbit burns only. The engine bell will be used for RTLS, TAL, and contingency aborts where maximum dumping is required to avoid violating constraints which may result in loss of vehicle. ATO dumps are designed to protect ET impact constraints and will not be performed (ref. Rule {A2-62E}, ET FOOTPRINT CRITERIA). ©[111298-6733]

During orbit, the suspect engine bell will not be used if other methods of propulsion are available. Rule {A8-53}, OMS TVC LOSS, references this rule.

A6-102 OMS PROPELLANT SETTLING REQUIREMENT

AN RCS SETTLING BURN (15 SECONDS 2 +X JETS) IS REQUIRED PRIOR TO EACH OMS ENGINE RESTART IF THE OMS PROPELLANT TANK (OXIDIZER OR FUEL) AFT QUANTITY < 11 PERCENT.

If the OMS aft quantity is less than 11 percent, bulkhead screens have been uncovered allowing helium to enter into the tanks aft compartment. The next OMS burn could pull this helium into the OMS engine unless a 15-second RCS +X burn is performed prior to the OMS burn. The RCS +X burn forces the propellant over the outlet tube of the tank, preventing helium ingestion and improper mixture ratio shifts.

A6-103 OMS BURN DOWNLIST REQUIREMENT

DURING OMS BURNS IN OPS 2 AND 3, 44.8 KBPS HIGH RATE GNC DOWNLIST DATA IS REQUIRED (EITHER REAL-TIME OR RECORDED AND DUMPED) EVEN IF THIS CAUSES TEMPORARY LOSS OF PAYLOAD DATA OR REAL-TIME LOW DATA RATE DOWNLINK.

There are parameters (e.g., OMS Pc, inlet pressure, etc.) that are not available in LDR OPS 2 and 3 GNC downlist that are mandatory to determine failure modes in the OMS system. If these data are not available either real time or in postburn dumps, relatively minor anomalies may result in severe mission action being required to cover the worst case failure mode since the exact mode cannot be determined. For example, in certain circumstances, the difference between an OMS engine failure and an OMS propellant system failure cannot be determined. The consequences of an OMS engine failure are loss of redundancy and possible mission termination; the consequences of an OMS propellant system failure include very shallow deorbit burns with RCS completions to the minimum requirements for entry control, plus Y CG offsets that may be unacceptable from the flight control standpoint. The inconvenience of not having a short period of real-time data or payload data (less than 2 minutes) is greatly outweighed by the consequences of not having OMS data to resolve anomalies during burns. Rule {A2-129}, ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS, references this rule.

FLIGHT RULES

A6-104

OMS ENGINE INSTRUMENTATION REQUIREMENT

- A. LOSS OF OMS ENGINE FUEL INJECTOR TEMPERATURE INDICATION (MDM FAIL, TRANSDUCER FAIL, ETC.) WILL BE CAUSE TO NO-GO FURTHER USE OF THE AFFECTED ENGINE FOR NONCRITICAL OMS BURNS IF THE OTHER OMS ENGINE IS STILL AVAILABLE. THE AFFECTED ENGINE WILL BE USED FOR CRITICAL BURNS TO MEET DOWNMODING CRITERIA PROVIDED ALL OTHER ENGINE PARAMETERS REMAIN WITHIN NORMAL OPERATING LIMITS. @[091098-6366]

The fuel injector temperature is a primary cue for monitoring engine health and analyzing engine failure. During normal engine operation, the nominal fuel inlet pressure often exceeds the documented engine fail limit. Without the fuel injector temperature, the crew monitoring capability is severely degraded and an engine failure may be impossible to distinguish from nominal engine operation.

For critical crew safety burns, such as OMS-1, -2, and deorbit, the affected engine will be used with the remaining good engine (two-engine burn) to provide a downmode capability. For safety critical on-orbit burns, such as an inertial upper stage (IUS) separation, the good engine should be used with downmode to RCS. If there is no remaining good engine, the FRCS -X jets can be used. For mission critical on-orbit burns that are too large for an RCS downmode, both engines can be used.

Other engine parameters also include Pc, oxidizer and fuel inlet pressures.

- B. THE FOLLOWING CRITERIA WILL BE USED TO DETERMINE SYSTEM STATUS FOR LOSS OF OMS INLET PRESSURE INSIGHT (MDM FAIL, TRANSDUCER FAIL, ETC.) IN COMBINATION WITH A FUEL INJECTOR TEMP HIGH ANNUNCIATION OR A PC LOW ANNUNCIATION (CONFIRMED BY DOWN ARROW OR GIMBAL MOVEMENT; NO CONFIRMATION IS AVAILABLE DURING PRE-MECO DUMPS).

AN ENGINE FAILURE WILL BE ASSUMED IF ALL OF THE FOLLOWING CONDITIONS ARE MET:

1. FAILURE OCCURS DURING POWERED FLIGHT.
2. PROPELLANT SYSTEM AND ENGINE PERFORMED NOMINALLY ON THE PREVIOUS FLIGHT.
3. NO INTRUSION WAS MADE INTO THE OMS FEEDLINES DURING VEHICLE TURNAROUND. @[091098-6366]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-104**OMS ENGINE INSTRUMENTATION REQUIREMENT (CONTINUED)**

OTHERWISE, A PROPELLANT FAILURE WILL BE ASSUMED UNTIL DATA REVIEW CAN CONCLUSIVELY DIAGNOSE THE FAILURE. ©[091098-6366]

This flight rule documents the decisions made at the March 9, 1995, PRCB stemming from the ROMS Oxidizer Inlet pressure bias observed prior to the liftoff of STS-66 (PCIN S062105).

Thirty hours before the scheduled liftoff of STS-66, the ROMS OX inlet pressure biased up approximately 6 psia. However, per Launch Commit Criteria (LCC), this is a NO-GO condition until the transducer is replaced. The OMS inlet pressure is the primary cue to determine and confirm engine fail, propellant fail, or instrumentation fail for FUEL INJECTOR TEMP HIGH and PC LOW FDA. Without this insight, the proper system diagnosis cannot be performed and the worst case, propellant fail, is assumed. Because of the launch impact of replacing the OMS Inlet Pressure transducers on the pad, the decision was made by the PRCB to waive the LCC. The decision was based on 1) the affected pod had considerable flight time without incident, 2) previous flight data indicated no problems, and 3) the propellant tank and feedline plumbing had not been breached during vehicle turnaround. The procedures were updated so that any ROMS PC annunciation during pre-MECO dumps would be assumed an engine failure. Post-MECO, any ROMS PC annunciation in combination with a failed acceleration check would be assumed to be a propellant failure to allow time for evaluation.

After STS-66, the PRCB elected to permanently change the LCC based on the rationale above. The PRCB discussions centered on internal contamination that could cause a blockage of the system resulting in a propellant failure. However, there are external conditions that can induce a blockage within the system. For example, if a propellant line has a small leak, the leaked propellant could freeze the OME inlet line. Engineering analysis shows that less than 1 pound of fuel can freeze a 3foot length of oxidizer feedline. A leak could develop that would be small enough that it would go undetected in tank pressure decay for some time and yet be sufficient to freeze the feedline. This condition is not applicable to powered flight because any leaked propellant would pool at the bottom of the pod and not affect the feedlines. If a detectable amount of propellant is leaked, it is understood that the pod could be adversely affected and a real-time evaluation of the situation would be required.

It should be noted that there are cases where, if an engine fail was assumed when an actual propellant fail has occurred, the loss of vehicle and crew would result. ©[091098-6366]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-104

OMS ENGINE INSTRUMENTATION REQUIREMENT (CONTINUED)

- C. FOR LOSS OF AN OMS ENGINE PRESSURIZATION VALVE POSITION INDICATION, THE AFFECTED ENGINE WILL BE USED ONLY FOR OMS-1 AND DEORBIT UNLESS USE OF THE ENGINE IS REQUIRED TO MEET OMS/RCS DOWNMODING CRITERIA, OR IF PROPER ENGINE PRESSURIZATION VALVE OPERATION CAN BE VERIFIED BY AN INCREASE IN THE OMS GN₂ REGULATOR PRESSURE AND/OR DECREASE IN THE GN₂ TANK PRESSURE PRIOR TO IGNITION.

For OMS burns, proper pressurization valve operation is required in order to ensure one start capability for the affected engine is retained for the deorbit burn. For OMS-1 the valve is assumed to be open for confirmed instrumentation losses because redundant hardwired command paths are used. The risk of using the last start if the valve is actually closed (dual failure) is accepted since the burn is critical for orbit insertion.

For burns other than OMS-1 and deorbit, it is prudent not to use the affected engine if the burn can be accomplished without it. The engine may be used, however, if proper valve operation can be verified, or if required to meet OMS/RCS downmoding requirements as defined by Rule {A2-114}, OMS/RCS MANEUVER CRITICALITY. For instance, the engine may be used for OMS-2 if proper valve operation has been verified prior to insight being lost as a result of an MDM FA3 or FA4 failure since a subsequent MDM FA1 or FA2 power failure would fail the other OME and four +X capability. If the OMS engine pressurization valve is actually failed closed, two OMS starts may still be available due to the initial, higher than normal regulator pressure available prelaunch, assuming the ARM/PRESS switch is taken to ARM before the purge. ©[091098-6366]

FLIGHT RULES

A6-105

OMS BURN MINIMUM PRESSURE REQUIREMENTS

AN OMS ENGINE WILL NOT BE USED FOR NONCRITICAL ON-ORBIT BURNS IF THE FUEL INLET PRESSURE < 244 PSIA OR OXIDIZER INLET PRESSURE < 244 PSIA OR N₂ TANK PRESSURE < 563 PSIA.

The OMS engine inlet pressure requirements preserve blowdown capability in an OMS system that has incurred a previously undetected failure of the pressurization system. The engine inlet pressure limits represent the bottom of the regulator band (252 psia) minus 2 percent instrumentation error (8 psia). If either inlet pressure cannot be repressed to above 244 psia, the system can be operated further in blowdown. However, the blowdown capability should be preserved for critical burns.

The nominal start envelope limits are 239 and 238 psia for the fuel and oxidizer inlet pressures, respectively (reference SODB, volume I, figure 4.3.3). The N₂ criteria represents the following:

(1)	Engine start	26 psia	(ref. SODB, volume I, fig. 4.3.3)
(2)	Purge	94 psia	
(3)	Accumulator start at 100 percent ball valve opening	283 psia	(ref. SODB, volume I, table 3.4.3.3)
(4)	Instrumentation error	<u>160 psia</u>	
	Total =	563 psia	

The limits defined in this rule are used in the FDF for noncritical on-orbit OMS burns.

FLIGHT RULES

A6-106

OMS ENGINE BURN TO DEPLETION

FOR A LEAKING PROPELLANT PERIGEE ADJUST BURN OR FOR A DEORBIT BURN, AN OMS ENGINE MAY BE BURNED TO DEPLETION (PC = 80 PERCENT). THE ENGINE WOULD BE USED SUBSEQUENTLY ONLY IF IT IS THE ONLY DEORBIT METHOD AVAILABLE. (REF. RULE {A6-3E}, OMS ENGINE.)

Critical OMS burns (leaking OMS perigee adjust and deorbit) may be continued to a depletion level (defined as an 80 percent chamber pressure and an OMS engine “?” on the MNVR EXECUTE display) to maximize delta V and minimize the residuals in the leaking tank. OMS propellant gage quantity will not be used as a cutoff cue since the hardware readings are unreliable. Consequently, no effort will be made to stop the burn prior to exhausting the propellant in the lines.

During depletion, the Pc decreases. The presence of a single propellant mixing with helium pressurant in the chamber prevents the Pc from reading zero. However, the Pc will fall below the fault detection threshold (80 percent) resulting in an alert. During WSTF tests to depletion in a one-g environment, engine damage did not occur. There are substantial unknowns regarding zero-g operations and crew response time to the failure to minimize damage. If engine damage occurs during the depletion cutoff, off-nominal mixture ratios may cause uncontained engine damage when the engine is restarted. Because of this potential for engine damage an engine which has failed due to depletion of either propellant (OX or FU) will not be reused unless mandatory and then only for the deorbit burn.

(Reference SODB, 3.4.3.3.)

FLIGHT RULES

A6-107

OMS ENGINE FAILURE MANAGEMENT

FOR THE LOSS OF ONE OMS ENGINE :

- A. THE REMAINING GOOD OMS WILL BE USED FOR ON-ORBIT BURNS ONLY IF THE FIRST FAILURE CAN BE IDENTIFIED AS AN ENGINE FAILURE AND IS UNDERSTOOD.

As long as the first failure is confirmed to be an engine failure, the affected pod's propellant will be available for use through the remaining good engine via crossfeed operation. Engine versus propellant failures must be determined prior to future crossfeed operations to protect against contamination affecting the remaining good OMS engine.

- B. RCS 4 +X JETS WILL BE HOT-FIRED PRIOR TO COMMITTING TO CONTINUE TO NOMINAL EOM UNLESS THE JETS HAVE PREVIOUSLY FIRED.

For the loss of an OMS engine, the good OMS engine and the RCS 4 +X jets are considered the remaining two deorbit methods (sufficient propellant to redline RCS steep deorbit must be available). If either of the remaining deorbit methods is lost, a next PLS must be invoked since zero fault tolerance exists (ref. Rule {A2-201}, DEORBIT GUIDELINES). If the 4 +X RCS jets have not fired previously, the health of the jets is unknown. As a result, if the jets have not fired, in order to gain confidence in the +X jets, the jets should be hot-fired. Since these jets are hot-fired the day before entry in the normal hot-fire procedure, the normal hot-fire procedure should be rescheduled to an earlier time.

FLIGHT RULES

A6-108**OMS BALL VALVE FAILURE MANAGEMENT**

AN OMS ENGINE WITH A FAILED OPEN BALL VALVE INDICATING GREATER THAN THE FAILED OPEN RANGE LOWER LIMIT (FLIGHT RULE {A6-3H}, OMS ENGINE) BUT < 47 (70) PERCENT POSTBURN WILL NOT BE USED UNLESS THE OTHER ENGINE HAS FAILED, AND THEN ONLY FOR THE DEORBIT BURN. HOWEVER, IF THE FAILED OPEN BALL VALVE INDICATES > 47 (70) PERCENT, THE ENGINE IS NOT CONSIDERED FAILED BUT WILL BE USED ONLY FOR THE DEORBIT BURN.

Each OMS engine has two ball valves in series (V1 and V2) for both the oxidizer and fuel lines. Instrumentation for V1 on both the oxidizer and fuel is measured by one potentiometer while both V2 valves are measured by another. Either V1 or V2 failed closed will prevent propellant from feeding the engines.

If postburn and either ball valve indicates open (after a nominal OMS burn cutoff), either the instrumentation has shifted high or the valve has failed partially open. There are no problems with burning an engine with failed instrumentation since the valves function properly. The lower limit of the failed open range is engine specific and is listed in Flight Rule {A6-3H}, OMS ENGINE. If the ball valve position is between the lower limit and 70 percent there is no guarantee that the affected ball valve will open properly. The possibility of engine hard start or combustion instability then exists, with the result of structural failure and/or chamber burn through.

If the other engine is failed, it is preferable to attempt to burn the engine with the failed ball valves, relying on them to open greater than 70 percent, rather than to attempt a 4 +X deorbit. Should the ball valves fail to open sufficiently, the 4 +X deorbit downmode is still available. With the 4 +X deorbit there is no downmode.

In any case, whenever a burn is attempted using an engine with failed open ball valves, the crew should be prepared to cut off the burn by closing the appropriate tank isolation valves if a generic problem keeps both sets of ball valves from closing.

If the ball valve indicates > 70 percent open, even a real valve problem will support a nominal engine flow rate. Consequently, the engine can be used for the deorbit burn. (Reference SODB, volume I, paragraph 3.4.3.3-17.) Rule {A6-3}, OMS ENGINE, references this rule.

A6-109 THROUGH A6-150 RULES ARE RESERVED

FLIGHT RULES

RCS THRUSTER MANAGEMENT

A6-151 RCS JET DRIVER MANAGEMENT [CIL]

- A. THE PRIMARY JET RJD CONFIGURATION WILL BE ALL ON DURING CREW AWAKE PERIODS INCLUDING PROXIMITY OPERATIONS, PAYLOAD DEPLOYMENT, AND RENDEZVOUS MANEUVERS. THE PRIMARY RJD'S WILL BE POWERED OFF DURING CREW SLEEP PERIODS AND EVA OUTSIDE THE PAYLOAD BAY.
- B. IF VERNIER JET CAPABILITY IS LOST, CREW SLEEP PERIODS WILL BE FLOWN PRCS, TAIL ONLY OPTION PRIMARY CONTROL WITH ALL RJD'S POWERED ON.
- C. IF A FAILURE IS DETECTED IN THE RJD LOGIC POWER CIRCUIT VIA MCC TELEMETRY, THE AFFECTED RJD POWER WILL REMAIN POWERED ON FOR CREW SLEEP PERIODS.

RJD system testing has resulted in a failure rate of one failure every 10 billion hours. With the possibility of failure so low, the RJD configuration will be all on during crew awake periods. If a failure were to occur, crew accessibility would allow prompt corrective action. During sleep periods, the RJD's will be powered off because of the crew response time to failures while sleeping in the middeck. For extravehicular activities (EVA's) outside the payload bay, plume impingement activities are the concern.

Failure of the RJD logic power circuit as detected by RJD logic switch telemetry has no immediate effect on the operation of the affected jets. However, if RJD power is removed per the normal presleep procedure, the jets will be permanently lost. In this instance, the risk of a failure causing an RCS jet to fail on is considered more acceptable than a definite loss of two manifolds of RCS jets. It is considered prudent to sleep in tail-only PRCS control. Rule {A15-22}, RCS/APU THRUSTER PLUME AVOIDANCE, references this rule.

A6-152 RCS ENTRY HOTFIRE CHECK

ALL ENTRY-CRITICAL JETS (OTHER THAN FIRST PRIORITY ON-ORBIT JETS) WILL BE HOT-FIRED ONCE DURING THE MISSION.

The hot-fire test is performed to verify that all primary jets needed for deorbit or entry are operating properly. The number one priority orbit DAP jets are fired during normal orbit ops and will not need to be fired again during the hot-fire test.

A special hot-fire test will be required for the first flight of a new vehicle to test all jets including the forward up-firing jets since these jets are not normally fired and need to be tested.

FLIGHT RULES

A6-153

RCS JET MAXIMUM BURN TIME

- A. THE OPERATIONAL LIMIT FOR CONTINUOUSLY FIRING PRCS JETS IS 150 SECONDS. THE CONTINUOUS FIRING LIMIT FOR VERNIER RCS JETS IS 275 SECONDS. THE VERNIER JETS ALSO HAVE A SEPARATE CONSTRAINT OF NO MORE THAN 1000 "ON" COMMANDS PER HOURS.
 ©[072398-6690] ©[110900-7249]

The limiting component of the primary thrusters is the titanium canister because it is heat-load sensitive. Exceeding temperature limits could damage adjacent components. The limiting component for the vernier thrusters is the aluminum structure since it too is heat-load sensitive. The 1000 "ON" commands limitation is driven by the PC transducer which could fail due to overheating leading to a false failoff. The 150-second firing limit is driven by a qualification limit and not by any data that shows damage occurs at these durations. (Ref. SODB, volume I, paragraph 3.4.3.2). Additional analysis data shows that the PRCS thrusters could be fired for 250 seconds without violating thermal limits even with entry heating immediately following the firing. WSTF testing in support of the Hubble reboost has demonstrated that 275-second VRCS firings do not violate any vernier jet thermal constraints (ref. SODB, volume I, paragraph 3.4.3.2). There is no minimum cooldown period required between 275-second VRCS firings. For on-orbit conditions where an extended cooldown period is available, consideration may be given to raising the limits to 400/710 seconds for primary and vernier jets respectively, with associated cooldowns of 2100/1400 seconds (35 minutes/23 minutes 20 seconds). (Ref. SODB, Volume III, Paragraph 4.3.2.9. (Caution: SODB, Volume III contains engineering estimates for non-nominal performance evaluation. Data may not be supported by test.)) ©[110900-7249]

- B. A SINGLE MISSION CONTINGENCY FIRING OF 800 SECONDS FOR ARCS (+X) THRUSTERS AND 300 SECONDS FOR FRCS (-X) THRUSTERS IS PERMISSIBLE.

The 800/300-second constraints represent the maximum +X/-X burn time that can be used in a contingency without resulting in structural damage due to overheating. (Ref. SODB, Volume I, Paragraph 3.4.3.2). Additional thermal analysis shows that a 1050-second (17 minutes 30 seconds) ARCS and 400-second FRCS thruster firing may be permissible. For these durations, the limiting component for the ARCS thrusters is the Kapton wire insulation. If the temperature limit is exceeded, it could jeopardize the capability to refire the jet if a 3500-second (58 minute 20 second) cooldown period is not allowed. The limiting component for the FRCS thrusters is the Inconel thermal barrier spring. If the limit is exceeded, the elasticity of the spring will be degraded and its life span shortened. (Ref. SODB, Volume III, Paragraph 4.3.3.2.9. (Caution: SODB, Volume III contains engineering estimates for non-nominal performance evaluation. Data may not be supported by test.)) ©[072398-6690]

FLIGHT RULES

A6-154

RCS VERNIER OPERATION TERMINATION

RCS VERNIER THRUSTER OPERATION SHALL BE TERMINATED AND SYSTEM OPERATION PERFORMED ON PRIMARY THRUSTERS WHENEVER:

- A. THE RCS FUEL TANK PRESSURE IS 20 (20)* PSID GREATER THAN THE OXIDIZER TANK PRESSURE. VERNIER OPERATION MAY BE RESUMED WHEN FUEL/OXIDIZER TANK PRESSURE DELTA < 20 (20) PSID.

NOTE: *ZERO INSTRUMENTATION ERROR IS USED SINCE SECONDARY REGULATOR OPERATION PLUS INSTRUMENTATION INACCURACY COULD EXCEED CONSTRAINTS.

Vernier thruster test data have demonstrated that low oxidizer/fuel mixture ratio (less than 1.6) shifts the main combustion from the center to near the wall of the chamber which results in high combustion chamber temperatures. Tests conducted at an oxidizer/fuel mixture ratio of 1.3 resulted in severe damage to the vernier thruster chamber protective coating. The test duration was equivalent to approximately one mission day. Continued operation at this mixture ratio would have resulted in chamber burnthrough. By limiting the differential of the oxidizer and fuel propellant tank pressures to 20 psid, the mixture ratio for the vernier thruster will not be less than 1.5. Tests were conducted at a mixture ratio of 1.5 for an equivalent of approximately 3 mission days with no detectable coating damage. Also, 20 psid allows vernier operation when the He system is operating on the secondary regulator (including system tolerances 2-sigma).

- B. THE HIGH-LOAD FLASH EVAPORATOR IS OPERATING FOR MORE THAN 20 MINUTES.

On STS-2, overtemperatures in the VRCS thrusters occurred during lengthy operation of the flash evaporator. The propulsive vent holds the DAP to one side of the deadband. The DAP continues to cycle the same jets at such a frequency that the thrusters do not have an opportunity to cool down. The best way to protect the vernier thrusters from overheating is to configure the DAP to the PRCS when the high load evaporator will be run for more than 20 or 30 minutes. Reference STS-3 Orbit Flight Techniques meeting number 14, March 30, 1982.

- C. THE VRCS DAP MODE IS LOST.

Reference Flight Rule {A8-60}, LOSS OF VERNIER RCS DAP MODE, to determine the status of the VRCS DAP mode following the loss of the six VRCS jets.

FLIGHT RULES

A6-155

SUSPECT RCS JET REPRIORITIZATION CRITERIA

- A. A SUSPECT PRIMARY JET WILL BE CHANGED TO LAST PRIORITY FOR THE FOLLOWING CONDITIONS:
1. CONFIRMATION OF OFF-NOMINAL OPERATING CONDITIONS (LOW PC, THRUST).
 2. SUSPECT INSTRUMENTATION (OXIDIZER/FUEL INJECTOR TEMPERATURE DELTA > 25 DEG LOW, BIASED PC WITH DELTA > 25 PSIA FROM NOMINAL).
- B. A VERNIER JET WITH SUSPECT INSTRUMENTATION (LOW PC) MAY BE DESELECTED DURING CREW SLEEP PERIODS TO AVOID NUISANCE ALARMS.

Low Pc confirmed with low rates (indicating low-thrust) identifies a real jet problem. Further use of the affected jet could create hot spots along the thruster wall damaging the jet.

Injector temperatures and Pc are used for determining jet leaks and jet fail-offs. Biased instrumentation could mask a real problem and, if the jet is fired, create a large jet leak or unstable combustion.

A jet placed in last priority will not be called on to fire unless the DAP determines it to be necessary due to additional jet failures in the associated direction. If the crew deselects the jet, it becomes one additional action required by the crew if the jet is later required. For entry, a yaw jet will be deselected because the DAP will command all available yaw jets to fire during roll reversals.

With either case, it is prudent to discontinue use of the jet when other jets are available. The affected jet will be placed in last priority so that if it is needed for achieving mission objectives, it can be used.

Vernier jets with suspect instrumentation may be deselected for sleep to avoid possible fail-off nuisance alarms. The affected jet must be hot fired to determine whether it is a real problem or instrumentation problem. For real problems, the jet will only be used for mission success. For instrumentation problems the jet will be used except for sleep.

- [2] JETS MAY BE RESELECTED TO MAINTAIN FAIL-SAFE REDUNDANCY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-156

RCS RM LOSS MANAGEMENT (CONTINUED)

A. VERNIER JETS

1. ORBIT DAP:

a. FAIL OFF

The vernier jets will continue to be used after the loss of fail-off protection. In the event of an undetected fail off of a vernier jet, drifting attitude control problems may result, but there are no system problems associated with additional firing on a vernier fail-off jet.

b. FAIL LEAK

WSTF testing has demonstrated that propellant leakage into the chamber may freeze and block the small vernier chamber. If the failure went undetected and the jet were allowed to fire, the blockage could cause severe damage. Therefore, for loss of failed leak protection, the jet will be deselected. If the remaining vernier jets have good RM and are adequate to maintain attitude control, vernier control may be selected; otherwise, primary jets must be selected.

c. FAIL ON

During active attitude hold, a vernier jet failed on would force the orbiter outside the DAP deadbands. Opposing jets would then fire to correct the attitude until the failed-on jet was stopped (i.e., manifold closure or RJD driver poweroff) or the propellant was depleted. Normally, the RCS RM would annunciate the failure but with loss of RM there would be no alarm. During crew awake periods, numerous jet firings would alert the crew to take corrective action before significant propellant loss occurs. However, during crew sleep, the failure could go undetected for several hours depleting the RCS tanks. Therefore, during crew sleep the vernier jets would not be used for loss of fail-on RM. Primary jets will be selected in the tail-only control mode to eliminate cabin noise associated with the firing of the FRCS thrusters.

d. TOTAL RM

An MDM comm fault or BCE bypass would cause loss of total RM on a pair of vernier jets (e.g., L5L and L5D). This would be at least equivalent to the worst case of loss of fail leak RM and therefore cause the loss of verniers and selection of primary jets.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-156

RCS RM LOSS MANAGEMENT (CONTINUED)

B. PRIMARY JETS

For any loss of RM protection during any DAP phase the affected jet will be changed to the lowest priority. The lowest priority jet will not fire during normal orbit/trans DAP operations. Jet availability (reselect/deselect) will be managed to minimize the use of the jet. For orbit/trans DAP, the affected jet (all axes) will remain available (reselected) to provide system redundancy should multiple failures (additional jet loss) occur. This allows the jet to be available without requiring crew actions during a time-critical phase.

For Aerojet/GRTLS DAP, only an affected yaw jet will be deselected. This prevents the affected yaw jet from being fired during roll reversals. The DAP commands all available yaw jets to provide attitude control. All other jet axes will remain available to provide system redundancy, since these jets will not fire while in lowest priority during normal operations of the Aerojet/GRTLS DAP.

RCS manifolds will not be closed due to the loss of RM protection on primary jets. Complications that may result from manifold closure are more probable than the failures due to loss of RM, such as manifold pressure decay resulting in jet leaks or possible staged repress procedures.

Firing jets with loss of fail leak or fail off detection may result in zots, valve damage, or contamination. This minimal risk is accepted to provide vehicle control capability should multiple failures occur.

1. ORBIT/TRANS DAP:

The orbit and trans DAP require one jet/direction/pod to maintain attitude control. Fail-safe redundancy (two jets/direction/pod) is required for time and safety critical events (RNDZ, deploy).

Action for loss of fail off, leak, on, or total RM will usually be delayed until after ET SEP or OMS-1 in order to minimize crew activity during the ascent phase.

a. FAIL OFF/LEAK

The affected jet will remain available and be put into last priority. The orbit and trans DAP will only fire one jet/direction/pod for rotational control. For translation the DAP may fire more than one jet/direction/pod. Multiple failures may require the use of the affected jet to maintain fail safe redundancy for time/safety critical events. The jet will be available without further crew action.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-156

RCS RM LOSS MANAGEMENT (CONTINUED)

b. *FAIL ON*

The affected manifold status will be set to “closed” and the RJD powered off. This will eliminate any chance of an undetected fail-on jet.

For high priority events which require the affected jet, such as -X jets for low-Z translations, the affected jet can be reselected and RJD power turned on. The risk of a jet fail-on is considered acceptable to achieve mission success activities.

While in the trans DAP for entry, manifold status actions may be performed to prepare for Aerojet DAP and deorbit burn.

c. *TOTAL RM*

The affected manifold status will be left “closed” and the RJD powered off. This will eliminate any possible chance of an undetected fail-on jet.

With an MDM comm fault or BCE bypass, the manifold status will be set to “closed” automatically. For OMS-1, -2 or deorbit any affected manifold with $\pm X$ jets will be set to “open” and associated RJD powered on. The risk of an undetected jet failure will be accepted to ensure RCS X jets are available for OMS-1, -2 or deorbit.

While in the trans DAP for entry, RJD actions may be performed to prepare for aerojet DAP and deorbit burn.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-156

RCS RM LOSS MANAGEMENT (CONTINUED)

2. AEROJET/GRTLS DAP:

Entry requires three yaw jets/pod and two pitch jets/direction/pod for the aft RCS to maintain fail-safe redundancy.

a. FAIL OFF/LEAK/ON

The Aerojet/GRTLS DAP will fire four yaw jets if available during roll reversals. Therefore a yaw jet with loss of fail off, leak or on detection will be deselected and placed in last priority. For subsequent/multiple failures the jet may be reselected per the reselection priority table (Rule {A6-159}, FAILED PRCS JET RESELECTION PRIORITY).

The possibility of firing three pitch jets in the Aerojet/GRTLS DAP exists; however, the probability of firing the last priority jet is small enough that it is an accepted risk not to deselect a pitch jet that has lost RM detection. Therefore, the pitch jet will be placed in last priority and reselected if it was autodeselected.

The affected jet may remain available if it is not a yaw jet. Multiple failures may require the use of the jet to maintain fail-safe redundancy. The jet will be available without further crew actions.

b. TOTAL RM

The affected manifold status will be set to "closed" and the RJD powered off. These actions provide a conservative approach to compensate for the loss of all three detection methods. Jets may be reselected, if necessary, depending on the cause of the failure and based on the criteria in Rule {A6-159}, FAILED PRCS JET RESELECTION PRIORITY.

FLIGHT RULES

A6-157

RCS JET FAILED OFF HOTFIRE TEST

FOR RM FAIL-OFF, VERNIER THRUSTERS WILL BE TESTED AFTER THE FIRST FAILURE. PRIMARY THRUSTERS, FOR UNKNOWN FAILURES, WILL BE TESTED IN ORDER TO MAINTAIN FAIL-SAFE REDUNDANCY.

Vernier thrusters will be hot fired for failures where the cause is unknown in an attempt to regain vernier control. Vernier jets are required for propellant conservation such that mission objectives can be completed and mission success achieved. Primary jets will not be hot fired after the first failure because of redundant jet availability and to avoid any unnecessary risks associated with the hot fire. If multiple failures make troubleshooting desirable because of loss of fail-safe redundancy, the primary jets may be hot fired, depending on the suspected failure. For example, if it is suspected that hot firing might result in loss of the entire manifold of jets, the test will not be performed. For suspected instrumentation failures, the jet may be hot fired after the first failure. The risk is low if the data indicate an instrumentation problem, plus accomplishing the hot fire may reduce vehicle turnaround time postlanding.

For real fail leak jets, the affected jet will not be hot fired because of possible ice in the chamber and injector plate. Reference Rule {A6-158}, RCS LEAKING JET MANAGEMENT.

FLIGHT RULES

A6-158

RCS LEAKING JET MANAGEMENT

A. PRIMARY JETS:

1. A LEAKING JET WILL NOT BE DESELECTED UNLESS THE INJECTOR TEMPERATURE VIOLATES THE RCS RM LIMIT OR PROPELLANT LEAKAGE IMPACTS CONTAMINATION SENSITIVE ORBIT ACTIVITIES.
2. FOR A LEAKING JET THAT HAS BEEN DESELECTED BY RCS RM, THE JET CAN BE RESELECTED AND USED ON A NONINTERFERENCE BASIS (NO IMPACT TO MISSION EVENTS) ONCE THE OXIDIZER AND FUEL INJECTOR TEMPERATURES WARM UP > 65 DEG F.
3. A LEAKING JET THAT HAS BEEN ANNUNCIATED "FAIL LEAK" ON TWO SEPARATE OCCASIONS WILL BE CHANGED TO THE LOWEST JET PRIORITY AND REMAIN DESELECTED UNLESS REQUIRED TO MAINTAIN ATTITUDE CONTROL. DURING ENTRY IF BOTH OF THE INJECTOR TEMPERATURES > 65 DEG F, THE JET WILL BE RESELECTED AS REQUIRED TO MAINTAIN FAIL-SAFE REDUNDANCY.

In three different leak cases (FIL on STS-4, R4U and L2D on STS-6), the leak always started coincident with the jet being fired. A sharp decay in the injector temperature occurs until thermal equilibrium is obtained or until the leak has stopped. Subsequent firing of the affected jet after the leak has stopped and warmed up to normal temperatures does not necessarily restart the leak as evidenced with FIL and R4U. These two cases showed no further leakage even after repeated jet use. Data have indicated that the leak will eventually stop and the temperatures warm up without firing the jet, i.e., applying pressure to jet injector valve may result in leak stoppage due to valve seat design and compression of valve into Teflon seat. The leaks that we have seen to date have been very small, on the order of 0.1 to 0.3 lb/hr or less than 100 cc/hr propellant leakage. It is felt that these sizes of leaks do not represent any impact to mission operations. However, the system will be configured to minimize any jet leakage that may occur by taking advantage of redundant jets and preclude further firing of the affected jet. Firing a leaking primary jet (RCS RM declared failed leak) presents no hardware concerns if the injector temperatures > 65 deg F. WSTF tests showed that with the injector temperatures < 65 deg F (ref. SODB, volume I, paragraph 3.4.3.2-12a), ZOT's could occur that may increase the jet leak and require a manifold be closed. However, if the primary jet is required for control during entry, the risk of further damage to the jet is low compared to the crew risk if not reselected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-158

RCS LEAKING JET MANAGEMENT (CONTINUED)

B. VERNIER JETS:

LEAKING VERNIER JETS WILL CONTINUE TO BE USED UNLESS DESELECTED BY RCS RM. SUBSEQUENT RESELECTION AND USE IS ONLY ALLOWED IF THE INJECTOR TEMPERATURES HAVE BEEN GREATER THAN THE RM LIMIT FOR 3 HOURS VERIFYING THAT NO ICE REMAINS IN THE INJECTOR. @[091098-6708]

A vernier jet known to be leaking will be used until the injector temperatures violate the RCS RM leak limit and is automatically deselected. Until this limit is violated, there are no risks associated with firing the jet. Conversely, after the RM limit has been violated, the leak freezes and plugs the small chamber quickly. Subsequent jet firings may result in possible uncontained damage.

Reference SODB Volume 1, Paragraphs 3.4.3.2.12.b and 3.4.3.2.13.b.

Rules {A6-9B}, RCS JET HEATER; {A6-157}, RCS JET FAILED OFF HOTFIRE TEST; and {A6-159}, FAILED PRCS JET RESELECTION PRIORITY, reference this rule. @[091098-6708]

FLIGHT RULES

A6-159

FAILED PRCS JET RESELECTION PRIORITY

FOR MULTIPLE PRIMARY JET/RM FAILURES RESULTING IN JET DESELECTION AND PRIORITY CHANGES, JET WILL BE RESELECTED, AS REQUIRED, TO PROVIDE ATTITUDE CONTROL OR FAIL-SAFE REDUNDANCY IN THE FOLLOWING ORDER (HIGHEST RESELECT FIRST):

- A. JET WHICH HAS BEEN ANNUNCIATED FAIL LEAK, AND BOTH INJECTOR TEMPERATURES > 65 DEG F.
- B. JET WITH DEGRADED INSTRUMENTATION.
- C. JET WITHOUT FAIL-ON RM.
- D. JET WITH DEGRADED OR LOSS OF FAIL-OFF RM.
- E. JET WITH DEGRADED OR LOSS OF FAIL LEAK RM.
- F. JET WITH LOSS OF TOTAL RM.
- G. JET WHICH HAS BEEN ANNUNCIATED FAIL LEAK TWICE AND BOTH INJECTOR TEMPERATURES > 65 DEG F.
- H. JET WHICH HAS BEEN ANNUNCIATED FAIL-OFF.
- I. JET WHICH HAS BEEN ANNUNCIATED FAIL LEAK AND INJECTOR TEMPERATURES < 65 DEG F (POSSIBLY STILL LEAKING).

The redundancy in primary jets allows a single jet failure to be deselected with little or no impact to the vehicle capability. If no capability is lost, it would be desirable to deselect the jet since subsequent failures may go undetected. For the second jet failure, fail-safe redundancy can be lost since two pitch jets and three yaw jets are required and only three pitch and four yaw jets are available. To maintain fail-safe redundancy, it may be worth the risk to reselect the jet and be exposed to a subsequent failure going undetected. After all, the jet with failed instrumentation or the jet that has stopped leaking are healthy and if used will be exposed to the same failures as a jet with no problem.

The priority for choosing which jet to reselect is provided in this rule starting with a jet with good RM and only slightly degraded instrumentation. Jets with no fail on RM will be reselected next since the chances of a failed-on jet are minimal compared to fail-off jets. Loss of leak RM would create more of a problem since a leaking jet undetected could cause the leak to increase. Loss of total RM (ON, OFF, LEAK) increases the chances of a failed jet being undetected.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-159 **FAILED PRCS JET RESELECTION PRIORITY (CONTINUED)**

Jets which have leaked once, but stopped as indicated by injector temperatures > 65 deg F, may be reselected and used on a noninterference basis (reference SODB, volume I, paragraph 3.4.3.2-12a). (See Flight Rule {A6-158}, RCS LEAKING JET MANAGEMENT.) Jets which have leaked twice, but stopped as indicated by injector temperatures > 65 deg F, may be reselected according to the priority listing above. For a jet that has failed leak, experience has shown that there are no means for determining whether the jet will leak again and be declared fail leak by RM. These jets will be selected before a jet that has failed off since these jets are known to be healthy. Since the failed-off jet status has not changed, the failed-off jet will most likely fail off.

Jets that have been annunciated fail off will have RM toggled so that it may be declared fail off again, if the failure is still present. Reselecting the jet would not be a safety hazard.

Jets which have been annunciated fail leak and may be still leaking will not be reselected except to maintain attitude control since firing a leaking jet may cause injector seal leakage to increase.

Rule {A6-156}, RCS RM LOSS MANAGEMENT, references this rule.

A6-160 THROUGH A6-200 RULES ARE RESERVED

FLIGHT RULES

OMS/RCS LEAK MANAGEMENT

A6-201

OMS/RCS LEAKING HE TANK BURN

FOR A LEAKING OMS/RCS HELIUM TANK, A BURN MAY BE SCHEDULED TO INCREASE THE PROPELLANT ULLAGE VOLUME.

It is important to increase the ullage volume for He tank leaks so that the delta velocity (V) lost with a He tank failure is minimized. If OMS propellant tank quantities are below 39 percent, the OMS tanks can be used in the blowdown mode (no He tank support) with little or no loss of capability. Ascent procedures for OMS He tank leaks have been developed to maximize blowdown capability by performing a contingency abort dump using the leaking OMS propellant. Post-OMS-2 quantities are sometimes below 39 percent and will not require a blowdown maximization burn. If post-OMS 2 quantities are above 39 percent, a maximum blowdown burn should be performed. After evaluating the total delta velocity available it may be desirable to perform a perigee adjust burn to achieve maximum blowdown. The RCS propellant tanks reach maximum blowdown at 22 (OX) and 23 (FU) percent. Maximum blowdown procedures for use on orbit are documented in the MALF PROC titled "LEAKING He RCS BURN" and in the Orbit Pocket titled, "OUT OF PLANE OMS PRPLT/He BURN" for the OMS. Next PLS may be required if propellant margins dictate.

Rule {A6-51B}, OMS FAILURE MANAGEMENT [CIL], references this rule.

A6-202

OMS LEAKING HE SYSTEM BURN

DURING OMS BURNS, A LEAKING HELIUM SYSTEM MAY BE USED TO FEED BOTH ENGINES TO INCREASE PROPELLANT ULLAGE VOLUME.

As long as the helium tank pressure supports a nominal propellant tank pressure, a leaking helium tank can be used to feed both OMS engines. This configuration attempts to maximize the blowdown delta V capability in the affected OMS system prior to the helium tank being declared failed. No risk of damage to the OMS engines exists because a good propellant feed source is always used. Starting two OMS engines from one pod is acceptable.

FLIGHT RULES

A6-203**OMS LEAKING INLET LINE PERIGEE ADJUST BURN**

FOR AN OMS INLET LINE LEAK WHICH HAS BEEN ISOLATED ON ORBIT, A PERIGEE ADJUST OR OUT-OF-PLANE BURN WILL BE PERFORMED AS SOON AS PRACTICAL TO ASSURE TIME FOR POSTBURN PROPELLANT SUBLIMATION. MISSION-CRITICAL EVENTS MAY BE COMPLETED PRIOR TO THE PERIGEE ADJUST BURN ONLY IF THE EVENT CANNOT BE COMPLETED AFTER THE PERIGEE ADJUST BURN AND IF THE EVENT DOES NOT RESULT IN A NET LOSS OF DELTA V CAPABILITY.

OMS inlet line leaks which have been isolated must be repressurized prior to performing a burn. The repressurization will create a surge which could cause the leak to increase, and as a result, it is unknown how much delta V may be available from the leaking system. Therefore, the remaining RCS and good OMS propellant must be conserved until after the burn. Also, the earlier the burn, the more time for propellant sublimation

Rule {A6-51T}, OMS FAILURE MANAGEMENT [CIL], references this rule.

A6-204**OMS GN₂ ACCUMULATOR LEAK DETERMINATION**

A LEAKING OMS GN₂ ACCUMULATOR MAY BE REPRESSURIZED TO DETERMINE THE LEAK RATE.

Since the leak rate is so critical in determining health of the OMS engine, the accumulator may be repressurized to determine the leak rate. If a leak occurs through the purge valves, each time the purge valves are used this leak rate may increase. Since the affected OMS engine may be used for OMS-1 and a purge will occur at OMS-1 cutoff, the leak rate should be checked before the deorbit burn to ensure the rate has not increased to beyond acceptable limits.

(Reference Rule {A6-51M}, OMS FAILURE MANAGEMENT [CIL]), ©[ED]

FLIGHT RULES

A6-205

RCS LEAKING PROPELLANT TANK BURN

FOR RCS PROPELLANT TANK LEAKS, A PERIGEE ADJUST OR OUT-OF-PLANE MANEUVER WILL BE EXECUTED IMMEDIATELY. PROPELLANT MAY BE DUMPED TO DEPLETION.

Thermal effects of a propellant leak and propellant sublimation rates vary as a function of which propellant is leaking, the location of the leak, the distribution of the propellant within the pod, and the thermal environment. As a result, to preclude propellant feedlines from freezing thus rendering the entire pod unusable, the propellant will be dumped immediately. If the tank is dumped to depletion, MALF RCS SSR-7 will be used to clear the helium from the propellant lines. (OMS tank leaks are handled in a similar manner.) This leak philosophy was agreed upon at the July 13, 1987, Flight Rules PRCB.

A6-206

RCS MANIFOLD/LEG LEAK REPRESSURIZATION

RCS LINE LEAKS WILL NOT BE REPRESSURIZED IN MM 602, 304 (POST Q-BAR = 20), AND 305 TO RECOVER RCS YAW JETS IF NO YAW JET DAP MODE IS AVAILABLE. RCS LINE LEAKS WILL BE REPRESSURIZED TO RECOVER FAIL CRITICAL JET REQUIREMENTS FOR ET SEPARATION AND PRIOR TO Q-BAR = 20 AFTER ALL OTHER OPTIONS HAVE BEEN ATTEMPTED (E.G., RESTRING, PORTMODE, ETC.)

GNC Flight Rule {A8-19}, YAW JET DOWNMODE, addresses entry yaw jet downmode for multiple failures. This rule prescribes No Yaw Jet selection if all four jets are failed on either side. No yaw jet DAP mode is a certified flight control mode, and without numerous failures further downmode will not be required. Leaking oxidizer (N_2O_4) or fuel (MMH) may create a greater flammability hazard due to the operation of the APU's. Fuel (MMH) has demonstrated a fire potential when leaked onto the internal thermal blankets. The vent doors must be opened for a nonisolated N_2O_4 leak during entry which will result in major vehicle damage and subsequent extended downtime for repairs. Additionally, leaking oxidizer (N_2O_4) will cause corrosion of internal components potentially requiring replacement. Flight Rules {A16-204}, WINDWARD APU OPERATIONS CONSTRAINT (oxidizer); and {A16-11}, EXPEDITED POWERDOWN (fuel), address the off nominal postlanding impacts for leaking propellants into the pods. Due to the nature of the propellants and the uncertainty of a successful repressurization, all other options should be pursued prior to attempting repressurization of a leaking line. If no other option exists, then the line will be repressed and the leak supported to a Q-bar = 20. At Q-bar = 20 no yaw jet DAP mode will be selected and the leaking RCS isolated. ©[021998-6485B]

A6-207 THROUGH A6-250 RULES ARE RESERVED

FLIGHT RULES

THERMAL REDLINES AND MANAGEMENT

A6-251

GENERAL

- A. IF INSTRUMENTATION IS LOST FOR VERIFICATION OF HEATER OPERATION, THE REDUNDANT SET (A OR B) WILL NOT BE BROUGHT ONLINE WITH THE EXCEPTION OF THE OMS/RCS CROSSFEED HEATERS.

The loss of insight into the heater operations does not make the heater suspect. The heater in use has been proven functional and there is no reason to switch to the redundant heater set with unknown operation.

The pod heaters are designed differently than the crossfeed heaters. If both sets of pod heaters are powered on possible heater patch delamination could occur since the patches (A and B) are laid on top of each other. The crossfeed line heaters are wrapped around the line, with A and B circuits wrapped together in a single "rope" heater. Consequently, both heaters can be powered on simultaneously to protect for failed-off heaters without risking damage to heater elements. The crossfeed line heaters also have series redundant thermostats for overtemperature protection.

- B. THE HEATERS WILL BE CYCLED TO THE REDUNDANT SET (A OR B) AT LEAST ONCE DURING THE MISSION.

Ensures two functioning heater systems.

- C. RCS PRIMARY THRUSTERS HEATERS WILL BE OFF FOR ASCENT, UNLESS THE AMBIENT TEMPERATURE AT THE LAUNCH SITE IS < 50 DEG F. THE HEATERS WILL BE ENABLED FOR ALL OTHER FLIGHT PHASES OF THE MISSION. VERNIER THRUSTER HEATERS WILL BE ENABLED PRIOR TO LAUNCH AND TURNED OFF FOR ENTRY.

Primary jet heaters are powered off for ascent to provide additional power savings.

For cold launch conditions where the ambient temperature at the launch site is < 50 deg F (reference OMRSD, general requirements, 9.2.5), the primary heaters may be powered on during ascent to preclude launch commit criteria (LCC) violations (injector temperature ? 64 deg F) (reference LCC page 6.3-28). The LCC limits preclude jet valve seat shrinkage and subsequent jet leakage during ascent.

Primary heaters can only be turned on if the ascent electrical load for the particular mission is small enough to allow the additional power consumption. However, if power requirements do not permit, heaters should be left on until T-20 minutes.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-251

GENERAL (CONTINUED)

Vernier jet heaters are on prelaunch through ascent to ensure proper operating temperature for on-orbit operations. They are turned off for entry since the jets are not used, and to prevent overtemping.

Jet heaters may be turned off in flight for contingency powerdowns.

- D. IN THE EVENT THAT ONE SET OF HEATERS IS NOT OPERATING IN ITS HEATER CONTROL RANGE AND THE THERMAL ENVIRONMENT CONDITIONS ARE NOT A FACTOR, THAT SET WILL BE TURNED OFF AND THE OTHER SET TURNED ON. IF THE APPROPRIATE TEMPERATURE INDICATES THAT THE HEATER IS THEN OPERATING WITHIN ITS HEATER CONTROL RANGE, THEN THE FIRST SET OF HEATERS WILL BE DECLARED FAILED.

After switching to another heater set which controls the thermal environment within normal limits, the first set of heaters is declared failed because no other factors were involved.

- E. ANY HEATER SET (A OR B) THAT IS FAILED ON WILL BE CONTROLLED BY MANUAL OPERATION AND STILL BE CONSIDERED OPERATIONAL IF THE OTHER SET FAILS.

Failed-on heaters are not considered failed because they can manually be controlled by cycling power on and off

Rule {A6-256}, OMS/RCS HEATER PERFORMANCE MONITORING, references this rule.

FLIGHT RULES

A6-252

OMS/RCS POD HEATER

LOSS OF REDUNDANT CRITICAL HEATER CIRCUITS IN THE OMS POD NECESSARY TO MAINTAIN CG CONTROL, PROPELLANT REDLINES, AND RCS ATTITUDE CONTROL FOR ENTRY IS CAUSE FOR ENTRY AT THE NEXT PLS IF THE ENVIRONMENT CANNOT MAINTAIN THERMAL REDLINES:

CRITICAL HEATER LOCATION	EQUIPMENT
A. KEEL WEB, INNER "Y" WEB	OMS/RCS TANKS, RCS HE LINES
B. RCS HOUSING HEATERS	RCS PROPELLANT LINES
C. (2 OF 3) - UPPER "Y" WEB, OUTBOARD "Y" WEB, GSE SERVICE PANEL	RCS MANIFOLD LINES
D. OME COVER	OME PROPELLANT FEEDLINES
E. OME COMPARTMENT	OME PROPELLANT FEEDLINES GN ₂ TANK AND ACCUMULATOR

All critical OMS/RCS heater circuits are redundant. For the loss of both A and B heaters, vehicle attitude may be used to maintain an acceptable thermal environment. The heater circuitry protects all equipment that contains propellant. The propellant temperatures must be maintained for each piece of equipment according to the Flight Rules. Violation of the thermal redlines will be cause for deorbit at the next PLS.

* Part C says "(2 of 3)" because all three heaters provide heating for the same vicinity.

A6-253

FORWARD RCS MODULE TEMPERATURE MANAGEMENT

WHEN NO SM MACHINE IS RUNNING, FRCS HEATERS WILL BE OFF. MANUAL CYCLING OF HEATER SWITCHES WILL BE MCC CALL.

The forward pod will stay within acceptable limits for a sufficient period of time without the heaters being powered on. The concern is that a failed-on heater will result in overtemping manifold lines without being annunciated by SM.

FLIGHT RULES

A6-254

OMS/RCS PODS TEMPERATURE MANAGEMENT

- A. ONE OF THE REDUNDANT SETS OF POD HEATERS WILL BE USED TO MAINTAIN ACCEPTABLE THERMAL CONDITIONS IN THE PODS. BOTH SETS OF HEATERS WILL NOT BE USED SIMULTANEOUSLY.

The OMS pod heaters are operated only one circuit at a time. The concern is that the heater patches will overtemperature and debond from the structure if both sets of heaters are operated concurrently. This would result in heater circuit failures in both circuits since both circuits are contained in each heater patch and the patches must be on the structure to work properly.

- B. DURING OPS 1, ALL POD HEATERS WILL BE TURNED OFF. MANUAL CYCLING OF HEATER SWITCHES WILL BE ON MCC CALL.

The OMS pods are warmed by hot GN₂ prelaunch. The heaters are off during ascent phase to reduce the power level in the event a power failure would occur during launch. Further, since the switches are not accessible during ascent, corrective action could not be taken for a heater failed on.

- C. ALL POD HEATERS WILL BE TURNED OFF AT CREW SEAT INGRESS FOR ENTRY AND WILL REMAIN OFF THROUGH ENTRY.

The OMS pods heaters are not required during entry due to aero heating. Also, the heaters are off during entry to reduce the power level in the event a power failure would occur during entry.

- D. WHEN THERE IS NO ONBOARD THERMAL VISIBILITY INTO THE PODS (NO SM AND NO BFS), ALL POD HEATERS WILL BE OFF. MANUAL CYCLING OF HEATER SWITCHES WILL BE ON MCC CALL.

An undetected fail-on heater may damage pod components. The ground will monitor the pod temperatures and cycle the heaters as required to maintain temperatures within limits.

FLIGHT RULES

A6-255

OMS/RCS CROSSFEED LINES TEMPERATURE MANAGEMENT

- A. DURING ASCENT, FROM LIFT-OFF UNTIL POST OMS-2, BOTH (A AND B) SETS OF HEATERS WILL BE ON.

The crossfeed line heaters are wrapped around the line, with A and B circuits wrapped together in a single "rope" heater. Consequently, both heaters can be powered on simultaneously to protect for failed-off heaters without risking damage to heater elements. The crossfeed line heaters also have series redundant thermostats for overtemp protection.

- B. DURING ON-ORBIT PERIODS, ONE OF THE REDUNDANT HEATERS (A OR B) WILL BE ON.

Heaters are required to maintain the crossfeed line thermal conditions within acceptable limits for interconnect and crossfeed operations.

- C. BOTH (A AND B) SETS OF HEATERS WILL BE TURNED ON AT CREW SEAT INGRESS FOR ENTRY AND WILL REMAIN ON THROUGH ENTRY.

The crossfeed line heaters are wrapped around the line, with A and B circuits wrapped together in a single "rope" heater. Consequently, both heaters can be powered on simultaneously to protect for failed-off heaters without risking damage to heater elements. The crossfeed line heaters also have series redundant thermostats for overtemp protection.

- D. WHEN THERE IS NO ONBOARD THERMAL VISIBILITY INTO THE CROSSFEED LINES (NO SM AND NO BFS), BOTH (A AND B) SETS OF HEATERS WILL BE TURNED ON.

The heater operation cannot be verified without instrumentation. Therefore both A and B heaters are turned on to provide fail-safe protection.

FLIGHT RULES

A6-256

OMS/RCS HEATER PERFORMANCE MONITORING

THE PARAMETERS MARKED IN THE TABLES WITH SINGLE ASTERISKS ARE LOCATED NEAR HEATER THERMOSTATS, AND ARE USED TO MONITOR HEATER OPERATION. THE NOMINAL TEMPERATURE RANGE FOR EACH HEATER IS VEHICLE/POD SPECIFIC. THE RANGE DEPENDS ON THE TESTED SET POINTS OF THE CONTROLLING THERMOSTATS, AS DOCUMENTED IN THE SPACE SHUTTLE SYSTEMS HANDBOOK DRAWINGS 11.7 THROUGH 11.9. THE TEMPERATURE INDICATED BY THE OI PARAMETER NEAR THE HEATER THERMOSTAT MAY VARY SLIGHTLY OUTSIDE THE SET POINT RANGE DUE TO THE DIFFERENCE IN LOCATION BETWEEN THE OI PARAMETER AND THE THERMOSTAT, AND DUE TO THE EFFECT OF VEHICLE ATTITUDE.

THE PARAMETERS USED TO MONITOR COMPONENT TEMPERATURES SHOULD NOMINALLY REMAIN WITHIN THE SYSTEM REDLINES:

@[062801-4341A]

The heater matrix allows a determination to be made on the health of the OMS/RCS heater system. The different heater systems are shown down to the heater/component level. The instrumentation used to verify the operation of each heater is defined.

Operating outside of the nominal temperature range (vehicle/pod and attitude-dependent) may identify a heater failure condition (refer to Rule {A6-251D}, GENERAL (thermal management)). The thermostat set points SSSH drawings are supplied by the Operational Space Shuttle Orbiter Heater Systems Book, JSC-18549, which is maintained by the JSC/ES311 Thermal Branch.

Several of the parameters in the tables monitor heater operation by close proximity to the heater thermostat. If the indicated temperature of such a parameter exceeds the thermostat set point range by 5 deg F or more, then this must be explained by the influence of sensor location with respect to the thermostat and/or by the vehicle attitude, else the heater will be declared failed.

The OMS and RCS thermal redlines are defined in the SODB tables 3.4.3.2-1 and 3.4.3-1. If a parameter directly measures the temperature of a component that has SODB constraints, then these constraints are listed in this rule under SYSTEM REDLINE. In several cases (as noted with asterisks in the SYSTEM REDLINE column), the parameter is mounted on the pod structure and is used to monitor heater performance only. These structure temperatures do not necessarily reflect the temperature of components that are warmed by the monitored heaters.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-256

OMS/RCS HEATER PERFORMANCE MONITORING (CONTINUED)

Thermal analysis (reference Data Request - RI-1512A) has shown that for the loss of temperature parameters listed as requiring thermal analysis it may be possible to tolerate a heater failing on or off. A thermal analysis for the specific planned attitude timeline will be required if loss of insight occurs to determine if vehicle attitude management and/or manual cycling of heaters will be required to protect SODB redlines. ©[062801-4341A]

The crossfeed flow lines and drain/bleed lines are all wrapped with rope-type heaters. The thermal status of each section of crossfeed line is monitored by the temperature parameters near the thermostat for that section of line. Although these parameters measure the line temperatures directly, the configuration of the rope heaters may allow warm spots to develop in the line away from any temperature parameter. For this reason, the fault detection annunciation (FDA) limits for these temperature parameters are well within the system redlines, allowing action to be taken before the redlines are violated anywhere in the lines. These FDA limits are documented in SSSH drawing 11.9, HTR AFT OMS/RCS.

Rule {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL], references this rule. ©[062801-4341A]

FLIGHT RULES

A6-257

RCS JET TEMPERATURE MANAGEMENT

A. PRIMARY JETS: @[091098-6708]

1. IN THE EVENT OF A FAILED-OFF PRIMARY RCS JET HEATER, THE AFFECTED THRUSTER MAY BE FIRED MANUALLY OR CHANGED TO FIRST PRIORITY, OR ORBITER ATTITUDE MAY BE CHANGED TO MAINTAIN INJECTOR TEMPERATURES > 42(47) DEG F (50 DEG AT VALVE SEAT).

The 50 deg F limit (ref. Shuttle Operational Data Book (SODB) volume I, table 3.4.3.2-1, note L) protects against increased risk of valve leakage. The corresponding injector temperature limit is derived from thermal math model analysis data for the case of a heater failed off and exposure to deep space. If the jet is exposed to some solar heating (but not enough to alleviate the leakage concern), then the injector/valve temperature differential may diminish slightly; however, since the rule assumes worst-case instrumentation error (5 deg F), the 50 deg valve limit is reasonably protected.

Note that a primary RCS jet heater is considered failed when the injector temperatures reach 55 deg F (ref. Rule {A6-9}, RCS JET HEATER). Firing the jet periodically will maintain the injector within operating limits. (Testing has shown that a 2-second firing will increase the jet injector temperature approximately 16 deg F.) If planned orbit activities would result in single minimum duration pulse firings, hot-fire the jet for a minimum of 2 seconds prior to changing the jet to first priority. A minimum duration pulse firing with the injector temperatures > 55 deg F can cause a jet leak due to cold Teflon valve seats not seating properly. (Ref. SODB, volume I, paragraph 3.4.3.2.13).

2. PRCS JETS MAY NOT BE FIRED IF INJECTOR TEMPERATURES EXCEED 162 (157) DEG F (150 DEG F AT VALVE SEAT) FOR A SUSTAINED PERIOD (EXCEPT AS DEFINED IN PARAGRAPH A.3 OF THIS RULE). TO STAY BELOW THIS OPERATIONAL THERMAL LIMIT:
 - a. ORBITER ATTITUDE MAY BE CHANGED
 - b. THE AFFECTED JET(S) MAY BE PLACED IN LAST PRIORITY
 - c. A FAILED-ON HEATER MAY BE SWITCHED OFF @[091098-6708]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-257

RCS JET TEMPERATURE MANAGEMENT (CONTINUED)

The 150 deg F limit (ref. SODB volume I, table 3.4.3.2-1, note L) protects against permanent deformation and damage to the Teflon valve seat due to the combined effects of high closing seat loads and degraded Teflon strength at the higher temperature. In turn, this protects against resulting valve leakage and reduced valve lifetime. The 157 deg F injector temperature limit is derived from the 150 deg F valve limit +12 deg F injector/valve differential (based on Rockwell-Downey thermal analysis) -5 deg F instrumentation error. Unrestricted thruster firings with valve seat temperatures above 150 deg F are not permitted. In this case, any DAP/RM configuration that could result in the firing of the affected primary thrusters is forbidden. Depending on the heat source (Sun, heat of combustion, or failed heater), a variety of actions may be performed, as appropriate, to keep a thruster operational. Note that the crew does not have insight into jet injector temperatures on board, so these actions must be initiated by the ground. Every reasonable effort will be made to do this in a timely manner such that jet firings above the operational limit may be avoided. ©[091098-6708]

3. PRCS JETS MAY BE FIRED IF INJECTOR TEMPERATURES HAVE EXCEEDED 162 (157) DEG F, BUT ONLY IF:
 - a. ALL JETS IN THE GROUP (SAME POD AND DIRECTION) HAVE EXCEEDED THIS OPERATIONAL LIMIT.
 - b. THE DAP IS CONFIGURED TO ENSURE A MINIMUM FIRING DURATION OF 400 MSEC.

The main concern with thruster operation above 157 deg F is the load imparted on the valve seat as the poppet closes. Since the real concern is at valve closing, increasing the minimum "on time" reduces the valve seat temperature to an acceptable level at shutdown. However, immediately following the firing, the temperatures will rise quickly back up due to thermal soak back effects. If a thruster needs to be fired, a minimum "on time" of 400 msec may be used to preclude valve seat degradation (ref. SODB volume III, paragraph 4.3.2.7. Note that SODB volume III contains engineering data which may not be supported by test.).

A thruster which has exceeded the operational limit of 157 deg F due to a high duty cycle will be placed in last priority in favor of a colder, redundant jet in the same group. If all jets in a group exceed the operational limit and use of the jet group is still required, then the DAP will be configured accordingly. This approach, documented in CHIT 013, was successfully utilized during STS-77 rendezvous activities. One re-prioritization was required for both of the first priority +X jets, but the redundant +X jets did not reach their operational limit for the remainder of the rendezvous and no further actions were required.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-257

RCS JET TEMPERATURE MANAGEMENT (CONTINUED)

4. ONE OF THE FOLLOWING ACTIONS WILL BE TAKEN TO PREVENT INJECTOR TEMPERATURES FROM EXCEEDING 187 (182) DEG F (175 DEG F AT VALVE SEAT): @[091098-6708]
 - a. ORBITER ATTITUDE WILL BE CHANGED. IF DOING SO WILL VIOLATE MISSION REQUIREMENTS, THEN RCS JET INJECTORS MAY BE EXPOSED TO TEMPERATURES UP TO 207 (202) DEG F (195 DEG F AT VALVE SEAT) FOR UP TO 12 HOURS PER SHUTTLE MISSION. @[091098-6708]
 - b. A FAILED-ON HEATER WILL BE SWITCHED OFF.

The 175 deg F limit (ref. SODB volume I, table 3.4.3.2-1, note L) protects against permanent deformation and damage (cold flow) to the Teflon seat from extended exposure to high temperatures and seal loads at system pressure. The 182 deg F injector temperature limit is derived from the 175 deg F valve limit +12 deg F injector/valve differential (based on Rockwell-Downey thermal analysis) -5 deg F instrumentation error.

The 195 deg F limit (ref. SODB volume I, table 3.4.3.2-1, note L) is a contingency value intended to accommodate predicted peak temperatures during continuous exposure to solar radiation. The 12-hour constraint is a cumulative total and is not "reset" if the thruster injector temperatures decrease to below the limit for any amount of time.

B. VERNIER JETS:

1. IN THE EVENT OF A FAILED-OFF VERNIER RCS JET HEATER OR INADEQUATE DUTY CYCLES, THE FOLLOWING STEPS MAY BE TAKEN TO INCREASE FIRING FREQUENCY AND DURATION, IF REQUIRED TO PREVENT A FALSE RM FAIL LEAK ANNUNCIATION:
 - a. BIAS THE ATTITUDE.
 - b. DESELECT AFT YAW VERNIERS.
 - c. TIGHTEN THE DEADBAND.

These methods have been employed on many previous flights. However, it has been shown that biasing the attitude (and taking advantage of gravity gradient torque) and deselecting the aft yaw verniers are better long-term methods of raising jet temperatures (as determined from STS-62 and STS-94) because both methods cause certain targeted jets to fire more frequently while allowing others to fire less frequently. Tightening the deadband increases jet firing frequency (which is undesirable for microgravity payloads) and unless the deadband is severely tightened may not solve the problem. Ref. Rule {A6-9B}, RCS JET HEATER, for relevant failed-heater definitions. @[091098-6708]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-257

RCS JET TEMPERATURE MANAGEMENT (CONTINUED)

2. A VERNIER JET THAT HAS INCURRED A FALSE RM FAIL LEAK ANNUNCIATION DUE TO A FAILED-OFF JET HEATER OR INADEQUATE DUTY CYCLES MAY BE USED WITHOUT ONBOARD LEAK RM UNDER THE FOLLOWING CONDITIONS: @[091098-6708]
 - a. JET IS USED DURING AOS PERIODS ONLY.
 - b. THE JET INJECTOR TEMPERATURES ARE > 90 DEG F AND < 140 DEG F.
 - c. THE JET INJECTOR TEMPERATURES HAVE NOT DECREASED > 20 DEG F PER MINUTE AT ANY TIME IN THE PAST HOUR.

Due to inadequate or failed heater operations, the forward vernier jets may cool during extended periods of low activity resulting in a violation of the 130 deg F RCS RM leak detection limit and a false leak annunciation. False annunciation can be distinguished from an actual leak based on ground data evaluation. The 130 deg F limit protects against leaking propellant freezing and plugging the combustion chamber and is not applicable if there is no leak; therefore, once it has been determined that a deselected jet is not leaking, it may be used without onboard RM as long as the injector temperatures remain above 90 deg F, which protects against seal shrinkage and propellant leakage (ref. Rule {A6-9B}, RCS JET HEATER).

Use of the jet must be confined to AOS periods since the MCC is now prime for leak detection, and the crew does not have onboard insight into jet injector temperatures. If/when the injector temperatures recover and are sufficiently above the RM limit (upon reaching 140 deg F), RM must be toggled for the jet so as to re-enable automatic onboard leak detection. For vernier operation below the RM limit, engineering analysis (ref. Marquardt Report No. TM05-V009, June 1980) has determined that a leak will be indicated by an injector temperature drop of more than 20 deg F per minute. In this case, the MCC will immediately instruct the crew to cease use of the jet (via jet deselection or DAP configuration).

Note that a 10-second steady-state firing will warm a vernier jet injector from 90 deg F to above the 130 deg F RM limit (ref. SODB volume 1, paragraph 3.4.3.2.13). Such a firing is particularly advisable after vernier injector temperatures have dropped significantly below 130 deg F (for example, when a deorbit backout and 24-hour waiveoff are declared and verniers are reactivated hours after their heaters have been turned off), and it is desired to immediately re-enable RCS RM. @[091098-6708]

FLIGHT RULES

A6-258

ARCS BULK PROPELLANT TEMPERATURE MANAGEMENT

VEHICLE ATTITUDE WILL BE CHANGED ON A NONINTERFERENCE BASIS TO PROVIDE ARCS BULK PROPELLANT TANK TEMPERATURE THERMAL CONDITIONING WHENEVER THE ARCS TANK TEMPERATURE IS < 68 DEG (70 DEG) F. IF AN ATTITUDE CHANGE IMPACTS HIGH PRIORITY FLIGHT OBJECTIVES, THE ARCS TANK TEMPERATURE LIMIT MAY BE REDUCED TO 65 DEG (67 DEG) F BEFORE ACTION IS REQUIRED. THE FOLLOWING ATTITUDES ARE DESIRABLE TO PROVIDE THERMAL CONDITIONING TO INCREASE PROPELLANT TEMPERATURES:

- A. NOSE SUN 10 DEGREES PITCHUP.
- B. NOSE SUN.
- C. TAIL SUN.
- D. BOTTOM SUN.

FOR HIGH BETA ANGLE (> 60 DEGREES) BOTTOM SUN WOULD BE PREFERRED OVER TAIL SUN TO AVOID ORBITER MANEUVERING ENGINE (OME) LINE TEMPERATURE CONSTRAINTS.

Rules {A6-6A}, OMS/RCS CROSSFEED LINE; and {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL], reference this rule.

Propellant temperatures must be maintained above the 70 deg F limit to avoid possible ZOT's during entry jet firings below 70,000 feet. WSTF testing has shown that 65 deg F propellant temperatures caused minor ZOT's without creating jet leaks. Similar tests with propellant temperatures at 60 deg F have caused several ZOT's which resulted in liquid leakage at the jet.

Because of the entry ZOT concern, the 70 deg F bulk propellant constraint will be protected if it can be done without violating mission objectives. If the mission objectives prevent the proper vehicle attitude required to maintain the 70 deg F limit, the bulk propellant constraint will be reduced to 67 deg F (65 deg plus 2 deg F instrumentation accuracy) with the understanding that an increased risk of ZOT's exists during entry. The decision to reduce the bulk propellant constraint will be a real-time call and will not be used as a premission planning tool. Because the 67 deg F limit resides in SODB, volume 3, the engineering community (MER) will be notified of the plan to reduce the bulk propellant temperature constraint and given the associated rationale.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-258

ARCS BULK PROPELLANT TEMPERATURE MANAGEMENT (CONTINUED)

To prevent cold tank temperatures, the vehicle can be oriented (OMS pods are in the shade) causing the heater to cycle on. Top to Sun and side to Sun attitudes prevent heater cycles and result in a decay in tank temperature. Changing attitudes will not result in immediate heater activation since heater thermostats are located on the warm pod deck (4 to 6 hours for first cycle). The following table was generated from flight data and will help determine which attitude provides the required response.

<i>Attitude</i>	<i>Equil. Temp (° F)</i>	<i>Rise rate (° F/day)</i>
<i>Nose Sun 10° Up</i>	74	5
<i>Nose Sun</i>	74	<i>No data</i>
<i>Tail Sun *</i>	75	>1
<i>Bottom Sun *</i>	75	>1

**High beta angles will cause bondline temperature limit concerns.*

FLIGHT RULES

CONSUMABLES DEFINITIONS AND REDLINES

A6-301 **OMS USABLE PROPELLANT**

A. OMS GAGED PROPELLANT IS DEFINED AS THE AMOUNT OF OMS PROPELLANT LOADED PER POD MINUS THE LINE TRAPPED:

$$\text{LINE TRAPPED: } \frac{\text{OX}}{50.5} \qquad \frac{\text{FU}}{26.5}$$

@[092701-4850]

B. OMS USABLE PROPELLANT IS DEFINED AS THE OMS GAGED PROPELLANT MINUS THE FOLLOWING RESIDUALS:

$$\begin{array}{l} \text{TANK TRAPPED: } \frac{\text{OX}}{212} \qquad \frac{\text{FU}}{110} \\ \text{DISPERSIONS: } \quad (\text{REF. PARAGRAPH C}) \quad (\text{REF. PARAGRAPH C}) \end{array}$$

C. OMS DISPERSIONS ARE DEFINED AS THE RSS OF (1) FLOW RATE AND MIXTURE RATIO ERROR BASED ON NOMINAL LOAD WITH 2 PERCENT ERROR AND (2) LOADING UNCERTAINTY. DISPERSIONS ARE CALCULATED AS FOLLOWS:

1. a = FLOW RATE AND MIXTURE RATIO ERROR.

$$a = 0.02 (\text{OX (FU) GAGED LBS PROPELLANT} - \text{OX (FU) TANK TRAPPED}).$$

2. b = LOADING UNCERTAINTY:

BENCHMARK	RESIDUALS	WSP AVAIL	LOADING UNCERTAINTY
GOOD	N/A	N/A	40 LB OX, 24 LB FU
OUT-OF-SPEC	N/A	N/A	81 LB OX, 49 LB FU
NO	N/A	YES	81 LB OX, 49 LB FU
NO	AFT GAGE	NO	1.5 PERCENT, PROP LOADED PLUS 40 LB OX, 24 LB FU
NO	CALCULATED	NO	1.5 PERCENT PROP LOADED

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-301

OMS USABLE PROPELLANT (CONTINUED)RESIDUALS

IF | AFT GAGE RESIDUALS - CALCULATED RESIDUALS | < 1 PERCENT

THEN USE ,

RESIDUALS = AFT GAGE RESIDUALS

OTHERWISE USE ,

RESIDUALS = CALCULATED RESIDUALS

$$\text{DISPERSION (OX (FU) PER POD)} = (a^2 + b^2)^{1/2}.$$

Since the OMS tank and line-trapped propellant cannot be burned, it must be accounted for when calculating usable propellant. Since OMS dispersions may or may not be in the tank, this propellant must also be accounted for when calculating usable propellant. The OMS tank and line-trapped quantities are documented in SODB, volume II, section 4.1.

The calculation for loading uncertainty is based on whether KSC gets a "benchmark" while loading. The "benchmark" is defined as the point at which the total quantity updates after the forward probe gets wet. A "good benchmark" is a benchmark that occurs at 45 ± 0.5 percent (quantity of propellant in tank is determined by a flowmeter). A "benchmark out-of-spec" is a benchmark that occurs greater than 45.5 percent or less than 44.5 percent. "No benchmark" is when the forward probe does not give a quantity reading.

The primary loading method uses the onboard OMS gages. Only for the no-benchmark loading cases are the wet sense point (WSP) and residuals considered. The WSP is the first edge of the forward probe which senses propellant. There is a delay between the forward probe getting wet and the total quantity gage update. The update is not triggered until a voltage threshold in the totalizer electronics is met. Normally this delay is not important, but for a no-benchmark case, the WSP is determined by interpreting graphical data of total quantity gage output versus time. These graphs show a distinct change in voltage which correlates to wetting of the forward probe.

The loading uncertainty for the good benchmark is defined as 40 lb OX and 24 lb FU equal to 0.5 percent of a full load. This 0.5 percent is the advertised accuracy of the onboard OMS gages. The out-of-spec benchmark adds an additional 0.5 percent for a total uncertainty of 81 lb and 49 lb. For the first of the three no-benchmark loading cases, the WSP is known. The confidence in loading with the WSP is considered equal to that of the out-of-spec case; therefore, the loading uncertainty is 81 lb OX and/or 49 lb FU.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-301 **OMS USABLE PROPELLANT (CONTINUED)**

For the next two no-benchmark cases, the WSP could not be determined, so a residuals check is made. The residuals check determines the confidence in the aft gages. If the absolute difference between the calculated residuals and aft gage residuals is less than 1 percent, then there is confidence in the aft gages (i.e., the aft gage and onboard totalizer is tracking the GSE). The problem; therefore, lies in the forward probe. Subsequently, the loading uncertainty retains the initial 40 lb and 24 lb, then adds 1.5 percent more loading uncertainty; that is, 1.5 percent of the remaining propellant to be loaded using the GSE flowmeters. This 1.5 percent additional loading uncertainty is the advertised accuracy of the GSE gages. The tanks are not drained and refilled because of the amount of work involved, the aft gages are working, and the 1.5 percent additional propellant is conservative.

In the final no-benchmark cases, the WSP is unknown and the absolute difference of the residuals is greater than 1 percent (i.e., the aft gage and onboard totalizer are not tracking the GSE). The problem lies in the totalizer, or both the aft and forward probes. In this case, the tanks are drained and the loading is restarted with zero percent residuals. Rules {A4-153K.1}, CG PLANNING; and {A6-303}, OMS REDLINES [CIL], reference this rule.

A6-302 **RCS USABLE PROPELLANT**

RCS USABLE PROPELLANT IS DEFINED AS THE AMOUNT OF RCS PROPELLANT LOADED MINUS THE FOLLOWING RESIDUALS:

ARCS	<u>OX</u>	<u>FU</u>
TANK TRAPPED	58	33
GAGE ERROR	50	34
LINE TRAPPED	<u>59</u>	<u>39</u>
LBS / POD	167	106
FRCS	<u>OX</u>	<u>FU</u>
TANK TRAPPED	139	84
GAGE ERROR	50	34
LINE TRAPPED	<u>38</u>	<u>21</u>
LBS / POD	227	139

Since the propellant trapped in the tank and lines cannot be burned, this propellant must be accounted for when calculating RCS usable propellant. Since the gage error may or may not be in the tank, this propellant must also be accounted for when calculating RCS usable propellant. (Reference SODB, volume II, table 4.2.)

- TBD** *OMS Steep* - *OMS steep delta V will be based on targeting constraints which require enough N-cycles (guidance cycles from closed-loop guidance initiation to the first non-zero roll command (ref. Rule {A4-152}, DEORBIT BURN TARGETING PRIORITIES) to protect 3-sigma entry dispersions. Note that real-time planning may reflect a delta V which protects more N-cycles, if propellant is available. In order to guarantee that there is sufficient propellant to perform an OMS steep deorbit, standard redlines must protect a delta V sufficient to deorbit at nominal end of mission, EOM plus 1 day, and EOM plus 2 days (ref. Rule {A2-103}, EXTENSION DAY REQUIREMENTS.) Standard redlines protect four attempts over 3 days; thus, the OMS steep delta V must cover the planned EOM opportunity, a one orbit late backup to the PLS, and the cheapest combination of a PLS opportunity with a one rev backup SLS opportunity for EOM +1 and +2. This level of protection is referred to as 2-1-1 deorbit opportunities. The specific opportunities protected may need to be modified in real time to account for trajectory variations, weather conditions, non-propulsive consumables margins, etc. If greater than 2-1-1 deorbit attempts are protected, OMS steep delta V may need to be increased.*
- TBD** *Nom D/O Prep* - *It is not operationally desirable to protect any part of the nominal deorbit prep in the OMS. However, if for any reason it cannot be protected in the Aft RCS, then it must be protected in the OMS.*

FLIGHT RULES

A6-303

OMS REDLINES [CIL] (CONTINUED)

156

- *Standard redlines protect as much of the deorbit wave-off extension day propellant as is operationally convenient in the OMS. This helps to assure that the aft RCS deorbit redline is protected at a higher priority than OMS steep deorbit propellant, because any excess usage during these extension days will come from the OMS. However, any or all of this propellant can be protected in the aft RCS in order to maximize capability and/or minimize crew workload. The extension day portion of the deorbit wave-off extension day protects 56 lb and is based on using Nose/Tail ALT control. An additional 100 lb of propellant are normally redlined in the OMS to perform a partial deorbit preparation after the extension day. This propellant covers the period from the start of deorbit preparation activities at TIG-4:40 to TIG-0:30 minutes. The remainder of this deorbit prep is normally redlined in the aft RCS. The 156 lb must be increased to 321 lb if Tail-Only control is required. The deorbit (systems) wave-off extension day propellant cannot be traded against other orbit activities. Per Rule {A2-108}, CONSUMABLES MANAGEMENT, the deorbit wave-off extension day must be protected using the primary jets since many of the orbiter contingencies which require such a wave-off also fail the vernier jets. Note also that the deorbit wave-off extension day assumes a specific attitude profile: -ZLV-XVV is the default attitude and was chosen to provide the minimum propellant consumption with maximum debris protection, and because it is relatively insensitive to altitude, thus providing the best protection for off-nominal (abort) orbits. However, if a different attitude profile is required for deorbit thermal conditioning, this must be protected. Ref. Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, and the Flight Rule Annex. The deorbit wave-off extension day requires 382 lb Nose/Tail ALT or 533 lb Tail-Only ALT with 10 hours of Tail-Only ALT 5 degrees PTC protected per Rule {A2-110}, STRUCTURES THERMAL CONDITIONING. According to an email dated June 5, 2000, from ES/Y. Chang, up to a 10-degree deadband for PTC is thermally acceptable.*

A6-303

OMS REDLINES [CIL] (CONTINUED)

106

- *Reference Rockwell International Internal Letter IL P&AS-DLJ-77-032, the OMS portion of OMS engine failure protection consists of out-of-plane thrusting during gimbal retrim (15 lb per pod) and increased tank residuals due to less favorable orientation of the propellant with respect to the acquisition screens (38.4 lb per pod). These increased tank residuals must be protected, especially after the loss of one OMS engine. However, because the residual propellant (77 lb) remains in the tank, it may be counted toward the CG ballast requirement. The original OMS engine failure requirement, as documented in the letter referenced above, also protected 14 lb of fuel per pod to account for the OMS crossfeed mixture ratio shift. This protection is no longer required since current propellant management procedures account for actual engine performance including crossfeed. Because the deorbit wave-off extension day is reserved specifically for orbiter contingencies (ref Rule {A2-103}, EXTENSION DAY REQUIREMENTS), the risk of having a major orbiter systems failure followed by an OMS engine fail is small. On a flight specific basis, it may be worth accepting that risk in order to accomplish high priority objectives, as documented in the Flight Rule Annex. If OMS engine fail protection is given up, then the deorbit wave-off extension day propellant should be distributed in the OMS and aft RCS to cover the equivalent of OMS engine failure propellant in each system at the nominal EOM deorbit burn. This implicit protection will be lost if the extension day propellant is used. Once an OMS engine failure occurs, then explicit OMS engine failure protection is mandatory. ©[091098-6711B]*

FLIGHT RULES

A6-303

OMS REDLINES [CIL] (CONTINUED)

TBD Wx W/O Day - *In order to protect against unforeseen weather that results in unacceptable deorbit/landing conditions, Rule {A2-108}, CONSUMABLES MANAGEMENT, provides a weather wave-off extension day. Although it would normally be desirable to protect the extension portion of the weather wave-off extension day in the OMS, a single maneuver and 19 hours of vernier attitude hold is only 23 lb which would require first establishing interconnect, performing a 15-minute maneuver, and then immediately performing an OMS tank switch, which is not practical. Thus, the propellant required to extend 24 hours on the vernier jets (or N/T ALT) is normally redlined in the Aft RCS. However, if failures or other considerations require an increase in the amount of propellant protected for the 24-hour extension, then it may become practical to protect the extension day propellant in the OMS. For example, if T/O ALT attitude hold (89 lb) is required for the extension day, it would normally be preferable to protect it in the OMS. Unlike the propellant redlined for the deorbit wave-off extension day, the weather wave-off extension day is tradable against critical on-orbit activities per the established priorities detailed in Rule {A2-108}, CONSUMABLES MANAGEMENT, and Rule {A6-358}, VIOLATION OF MISSION COMPLETION REDLINES MATRIX. Note that the weather wave-off extension day assumes a specific attitude profile: -ZLV -XVV is the default attitude and was chosen to provide the minimum propellant consumption with maximum debris protection, and because it is relatively insensitive to altitude, thus providing the best protection for off-nominal (abort) orbits. However, if a different attitude profile is required for deorbit thermal conditioning, this must be protected. Ref. Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, and the Flight Rule Annex. The weather wave-off extension day requires 98 lb of OMS with 10 hours of vernier 1 deg PTC protected (250 lb Nose/Tail ALT or 301 lb Tail-Only ALT, both with 10 hours of 5 deg Tail-Only PTC) per Rule {A2-110}, STRUCTURES THERMAL CONDITIONING. According to an email dated June 5, 2000 from ES/Y. Chang, up to a 10-deg deadband for PTC is thermally acceptable. ©[091098 6711B] ©[092800-7247A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-303

OMS REDLINES [CIL] (CONTINUED)

TBD *D/O Attempts* - Propellant for additional deorbit attempts, such as extra orbits of attitude hold in the deorbit burn configuration, may be protected on a flight specific basis as documented in the Flight Rule Annex. Propellant for extra deorbit attempts is typically reserved in the Aft RCS, but may be protected in the OMS, Aft RCS, or both. ©[091098-6711B] ©[092800-7247A]

TBD *CG Ballast* - Propellant may be redlined to act as ballast to maintain the X and Y CG within limits. The amount of propellant required for CG ballast (ref. Rule {A4-153}, CG PLANNING) is determined during preflight analysis and updated in real time. Ballast will be protected in the OMS, the Aft RCS, or both. Care must be taken in apportioning ballast because OMS and ARCS propellant are not equivalent for ballast purposes. CG ballast cannot be traded against other orbit activities. CG ballast can be traded against other redline items only if the ballast requirement changes for extension day deorbit opportunities.

B. OMS TANK FAIL:

OMS TANK FAIL IS NOT PROTECTED.

There is no requirement to protect for an OMS tank failure.

C. OMS REDLINE FOR RCS DEORBIT [CIL]:

AFTER THE LOSS OF ONE OMS ENGINE, ADDITIONAL OMS PROPELLANT WILL BE REDLINED TO PROTECT 4+X RCS DEORBIT TO STEEP TARGETS. IF INSUFFICIENT OMS PROPELLANT IS AVAILABLE, ADDITIONAL RCS PROPELLANT MUST BE REDLINED. IF INSUFFICIENT OMS AND RCS PROPELLANT IS AVAILABLE TO PROTECT 4+X RCS DEORBIT TO STEEP TARGETS, DEORBIT WILL BE PLANNED FOR THE NEXT PLS OPPORTUNITY.

If RCS propellant must be used to supplement OMS propellant during a deorbit burn, a two-stage deorbit burn is preferred in order to simplify execution of the actual deorbit burn. ©[091098-6711B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-304

FORWARD RCS REDLINES (CONTINUED)

THE WEATHER WAVE-OFF ACTIVITIES MAY BE DELETED IN FAVOR OF CRITICAL PAYLOAD ACTIVITIES AS DOCUMENTED IN RULE {A2-108}, CONSUMABLES MANAGEMENT, AND THE FLIGHT RULE ANNEX. OMS ENGINE FAILURE FOR THE DEORBIT WAVE-OFF EXTENSION DAY MAY BE DELETED FOR HIGHER PRIORITY ACTIVITIES AS DOCUMENTED IN THE FLIGHT RULE ANNEX. ADDITIONAL DEORBIT ATTEMPTS MAY BE PROTECTED AS DOCUMENTED IN THE FLIGHT RULE ANNEX. VIOLATION OF THE FRCS DEORBIT REDLINE IS CAUSE FOR DEORBIT AT NEXT PLS IF INSUFFICIENT PROPELLANT IS AVAILABLE TO PROTECT THE OMS AND ARCS DEORBIT REDLINES USING TAIL-ONLY CONTROL. @[091098-6711B] @[092800-7247A]

NOTE: [1] ASSUMES ATTITUDE CONTROL IN -ZLV -XVV PER RULE {A2-108}, CONSUMABLES MANAGEMENT. IF THERMAL CONDITIONING IS REQUIRED, UTILIZE ATTITUDE PROFILE PER RULE {A2-110}, STRUCTURES THERMAL CONDITIONING, OR AS SPECIFIED IN THE FLIGHT RULES ANNEX. @[092800-7247A]

- 57 - *Reserved for nominal deorbit prep.*
- 12 - *If an OMS engine fails during the deorbit burn, the FRCS will control the attitude excursions that will occur while the OMS engine gimbals to realign the thrust vector through the CG. Propellant is normally redlined to protect for this contingency. FRCS is not necessarily required if sufficient aft propellant is redlined to control the attitude excursion using tail only control. The requirement for OMS engine fail protection after a deorbit wave-off extension may be deleted in order to accomplish higher priority activities as documented in the Flight Rule Annex. If so, engine fail protection should still be provided at nominal end of mission using the deorbit wave-off extension allotment or the FRCS contingency propellant (ref. Rule {A6-357}, FORWARD RCS CONTINGENCY PROPELLANT AVAILABLE).*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-304

FORWARD RCS REDLINES (CONTINUED)

- 110
- *The deorbit wave-off extension day consists of 66 lb for a deorbit prep plus 11 lb for the waveoff, which will sustain nose-tail control for 1 hour until vernier control can be established, plus 33 lb for the extra day Nose/Tail ALT. Note that Nose/Tail ALT is assumed because many failures which require a deorbit wave-off extension day also fail the vernier jets, reference Rule {A2-108}, CONSUMABLES MANAGEMENT. Nose/Tail ALT control is normally protected instead of Tail-Only ALT control because it requires less propellant overall and also provides sufficient propellant to utilize the vernier jets if they actually are available. Note also that the deorbit wave-off extension day assumes a specific attitude profile: -ZLV -XVV is the default attitude and was chosen to provide the minimum propellant consumption with maximum debris protection, and because it is relatively insensitive to altitude, thus providing the best protection for off-nominal (abort) orbits. However, if a different attitude profile is required for deorbit thermal conditioning, this must be protected. Ref. Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, and the Flight Rule Annex. The deorbit wave-off extension day requires 92 lb for Nose-Tail ALT with 10 hours of Tail-Only 5 deg PTC protected per Rule {A2-110}, STRUCTURES THERMAL CONDITIONING. According to an email dated June 5, 2000, from ES/Y. Chang, up to a 10 deg deadband for PTC is thermally acceptable. ©[092800-7247A]*
- 85
- *As part of the weather wave-off extension day, propellant is provided to perform a wave-off/backout (11 lb), a vernier extension day (17 lb), and an additional nominal deorbit prep (57 lb). This item requires 107 lb if protected Nose/Tail ALT. Propellant budgeted for the weather wave-off extension day may be traded for critical on-orbit activities as defined in Rule {A2-108}, CONSUMABLES MANAGEMENT, and the Flight Rule Annex. Note that the extension day portion of the weather wave-off extension day assumes a specific attitude profile: -ZLV -XVV is the default attitude and was chosen to provide the minimum propellant consumption with maximum debris protection, and because it is relatively insensitive to altitude, thus providing the best protection for off-nominal (abort) orbits. However, if a different attitude profile is required for deorbit thermal conditioning, this must be protected. Ref. Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, and the Flight Rule Annex. The weather wave-off extension day requires 134 lb with 10 hours of vernier 1 deg PTC protected (115 lb for Nose-Tail ALT with 10 hours of 5 deg Tail-Only PTC) per Rule {A2-110}, STRUCTURES THERMAL CONDITIONING. According to an email dated June 5, 2000, from ES/Y. Chang, up to a 10-deg deadband for PTC is thermally acceptable. ©[092800-7247A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-304

FORWARD RCS REDLINES (CONTINUED)

- 17 - As part of the weather wave-off extension day, propellant to perform one rev of attitude hold on the TRANS DAP is provided to ensure 2 consecutive deorbit attempts on one of the three deorbit days. Propellant budgeted for the weather wave-off extension day may be traded for critical on-orbit activities as defined Rule {A2-108}, CONSUMABLES MANAGEMENT, and the Flight Rule Annex. ©[092800-7247A]
- TBD** D/O Attempts - Propellant for additional deorbit attempts, such as extra orbits of attitude hold in the deorbit burn configuration, may be protected as specified in the Flight Rule Annex. One orbit of Nose/Tail Trans DAP with FES will cost 17 lb Fwd RCS. ©[091098-6711B]
- TBD** D/O Supplement- If Forward RCS propellant is required to supplement the OMS deorbit steep propellant, either for +X translation, +Z translation, or for attitude hold during aft RCS +X translation, then this propellant, as well as any associated maneuvers, must be protected. ©[091098-6711B]
- TBD** CG Ballast - Propellant may be redlined to act as ballast to maintain the X and Y CG within limits. The amount of propellant required for CG ballast (ref. All Flights Rule {A4-153}, CG PLANNING) is determined during preflight analysis and updated in real time. CG ballast cannot be traded against other orbit activities. CG ballast can be traded against other redlined items only if the ballast requirement changes for extension day deorbit opportunities.

B. FORWARD RCS REDLINE FOR OMS TANK FAIL

FORWARD RCS DELTA V IS NOT CONSIDERED WHEN DETERMINING OMS TANK FAIL CAPABILITY. IF FORWARD RCS PROPELLANT IS TO BE USED FOR A PERIGEE ADJUST AFTER AN OMS TANK FAIL, SUFFICIENT AFT RCS PROPELLANT MUST BE REDLINED TO ACCOUNT FOR ATTITUDE CONTROL DURING THE -X TRANSLATION (**TBD**), PLUS TWO VERNIER MANEUVERS (6 LB FORWARD RCS, 19 LB AFT). ©[092800-7247A]

Forward RCS cannot be committed to the deorbit burn when computing OMS tank fail capability, e.g., steep vs. shallow, in-plane vs. out-of-plane dump, etc. (ref. Flight Rule {A4-104}, OMS LEAK/PERIGEE ADJUST). However, Forward RCS delta V is available for a -X perigee adjust if required to supplement the Aft RCS/OMS. OPS 2 2-X with forward pitch control requires 2.5 lb of Aft RCS attitude hold per fps.

ADDITIONAL DEORBIT ATTEMPTS	<u>TBD</u>	<u>TBD</u>
CG BALLAST (IF REQUIRED)	<u>TBD</u>	<u>TBD</u>
PREBANK (IF REQUIRED)	150	150

NOMINAL DEORBIT PREP, DEORBIT WAVE-OFF AND MIN ENTRY PREP, WEATHER WAVE-OFF ACTIVITIES, AND ADDITIONAL DEORBIT ATTEMPTS MUST BE PROTECTED IN THE OMS IF NOT PROTECTED IN THE ARCS. WEATHER WAVE-OFF ACTIVITIES MAY BE DELETED IN FAVOR OF CRITICAL ON-ORBIT ACTIVITIES PER RULE {A2-108}, CONSUMABLES MANAGEMENT, AND THE FLIGHT RULE ANNEX. OMS ENGINE FAILURE MAY BE DELETED FOR THE DEORBIT WAVE-OFF EXTENSION DAY IN ORDER TO ACCOMPLISH HIGHER PRIORITY ACTIVITIES AS DOCUMENTED IN THE FLIGHT RULE ANNEX. VIOLATION OF THE AFT RCS DEORBIT REDLINE IS CAUSE TO DEORBIT AT NEXT PLS IF NO FURTHER PROPELLANT TRADE-OFFS CAN BE ACCOMPLISHED AS LISTED IN RULE {A2-108}, CONSUMABLES MANAGEMENT.

NOTE: [1] ASSUMES ATTITUDE CONTROL IN -ZLV -XVW PER RULE {A2-108}, CONSUMABLES MANAGEMENT. IF THERMAL CONDITIONING IS REQUIRED, UTILIZE ATTITUDE PROFILE PER RULE {A2-110}, STRUCTURES THERMAL CONDITIONING, OR AS SPECIFIED IN THE FLIGHT RULES ANNEX. @[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A6-305****AFT RCS REDLINES (CONTINUED)**

- 162 - *Aft portion of nominal, vernier deorbit prep. Tail-Only control requires 298 lb. ©[092800-7247A]*
- 160 - *Required to support attitude control from the deorbit burn to entry interface. This is mean usage and is confirmed by actual flight data. ©[091098-6711B]*
- 1175/1375 - *The amount of Aft RCS required to perform an entry from EI to Mach 1 given a specific orbiter X CG location, reference A/E Flight Techniques #150. The X CG constraint applies throughout the entry profile (ref. Rule {A4-153}, CG PLANNING), but because the X CG moves forward from EI to Mach 1, the X CG at EI is used to determine the redline. These numbers were chosen to provide 99.5 percent WRAP DAP protection based on Weissman's estimator for non-normal distributions. The Monte Carlo data were generated with STS-1 through STS-89 (less STS-4) reconstructed flight atmospheres using both SES and SDAP simulators. ©[091098-6711B]*
- 70 - *If an OMS engine failure should occur during the deorbit burn, 70 lb of Aft RCS usage are required to perform single OMS engine attitude control (reference STSOC Transmittal Form No. 330-320-352). This number should be increased to 82 lb if Tail-Only control is required. OMS engine fail protection may be given up for the deorbit wave-off extension day in order to accomplish high priority mission success activities as documented in the Flight Rule Annex. If OMS engine fail protection is given up, then the deorbit wave-off extension day propellant should be redistributed in the OMS and Aft RCS in order to retain the equivalent of the OMS engine failure propellant in each system at nominal end of mission. This implicit protection will be lost if the deorbit wave-off extension day is used. If an OMS engine has previously failed, then this allotment must be redlined in the Aft RCS or OMS to provide roll control during the deorbit burn. ©[091098-6711B]*
- 81 - *Normally, as part of the deorbit wave-off extension day, the propellant required for a deorbit prep backout and the last 30 minutes of a subsequent deorbit preparation is protected in the Aft RCS deorbit redline. This consists of 43 lb that is budgeted to support PRCS attitude control for 1 hour until the RCS system can be interconnected to the OMS, and 38 lb to perform the last 30 minutes of deorbit preparation. This propellant can be protected in the OMS if required. The equivalent quantity for Tail-Only control is 147 lb. ©[091098-6711B] ©[092800-7247A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

- 228 - *Propellant reserved as part of the weather wave-off extension day to back out of the deorbit burn config (43 lb), extend one day (23 lb), and then complete a second nominal deorbit prep (162 lb). The extension day propellant is protected in the Aft RCS because it is such a small amount of propellant that it is not operationally convenient to protect it in the OMS. Similarly, Nose/Tail ALT control requires 43 lb for the backout, 53 lb for the extension day, and 137 lb for the deorbit prep, total 233 lb. Note that if the propellant required for the extension day increases, such as for Tail-Only ALT control (as mentioned below), or because an alternate attitude profile is required for structural thermal conditioning, the extension day may be protected either in the OMS or the Aft RCS. Tail-Only ALT control requires 75 lb for the deorbit backout and 298 lb for the deorbit prep, total 373 lb, with the extension day propellant (89 lb) normally protected in the OMS. Note also that the weather wave-off extension day assumes a specific attitude profile: -ZLV -XVV is the default attitude and was chosen to provide the minimum propellant consumption with maximum debris protection, and because it is relatively insensitive to altitude, thus providing the best protection for off-nominal (abort) orbits. However, if a different attitude profile is required for deorbit thermal conditioning, this must be protected. Ref. Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, and the Flight Rule Annex. The weather wave-off extension day requires 205 lb of aft RCS with 10 hours of vernier 1 deg PTC protected (180 lb Nose/Tail ALT, 373 lb Tail-Only ALT, both with 10 hours of 5 deg Tail-Only PTC) per Rule {A2-110}, STRUCTURES THERMAL CONDITIONING, with the remainder of the extension day propellant protected in the OMS. According to an email dated June 5, 2000, from ES/Y. Chang, up to a 10-deg deadband for PTC is thermally acceptable. All propellant budgeted for the weather wave-off extension day may be traded for critical on-orbit activities as defined in Rule {A2-108}, CONSUMABLES MANAGEMENT, and the Flight Rule Annex. ©[092800-7247A]*
- 65 - *Also as part of the weather wave-off extension day, propellant is provided to perform one rev of attitude hold on the TRANS DAP to ensure two consecutive deorbit attempts on one of the three days. All propellant budgeted for the weather wave-off extension day may be traded for critical on-orbit activities as defined in Rule {A2-108}, CONSUMABLES MANAGEMENT, and the Flight Rule Annex. One orbit of Nose/Tail Trans DAP with FES will cost 65 lb aft (113 lb Tail-Only control). This propellant may be protected in the OMS if required. ©[092800-7247A]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

TBD *D/O Supplement* - If Aft RCS propellant is required to supplement the OMS deorbit steep propellant, either for +X translation, +Z translation, or for attitude hold during FRCS -X translation, this propellant, plus any associated maneuvers, must be protected.

TBD *D/O Attempts* - Propellant for additional deorbit opportunities, such as extra orbits of attitude hold in the deorbit burn configuration, may be protected on a flight specific basis as documented in the Flight Rule Annex. One orbit of Nose Tail Trans DAP with FES will cost 65 lb aft (113 lb Tail-Only control). This propellant may be protected in the OMS if required. ©[092800-7247A]

TBD *CG Ballast* - Propellant may be redlined to act as ballast to maintain the X and Y CG within limits. The amount of propellant required for CG ballast (ref. Rule {A4-153}, CG PLANNING) is determined during preflight analysis and updated in real time. Ballast will be protected in the OMS, the Aft RCS, or both. Note that OMS and ARCS propellant cannot be traded 1:1 for ballast purposes. CG ballast cannot be traded against other orbit activities. CG ballast can be traded against other redlined items if the ballast requirement changes for extension day deorbit opportunities.

150 - If the OMS targets are shallowed, an extra 150 lb of Aft RCS propellant must be redlined to perform the prebank maneuvers. The size of the prebank maneuver is not a factor; a 1-degree prebank maneuver is estimated to use as much propellant as a 90-degree prebank. A shallow deorbit causes the vehicle to enter the atmosphere at a shallower angle than usual and is more prone to “skip” off the atmosphere back into orbit. To avoid skipping off the atmosphere, the vehicle is rolled (“banked”) so that the lift from the orbiter wings is minimized. This increases the sink rate and decreases the possibility of skipping back out of the atmosphere. The consequences of skipping back out are likely to be catastrophic - at the very least, the planned landing site would be missed. ©[091098-6711B] ©[092800-7247A]

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

B. MISSION COMPLETION REDLINE @[091098-6711B]

THE AFT RCS MISSION COMPLETION REDLINE IS DEFINED AS THE NOMINAL AFT RCS DEORBIT REDLINE PLUS ENOUGH PROPELLANT TO EXECUTE THE REMAINING FLIGHT PLAN ACTIVITIES. @[092800-7247A]

The mission completion redline is the amount of RCS propellant required to perform the flight plan activities, PTI's, DTO's, while still protecting the deorbit redline requirements.

C. AEROCAPTURE AFT RCS REDLINE:

THE TOTAL AFT RCS REQUIRED FOR AEROCAPTURE ENTRY IS 460 LBS. THIS INCLUDES DEORBIT TO EI USAGE (160 LB) AND MEAN SHALLOW EI TO QBAR 20 USAGE (300 LB).

The aerocapture RCS redline defines a theoretical minimum amount of Aft RCS propellant required to control the vehicle from deorbit to the point at which NO YAW JET option can be selected (Qbar = 20 psf; ref. All Flights Rule {A4-207C}, ENTRY LIMITS). 300 lb protects mean RCS usage for a shallow entry from EI to Qbar = 20 based on data supplied by DM after AEFTP #150. The propellant protected by this redline is used (see Aft RCS Quantity 2 below) to define the maximum propellant that may be used for the deorbit burn in an emergency and still have some chance for a successful entry. @[092800-7247A]

D. ON ORBIT AFT RCS SINGLE POD QUANTITY REDLINE:

ARCS ON ORBIT TANK FAIL	440
MEAN USAGE DEORBIT TO EI	160
MEAN USAGE STEEP EI TO 0.05G	<u>96</u>
TOTAL	696

THE ON-ORBIT AFT RCS SINGLE POD QUANTITY REDLINE IS THE MINIMUM QUANTITY ALLOWED IN EACH AFT RCS SYSTEM DURING ORBIT OPERATIONS. LEFT AND RIGHT RCS PROPELLANT WILL BE MANAGED TO ENSURE THIS QUANTITY IS NOT VIOLATED PRIOR TO NOMINAL EOM. VIOLATION OF THIS REDLINE IS CAUSE FOR DEORBIT AT NEXT PLS.

System failures could result in an imbalance between left and right RCS usable quantities (i.e., maximum blowdown burn after a helium tank leak) while the total ARCS usable is greater than the nominal RCS Deorbit Redlines. However, if either RCS system cannot individually protect the NO YAW JET entry redline, a PLS must be executed. RCS tank fail protection is required in order to stay on orbit. @[091098-6711B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

The ON-ORBIT AFT RCS SINGLE POD QUANTITY REDLINE represents the minimum quantity required per side to protect for an RCS tank failure and still guarantee a no yaw jet entry. This quantity assumes that OMS propellant will not be available after the deorbit burn for OMS to RCS interconnect (quantity < 11 percent per pod, ref. SODB 3.4.3.3.6d). Deorbit to EI (160 lb) and EI to .05g (96 lb) propellant usages must come out of the remaining RCS system. During this time period, since there is no appreciable acceleration on the vehicle, the AFT RCS ON-ORBIT TANK FAIL limit (ref. All Flights Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL)) applies. The 440 lb of trapped propellant will become available once the entry g-load on the vehicle increases to the 0.05g level. At Qbar = 20, NO YAW JET may be selected and RCS propellant is no longer required.
 ©[091098-6711B]

E. AFT RCS QUANTITY 1 IS DEFINED AS SUFFICIENT AFT RCS PROPELLANT TO GUARANTEE 1134 LB AT EI AND PROVIDES 97.5 PERCENT CONFIDENCE FOR SHALLOW EI TO 0.05G USAGE ABOVE ARCS ON ORBIT TANK FAIL. AFT RCS PROPELLANT ABOVE AFT RCS QUANTITY 1 WILL BE USED DURING THE DEORBIT BURN FOR DELTA-V PURPOSES PRIOR TO USE OF FWD RCS PROPELLANT, REDESIGNATION, OR PREBANK. AFT RCS QUANTITY 1 IS DEFINED AS:

ARCS ON ORBIT TANK FAIL	880
97.5 PERCENT SHALLOW USAGE FROM EI TO NZ 0.05G	254
PREBANK	150
USAGE DEORBIT TO EI	160
ATTITUDE HOLD FOR FRCS (-X) TRANS	<u>TBD</u>
FAST FLIP	100
CG BALLAST (IF REQUIRED)	<u>TBD</u>

If OMS propellant is depleted during the deorbit burn prior to the completion of the targeted delta V, the crew will use the Aft RCS propellant through the +X jets until either the desired targets are achieved, or until the Aft RCS propellant quantity decreases to "Aft RCS Quantity 1." If deorbit targets still have not been achieved, the crew will utilize the aft Hp, target Hp, and flip Hp cues (calculated by MCC) to determine the actions required to complete the deorbit burn. These actions may include requiring prebank, utilizing the FRCS -X jets which requires a fast flip maneuver and attitude hold propellant, and/or redesignation. Since these tools will not be used until after the +X translation, their propellant requirement is included in the definition of "Aft RCS Quantity 1." The propellant required to control the vehicle during the FRCS -X translation is a function of FRCS propellant available and is calculated by the PROP console prior to deorbit. The amount of propellant required for CG ballast (if any) to protect the nominal CG box (ref. Rule {A4-153}, CG PLANNING) will be determined during preflight analysis for AOA/Orbit 3 scenarios. Preflight analysis will also determine nominal end-of-mission ballast requirements, which may be updated during real-time operations. Ballast will normally be protected in the RCS for AOA/Orbit 3, and in the OMS for EOM, but may be protected in the OMS, or RCS, or divided between the two systems. ©[901-98-6711B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

Per A/E Flight Techniques Meeting #150, lowering the EI to Mach 1 usage protection to 97.5 percent confidence is preferred over fast flip, redesignation, or prebank. Even so, a steep entry cannot be guaranteed in a case where AQ1 is applied, and a shallow entry uses more propellant in the EI to Nz=0.05g region. To provide 97.5 percent protection from EI to Nz=0.05g for a shallow entry requires 254 lb over and above the 880 lb AFT RCS ON-ORBIT TANK FAIL quantity (ref. All Flights Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL)). The total EI to Mach 1 requirement is 1134 lb. and may be reduced to 1028 lb if steep targets are achieved (see section H, Aft Hp Quantity). Note that this may provide slightly less than the 97.5 percent EI to Mach 1 usage and so may require the use of NO YAW JETS if worst case entry conditions are encountered. ©[091098-6711B] ©[092800-7247A]

F. AFT RCS QUANTITY 2 IS DEFINED AS SUFFICIENT AFT RCS PROPELLANT TO PROTECT AEROCAPTURE REQUIREMENTS. AFT RCS PROPELLANT AVAILABLE ABOVE AFT RCS QUANTITY 2 WILL BE USED FOR DELTA V PURPOSES ONLY IF FORWARD RCS PROPELLANT, REDESIGNATION, AND PREBANK ARE NOT SUFFICIENT. AFT RCS WILL BE USED NO LOWER THAN AFT RCS QUANTITY 2 TO SUPPORT DEORBIT. AFT RCS QUANTITY 2 DOES NOT GUARANTEE A SUCCESSFUL ENTRY. AFT RCS QUANTITY 2 IS DEFINED AS:

DEORBIT TO EI	160
EI TO QBAR ? 20	300
PREBANK	150
ATT HOLD FOR FRCS TRANS	TBD
FAST FLIP	100
©[091098-6711B]	

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

If, using all the Aft RCS available above Aft RCS Quantity 1, all the Forward RCS available, redesignation (if available), and prebank to 90 degrees, insufficient delta V is available to complete the deorbit burn, additional Aft RCS must be used. However, to run completely out of Aft RCS during the deorbit burn is also catastrophic. Some minimum amount of Aft RCS must be protected to maintain vehicle control until the aerosurfaces have some chance of maintaining control. When completing a deorbit burn, if the Aft RCS propellant available decreases to Aft RCS Quantity 1, and the other resources cannot meet the target (as calculated by the MCC and provided in the form of aft Hp, target Hp, and flip Hp), rather than flip, crew procedures will continue to use Aft RCS through the +X jets. Note that time is not available to flip to use Forward RCS to depletion and then flip back to complete with Aft RCS, even though this is probably the optimum use of the propellant. Crew procedures continue to use Aft RCS until the delta V requirement decreases to the point that the other tools (Forward RCS, redesignation, and prebank) can meet the target. At that time (or when Aft RCS propellant decreases to Aft RCS Quantity 2), the procedures execute the other options; first flip to use Forward RCS to depletion, then redesignation and prebank. All three options will be fully utilized; therefore, the Aft RCS propellant requirements for these additional options must be protected. As in the case of Aft RCS Quantity 1, the Forward RCS attitude control propellant is calculated in the MCC prior to deorbit. No ballast is protected in Aft RCS Quantity 2 because a propellant failure is the most likely reason for using Aft RCS below Aft RCS Quantity 1, in which case the propellant trapped in the failed tank can serve as ballast. Further, completion of the deorbit burn is a higher priority than any ballast requirement. ©[091098-6711B]

Aft Quantity 2 does not protect the AFT RCS ON ORBIT TANK FAIL limit (ref. All Flights Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL)). Below 20 percent remaining, with Nz < 0.05g, the Aft RCS tanks may not be able to supply propellant to the RCS jets. ©[092800-7247A]

G. THE AFT RCS PRESS QUANTITY IS THE AMOUNT OF AFT RCS PROPELLANT THAT MUST BE PROTECTED IN ORDER TO PROVIDE 97.5 PERCENT ENTRY CONFIDENCE FOR AN AOA OR ATO. AFT RCS USABLE PROPELLANT IN EXCESS OF THE AFT RCS PRESS QUANTITY IS COMMITTED TO THE PRESS TO ATO CALL. THE AFT RCS PRESS QUANTITY IS DEFINED AS: ©[012402-5112B]

ARCS ON ORBIT TANK FAIL	880
USAGE EI TO NZ 0.05G SHALLOW/STEEP	254/148
PREBANK (IF REQUIRED)	150
USAGE DEORBIT TO EI	160
OMS ENGINE FAIL ATTITUDE CONTROL	70
USAGE MECO TO DEORBIT AOA/ORBIT 3/ORBIT 7/FD2	259/427/495/525
MNVRs TO SUPPORT OPS 2 FRCS BURNS (FD2 ONLY)	38
ATTITUDE HOLD FOR OPS 2 FRCS BURNS (FD2 ONLY)	<u>TBD</u>
CG BALLAST (IF REQUIRED)	<u>TBD</u>

©[092800-7247A] ©[012402-5112B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

- 880 - *At $N_z=0.05g$, the AFT RCS ON-ORBIT TANK FAIL constraint (ref. All Flights Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL)) is released and 880 lb of additional Aft RCS becomes available to support entry usage. ©[091098-6711B]*
- 254/148 - *Data presented at A/E Flight Techniques #150 showed 254 lb required for shallow EI to $N_z=0.05g$ usage with 97.5 percent protection. For a steep entry, 148 lb of EI to $N_z=0.05g$ usage provides the same level of protection. ©[091098-6711B]*
- 150 - *For an AOA or ATO shallow, prebank must be protected. Prebank is not required for a steep entry.*
- 160 - *Required to support attitude control from the deorbit burn to entry interface.*
- 70 - *For a press case, the OMS engines are deliberately burned to depletion. The OMS engine fail propellant will be used to control the attitude transients resulting from sequential OME shutdown during the depletion sequence. This quantity cannot be traded against any other events or activities (ref. All Flights Rule {A6-352}, OMS PROPELLANT BUDGET GROUND RULES).*
- 259/427/495/525 - *Aft RCS usage required for mated coast/ET SEP through the maneuver to the deorbit burn. Usage from MECO to deorbit for the ATO case is dependent on when the FD1 or FD2 deorbit opportunity occurs. FD2 assumes OPS 2 and vernier jets.*
- 38 - *The Forward RCS will be utilized in OPS 2 to raise or lower the orbit as needed in support of a FD2 PLS. Four vernier maneuvers will be protected to support two Forward RCS burns. This applies to the FD2 Aft RCS press quantity only. ©[012402-5112B]*
- TBD** Attitude Hold - *The amount of propellant required to control the vehicle during the OPS 2 Forward RCS -X burns is a function of Forward RCS propellant available above the FD2 Forward RCS press quantity, which is defined by Flight Rule {A6-304D}, FORWARD RCS REDLINES. This applies to the FD2 Aft RCS press quantity only. ©[012402-5112B]*
- CG Ballast - *The amount of CG ballast required will be determined during preflight analysis. This ballast will nominally be protected in the RCS. The nominal CG box (ref. Rule {A4-153}, CG PLANNING) is used for AOA steep ballast determination and the contingency CG box is used for AOA shallow.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

H. AFT HP QUANTITY

AFT HP QUANTITY IS DEFINED AS THE AMOUNT OF PROPELLANT RESERVED IN AFT QUANTITY 1 FOR FAST FLIP, AFT ATT HOLD FOR FORWARD RCS (-X) TRANSLATION, PREBANK, AND EXTRA USAGE DURING A SHALLOW ENTRY. THIS PROPELLANT CAN BE USED TO COMPLETE THE DEORBIT BURN IF IT IS SUFFICIENT TO COMPLETE THE STEEP TARGET REQUIREMENT. AFT HP QUANTITY IS COMPUTED AS FOLLOWS: @[092800-7247A]

FAST FLIP	100
AFT ATT HOLD FOR FRCS (-X) TRANSLATION	TBD
EI TO 0.05G REDUCTION FOR STEEP ENTRY	<u>106</u>
PREBANK	150

Fast flip and shallow targets are less desirable than steep targets. If burning the aft propellant reserved for these activities will allow the steep target to be met that is the preferred action. 97.5 percent protection for shallow EI to Nz=0.05g requires 254 lb while equivalent protection for a steep entry only requires 148 lb. The difference is 106 lb. @[091098-6711B]

I. ENGAGE NO YAW JET QUANTITY @[091098-6711B]

DURING ENTRY, BETWEEN QBAR=20 AND MACH 6, WHEN THE TOTAL AMOUNT OF AFT RCS USABLE PROPELLANT FALLS BELOW 10 PERCENT (220 LBS), NO YAW JET WILL BE ENGAGED. BELOW MACH 6, NO YAW JET WILL BE DISENGAGED. NO YAW JET WILL NOT BE RE-ENGAGED BELOW MACH 6 UNLESS MULTIPLE RCS JETS FAIL OFF (PROPELLANT DEPLETION).

According to study results presented at the A/E Flight Techniques #150, less than 132 lb (6 percent) is required for the Mach 6 to Mach 1 regime. To reduce the likelihood of a time critical RCS crossfeed being required, the number actually protected is 10 percent or 220 lb. Above Mach 6, once 10 percent total (L+R) quantity is reached, NO YAW JET will be selected, preserving the 220 lb for any control problems which might be encountered in NO YAW JET. Once Mach 6 is reached, the 220 lb remaining should be more than adequate to complete a normal entry, so AUTO will be selected to lower the crew workload.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

J. AFT RCS OMS TANK FAIL QUANTITY

THE AFT RCS OMS TANK FAIL QUANTITY IS DEFINED AS THE AMOUNT OF AFT RCS PROPELLANT THAT MUST BE RESERVED FOR OMS TANK FAIL DETERMINATION. ONLY AFT RCS USABLE PROPELLANT IN EXCESS OF THE AFT RCS OMS TANK FAIL QUANTITY CAN BE COMMITTED TO DEORBIT DELTA V. THE AFT RCS OMS TANK FAIL QUANTITY IS DEFINED AS:

ARCS ON ORBIT TANK FAIL	880
97.5 PERCENT SHALLOW USAGE EI TO NZ 0.05G	254
PREBANK	150
DEORBIT TO EI	160
ENGINE FAIL	70
NOMINAL (VERNIER) DEORBIT PREPARATION USAGE TO DEORBIT TIG - 5 HOURS	162
VRCS EXTENSION DAY	<u>TBD</u> 64
ATTITUDE HOLD FOR FRCS TRANS	<u>TBD</u>
MANEUVERS TO FRCS BURN ATTITUDE	<u>TBD</u>
TWO ULLAGE BURNS	188
MANEUVERS TO OMS BURN ATTITUDE	39
CG BALLAST (IF REQUIRED)	<u>TBD</u>

©[092800-7247A]

The Aft RCS OMS Tank Fail Quantity is used to determine whether a leaking OMS propellant burn will be done retrograde or out-of-plane (ref. All Flights Rule {A4-104}, OMS LEAK/PERIGEE ADJUST).

©[091098-6711B]

- 880 - *The AFT RCS ON-ORBIT TANK FAIL limit applies until the G-load on the vehicle reaches 0.05G. This propellant is then available for entry control (ref. All Flights Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL)). All Aft RCS propellant available above this quantity will be committed to OMS tank fail protection. By not protecting the full EI to Mach 1 propellant requirements, it is possible that NO YAW JET will have to be engaged if worst case entry conditions are present (bent airframe, wind and turbulence, and aero variations). However, the RCS propellant gained to commit to OMS tank fail may prevent a southern hemisphere ELS after an OMS propellant tank leak.*

©[091098-6711B] ©[092800-7247A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305

AFT RCS REDLINES (CONTINUED)

- 254 - *The EI to Nz of 0.05G usage must be protected above the AFT RCS ON-ORBIT TANK FAIL limit to ensure attitude hold propellant is available until 0.05G when the propellant trapped on orbit becomes usable; 254 lb provides 97.5 percent protection for a shallow entry.*
- 150 - *A prebank maneuver will be performed in an OMS tank fail case since the determination of OMS tank fail capability is based on shallow deorbit.*
- 160 - *Required to support attitude control from the deorbit burn to entry interface.*
- 70 - *Since one engine will have failed at the end of the leaking OMS depletion burn, the ensuing deorbit burn will generally be performed with a single engine; accordingly, propellant for roll control must be protected. Furthermore, if RCS completion is required during the deorbit burn, propellant is needed for the maneuver to RCS 4+X attitude. The 70 lb protects both of these requirements.*
- 162 - *Protects a nominal deorbit prep with no additional thermal conditioning.*
- *USAGE TO DEORBIT TIG-5 HOURS - Determined real time based on the actual NPLS TIG.*
- 64 - *A vernier extension day is protected to allow for propellant sublimation prior to deorbit. ©[092800-7247A]*
- *ATTITUDE HOLD FOR FRCS TRANS - Determined real time based on the amount of FRCS propellant available. This will not be the standard 1:3 since fast flip is not to be used during the deorbit burn. Instead, the FRCS will be used for a perigee adjust burn prior to deorbit (ref. All Flights Rule {A4-104}, OMS LEAK/PERIGEE ADJUST). This will require 2.5 lb Aft RCS per fps.*
- *MANEUVERS TO FRCS BURN ATTITUDE - If an FRCS -X perigee adjust is to be performed after an OMS tank fail, two vernier maneuvers (19 lb) are required to maneuver to and from the -X burn attitude. ©[091098-6711B]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-305 AFT RCS REDLINES (CONTINUED)

- 188 - *Two 15-second ullage burns are protected. The first ullage burn is required for either the perigee adjust or the dump out of plane. The second ullage burn is required if the leaking propellant tank is not depleted during a perigee adjust burn.* ©[091098-6711B] ©[092800-7247A]
- 39 - *MANEUVERS TO BURN ATTITUDE (two primary maneuvers) are required for the leaking OMS perigee adjust burn and the subsequent out-of-plane burn to depletion.* ©[091098-6711B] ©[092800-7247A]
- TBD** CG Ballast - *The amount of propellant, if any, to protect the contingency CG box (ref. Rule {A4-153}, CG PLANNING) required for CG ballast will be determined real time, based on the next PLS deorbit TIG. Ballast will be protected in the OMS or the RCS, or divided between the two systems.*

@[051194-1612A] @[092701-4850]

The OMS propellant matrix details the propellant required to be protected in order to fly to nominal, ATO, or AOA targets as well as the daily PLS GO/NO-GO. These requirements are protected by the abort maneuver evaluator (AME) during ascent and by the OMS propellant redlines during orbit. The ground rules are documented in Rule {A6-352}, OMS PROPELLANT BUDGET GROUND RULES.

FLIGHT RULES

A6-352

OMS PROPELLANT BUDGET GROUND RULES

- A. COMMITTING TO A NOMINAL ASCENT WILL BE CONSERVATIVE WITH REGARD TO OMS PROPELLANT EXPENDED. DISPERSIONS IN OMS ENGINES FOR FLOW RATE, MIXTURE RATIO, OMS TRAPPED, ONE ENGINE FAILURE, AND GAGING ERROR WILL BE ACCOMMODATED WHILE MAINTAINING NOMINAL ENTRY X AND Y CG, PAYLOAD SEPARATION REQUIREMENTS, AND OMS STEEP DEORBIT TARGETS, WITH PARTIAL PROPULSION DOWNMODING CAPABILITY (2-1 OMS).

Ascent to nominal targets will occur only if propellant is available for the above items. For cases where insufficient propellant exists to continue to nominal targets, ATO/AOA capability will be evaluated. Because an ATO orbit can be reevaluated and subsequently raised to an orbit on a future revolution depending upon the OMS propellant available, the requirements are conservative towards the nominal targets.

- B. ALL OMS PROPELLANT WILL BE USED TO AVOID AN AOA EXCEPT THE PROPELLANT BUDGETED FOR OMS SHALLOW TARGETS (INCLUDES 90 DEGREES PREBANK), OMS TRAPPED, DISPERSIONS, AND OMS ENGINE FAIL.

Since an AOA is not desirable due to increased trajectory dispersion sensitivity, high crew work load, and assured loss of mission, an AOA will be avoided if at all possible. In order to avoid an AOA, more OMS propellant is committed to achieve an ATO. OMS shallow deorbit, OMS dispersions, and OMS engine fail will be protected in the AME. Since aft RCS to RCS PRESS QTY is committed to achieve an AOA or ATO, during propellant critical situations it is expected that OMS depletion will occur during the deorbit burn and four +X RCS will be used to complete the burn. As a result, OMS engine fail propellant must be protected to protect this sequential shutdown during the deorbit burn. If propellant is not available to protect the above items, an AOA will be selected by the AME.

- C. OMS TANK FAILURE PROTECTION IS NOT REQUIRED TO CONTINUE THE NOMINAL ASCENT, TO CONTINUE PAST THE FIRST DAY PLS OR WHEN RAISING AN ATO ORBIT. OTHERWISE, ALL THE PROPELLANT CONSERVATISM INVOLVED IN COMMITTING TO THE NOMINAL ORBIT WILL BE OBSERVED PLUS CG MANAGEMENT AT EI/MACH 3.5, WHILE MAINTAINING OMS STEEP DEORBIT TARGETS WITH PARTIAL PROPULSION DOWNMODING CAPABILITY (2-1 OMS).

Decision was made to delete the tank fail requirement because of the low probability of occurrence and because the large tank fail redline did not provide sufficient propellant margins for on-orbit activities.

Although tank fail redlines can be protected during the early part of a flight, there is not sufficient propellant during the latter part. The Flight Director will be advised of the tank fail status but there has been no requirement to protect a tank failure since STS-3.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-352

OMS PROPELLANT BUDGET GROUND RULES (CONTINUED)

In the event of an OMS tank leak, a perigee adjust burn will be performed ASAP to make use of the leaking propellant.

- D. OMS PROPELLANT PREVIOUSLY ALLOCATED FOR A DEORBIT WAVEOFF EXTENSION DAY MAY BE COMMITTED TO SUPPORT THE DEORBIT BURN. ©[051194-1612A]

The probability of a failure occurring that requires the deorbit burn to be terminated above safe H_p is low. The failures identified are redundant set fail, GPC splits, two main buses, IMU dilemma, and an OMS propellant tank fail. Because of this low probability, the propellant allocated for the deorbit wave-off extension day may be used in calculating deorbit burn targets. If the deorbit burn should be terminated above the safe H_p , the deorbit wave-off extension day propellant requirements could be obtained from the margins in the ARCS (if any margins are available) or by using OMS propellant below the 5 percent remaining (Rule {A6-356}, DEORBIT PLANNING CRITERIA) to the redlined OMS trapped/dispersion value. If the deorbit waveoff extension day capability cannot be obtained from these sources, the propellant allocated for the deorbit burn must be used to provide the deorbit waveoff extension day capability (results in shallow deorbit targets). ©[051194-1612A]

- E. NOMINALLY, OMS AND RCS PROPELLANT WILL BE BUDGETED FOR A DEORBIT WAVE-OFF EXTENSION DAY. IF OMS PROPELLANT IS NOT AVAILABLE, AFT RCS PROPELLANT WILL BE BUDGETED FOR THE DEORBIT WAVE-OFF EXTENSION DAY. ©[051194-1612A]

The OMS will be interconnected to the RCS jets to provide the extension day using tail-only ALT control and deorbit preparation using nose-tail control. RCS is budgeted for wave-off, until interconnect is established, and entry preparation (TIG - 30 minutes). ©[051194-1612A]

Rule {A6-351}, OMS PROPELLANT MANAGEMENT MATRIX, references this rule.

FLIGHT RULES

A6-353

CG MANAGEMENT

- A. OMS BALLAST FOR X CG MANAGEMENT IS NOT REQUIRED TO CONTINUE PAST THE FIRST DAY PLS IF FORWARD RCS PROPELLANT IS AVAILABLE TO DUMP POST-DEORBIT BURN.

The CG can be moved aft by two methods: (1) allocating OMS propellant for CG management versus delta V ("liquid ballast"), or (2) performing an FRCS dump after the deorbit burn. Either method can improve the CG for entry aerodynamics but the latter is preferred because it does not require additional propellant to be saved to EOM.

- B. OMS PROPELLANT WILL BE MANAGED IN AN ATTEMPT TO ACHIEVE A ZERO Y CG OFFSET. CHANGES IN THE NOMINAL INTERCONNECT SCHEDULE MAY BE MADE IN ORDER TO IMPROVE THE Y CG PRIOR TO DEORBIT.

The OMS propellant will be budgeted such that the left and right pod imbalance will achieve the desired Y CG. This may be achieved by feeding from either OMS system during on-orbit RCS activities or during OMS burns.

The left and right pod interconnect schedule will be modified to achieve the desired imbalance for CG management.

- C. THE PROJECTION OF PROPELLANT USAGE RESULTING IN VIOLATION OF THE CG ENVELOPE (REF. RULE {A4-153}, CG PLANNING) AT THE NEXT PLS WILL BE CAUSE FOR ENTRY AT THE NEXT PLS OPPORTUNITY.

If propellant usage cannot be budgeted to assure a satisfactory CG at the next PLS, entry will be performed at the next PLS prior to violating the CG envelope.

Rule {A6-351}, OMS PROPELLANT MANAGEMENT MATRIX, references this rule.

FLIGHT RULES

A6-354**RCS ENTRY REDLINE PROTECTION**

THE OMS/RCS INTERCONNECT WILL BE USED TO PROTECT THE RCS ENTRY REDLINES EVEN AT THE EXPENSE OF STEEP DEORBIT PROTECTION.

OMS tank fail protection is not required to continue to the nominal end of mission. However, if tank fail protection is available, it will be traded off to protect the RCS entry redlines.

The OMS propellant is not available to feed the RCS jets during entry due to tank feed limitations (location of propellant). The RCS can be used to supply deorbit delta V and entry attitude control. Therefore, the OMS is used on-orbit in an OMS/RCS interconnect mode to protect RCS redlines realizing that the RCS can be used to supplement the deorbit delta V required. The deorbit targets are shallowed to 45 deg prebank to achieve the priority mission or to 90 deg prebank to protect the RCS entry requirements. This can be seen in the Propellant Consumables Management Table (ref. Rule {A2-108}, CONSUMABLES MANAGEMENT).

Rule {A6-304C}, FORWARD RCS REDLINES, references this rule.

A6-355**OMS PROPELLANT DEFICIENCY FOR DEORBIT**

IF INSUFFICIENT PROPELLANT EXISTS IN THE OMS TO MEET THE REQUIRED DEORBIT TARGETS, IT IS ACCEPTABLE TO REDLINE PROPELLANT IN THE RCS TO PERFORM A TWO-STAGE DEORBIT TO THE REQUIRED TARGETS ONLY IF THERE IS FAIL-SAFE JET REDUNDANCY FOR TRANSLATION IN THE AFFECTED RCS.

Additional propellant can be redlined in the RCS in the event of an OMS/RCS problem (i.e., isolatable propellant or helium leak or high usage) resulting in insufficient OMS propellant to achieve the steep deorbit targets. Rather than performing a single stage burn such that the crew must downmode to RCS in a time-critical period, a two-stage deorbit is preferred. This provides steep deorbit capability while maintaining at least four revs between burns for guidance and crew planning. However, this is acceptable only if fail-safe redundancy exists in the RCS jets which means 4+X or 3-X jets are required prior to the first stage of the deorbit. If a two-stage deorbit is required, RCS propellant will be redlined to protect 2 + X for the RCS perigee adjust. This provides downmode capability from 4+X to 2 +X to protect for a +X jet failure during the burn. 2 +X is protected since this capability is cheaper than 3 +X. (Ref. Rule {A2-108}, CONSUMABLES MANAGEMENT, for propellant trade-offs.)

Rules {A2-201B}.4, DEORBIT GUIDELINES; and {A6-303C}, OMS REDLINES [CIL];, reference this rule.

FLIGHT RULES

A6-356**DEORBIT PLANNING CRITERIA**

FOR DEORBIT PLANNING PURPOSES, OMS PROPELLANT CAN BE USED TO SUPPORT RCS DOWNMODE CAPABILITY AND/OR PROTECT VEHICLE CG/LANDING WEIGHT CONSTRAINTS PROVIDED THAT THE OMS REMAINING POST-DEORBIT BURN (NO FAILURES) IS GREATER THAN 5 PERCENT PER POD.

RCS downmode protection is not required as long as two OMS engines are available. If OMS propellant margin is available to support RCS downmode, deorbit planning will protect RCS downmode capability subject to the constraints identified in this rule. To provide for TIG SLIP, RCS downmode capabilities and to protect vehicle CG and downweight constraints, additional OMS propellant (above the OMS deorbit optimal requirements) may be required. Backing up TIG requires additional delta V to satisfy deorbit targets. The 5 percent propellant remaining constraint in each OMS tank (403 lb oxidizer, 245 lb fuel) provides optimum delta V capability while protecting the worst case OMS dispersions which could occur in either the straight feed or crossfeed OMS burn configurations. The 5 percent remaining constraint also prevents inadvertent engine depletion. Engine depletion during zero gravity (either oxidizer or fuel) is undesirable during nominal deorbit conditions because it may result in damage to the OMS engines. This damage to the OMS engine is contained damage and will not damage the orbiter. OMS engine replacement will be required.

Rules {A4-153C}.3, CG PLANNING; and {A6-352}, OMS PROPELLANT BUDGET GROUND RULES, reference this rule.

A6-357**FORWARD RCS CONTINGENCY PROPELLANT AVAILABLE**

DURING CONTINGENCY OPERATION INCLUDING OMS ENGINE FAILURE, OMS TANK FAILURE AND RENDEZVOUS BREAKOUT MANEUVER, THE FRCS MAY BE USED TO 1.5 PERCENT BELOW THE ONBOARD GAGE READING OF ZERO PERCENT.

SODB paragraph 4.3.2.3 (III) (CAUTION: SODB, volume III, contains engineering estimates for non-nominal performance evaluation. Data may not be supported by test.) indicates that a gauge reading of 1.5 percent below zero assures gas free propellant (no helium ingestion) flow to thrusters with reasonable risk. This assumes a factor of safety of 1.0 on tank expulsion performance and actual worst case gauging error (based on WSTF test data). Rule {A6-7}, RCS PROPELLANT TANK (OXIDIZER OR FUEL), references this rule.

FLIGHT RULES

A6-358

VIOLATION OF MISSION COMPLETION REDLINES MATRIX

MISSION COMPLETION REDLINE VIOLATED	ACTION
LEFT OR RIGHT OMS	<ol style="list-style-type: none"> 1. PERFORM FLIGHT PLAN INTERCONNECTED FROM GOOD OMS TO THE TOTAL OMS MISSION COMPLETION REDLINE. 2. PERFORM RCS FLIGHT PLAN ACTIVITIES NORMALLY SCHEDULED FOR INTERCONNECT WITH RCS PROPELLANTS IF AVAILABLE ABOVE THE MISSION COMPLETION REDLINE. 3. DELETE FLIGHT PLAN ACTIVITIES AS DEFINED IN RULE {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES.
LEFT OR RIGHT AFT RCS	<ol style="list-style-type: none"> 1. INTERCONNECT TO OMS MISSION COMPLETION REDLINE. 2. CROSSFEED FROM OTHER RCS UNTIL TOTAL RCS (LEFT AND RIGHT) MISSION COMPLETION REDLINE. 3. DELETE FLIGHT PLAN ACTIVITIES AS DEFINED IN RULE {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES.
FORWARD RCS	<ol style="list-style-type: none"> 1. DECREASE FRCS SUPPLEMENT TO OMS/RCS DEORBIT REDLINE IF PROPELLANT AVAILABLE ABOVE OMS/RCS MISSION COMPLETION REDLINE. 2. DELETE FLIGHT PLAN ACTIVITIES AS DEFINED IN RULE {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES.

The table describes what action can be taken when the mission completion redline (MCR) has been violated. These actions attempt to regain propellant margins required to continue to the nominal end of mission.

LEFT OR RIGHT OMS MCR:

The first action to maintain positive propellant margins would be to crossfeed to the OMS pod with margin to protect the total OMS MCR (left and right)

The second is to cancel planned interconnects. This requires the interconnect propellant to be budgeted in the RCS, increasing the RCS MCR and reducing the OMS MCR. Again the total OMS MCR is protected.

The third action to take is to minimize RCS usage as described in Rule {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES.

LEFT OR RIGHT AFT RCS MCR:

The first action required to lower the RCS MCR can be to interconnect to an OMS pod with margin above the MCR. Secondly, if one pod has more propellant than the other the lower RCS pod can be fed from the higher RCS pod. This protects the total (left and right) MCR. Thirdly, the mission extension propellant budget can be reduced according to Rule {A2-108}, CONSUMABLES MANAGEMENT. Fourthly, implement minimized techniques in Rule {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES, and if needed delete flight plan activities according to the Propellant Usage versus Flight Activity table.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-358

VIOLATION OF MISSION COMPLETION REDLINES MATRIX
(CONTINUED)*FORWARD RCS MCR:*

The first action when the forward RCS MCR has been violated will be to reduce the supplement to the OMS/RCS deorbit redline. The OMS supplement was used for tank fail protection in earlier flights (tank fail requirements have since been eliminated) and is now used only after failures dictate. During an RCS deorbit, selecting tail-only control during the 4 +X deorbit eliminates the need for forward RCS propellant thus reduces the FRCS deorbit redline while increasing the OMS/RCS deorbit redline due to the lower ISP associated with the 4 +X deorbit. The second action will be to minimize RCS usage as defined in Rule {A6-359}, RCS PROPELLANT CONSERVATION PRIORITIES.

Rules {A6-61}, RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL]; and {A6-303D}, OMS REDLINES [CIL]; reference this rule.

FLIGHT RULES

A6-359

RCS PROPELLANT CONSERVATION PRIORITIES

RCS minimization techniques will be utilized after redline margins have been exhausted in each of the five OMS/RCS systems (FRCS, LRCS, RRCS, LOMS, ROMS). Redlines are protected by redlining additional propellant in the remaining tanks if margins exist.

A. UTILIZE NOSE-ONLY/TAIL-ONLY CONTROL MODES.

If margins exist in either the forward or aft tanks, attitude control can be performed using either the nose-only or tail-only control technique. This reduces propellant usage in either the aft or forward RCS to protect the deorbit redline. Nose-only control mode requires aft RCS for roll control.

B. VERNIER OR PRIMARY CONTROL WIDE DEADBANDS.

Widening deadbands during periods of attitude hold will reduce total propellant consumption. Care must be taken not to impact specific mission objectives requiring tight deadbands.

C. DELETE MISSION ACTIVITIES AS REQUIRED (REF. FLIGHT RULE ANNEX FOR PRIORITIES).

If further propellant consumption is required, DTO's will be deleted from the Flight Plan starting with the lowest priority defined in the Flight Rule Annex.

D. GRAVITY GRADIENT/FREE DRIFT DURING CREW AWAKE PERIODS.

In an attempt to remain on orbit for the priority flight, gravity gradient or free drift will be selected during crew awake periods.

E. MINIMIZE ENTRY PREPARATION.

Entry preparation is a relatively high usage phase 4 hours prior to deorbit. Releasing pre-entry checkout requirements would be the last resort to protect propellant for the entry or deorbit phase. Rule {A6-358}, VIOLATION OF MISSION COMPLETION REDLINES MATRIX, references this rule.

FLIGHT RULES

A6-1001 **OMS/RCS GO/NO-GO CRITERIA [CIL] (CONTINUED)**

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, references this rule.

The rationale for this matrix is explained in three categories as follows:

- a. Continue nominal ascent if:*
- b. Invoke MDF if:*
- c. Enter next PLS if:*

CONTINUE NOMINAL ASCENT IF:

- **1 OMS ENGINE LOST:**
 - *Nominal ascent can be continued with the remaining engine; there has been no loss of delta V capability.*
- **1 OMS N₂ TANK LOST:**
 - *Nominal ascent can be continued on the remaining engine; there has been no loss of delta V capability.*
- **2 AFT RCS He OR PROP TANK LEAK:**
 - *Leaves only the good system for entry control and ET separation; loss of the good system means no control during early entry.*

INVOKE MDF IF:

- **1 OMS/RCS FLOW PATH (XFD) LOST:**
 - *An MDF is required only if procedural workarounds are not available to guarantee the remaining flow path (i.e., open the remaining crossfeed valve to guarantee crossfeed capability). If no workaround is available, then single fault tolerance remains to protect against engine/RCS propellant failures that require crossfeed.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A6-1001 OMS/RCS GO/NO-GO CRITERIA [CIL] (CONTINUED)**

ENTER NEXT PLS IF:

- **2 OMS ENGINES LOST:**
 - *Only deorbit method is RCS, next failure means loss of deorbit capability (fail critical for deorbit).*
- **1 OMS PROP TANK LEAK:**
 - *OMS tank failure no longer covered through end of mission. Failure means loss of deorbit capability (fail critical for deorbit).*

Propellant budgeting for any flight is such that the loss of an OMS propellant tank early in flight (post-OMS-2) may not leave sufficient propellant between the good OMS, FRCS, and ARCS (above the entry redline) to achieve the shallow target line deorbit. Similarly, for the loss of both OMS engines plus one or more +X jets, there may be enough propellant to achieve the steep deorbit targets.

- **1 OMS INLET LINE LEAK:**
 - *Due to high pressure surges during repress of the OMS inlet line, it may not be possible to use the propellant for deorbit. In this case, the inlet line leak will be treated as an OMS propellant tank fail. The only guaranteed deorbit method is the good OMS engine supplemented by the FRCS and aft RCS.*
- **1 AFT RCS He OR PROP TANK LEAK:**
 - *Leaves only the good system for entry control; loss of the good system means no control during early entry (fail critical for entry control).*
- **2 AFT RCS MANIFOLD LOST - SAME SIDE:**
 - *Next RCS jet lost could result in no control for entry/no RCS downmode for deorbit (fail critical for entry control/fail safe for deorbit since propellant not available for 2 +X deorbit).*
- **2 OMS/RCS FLOW PATH (XFD) LOST:**
 - *Failure of OMS engine is same as OMS tank failure which is loss of deorbit capability (fail critical for deorbit).*
 - *Failure of RCS prop tank or He tank is loss of RCS jets on same side, which is no control for entry (fail critical for entry).*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A6-1001

OMS/RCS GO/NO-GO CRITERIA [CIL] (CONTINUED)

- *1 OMS ENGINE AND 1 ?X RCS JET LOST:*
 - *Only the remaining OMS engine and three ?X jets are available to provide deorbit capability. Flight rules define four ?X jets to steep targets as the only acceptable RCS deorbit method. Three ?X jets can provide a deorbit capability if sufficient propellant is available. Because flight rules do not recognize three -X jets as a deorbit option; loss of one +X jet and one OMS engine require a deorbit at the next PLS, because only one deorbit method remains (fail critical).*
- *1 OMS ENGINE AND < RCS STEEP DEORBIT PROPELLANT REQUIREMENTS:*
 - *RCS steep propellant is redlined for the loss of one OMS engine per Rule {A6-303}, OMS REDLINES [CIL]. Unavailability of the propellant necessary for an RCS steep deorbit in conjunction with the loss of one OMS engine leaves only one safe deorbit method and results in a next PLS deorbit (loss of deorbit redundancy). RCS shallow targets may be acceptable on a flight-specific basis if defined in the Flight Rule Annex Priority Table.*
- *2 OMS/RCS FLOW PATH (CROSSFEED) LOST:*
 - *Failure of OMS engine is same as OMS tank failure which is loss of deorbit capability (fail critical for deorbit). Failure of RCS propellant tank or He tank is loss of RCS jets on same side, which is no control for entry (fail critical for entry).*

FLIGHT RULES

SECTION 7 - DATA SYSTEMS

GPC & DATA PATH MANAGEMENT

A7-1 PASS DPS FAILURE

PASS DPS FAILURES ARE DECLARED BY THE FOLLOWING GUIDELINES USING ONBOARD AND GROUND MONITORING:

A. REDUNDANT SET (RS) FAILURE - DURING ASCENT OR ENTRY, AN RS FAILURE IS DEFINED AS FOLLOWS:

1. ALL PASS GPC'S QUIT OR HALT (POSSIBLE ANNUNCIATION OF THREE OR FOUR COMPUTER ANNUNCIATION MATRIX (CAM) DIAGONALS).

A QUIT or HALT state means that no software is being executed.

2. RS BREAKUP TO ALL SIMPLEX (THREE OR FOUR DIAGONALS).

An RS breakup can be induced by a GPC software or hardware problem. When an RS breakup occurs, each simplex GPC uses only the response data from its assigned string; it no longer incorporates response data from LRU's/BTU's controlled by the other GPC's. The PASS set is no longer operating on the same information and individual GPC's may send conflicting commands to subsystems.

B. AN RS SPLIT IS DEFINED AS FOLLOWS:

1. DURING ASCENT OR ENTRY, THE ORIGINAL SET OF FOUR PASS GPC'S SPLIT INTO TWO SETS OF TWO GPC'S (CALLED A TWO-ON-TWO) WITH EACH SET OF GPC'S VOTING AGAINST THE OTHER, OR TWO GPC'S EACH SPLIT FROM THE REMAINING SET OF TWO GPC'S, RESULTING IN A 2-1-1 SPLIT.

A GPC software or hardware failure can induce an RS split. With this type of failure, each set of two GPC's continues to process as if that set were the only one running. Although information is no longer exchanged between the two sets, both GPC's within each set maintain coordination. Unlike the redundant set breakup to all simplex, incorporation of flight-critical MDM response data is maintained within each set. In this configuration, the sets may send conflicting commands to subsystems. Additionally, it is possible for two GPC's to each split from the remaining redundant set of two GPC's. The result is three separate groups of GPC's that may each be issuing commands to subsystems that could be conflicting.

2. ON ORBIT, WHEN RS GNC GPC'S DO NOT MAINTAIN RS SYNC BUT DO MAINTAIN COMMON SET (CS) SYNC WITH EACH OTHER.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-1 PASS DPS FAILURE (CONTINUED)

A GPC software or hardware problem can induce an RS split. With this type of failure, the GNC GPC uses only response data from its assigned strings; it no longer incorporates response data from LRU's/BTU's controlled by the other GNC GPC. The GNC GPC's do maintain common set coordination with each other and other GPC(s) in the common set. In this configuration, the sets may send conflicting commands to subsystems.

C. A GPC FAILURE IS DEFINED AS FOLLOWS:

1. A GPC FAILS OUT OF CS OPERATIONS OR ANNUNCIATES MULTIPLE "GPC BITE" FAULT MESSAGES.

GPC BITE fault messages indicate GPC software or hardware problems exist. A GPC BITE fault message annunciated multiple times by a single GPC implies that the GPC has ceased running a software module for multiple cycles. This cessation is considered an abnormal early termination of software capability and the GPC is considered failed. However, a GPC which only experiences a single GPC BITE and still maintains common set synchronization implies that no critical processes have been affected by the one-time early termination and that no immediate action is required.

2. A SINGLE GPC ANNUNCIATES A "SUMWORD ICC X" FAULT MESSAGE WHILE OPERATING IN THE CS WITH OTHER GPC'S IN MM 105, MM 106, OPS 2, MM 301, MM 302, OR MM 303.

A SUMWORD ICC X fault message notifies the crew of data mismatches between the CS GPC's on specific parameters being passed via ICC buses. To avoid possible use of incorrect GPC data that may cause subsequent OPS transition failures, this single GPC is treated as failed.

3. DURING ASCENT (MM 102 TO MM 104) OR ENTRY (MM 304, MM 305, MM 601 TO MM 603), A GPC ANNUNCIATING A "SUMWORD ICC X" FAULT MESSAGE AND NOT FAILED-TO-SYNC WILL BE ALLOWED TO CONTINUE OPERATING IN THE REDUNDANT SET AND DECLARED FAILED FOR THE NEXT OPS TRANSITION. MANAGEMENT OF THE GPC SHALL BE PER FIGHT RULE {A7-3A}, GPC FAILURE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-1 PASS DPS FAILURE (CONTINUED)

A SUMWORD ICC X message is not indicative of a GPC's ability to command a FC bus. If the GPC remains in the RS after the message is annunciated, it is expected that the set will remain intact until the next OPS transition when the GPC should be moded to HALT. If the GPC remains in the set, control redundancy is not affected and action to remove the GPC from the set is not warranted since the worst-case result would be a forced FTS. The GPC is expected to FTS at the OPS transition and should be removed prior to attempting the transition.

The response to this condition is divided into two groupings because of the opportunities to respond to the condition. During ascent through MM 104, GPC MODE/POWER switches are considered to be inaccessible. Therefore, a non-FTS GPC cannot be taken to HALT. The dynamic part of entry starts with MM 304. Although GPC MODE switches are accessible, DPS system reconfiguration is not allowed except for certain failure conditions as stated in All Flights Rule {A-254C}, ENTRY STRING REASSIGNMENT. Therefore, removing an annunciating GPC would reduce system redundancy. Prior to MM 304, an annunciating GPC still in the RS can be HALTED and the DPS system reconfigured to maintain redundancy (Rule {A2-254A}, ENTRY STRING REASSIGNMENT)).

This rule is referenced by Rule {A7-3A}, GPC FAILURE.

D. A DATA PATH FAILURE IS DEFINED AS THE LOSS OF CORRECT COMMUNICATION BETWEEN A GPC AND A BTU OR LRU (I.E., MDM, MMU, DEU, IMU, HUD, ETC.). ©[040899-2459B]

A data path failure is manifested when problems occur at the GPC, BTU, or LRU. Loss of information to/from a GPC may be indicated by an INPUT/OUTPUT (I/O) ERROR fault message, BCE STRING fault message, BCE BYPASS fault message, or MDM OUTPUT fault message. However, failures exist (i.e., GPC to BTU/LRU output failures) where no message is annunciated. Failures where no message is annunciated may be detected by the flight control community and/or by crewmembers using subsystems performance or onboard indications.

Rules {A2-59}, BFS ENGAGE CRITERIA, {A2-258A}, BFS ENGAGE, and {A7-4}, TRANSIENT GPC, reference this rule.

FLIGHT RULES

A7-2

UNRECOVERABLE GPC

AN UNRECOVERABLE GPC IS DEFINED AS FOLLOWS:

An unrecoverable GPC will not be used for PASS redundant/common set operations, or as a BFS GPC.

A. THE GPC FAILS AND WILL NOT RESPOND TO AN IPL.

A GPC that does not respond to an IPL after experiencing a failure is indicative of a hardware problem. The GPC is considered failed and cannot be used.

B. THE GPC FAILS FOR UNKNOWN CAUSES MORE THAN ONCE EVEN THOUGH IT RESPONDS TO AN IPL.

A GPC that responds to an IPL even after it has failed more than once does not ensure the GPC is healthy. IPL'ing a computer more than once for unexplained failures points to an unreliable GPC.

C. THE GPC HAS ONE OR MORE FAILED INPUT/OUTPUT PROCESSOR (IOP) RECEIVER ON BUS CONTROL ELEMENT (BCE) FC 1, 2, 3, 4, 5, 6, 7, 8 OR ANY ICC BCE (EXCEPT AS NOTED IN RULE {A7-5}, PASS GPC BCE FAILURE MANAGEMENT).

A PASS GPC with an ICC receiver failure prevents that GPC from operating in a redundant or common set. A PASS GPC with a flight-critical receiver failure prevents that GPC from operating in a redundant set. Although a PASS GPC with a flight-critical receiver failure could operate in the common set, that GPC could not operate in the redundant set for entry. Hence, it is declared unrecoverable. ©[101096-4516]

The exception as noted in Rule {A7-5}, PASS GPC BCE FAILURE MANAGEMENT, is for BCE FC4 (primary ports) or FC8 (secondary ports) receiver failures where FF4 MDM is bypassed. For this case, turning off MDM FF4 allows the GPC with the receiver failure to be assigned any string and operated in the redundant set to allow us to retain GPC redundancy. ©[101096-4516]

FLIGHT RULES

A7-3

GPC FAILURE

- A. DURING ASCENT (MM 102 TO 104) OR ENTRY (MM 304, 305, 601 TO 603), MODE A FAILED GPC TO "HALT" ASAP. POST-MM 104 OR PRE-MM 304, POWER OFF A FAILED GPC ASAP.

A GPC that experiences a fail-to-sync can send erroneous commands to the orbiter subsystems. To prevent a failed GPC from sending erroneous commands, the GPC is moded from RUN to STANDBY then HALT when the power switch is not accessible, otherwise GPC power is removed to preserve data for analysis.

In general, reach and visibility constraints do not allow the crew to reach the GPC mode switches until post-MECO. The exception to the MECO cutoff point is the SSME command path recovery restring done post-SRB SEP when the g-forces have decreased and the crew can reach the switches. The failed GPC will have to be moded to HALT prior to the restring to avoid dual commands. This rule is referenced by Rule {A7-1C}, PASS DPS FAILURE.

- B. ON ORBIT, POWER OFF FAILED GPC, CONFIGURE DPS PER RULES {A7-13}, GPC MAJOR FUNCTION CONFIGURATION, AND {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA, AND ATTEMPT TO RECOVER FAILED GPC.

A GPC failure will create a loss of GPC redundancy. Depending on the flight requirements, different GPC configurations may be required. Until GPC recovery can be performed, the referenced rules can be used as a guideline for reconfiguring the DPS system following GPC failures.

FLIGHT RULES

A7-4 TRANSIENT GPC

A TRANSIENT GPC IS DEFINED AS:

- A. A GPC WHICH HAS FAILED ONLY ONCE, BUT HAS SUCCESSFULLY RESPONDED TO AN IPL.

A GPC failure is generally thought to be caused by hardware failures more than software problems. Even if the failed GPC recovers by doing an IPL, there is concern that the GPC will fail again. If dump analysis can confirm a software-induced failure, the GPC will be considered recovered. ©[092195-1798]
©[101096-4516]

- B. A GPC (101S) WHICH EXPERIENCES SOFT ERRORS AGAINST THE LOWER PAGE FOR A PASS OR BFS, OR UPPER PAGE FOR A PASS GPC, OF MEMORY AT A CONSTANT RATE OR EXPERIENCES A SOFT ERROR COUNT OF 7F. ©[101096-4477]

Random single-memory hits are expected to occur at a rate of several per day or in single bursts of several errors. A constant incrementing of the error count is indicative of a hard-memory failure. Although a single hard bit error in a GPC memory location is corrected by the error detection and correction code, an additional error in this memory location cannot be corrected, and if accessed by the computer would cause the GPC to fail. Errors in the upper page of memory are not reflective of errors in the lower page of memory. ©[101096-4477]

The upper page of memory in PASS GPC's is used for G3 archive. Starting with OI-25, the upper page of PASS GPC's is also used to store certain software library routines. Therefore, a hard memory error in the upper memory of a PASS GPC becomes significant to normal operation in addition to the concern for the G3 archive software. G3 archive concerns with soft errors against the upper page of memory are addressed in Rule {A7-14}, GNC 3 ARCHIVE MANAGEMENT. Upper memory in a BFS GPC is currently not utilized. ©[101096-4477]

- C. A GPC WHICH ANNUNCIATES A SINGLE "GPC BITE" FAULT MESSAGE.

A GPC BITE fault message indicates that a GPC software or hardware problem exists and the GPC has ceased running a software module for at least one cycle. This cessation is considered an abnormal early termination of software capability. If only a single BITE condition is annunciated, then the cause of the problem is considered transient and the GPC should be treated as such under Rule {A7-13C}, GPC MAJOR FUNCTION CONFIGURATION. If the GPC fails-to-sync, then the GPC is declared failed per Rule {A7-1C}.1, PASS DPS FAILURE.

FLIGHT RULES

A7-5

PASS GPC BCE FAILURE MANAGEMENT

PASS GNC 3 GPC'S THAT INCUR BCE FAILURES WILL BE CONFIGURED ACCORDING TO THE FOLLOWING GUIDELINES:

- A. PRE-DEORBIT BURN: FOR BCE FAILURES AFFECTING STRINGS 1, 2, OR 3, RESTRINGING WILL BE PERFORMED WITH STRINGS ASSIGNED PER RULE {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA. FOR STRING 4 FAILURES, PORT MODING WILL BE DONE TO RECOVER FA4.
- B. POST-DEORBIT BURN: PORT MODING WILL BE DONE FOR BCE FAILURES IN ORDER TO RECOVER THE CAPABILITY OF FF1, 2, OR 3, AND FA4. FA1, 2, OR 3 WILL BE GIVEN UP IN FAVOR OF FF1, 2, OR 3, AND FF4 WILL BE GIVEN UP IN FAVOR OF FA4.

GPC's incurring FC BCE failures will be reconfigured by port moding or restringing to obtain the most optimum flight-critical capabilities depending on flight phase. Pre-deorbit burn restringing will be done to regain the full capability of strings 1, 2, and 3. Restringing will not be performed for string 4 BCE failures due to its lack of sensor authority with respect to strings 1 to 3. String 4 will be port moded to recover FA4 to obtain FCS channel capability. Post-deorbit burn, port moding will be done to recover the capability of FF1, 2, or 3 and FA 4. Post-deorbit burn restringing will not be performed for FC BCE failures due to concerns for the hazards of dynamic restringing. Port moding recovers nearly the same capability as restringing, while avoiding a restring.

- C. FOR HARD OR TRANSIENT PASS GPC BCE RECEIVER FAILURES THE GNC OPS 3 SET WILL BE CONFIGURED USING THE FOLLOWING CRITERIA FOR SYSTEM RECONFIGURATION:
 1. FOR BCE RECEIVER FAILURES AFFECTING STRINGS 1, 2, OR 3 THE GPC WILL BE GIVEN UP IN FAVOR OF THE MDM WITH STRINGS ASSIGNED PER RULE {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA.
 2. FOR FC4 (FF4) RECEIVER FAILURES, MDM FF4 MAY BE POWERED OFF TO RETAIN GPC REDUNDANCY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-5

PASS GPC BCE FAILURE MANAGEMENT (CONTINUED)

3. FOR FC8 (FA4) RECEIVER FAILURES, STRING 4 MAY BE MODED TO SECONDARY PORTS AND MDM FF4 MAY BE POWERED OFF TO RETAIN GPC REDUNDANCY.

GPC's that experience flight-critical BCE receiver failures will force fail to sync due to nonuniversal I/O errors that result from RS GPC's disagreeing on the occurrence of the error. In the deorbit preparation timeframe, IFM's are not routinely done (ref. Rule {A2-105}, IN-FLIGHT MAINTENANCE (IFM)), so reconfiguration can be done to optimize GPC or LRU redundancy for entry. A GPC with a receiver failure affecting strings 1, 2, or 3 will be given up in favor of recovering full LRU redundancy. For string 4 failures, FF4 may be given up in order to maintain GPC redundancy, since FF4 is the "least critical" FC MDM. ©[101096-4516]

If the failure is FC4 (FF4), MDM FF4 may be powered off prior to adding the previously failed GPC back into the GNC 3 set. This causes all GPC's to see I/O errors against FF4, therefore FF4 is bypassed and the recovered GPC does not fail to sync.

If the failure is FC8 (FA4), port moding string 4 will cause the failed BCE (FC8) to attempt to communicate with FF4's secondary port. FF4 can then be powered off and the failed GPC can be recovered.

- D. WHEN A CHOICE EXISTS BETWEEN LOSS OF A PASS GPC AND A DEU, THE DEU WILL NOT BE USED WITH PASS GPC'S AND WILL BE ASSIGNED TO THE BFS FOR ENTRY. FOR MEDS CONFIGURED VEHICLES, AN IDP MAY STILL BE USED IN A NON-DPS MODE ONCE IT HAS BEEN DEASSIGNED FROM ALL PASS GPC'S. ©[040899-2459B]

Each GPC in a redundant set listens to all data to and from the DEU's assigned to the RS. Should a single RS GPC have a receiver failure on a DK data bus, that GPC will fail to sync with the rest of the redundant set. The GPC can be recovered by assigning the DEU that caused the problem to the BFS because the RS will stop listening to the data from that DEU. IDP's which are not assigned to a PASS computer may still be used with a PASS GPC in a non-DPS mode since only the DPS mode requires the DK data bus interface. ©[040899-2459B]

Rules {A2-5}, PORT MODING/RESTRINGING GUIDELINES; {A7-2}, UNRECOVERABLE GPC; and {A7-6}, DATA PATH FAILURE, reference this rule.

FLIGHT RULES

A7-6

DATA PATH FAILURE

- A. DURING ASCENT OR ENTRY, DPS RECONFIGURATION MAY BE PERFORMED PER RULES {A2-63}, ASCENT STRING REASSIGNMENT; {A2-254}, ENTRY STRING REASSIGNMENT; {A7-102C}, PASS DATA BUS ASSIGNMENT CRITERIA; OR {A7-5}, PASS GPC BCE FAILURE MANAGEMENT, TO RECOVER DATA PATHS LOST DUE TO GPC FAILURES.

Data-path loss due to GPC failures results in a bypass of an entire or half-string. Although the string is downmoded, the attached peripheral devices are healthy. Communication may be reestablished with the string by reassigning the bypassed string(s) to a good GPC.

For failure of a PASS GPC BCE transmitter and/or receiver, communications may be reestablished by reassigning the entire string to another GPC with a good BCE, or port moding will regain the bypassed MDM at the expense of the alternate MDM on the same string.

For string reassignment criteria, refer to Rules {A2-63}, ASCENT STRING REASSIGNMENT; {A2-254}, ENTRY STRING REASSIGNMENT; and {A7-102C}, PASS DATA BUS ASSIGNMENT CRITERIA. For PASS GPC BCE failure management, refer to Rule {A7-5}, PASS GPC BCE FAILURE MANAGEMENT.

- B. ON ORBIT, RECONFIGURE PER RULES {A7-13}, GPC MAJOR FUNCTION CONFIGURATION; {A7-102}, PASS DATA BUS ASSIGNMENT CRITERIA; AND {A7-105}, MDM PORT MODING. @ED]

Data path lost because of GPC failures implies communication with the affected string is lost temporarily, but the attached LRU's are healthy. Communications may be reestablished by reassigning the affected string to a good GPC. This rule identifies the legal reassignment phases.

- C. ON ORBIT, A BTU OR LRU MAY BE DEACTIVATED TO PRECLUDE RECURRING NUISANCE FAULT MESSAGES.

A recurring fault message may become a nuisance to the crew. If the cause of the annunciation can be isolated to a BTU or LRU, consideration will be given to deactivating the erring unit. This will eliminate the repeat generations of the fault message. Deactivation may take the form of MCDS entered item entries which reconfigure the subsystem, or the unit may be powered off.

FLIGHT RULES

A7-7 **POWERED OFF GPC ACTION (101S)**

A GPC (101S) THAT HAS HAD POWER REMOVED SHOULD BE RE-IPL'D BEFORE USE, TIME PERMITTING.

The GPC (101S) battery maintains memory during GPC poweroff but does not support memory error correction. This allows memory errors to accumulate. If this results in a double-bit error, the GPC will fail when the location is accessed. Re-IPL'ing the GPC will remove all soft errors and reestablish memory integrity.

Re-IPL'ing a GPC may not, however, be the best action in all cases because the GPC can require multiple uplinks before it can be used. Therefore, for time-critical cases where the IPL/uplink recovery sequence takes too much time, it may be desirable to accept the risk of a double-bit error. This risk is not constant and is directly related to the amount of time the GPC is powered off. As that time is reduced, the risk decreases.

A7-8 **REDUNDANT SET FAILURE**

FOR AN RS FAILURE DURING ASCENT AND ENTRY DYNAMIC PHASES, ENGAGE BFS.

This rule calls for a BFS engage to regain vehicle control due to a redundant set failure.

FLIGHT RULES

A7-9

REDUNDANT SET SPLIT

A. ASCENT:

1. ASCENT, PRE-MECO, FOR MULTIPLE, NEAR SIMULTANEOUS GPC FAILURES WHERE AT LEAST ONE IS FAIL-TO-SYNC (INCLUDING 2-ON-2 SPLITS), ENGAGE BFS (REF. RULE {A2-59}, BFS ENGAGE CRITERIA). IF THE BFS IS TRACKING AND BOTH OF THE FOLLOWING ARE TRUE, THEN THE PASS SET WILL BE RECONFIGURED RATHER THAN BFS ENGAGE:
 - a. RECONFIGURATION CAN BE COMPLETED PRE-MECO (E.G., CREW CAN REACH THE AFFECTED GPC SWITCHES AND SUFFICIENT TIME IS AVAILABLE TO COMPLETE THE PROCEDURE).
 - b. NO ADDITIONAL COMPLICATING FAILURES ARE PRESENT.
2. IF PASS SET RECONFIGURATION IS TO BE PERFORMED, MCC WILL COORDINATE WITH THE CREW THE FOLLOWING STEPS PRE-MECO:
 - a. HALT SIMPLEX (OR NONPREFERRED PAIR) GPC'S.
 - b. MANUALLY SHUT DOWN THE ENGINE(S) WITH COMMAND PATH FAILURES PER RULE {A5-106}, MANUAL SHUTDOWN FOR COMMAND/DATA PATH FAILURES.
 - c. RESTRING ONLY IN ACCORDANCE WITH RULE {A2-63}, ASCENT STRING REASSIGNMENT.

If the BFS is standalone at the set split during powered flight, then its navigation state will quickly diverge, which eliminates the BFS engage option (ref. Rule {A7-51B}.1, BFS DPS FAILURE). In this case immediate engagement is the only acceptable action. Even if the BFS is tracking, BFS engagement is the quickest and simplest option to regain full vehicle control and LRU redundancy (except for GPC redundancy, of course). As long as the BFS continues to track the PASS following a set split, then reconfiguration of the PASS set is a viable option. However, adequate time must be available to complete the procedures before MECO; the crew must be physically capable of reaching the required switches under g-loads; and the overall crew/MCC work load due to additional complicating factors is not excessive.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-9

REDUNDANT SET SPLIT (CONTINUED)

Due to the extremely low probability of this failure case, no additional procedures will be documented nor valuable integrated simulation time expended. Any crew training will be limited and will emphasize the BFS engage procedure as this is the preferred option and will safely allow recovery from this failure scenario.

The PASS GPC fail procedure in the ascent cue cards is considered to be sufficient to specify those crew actions essential to immediately safing the vehicle in the event of a set split. Also, additional failures (at least two) in the communications system that preclude MCC instructions to the crew in this situation is not considered credible. Therefore, all remaining actions will be by MCC call.

In a two-on-two set split, the flight control team will identify the GPC's with the best remaining capability; the nonpreferred set will be moded to halt pre-MECO to avoid erroneous outputs from those GPC's.

The major reason for requiring pre-MECO crew action is to avoid a catastrophic SSME shutdown. For the 2-1-1 case, two or three engines could have command path failures at MECO with possible loss of crew and vehicle.

A manual shutdown of all three engines will not work because of LO₂ NPSP problems caused by a zero-g shutdown. Manual shutdown for the case of two command path failures could result in loss of vehicle control because guidance may not recognize all engines that are shutdown. Single Engine Roll Control (SERC) will activate immediately after the second engine failure, due to the sensed loss of vehicle acceleration; however, degraded control will result if guidance does not recognize the second engine out failure flag to properly establish ascent DAP flight control gains. To preclude these problems, the simplex GPC's must be prevented from commanding engines. This can be done by taking the simplex GPC's to HALT, if the crew can reach the MODE switches. This may cause one engine to have a command path failure, but this is less severe than two or three engines with a command path failure. If only one GPC is halted, then two engines could still have command path failures. After the GPC(s) are moded to HALT, there will be no more than one engine with a command path failure that will need to be shut down manually. If the simplex GPC's cannot be halted, then engaging the BFS is the only other method to ensure a safe MECO. After the second SSME failure, BFS engage is no longer an option since the BFS does not support SERC and a loss of control will likely occur on the BFS. (Ref. A/E FTP #74 Minutes of 1/18/91.) ©[022802-5250]

B. DURING ASCENT OR ENTRY, FOR LOSS OF CONTROL, ENGAGE BFS.

This rule calls for a BFS engage to regain vehicle control for the case where a redundant set split causes a loss of control situation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-9 REDUNDANT SET SPLIT (CONTINUED)

- C. ON ORBIT, A SELECTION MAY BE PERFORMED BY IDENTIFYING THE GPC THAT IS COMMANDING TWO OF THREE IMU'S. THE OTHER GPC WILL BE POWERED OFF AND A RESTRING WILL BE PERFORMED TO RECOVER ALL STRINGS.

An initial selection of the GPC commanding two of three IMU's will provide IMU redundancy. The remaining GPC will be powered off to cease software execution and allow for a restring to be performed. If the GPC is not powered off and a restring is performed, dual commands will result.

Rule {A2-59}, BFS ENGAGE CRITERIA, references this rule.

A7-10 GNC GPC REACTIVATION PRIORITY

THE ORDER OF PREFERENCE FOR REGAINING VEHICLE CONTROL FOR LOSS OF ALL OPERATING GNC GPC(S) ON ORBIT IS:

- A. FREEZE-DRY GNC 2.
- B. FREEZE-DRY GNC 3 (IF AVAILABLE).
- C. BFS.

Activation of the G2FD GPC would recover full vehicle control with minimal impact to nominal-orbit configuration. Activation of the G3FD GPC requires activation of special LRU's needed by the OPS 3 software. A G3FD GPC will only be available if G3 archive capability has been lost and a G3FD has been established. In addition, the crew procedures for recovering and/or reconfiguring the PASS are simplified if the BFS has not been engaged. Ref. Rule {A7-14}, GNC 3 ARCHIVE MANAGEMENT.

FLIGHT RULES

A7-11 **GNC GPC REDUNDANCY REQUIREMENTS**

REDUNDANT GNC GPC'S ARE REQUIRED FOR THE FOLLOWING ORBIT OPERATIONS :

- A. RNDZ/PROX OPS.
- B. PAYLOAD RETRIEVAL.
- C. EVA OPERATIONS WITH MANNED FREE FLYER OPS. @[090894-1667]
- D. OMS/RCS BURNS WHICH ARE CRITICAL FOR CREW SAFETY AND/OR WHICH ARE CLASSIFIED AS FLIGHT SUCCESS DELTA V MANEUVERS.

Redundant GNC GPC's meet the fail-safe capability that is required for these operations. Rendezvous requires redundancy at the point in the profile where on-time execution of delta V maneuvers becomes critical to mission success and when a breakout capability is required. For crew safety, proximity operations and payload retrieval operations require +Z redundancy for translation separation maneuvers. For EVA operations involving an untethered crewmember, vehicle control is required in order to rescue a crewmember for certain free flyer apparatus (i.e., SAFER) failures. OMS burns require a downmode capability for delta V maneuvers which are critical for crew safety (such as some postdeployment separation burns) and flight success. RCS burns require +Z redundancy for translation separation maneuvers that are critical for crew safety (such as IPS, RMS, or KU jettison). With redundant GPC's, uninterrupted vehicle control would be provided even if one GNC GPC fails.

Rule {A7-13A}, GPC MAJOR FUNCTION CONFIGURATION, references this rule.

In general, reference rules {A2-114}, OMS/RCS MANEUVER CRITICALITY, and {A2-120}, RNDZ/PROX OPS DPS SYSTEMS MANAGEMENT, for related requirements. @[090894-1667]

A7-12 **PASS/BFS REDUNDANCY**

THE BFS IS NOT CONSIDERED IN THE PASS DPS REDUNDANCY REQUIREMENTS.

The BFS software was not designed with the requirement to accomplish on-orbit operations. It was designed to assume control of the vehicle in the event the PASS can no longer control the vehicle during dynamic flight regimes. Unlike the PASS, the BFS cannot perform IMU alignments or MDM port moding; and it does not have any time management controls. The system management (SM) function is limited in the sense that all PASS SM capabilities are not available in the BFS. With this in mind, the BFS cannot be considered as being interchangeable or redundant to the PASS GPC's.

FLIGHT RULES

A7-13

GPC MAJOR FUNCTION CONFIGURATION

GPC MAJOR FUNCTION CONFIGURATION WILL BE PERFORMED PER THE FOLLOWING GUIDELINES:

A. ORBIT CONFIGURATION @[082593-1538]

1. NOMINAL ON-ORBIT GPC DISTRIBUTION BY MAJOR FUNCTION WILL BE AS FOLLOWS:

GPC 1 - GNC 2

GPC 2 - GNC 2 (FREEZE-DRY, IF REQUIRED FOR POWER SAVINGS)

GPC 3 - GNC 2 FREEZE-DRY (GNC 3 FREEZE-DRY)

GPC 4 - SM 2

GPC 5 - BFS

Two GNC GPC's are required to satisfy Rule {A7-11}, GNC GPC REDUNDANCY REQUIREMENTS. One GPC is required to accomplish the systems management functions. The BFS is always loaded in a GPC to gain vehicle control, if lost, from the PASS GPC's. The last GPC is loaded with G3 software to protect against mass memory failures if no G3 archive is resident in a nonfailed GNC major function GPC, otherwise G2 software will be loaded into this GPC.

2. DURING RENDEZVOUS/PROX OPS, A REDUNDANT SET (RS) OF THREE GPC'S MAY BE UTILIZED.

Three GNC GPC's are preferred for rendezvous/prox ops to simplify recovery procedures if a GNC GPC fails during the period when rendezvous nav is enabled. Only two GPC's are actually required (ref. Rule {A7-11}, GNC GPC REDUNDANCY REQUIREMENTS). If a GNC GPC fails, a restring to the remaining two GPC's recovers all LRU redundancy, still meets rendezvous GPC requirements and does not affect rendezvous nav functions as long as the target set is not changed. Since all PASS GPC's have G3 software stored in high memory, there is not a concern with giving up the G3 FD GPC prior to rendezvous to form a three GPC set. @[082593- 1538]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-13

GPC MAJOR FUNCTION CONFIGURATION (CONTINUED)

- B. A REDUNDANT GNC GPC MAY BE CONFIGURED TO PL9 FOR THE FOLLOWING:

Using a redundant set GPC would not give up existing capability, only redundancy.

1. A PASS DEU IPL

A DEU can only be IPL'ed from PL9, SM OPS 2/4, a post-IPL OPS 0 GPC, or the BFS. If available, an SM 2/4 DEU IPL is preferred over a PL9 DEU IPL in order to preserve GNC GPC redundancy. A PL9, SM OPS 2/4, or post-IPL OPS 0 GPC provides full PASS DEU IPL capability. PASS critical formats will not be available after loading a DEU from the BFS, so it is preferable not to perform a BFS DEU IPL on a DEU which is to be driven by the PASS when one of the other viable alternatives exists.

2. A MASS MEMORY DUMP/PATCH

SM will normally be used for an MMU dump or patch as long as the MMU load block is less than or equal to 2,048 halfwords. PL9 has capability to accommodate an MMU dump or patch involving large MMU load blocks up to 16,384 halfwords.

- C. A TRANSIENT GPC WILL BE MADE THE REDUNDANT GNC GPC ON ORBIT, EXCEPT FOR SAFETY-CRITICAL OPERATIONS. A TRANSIENT GPC MAY BE MADE THE FREEZE-DRY GNC 2 IF REQUIRED FOR POWER SAVING ON ORBIT. IF USED FOR ENTRY, A TRANSIENT GPC WILL BE ASSIGNED STRING 4.

A transient GPC may fail again and, therefore, will not be used for orbit periods of safety-critical operations such as proximity operations where continuous and complete vehicle control is required to preclude collisions. For other periods, running the transient GPC in a redundant set may provide more data relating to the original failure. The use of a transient GPC for entry will generally be avoided, but if conditions cause a transient to be used for entry, then it will be assigned string 4 because string 4 interfaces with fewer LRU's and loss of this string is less significant than loss of any other string during the entry timeframe.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-13

GPC MAJOR FUNCTION CONFIGURATION (CONTINUED)

- D. FOR TWO PASS GPC'S FAILED DURING ASCENT, ATTEMPTS TO RECOVER THE GPC'S WILL BEGIN FOLLOWING THE FIRST DPS TRANSITION. THE CONFIGURATION DURING THIS PERIOD WILL BE ONE GNC 2 GPC, ONE SM GPC, AND THE BFS (EXCEPT AS NOTED IN PARAGRAPH E).

Recovery will be attempted as soon as possible after the data processing system is configured for orbit. One GNC GPC, one SM GPC, and one BFS provide the best configuration to continue with a minimum duration mission and accomplish mission objectives (i.e., one GNC GPC for vehicle control, one SM GPC for system management, and the BFS for backup in case a PASS failure occurs).

The exception reference refers to those operations that require redundant GNC GPC's. Orbit operations that require redundant GNC GPC's should be delayed, if possible, until GPC recovery is complete. The SM GPC would be given up to provide a redundant GNC GPC and the BFS should be activated to provide systems monitoring if a redundant GNC GPC is required for crew safety or total loss of major mission objectives. The BFS should not be given up to allow the SM GPC to support payload operations.

- E. FOR A GENERAL PURPOSE COMPUTER (GPC) FAILURE ON ORBIT:
@[011295-1746]

1. A BFS WILL BE MAINTAINED AS LONG AS AT LEAST TWO GPC'S ARE OPERABLE.

The BFS can perform limited systems management and it is preferred over the PASS SM when only two GPC's are available because of its entry capability.

2. RECONFIGURATION WILL BE BASED ON GPC AVAILABILITY PER THE FOLLOWING PRIORITIES:
 - a. IF A G2FD (FREEZE DRY) IS AVAILABLE, THIS GPC MAY BE RECONFIGURED AS A GNC, SM, OR BFS GPC.
 - b. IF A G3FD IS CONFIGURED (DUE TO A LOSS OF G3 ARCHIVE):
 - (1) THE G3FD GPC MAY BE RECONFIGURED AS A GNC, SM, OR BFS GPC IF BOTH MASS MEMORY UNITS (MMU'S) ARE OPERATIONAL.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-13

GPC MAJOR FUNCTION CONFIGURATION (CONTINUED)

(2) IF AN MMU IS FAILED, THE G3FD WILL NOT BE SACRIFICED.

- c. IF THE ORIGINAL CONFIGURATION WAS MULTIPLE G2, RECONFIGURATION WILL BE PERFORMED AS NEEDED TO MAINTAIN DUAL G2 IF REQUIRED PER THE FLIGHT RULE ANNEX (I.E., SACRIFICE THE SM IF NECESSARY). IF NO REQUIREMENT EXISTS FOR DUAL G2'S, THEN A SINGLE GNC GPC WILL BE MAINTAINED.

For normal DPS orbit operations, there will be either one or two G2FD GPC's since nominally three sources of entry software will exist onboard (two MMU's and G3 archive present in all PASS GPC's). A G2FD will be given up for any GPC failure. If G3 archive is lost in all GNC major function base GPC's, a G3FD will be established. The G3FD will only be given up as long as both MMU's are operational.

If dual G2 is required and only 3 GPC's are available, the SM GPC will be sacrificed as opposed to the BFS because of the rationale provided in paragraph 1 above.

Reference {A7-3B}, GPC FAILURE; {A7-14A}, GNC 3 ARCHIVE MANAGEMENT; and {A7-201C} and D, DPS REDUNDANCY REQUIREMENTS. ©[011295-1746]

- f. IF BOTH MMU'S HAVE FAILED PRIOR TO SUCCESSFUL COMPLETION OF THE GNC OPS 3 TRANSITION, THE SM GPC WILL BE RETAINED UNTIL TIG-50 MINUTES.

The SM software is only available from an MMU. In this case, where both MMU's are failed, once the SM function is given up to build another G3 GPC, it is not possible to reestablish an SM GPC if deorbit is waived off and a return to orbit ops is desired. An SM machine offers advantages over a BFS for use in systems monitoring and provides for the use of the Ku-band system, which the BFS GPC cannot provide. TIG-50 minutes is chosen as a convenient point to finally give up the SM machine and configure to a full up G3 set of GPC's before stowing all the orbit FDF and going to the Entry Checklist at TIG-50 minutes.

- g. IF PASS GPC'S INCUR HARD IP BCE FAILURES, DPS RECONFIGURATION, IF POSSIBLE, WILL BE PERFORMED TO REGAIN A MAJOR FUNCTION'S DOWNLIST.

Each GPC has a single IP bus to transmit data to the PCMMU for downlist. The redundant set designates a single GPC as the prime downlist GPC. Therefore, if a downlisting GPC can be recovered by simply redesignating the downlist GPC via item number on SPEC 0, it will be done. If the GPC with the IP bus failure is the SM GPC, the downlist can be recovered by placing SM in one of the redundant GNC GPC's and putting GNC back into the GPC previously loaded with SM.

Rules {A7-3B}, GPC FAILURE; and {A7-6B}, DATA PATH FAILURE, reference this rule.

FLIGHT RULES

A7-14

GNC 3 ARCHIVE MANAGEMENT

- A. A GNC 3 FREEZE-DRIED GPC WILL NOT BE ESTABLISHED IF A COPY OF GNC 3 ARCHIVED SOFTWARE IS RESIDENT IN A NONFAILED GNC MAJOR FUNCTION GPC. IF NO GNC MAJOR FUNCTION GPC'S HAVE A COPY OF GNC 3 ARCHIVE RESIDENT IN UPPER MEMORY, A GNC 3 FREEZE-DRIED GPC WILL BE ESTABLISHED AS SOON AS PRACTICAL.

As long as a GNC major function GPC that has not failed or been re-IPL'ed on orbit has a copy of G3 archive software, it will be considered a redundant source of G3 software. If no such GPC exists, a G3FD GPC will be loaded to provide an additional onboard G3 software source.

Reference Rule {A7-13E}, GPC MAJOR FUNCTION CONFIGURATION. ©[011295-1746]

- B. A GPC CONTAINING ARCHIVED GNC 3 SOFTWARE, WHICH EXPERIENCES AN UPPER MEMORY SOFT ERROR COUNT OF 7F, OR A CONSTANTLY INCREMENTING COUNT WILL NOT BE USED AS A SOURCE OF ENTRY SOFTWARE FOR NON-TAL OPS 3 TRANSITIONS. FOR TAL TRANSITIONS, THE GPC WILL BE USED.

A soft error counter increment is indicative of a single location memory error that was successfully corrected by the memory scrub circuitry. Random single-memory hits are expected to occur at a rate of several per day or in single bursts of several errors. A constant incrementing of the error count is indicative of a hard-memory failure.

All targeted G3 GPC's with G3 archive resident in upper memory will transfer the OPS 3 overlay to lower memory at initiation of OPS 3 when archive retrieve is enabled. Any targeted GPC's without G3 archive resident in upper memory will then receive the overlay from the lowest ID GPC that has the overlay in lower memory. If the archive retrieve is disabled, then the OPS 3 transition will utilize the mass memory units (MMU's) as the source for the G3 software. If one memory location in upper memory has two hard errors and the location is used to store the G3 software, then the GPC will fail-to-halt at the transition. If the location is not used to store G3 software, then the GPC will continue to operate without failing. If there exists only a single error in any upper memory location, then the error correction code will correct the data before it is moved into lower memory and the subsequent execution of G3 from lower memory is not impacted.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-14**GNC 3 ARCHIVE MANAGEMENT (CONTINUED)**

For non-TAL G3 transitions, there is no time criticality, and therefore certain actions can be taken to eliminate the chance of having a GPC fail because of upper memory errors. The easiest action for the crew is to simply disable the archive retrieve by entering a single item entry before execution of the OPS transition. The rest of their procedures can then be run without changes.

Due to the highly dynamic and time critical nature of TAL transitions, time delays in entering OPS 3 are critical. Therefore, disabling the archive retrieve and going to the MMU's introduces delays that should be avoided. The chance of having two errors in a single memory location is considered to be very slight, and therefore accepting the possibility of a single GPC fail versus delaying the entry into OPS 3 by using the MMU's is reasonable.

Errors in the upper page of memory are not reflective of problems with the lower page of memory. Rule {A7-10}, GNC GPC REACTIVATION PRIORITY, references this rule.

A7-15**SM OPS 4 TRANSITION REQUIREMENTS**

FOR FLIGHTS WHERE SM OPS 4 IS NOT SUPPORTED IN THE FLIGHT SOFTWARE TESTING CYCLE, A TRANSITION TO SM OPS 4 WILL NOT BE PERFORMED.

In order to reduce FEID and testing times for flight software loads, missions that require SM OPS 2 only will not have a requirement for SM OPS 4 S/W testing and verification. Therefore, for flights where SM OPS 4 S/W has not been tested, an SM OPS 4 transition will not be performed. Beginning with OI-20, a transition to SM OPS 4 will be prohibited by the flight S/W (by generating an ILLEGAL ENTRY message on the scratch pad line (SPL)) when SM OPS 4 S/W testing is not supported or required for the flight.

FLIGHT RULES

A7-16

GPC MEMORY WRITE CRITERIA [CIL]

THE USE OF GPC MEMORY WRITE PROCEDURES ARE SUBJECT TO THE FOLLOWING GUIDELINES:

- A. ONLY THOSE WRITE PROCEDURES WHICH HAVE COMPLETED SOFTWARE DEVELOPMENT LEVEL VERIFICATION, CREW PROCEDURAL VERIFICATION, AND HAVE BEEN DOCUMENTED IN A CONTROLLED MANNER WILL BE CONSIDERED FOR USE.

Changing GPC memory contents in an uncontrolled manner can lead to catastrophic results. Therefore, this rule is designed to prevent real-time write procedures from being used before they have been evaluated and tested.

- B. GPC MEMORY PROCEDURES THAT MODIFY PERFORMANCE RELATED PARAMETERS WILL BE VERIFIED AND APPROVED IN REAL TIME PRIOR TO THEIR EXECUTION.

This rule documents an agreement that Systems Division made with the Orbiter Project Office.

- C. ONLY PREFLIGHT APPROVED AND VERIFIED (PREAUTHORIZED) GMEM WRITE PROCEDURES NEEDED IN TIME-CRITICAL SITUATIONS WILL BE USED WITHOUT FURTHER VERIFICATION. WHEN TIME PERMITS, THEY WILL BE REVERIFIED BEFORE USE. IF REVERIFICATION IS NOT COMPLETE BEFORE THE LAST IMPLEMENTATION OPPORTUNITY FOR A PREAUTHORIZED GMEM WRITE PROCEDURE, IT WILL BE IMPLEMENTED. ALL GMEM WRITE PROCEDURES THAT ARE NOT PREAUTHORIZED MUST UNDERGO FULL VERIFICATION BEFORE USE.

Certain GMEM's were approved with the understanding that they might be executed in time-critical situations. These GMEM's have been extensively verified by testing prior to release and can be used without further verification when required. An informational SPAN/MER chit should be initiated following such use. Good practice and NSTS policy require any countdown or in-flight GMEM to be verified to the greatest possible extent in real-time before being implemented. Therefore, when time permits, a SPAN/MER chit should be initiated requesting reverification of any preauthorized GMEM before its use. Waiting for that reverification to be completed, however, is not grounds to delay implementing a preauthorized GMEM beyond when it is needed. For GMEM's that have not been preauthorized, a chit requesting verification must be submitted, and the verification must be completed before the GMEM is authorized for use. The specific conditions, including major mode restrictions governing their use, are contained in the PASS Release Authorization Documents (RAD's) and the BFS Engineering Orders (EO's) that authorize their use. The authorizing document of the preflight approved GMEM's is the Release Authorization for Shuttle Software (RASS).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-16

GPC MEMORY WRITE CRITERIA [CIL] (CONTINUED)

- D. UPLINK COMMAND LOADS WILL BE USED WHERE PRACTICAL FOR INCORPORATION OF GPC MEMORY WRITE PROCEDURES. PARAGRAPH G LISTS APPROVED AND DOCUMENTED GENERAL MEMORY WRITE PROCEDURES. WRITE PROCEDURES THAT WILL NOT BE PERFORMED BY UPLINK ARE SO NOTED.

Uplink command loads from the ground offer more flexibility and assurance of the accuracy of the GPC memory procedure. This procedure also allows a change of a larger set of GPC memory addresses as opposed to only six at a time via the GPC memory SPEC. Additionally, it allows real-time review by the MCC personnel before its use (more eyes to detect errors).

- E. GPC MEMORY WRITE PROCEDURES WILL BE IMPLEMENTED AS PATCHES TO GPC RESIDENT SOFTWARE ONLY, AND WILL NOT BE IMPLEMENTED AS PATCHES TO THE MMU'S.

The MMU's are loaded prelaunch with all three areas the same or with approved and verified changes. The intent here is to not pollute the MMU contents in real time because of lack of appropriate time to permit verification and testing.

- F. FOLLOWING THE IMPLEMENTATION OF THE FIRST IN-FLIGHT GPC MEMORY WRITE PROCEDURE, ADDITIONAL PREFLIGHT APPROVED GMEM WRITES WILL NOT BE USED UNTIL REVERIFICATION BY THE APPROPRIATE SOFTWARE DEVELOPER IS PERFORMED, UNLESS AUTHORIZED FOR CONCURRENT USE.

Once a GPC write procedure has been implemented, it is necessary to ensure that subsequent use of GMEM's do not induce failures in the system. Unless authorized for concurrent use while maintaining approved configuration, reverification is required to confirm that the next GMEM considered for use can be used in conjunction with at most one other GMEM in the system without any impact to the system. The appropriate PASS or BFS software developer is responsible for reverifying all subsequent GPC write procedures prior to their use. For GMEM write procedure(s) which can be used concurrently, refer to the authorizing document.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-16

GPC MEMORY WRITE CRITERIA [CIL] (CONTINUED)

G. GPC MEMORY WRITE CRITERIA: PREFLIGHT APPROVED AND VERIFIED GENERAL MEMORY WRITE PROCEDURES. EXCEPT AS NOTED, THESE GMEM'S WILL NORMALLY BE IMPLEMENTED VIA UPLINK:

<u>TITLE</u>	<u>APPROVED IMPLEMENTATION</u>
OMS MIXED CROSSFEED (PASS) (CR 89577B) *	U/L AND KYBD [1]
* PLANNED FOR EXECUTION IN A CRITICAL PHASE	

NOTE: THE GMEM WRITE UPLINK OPERATION CODES ARE NOT LEGAL IN PASS OPS 1 AND 3. THE DEU EQUIVALENT UPLINK IS THE ONLY OPTION. DUE TO THE RELATIVELY LONG UPLINK TIME OF A DEU EQUIVALENT AND THE POSSIBILITY OF DATA DROPOUTS, THE CREW KEYBOARD IMPLEMENTATION IS PREFERRED OVER THE DEU EQUIVALENT UPLINK OPTION IF THIS GMEM WRITE IS IMPLEMENTED DURING TIME-CRITICAL ASCENT OR DEORBIT OPERATIONS. THIS GMEM WRITE WILL BE IMPLEMENTED VIA UPLINK IF REQUIRED FOR A NONTIME-CRITICAL DEORBIT. @[111094-1731]

Reapplication of a previously applied GMEM write is permitted and is not considered a second GMEM write application.

The list of GPC memory read/write procedures contained in paragraph G is considered critical enough to the crew and/or orbiter safety that preflight approval and verification for their use is obtained prior to the flight. Reverification is required unless specific authorization provides for procedures used in conjunction with another GPC memory altering procedure.

Rule {A2-111}, DPS COMMAND CRITERIA, references this rule.

H. GPC MEMORY WRITE CRITERIA: PREFLIGHT APPROVED, UNVERIFIED GENERAL MEMORY WRITE PROCEDURES:

<u>TITLE</u>	<u>IMPLEMENTATION</u>
NONE CURRENTLY DEFINED	N/A

Rule {A2-111}, DPS COMMAND CRITERIA, references this rule.

I. FOR PASS REDUNDANT SET GMEM'S APPLIED TO PERMANENTLY RESIDENT SYSTEM SOFTWARE, GMEM'S WILL BE APPLIED TO A RE-IPL'ED GPC BEFORE THE GPC IS ADDED TO THE REDUNDANT SET.

The PASS software is required to be functionally identical in each GPC of the redundant set. A re-IPL'ed GPC would not have GMEM's installed, so reapplying active GMEM's would be necessary for the redundant system software to be identical. This rule is limited to the system software because GMEM's in the ops application software would be loaded from the PASS prime GPC during the ops transition. @[030994-1611]

FLIGHT RULES

A7-17

GPC MEMORY DUMP CRITERIA

GPC MEMORY DUMPS, ASSOCIATED PROCESSING, AND ANALYSIS WILL BE ACCOMPLISHED USING THE FOLLOWING GUIDELINES:

- A. IF THE BFS IS RECALLED FROM MASS MEMORY, THE ENTIRE INVARIANT MEMORY CONTENTS OF THE RELOADED GPC WILL BE VERIFIED, TIME PERMITTING.

If a PASS RS GPC is re-IPL'ed, the verification of a good IPL is essentially provided by its ability to run in a redundant set. Since the BFS is used alone, the dump and compare is the only complete verification process available to ensure the validity of the reload software.

- B. IN GENERAL, FOR FAILED GPC'S, A HARDWARE-INITIATED DUMP WILL BE PERFORMED, TIME PERMITTING, TO SUPPORT GROUND ANALYSIS. WHEN POSSIBLE, A SOFTWARE DUMP OF A LIKE MEMORY CONFIGURATION GPC WILL BE OBTAINED.

A hardware dump of a failed GPC (PASS or BFS) is taken because it does not require a good software load to obtain the dump. A software dump of a nonfailed, like-configuration GPC is done because a software dump can be done without affecting the ability of a GPC to continue its operation after the dump. The two dumps can then be compared to help find where the problem that caused the GPC failure occurred. Although during entry there will probably not be enough time to complete the dump analysis prior to landing, collecting the data at the time of the failure and prior to any GPC reconfiguration allows the greatest probability of being able to determine the cause of the GPC failure. Also, in the event of a day(s) waveoff, the dumps can be analyzed to determine possible impacts to the subsequent entry attempt. These impacts may include, but are not limited to, GPC reconfigurations and/or GPC memory read/writes. If the dumps are not performed and the problem cannot be recreated during postflight analysis, the failure would be treated as an unexplained anomaly. With TDRS coverage for entry, downlist interruption by a GPC dump is no longer a concern as it once was with STDN only coverage. (Ref. Rule {A2-203E}, DEORBIT DELAY GUIDELINES.) @[121593-1585A]

- C. INABILITY TO OBTAIN, PROCESS, OR COMPLETE GROUND ANALYSIS OF MEMORY DUMP DATA IS NOT CAUSE TO DELAY RECOVERY OF A FAILED GPC.

Recovery procedures should not be dependent upon the results of ground-based memory dump processing since ground-based processing can be delayed by numerous external factors.

@[121593-1585A]

A7-18 THROUGH A7-50 RULES ARE RESERVED

FLIGHT RULES

BFS SYSTEMS MANAGEMENT

A7-51

BFS DPS FAILURE

BFS DPS FAILURES ARE DECLARED BY THE FOLLOWING GUIDELINES:

- A. THE BFS WILL BE DECLARED FAILED IF NO FORWARD DEU INTERFACE EXISTS (POSSIBLY CONCURRENT WITH "SELF FAIL" COMPUTER ANNUNCIATION MATRIX (CAM) LIGHT). [ED] [040899-2459B]

If no forward DEU interface exists, the crew has no insight or interface with the BFS. The CAM light may blink for some BFS GPC hardware failures where the BFS is restarting on multiple major cycles. One point worth noting is that the CAM light will not illuminate for the total GPC power loss failure. Reference Rule {A7-52A}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES. [040899-2459B]

- B. THE BFS WILL BE "NO-GO FOR ENGAGEMENT" FOR THE FOLLOWING:

BFS is no-go if it cannot be relied upon to back up the PASS because it either (1) cannot be engaged or (2) the hardware/software of the BFS GPC cannot control the vehicle subsequent to engage.

1. BFS HAS OPERATED IN STANDALONE MODE (WILL NOT TRACK PASS) IN:
 - a. MM 102, 103, AND 601 FOR 10 SECONDS.
 - b. MM 304, 305, 602, AND 603 FOR 45 SECONDS.

The BFS is NO-GO when sensor data are lost due to not listening to any PASS-initiated input transactions because the BFS has lost the ability to accurately update the vehicle's state vector. GNC degradation rate is not exactly known; however, 10 seconds in ascent powered flight and 45 seconds in entry dynamic flight were estimated pre-ST5-1. Reference Rule {A7-52B}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES.

2. CONTROL CA1 BUS FAILED.

If CNTL CA1 is lost and BFS resides in GPC's 3 or 5, the BFS will not receive engage discretetes. (For BFS in GPC's 1, 2, or 4, failure of CNTL AB3 bus will cause the loss of engage discretetes.) It is important to note, if the engage is attempted, BFS will not recognize the engage and part of the PASS set will go to software halt. Reference Rule {A7-52C}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES.

3. LOSS OF ESS 3AB.

For loss of ESS 3AB power, the BFS select capability is lost and no GPC's can be selected as the BFS. If an engage is attempted, BFS will not recognize the engage, and all of the PASS set will go to software halt. Reference Rule {A7-52C}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-51

BFS DPS FAILURE (CONTINUED)

4. IF THE BFS I/O TERM B FAILS HIGH.

If the BFS I/O TERM B is failed high, then the BFS cannot be engaged since this input must be low for the BFS to recognize an engage. If an engage is attempted with the BFS I/O TERM B failed high, the BFS will not recognize the engage and PASS will go to software halt. Since the I/O TERM B is normally high for the BFS pre-engage, this failure will probably not be recognized unless the BFS internal receiver 2 of hybrid receiver 4 failed. The "half-hybrid" failure will cause the BFS I/O TERM A to go high since the I/O TERM B and I/O TERM A are paired together on internal receiver 2 of hybrid 4 (ref. paragraph C7 and Rule {A7-52D}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES).

5. BOTH BFS BFC CRT SEL DISCRETES AND THE BFS I/O TERM B DISCRETE FAIL LOW SIMULTANEOUSLY.

The simultaneous failure of both the BFS BFC CRT SEL discretets and the BFS I/O TERM B discrete is indicative of a 5 volt power supply failure in the BFS BFC module. The BFS BFC module will not respond to the engage with the 5-volt power supply failed, and the BFS will not engage. PASS will recognize the engage and go to software halt.

- C. THE BFS WILL BE DECLARED "SUSPECT" FOR THE FOLLOWING:

An operating BFS (GNC and SM) is considered suspect when its ability to respond to an engage or to control the vehicle subsequent to engage is in doubt due to a hardware/software failure.

1. BFS HAS EVER ENTERED THE HALT STATE WITHOUT FIRST EXECUTING AN OPS 000 PRO AND HAS SUBSEQUENTLY BEEN RETURNED TO STANDBY OR RUN.

The BFS performs a cleanup when an OPS 000 PRO is performed. Without proper cleanup, the BFS may not be initialized correctly when placing the mode switch back to standby (User Note B04524C). This same situation can occur after the BFS experiences a transient halt state and subsequently returns to standby or run.

2. BFS HAS BEEN RE-IPL'D DURING ASCENT PER RULE {A7-52E}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES. A BFS RE-IPL'D DURING ASCENT WILL NOT BE USED FOR GNC PURPOSES.
@[071494-1641]

A BFS which failed and was re-IPL'd during ascent should not be used for GNC purposes. Since the GPC has failed once, the hardware and software integrity of the BFS cannot be assured. Therefore, a BFS so 'recovered' should only be used for systems monitoring and should not be engaged except as a last resort in the event of loss of vehicle control.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-51

BFS DPS FAILURE (CONTINUED)

3. BFS HAS EXPERIENCED SOFT ERRORS AGAINST THE LOWER PAGE OF MEMORY AT A CONSTANT RATE OR EXPERIENCED AN INSTANTANEOUS SOFT ERROR COUNT OF 7F. @[041896 1872]

Random single-memory hits are expected to occur at a rate of several per day or in single bursts of several errors. A constant incrementing of the error count is indicative of a hard-memory failure. Errors in the upper page of memory are not reflective of errors in the lower page of memory. Currently, the upper page of memory is not used for BFS and; therefore, soft errors in this portion of memory will have no impact to the operating ability of the BFS. @[041196 1872]

4. UNEXPLAINED "GPC BITE" FAULT MESSAGE.

The BFS generates a GPC BITE fault message when it encounters a condition requiring a software restart for error recovery. This could also point to a software or hardware problem. The BFS may not function properly in the event that a BFS engage is required.

5. UNEXPLAINED "GPC PWR" FAULT MESSAGE.

A GPC PWR fault message is an indication that the BFS GPC has experienced a power transient. The BFS may not function properly in the event that a BFS engage is required. Rules {A7-53}, ON-ORBIT BFS MANAGEMENT GUIDELINES, and {A7-9}, REDUNDANT SET SPLIT, reference this rule.

6. IF THE BFS I/O TERM B FAILS LOW.

The I/O TERM B and the engage discrete inputs to the BFS are generated by logic contained within the BFC. The BFC depends on power to and the configuration of the GPC OUTPUT switches on panel 06. If the fuse leading to the output switches fails or if the BFC experiences an internal power failure, the I/O TERM B will go low at the BFS. While the lack of an I/O TERM B discrete input to the BFS will not prevent the BFS from recognizing an engage, it does cast doubt on the inputs to the BFC and/or its ability to properly process the engage discretely and I/O TERM B. If the problem is within the BFC module serving the BFS or the inputs to this module, then the PASS set will go to software halt upon engage and the BFS may not engage. Since the source of the problem cannot be determined, the BFS should be declared suspect.

7. IF THE BFS I/O TERM A FAILS HIGH.

The I/O TERM A and the I/O TERM B share a common internal receiver in GPC hybrid receiver 4. An I/O TERM A failure could be indicative of a single discrete failure on hybrid receiver 4 or could indicate the loss of both the I/O TERM A and I/O TERM B if the common internal receiver has failed. Since the pre-engage state of the BFS I/O TERM B is high, it is not possible to determine the health of the I/O TERM B discrete without moding the BFS OUTPUT switch to NORMAL. If the common receiver has failed high, then the BFS cannot be engaged since the I/O TERM B must be low for the BFS to recognize the engage. If an engage is attempted with the common receiver failed high, the BFS will not recognize the engage and PASS will go to software halt. The BFS should be declared suspect until the status of the I/O TERM B can be verified (ref. paragraph B,4).

FLIGHT RULES

A7-52

ASCENT/ENTRY BFS MANAGEMENT GUIDELINES

DURING ASCENT (POST-MECO) AND ENTRY (POST-TIG), THE FOLLOWING GUIDELINES WILL BE FOLLOWED:

- A. FOR LOSS OF FORWARD DEU INTERFACE, MODE THE BFS GPC TO "HALT" AND PLACE THE OUTPUT SWITCH IN "TERMINATE". ©[040899-2459B]

If no forward DEU interface exists after the crew performs BFS/DEU recovery procedures, they will have no interface with the BFS; hence, the BFS is unusable. As a cleanup item, the BFS GPC will be moded to HALT to cease software execution, and the output switch will be placed in the TERMINATE position to protect the PASS from going to software halt in the event of an inadvertent engage. The TERMINATE position will be used instead of NORMAL for consistency with BFS standalone actions (ref. paragraph B). ©[040899-2459B]

- B. FOR BFS STANDALONE MODE, MODE THE BFS GPC TO "STANDBY", AND PLACE THE BFS OUTPUT SWITCH IN "TERMINATE".

If the BFS continues in a standalone mode after the crew performs BFS recovery procedures, the BFS will be unable to perform SM antenna management. In addition, the ground will be unable to command via the payload buses. Moding the mode switch to STANDBY causes the BFS to relinquish the PL buses to the PASS. In the STANDBY position, the BFS can continue to perform FDA processing on orbiter OI subsystems. The output switch in the TERMINATE position will protect the PASS from going to software halt in the event of an inadvertent engage. The switch is placed in TERMINATE rather than NORMAL to keep the I/O TERM B discrete input high at the BFS, thus preventing a single-point BFS GPC failure (either full or half hybrid receiver 10 failing high) from causing the BFS to self-engage.

- C. FOR LOSS OF CONTROL CA1 (AB3) OR ESSENTIAL 3AB BUS, PLACE THE BFS OUTPUT SWITCH IN "TERMINATE".

The loss of control CA1 prevents the BFS from processing engage discretets for GPC's 3 and 5. If the BFS is in one of these GPC's, then it cannot be engaged and it is necessary to protect the PASS from going to software halt in the event of an inadvertent engage. This is accomplished by placing the BFS output switch in TERMINATE. The switch is placed in TERMINATE rather than NORMAL to keep the I/O TERM B discrete input high at the BFS, thus preventing a single-point BFS GPC failure (either full or half hybrid receiver 10 failing high) from causing the BFS to self-engage. The same rationale can be applied to the loss of control AB3 if the BFS is in GPC 1, 2, or 4.

The loss of essential 3AB prevents any GPC from properly processing the engage discretets as a BFS (ref. Rule {A7-51B}.3, BFS DPS FAILURE). This also places the BFS one failure away from self-engage by removing the I/O TERM B input to the BFS GPC. If the BFS is in GPC 1, 2, 4, or 5, the I/O TERM B can be reapplied by placing the BFS output switch in TERMINATE since this position is powered by a different bus. The I/O TERM B cannot be recovered if the BFS is in GPC 3 since the TERMINATE position is also powered by ESS3AB. However, placing the switch in TERMINATE for this case will maintain procedural consistency without placing the BFS or PASS in a worse configuration.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-52

ASCENT/ENTRY BFS MANAGEMENT GUIDELINES (CONTINUED)

- D. FOR BFS GPC I/O TERM B FAIL HIGH, PLACE THE BFS OUTPUT SWITCH IN "TERMINATE".

If the BFS/I/O TERM B is failed high, then the BFS cannot recognize an engage and it is necessary to protect the PASS from going to software halt in the event of an inadvertent engage. This is accomplished by placing the BFS output switch in TERMINATE. The switch is placed in TERMINATE rather than NORMAL for consistency with other BFS NO-GO actions.

- E. FOR BFS GPC FAIL DURING ASCENT, A BFS IPL MAY BE ATTEMPTED IN GPC 5 POST ET SEP.

BFS IPL during ascent is an MCC call to regain crew insight into critical systems.

BFS IPL will only be requested when there is adequate time to complete the procedure before the OMS-2 burn, and it would not interfere with other activities. A GPC 5 hardware dump will normally be performed before IPL'ing.

The BFS IPL is performed only on GPC 5 because we are unwilling to give up a good PASS GPC during ascent.

DPS will not recommend a BFS IPL in GPC 5 if GPC 5 has exhibited symptoms of erroneous output or degraded IOP functions.

Even if GPC 5 recovers via IPL, the BFS will be moved on orbit per Rule {A7-53}, ON-ORBIT BFS MANAGEMENT GUIDELINES.

- F. IF DECLARED "SUSPECT", THE BFS WILL BE CONSIDERED "NOT AVAILABLE" FOR ASCENT/ENTRY RESTRICTING PURPOSES (RULE {A2-63}, ASCENT STRING REASSIGNMENT, AND RULE {A2-254}, ENTRY STRING REASSIGNMENT) AND WILL ONLY BE ENGAGED AS A LAST RESORT.

The difference between a "NO-GO for engagement" call and a "suspect" call is that in "NO-GO for engagement" the BFS will not fly the vehicle. In the "suspect" case, the BFS may fly the vehicle but it cannot be guaranteed.

Rule {A7-51}, BFS DPS FAILURE, references this rule.

FLIGHT RULES

A7-53

ON-ORBIT BFS MANAGEMENT GUIDELINES

ON ORBIT (POST-OPS 2 THROUGH PRE-TIG), FOR ANY BFS INDICATION DETERMINED TO BE A FAULT CONDITION INCLUDING THOSE LISTED BELOW, THE BFS WILL BE RELOADED INTO A GPC THAT HAS NOT EXPERIENCED ANY FAILURES. @[101096-4516]

A reload of the BFS (into a PASS GPC) regains the BFS function and provides a backup means during entry to assume control of the vehicle in the event the PASS set can no longer maintain vehicle control. Reassignment of the BFS should be performed as soon as practical to protect for contingency deorbit.

The BFS GPC is the last means of recovery for loss of the PASS set and is therefore critical to vehicle safety if it is engaged. The BFS will always be maintained in a GPC without any previous failures.
@[101096-4516]

- A. BFS GPC HAS BEEN DECLARED FAILED.
- B. BFS HAS BEEN DECLARED NO-GO FOR ENGAGEMENT DUE TO LOSS OF CONTROL CA1 BUS.

For loss of control CA1 bus, the BFS engage capability can be regained by reloading the BFS into another GPC except GPC 3 (or 5).

- C. THE BFS HAS BEEN DECLARED SUSPECT.

BFS "suspect" is defined in Rule {A7-51}, BFS DPS FAILURE.

- D. BFS GPC HAS AN INSTRUMENTATION PCMMU (IP) BUS CONTROL ELEMENT (BCE) FAILURE (LOSS OF DOWNLIST), TIME PERMITTING.

An IP BCE failure results in a loss of downlist and results in loss of OI data to the crew. With this type of failure, the MCC has no insight into orbiter systems performance. In addition, insight on two-stage command feedback is not available. It is highly desirable to have insight into the BFS; hence, the BFS will be reloaded time permitting. @[101096-4516]

- E. BFS GPC HAS A PL1 OR PL2 BCE FAILURE, TIME PERMITTING.

A loss of a PL1 or PL2 BCE failure results in a loss of redundancy for antenna management. It is preferred to have redundancy for SM antenna management; hence, the BFS will be reloaded into another GPC.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-53

ON-ORBIT BFS MANAGEMENT GUIDELINES (CONTINUED)

F. BFS GPC HAS ONE OR MORE FC BCE RECEIVER FAILURES, TIME PERMITTING.

Loss of one flight-critical BCE receiver results in loss of data from the associated MDM/BTU's to the BFS. Upon a BFS engage, the BFS would start without a full flight-critical redundancy. It is desirable to have the BFS track all PASS strings upon an engage; consequently, the BFS will be reloaded into another GPC time permitting.

Rules {A2-301} (NOTE 71), CONTINGENCY ACTION SUMMARY; and {A7-52}, ASCENT/ENTRY BFS MANAGEMENT GUIDELINES, reference this rule.

A7-54 THROUGH A7-100 RULES ARE RESERVED

FLIGHT RULES

OTHER DPS SYSTEMS MSNAGEMENT

A7-101 POWER CYCLING/MANAGEMENT

A. FAILURES

GPC'S, MMU'S, DEU/DU'S, AND MDM'S WILL BE POWERED OFF IF THEY INCUR HARD FAILURES. MDM'S WILL BE CYCLED "OFF" THEN "ON" TO RESET OUTPUTS FOLLOWING A DATA PATH FAILURE. MDM'S MAY BE CYCLED "OFF" THEN "ON" FOR GPC FAILURES. @[040899-2459B]

LRU's experiencing hard failures may be powered off to save power if they are nonfunctional.

B. POWER MANAGEMENT

MMU'S, DEU/DU'S, AND MDM'S MAY BE POWERED OFF FOR POWER MANAGEMENT. GPC'S (101S) WILL NOT NORMALLY BE POWERED OFF FOR POWER MANAGEMENT. @[040899-2459B]

LRU's, except for the new GPC's (101S), may be powered off for power management. Mission extensions or unique flights may require minimization of power consumption. The 101S GPC's power consumption in the sleep mode is 56 watts, less than one tenth of its operating power consumption. Since removing power from the 101S GPC causes loss of memory integrity, a 101S GPC will only be powered off under extreme powerdown conditions. @[092701-4872]

A7-102 PASS DATA BUS ASSIGNMENT CRITERIA

PASS GPC DATA BUSES WILL BE ASSIGNED USING THE FOLLOWING GUIDELINES:

A. DISPLAY/KEYBOARD (DK) BUSES:

1. FOR RS OPERATION, THE CDR'S (PLT'S) DEU AND DDU WILL NOT BE ASSIGNED TO THE SAME GPC. DISTRIBUTION OF THE DEU'S AND DDU'S PREVENTS LOSS OF CDR'S (PLT'S) INSTRUMENTATION AND DEU DISPLAYED DATA FOR A SINGLE GPC FAILURE (N/A FOR MEDS VEHICLES). @[040899-2459B]

Three DEU's and two DDU's are available during RS operation. The DEU's are nominally assigned to different GPC's (ref. paragraph A.2). The DDU's are driven from a flight-critical bus as selected by the data bus switches on panels F6 and F8. By proper data bus selection, the CDR's (PLT's) DEU and flight instruments can be driven by different GPC's providing protection against total data loss for a single GPC failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-102

PASS DATA BUS ASSIGNMENT CRITERIA (CONTINUED)

2. FOR RS OPERATION IN A MEDS ENVIRONMENT, ALL OF THE CDR'S (PLT'S) DISPLAYS WILL NOT BE DRIVEN BY THE SAME GPC.

The DPS displays are driven via the DK buses that are nominally assigned to different GPC's. The flight instrument displays are driven from flight critical buses selected by the edge keys. By proper data bus selection, the CDR's (PLT's) DPS displays and flight instrument displays can be driven by different GPC's and IDP's providing protection against total data loss for a single GPC or IDP failure.

3. ALL DEU'S IN A PASS COMMON SET WILL NOT BE ASSIGNED VIA MAJOR FUNCTION SWITCH OR GPC/CRT KEY TO ANY ONE GPC.

If all DEU's were assigned to a single GPC, and this GPC failed, the crew would lose insight into healthy GPC's and would be unable to communicate with the GPC's. ©[040899-2459B]

- B. MMU BUSES WILL BE ASSIGNED TO DIFFERENT GPC'S FOR RS OPERATION.

The MMU buses will be distributed via NBAT assignment to different redundant set GPC's to provide different commanding GPC's on each MMU bus. This provides redundant GPC-to-MMU data paths.

- C. FLIGHT CRITICAL (FC) BUSES:

1. ALL STRINGS WILL BE USED BY THE RS REGARDLESS OF THE NUMBER OF GPC'S IN THE SET.

All strings will be used by the redundant set to maintain full flight-critical systems redundancy except for cases of non-universal I/O errors (ref. Rule {A7-104}, NONUNIVERSAL I/O ERROR ACTION).

2. ORBIT STRINGING ©[082593-1538]
 - a. NORMAL STRINGING FOR ORBIT OPERATIONS WHEN THERE ARE TWO GNC GPC'S WILL BE STRINGS 1 AND 3 ASSIGNED TO ONE GPC AND STRINGS 2 AND 4 ASSIGNED TO THE OTHER.

This stringing provides optimal redundancy; it will provide continuous uninterrupted vehicle control (assuming no other failures) even if one GNC GPC fails. This string combination will provide jet redundancy for translation and LO Z rotation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-102

PASS DATA BUS ASSIGNMENT CRITERIA (CONTINUED)

- b. NORMAL STRINGING FOR ORBIT OPERATIONS WHEN THERE ARE THREE GNC GPC'S WILL BE STRING 1 TO ONE GPC, STRING 2 TO ANOTHER GPC, AND STRINGS 3 AND 4 TO THE THIRD GPC.

For a rendezvous/prox ops with three GPC's, pairing strings 3 and 4 together provides the best jet authority protection against a GPC failure. If a GPC fails, there is no jet authority requirement that forces an immediate restrung. There is no other LRU failure that will force a restrung. This is true whether norm-Z or low-Z is being used. This stringing also keeps the three IMU's separated. ©[082593-1538]

3. FOR HARD OR TRANSIENT FLIGHT-CRITICAL (FC) BCE TRANSMITTER-ONLY FAILURES IN GPC'S, STRING REASSIGNMENT MAY BE UTILIZED TO REGAIN THE DATA PATH.

A GPC BCE transmitter-only failure results in a data path loss; reassigning the bypassed BTU's/LRU's to a GPC with a healthy transmitter will restore communications with the bypassed BTU's/LRU's. Because the GPC with the BCE transmitter-only failure will continue to operate in the redundant set and is capable of commanding a different string, it will be assigned a different string and full flight-critical systems redundancy is maintained.

4. DURING ASCENT, STRING REASSIGNMENT WILL BE PERFORMED PER RULE {A2-63}, ASCENT STRING REASSIGNMENT.

Reference Rule { A2-63}, ASCENT STRING REASSIGNMENT.

5. FOLLOWING GPC FAILURES, THE CRITERIA FOR ASCENT STRING ASSIGNMENTS IN ORDER OF PRIORITY ARE (ASSUMES NO LRU FAILURES):

To maintain a fail-safe operational configuration, a set of priorities was established for string assignments.

- a. STRINGS 1, 2, AND 3 WILL NOT BE ASSIGNED TO THE SAME GPC TO PROTECT IMU REDUNDANCY.

Self-explanatory.

- b. STRINGS 1 AND 3 WILL NOT BE ASSIGNED TO THE SAME GPC TO PROTECT NSP REDUNDANCY.

Assigning strings 1 and 3 together causes a potential for loss of command and communication with the crew if the commanding GPC failed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-102

PASS DATA BUS ASSIGNMENT CRITERIA (CONTINUED)

6. FOR A PASS SET OF FOUR GPC'S, A TRANSIENT GPC WILL BE ASSIGNED STRING 4 DURING ENTRY. ©[101096-4516]

A transient GPC may fail again during entry. Because string 4 has fewer LRU's, loss of string 4 is of less significance than loss of other strings. ©[101096-4516]

7. ENTRY STRINGING WILL BE ESTABLISHED PRE-TIG AND WILL NOT BE CHANGED POST-TIG UNLESS REQUIRED BY SUBSEQUENT FAILURES AS SPECIFIED IN RULE {A2-254}, ENTRY STRING REASSIGNMENT.

An NBAT assignment is agreed on prior to MM 302 to maximize flight-critical redundancy for entry control. A string assignment criteria has been established for a redundant set with less than four PASS GPC's. Reference paragraph C.8 for additional details.

8. FOR DEORBIT BURN AND ENTRY, IF LESS THAN FOUR PASS GPC'S ARE AVAILABLE, THE STRINGS WILL BE DISTRIBUTED TO MINIMIZE THE LOSS OF CRITICAL FUNCTIONS FOR A SUBSEQUENT GPC FAILURE. THE PRIORITIZED LIST OF FUNCTIONS TO BE PROTECTED BY SELECTING THE STRING ASSIGNMENTS IS SHOWN BELOW, STARTING WITH THE HIGHEST PRIORITY. STRING ASSIGNMENTS WILL BE BASED ON DISTRIBUTION CONSIDERATIONS FIRST (DISTRIBUTING STRINGS AS EVENLY AS POSSIBLE OR AVOIDING CERTAIN STRING COMBINATIONS). AFTER DISTRIBUTION CONCERNS ARE MET, FINAL STRING ASSIGNMENT SELECTION WILL BE BASED ON AVOIDING ASSIGNMENT TO ANY TRANSIENT GPC'S, IF POSSIBLE.
- a. ONE IMU (TRANSIENT GPC CONCERN ONLY)
 - b. TWO ASA'S
 - c. TWO RGA'S
 - d. TWO AA'S
 - e. TWO IMU'S
 - f. TWO YAW JETS
 - g. PITCH JETS (ONE FAULT TOLERANT)
 - h. RHC CONTACTS (ONE FAULT TOLERANT)

FLIGHT RULES

A7-102 PASS DATA BUS ASSIGNMENT CRITERIA (CONTINUED)

NOTE :

[1] CURRENT CHANNELIZATION FOR NWS IS THE SAME AS FOR VENT DOOR FUNCTION, I.E., PROTECTING ONE COVERS BOTH.

Rationale TBS.

9. IF THERE ARE MULTIPLE STRINGING COMBINATIONS WHICH SATISFY THE ABOVE CRITERIA, THE COMBINATION CLOSEST TO NOMINAL WILL BE SELECTED.

It is preferred to stay close to nominal because it reduces the risk of inducing errors when the crew responds to subsequent failures.

Rules {A7-3B}, GPC FAILURE; {A7-6B}, DATA PATH FAILURE; {A7-5A} and B, PASS GPC BCE FAILURE MANAGEMENT; and {A8-55}, ET SEPARATION RCS REQUIREMENTS, reference this rule.

A7-103 I/O RESET

I/O RESET KEY MAY BE USED ANYTIME IN PASS AND BFS TO ATTEMPT RESTORATION OF NOMINAL I/O, EXCEPT FOR CASES OF NONUNIVERSAL I/O ERROR. (REF. RULE {A7-104}, NONUNIVERSAL I/O ERROR ACTION.)

An I/O reset provides resetting of hardware electronics that reinitiates I/O and may clear transient I/O functions. Reinitiating I/O if a nonuniversal I/O error condition has occurred could cause a FTS or set split. Reference Rule {A7-104}, NONUNIVERSAL I/O ERROR ACTION (ref. FRCB meeting #49 held on January 23, 1991).

FLIGHT RULES

A7-104

NONUNIVERSAL I/O ERROR ACTION

RESTRINGING OR I/O RESETS WILL NOT BE PERFORMED FOR RECOVERY OF A BCE ELEMENT BYPASS NOR WILL AN OPS TRANSITION BE PERFORMED IF A NON-UNIVERSAL I/O ERROR CONDITION HAS OCCURRED ON ANY BUS UNLESS CRITICAL CAPABILITY RECOVERY IS BEING ATTEMPTED, OR UNTIL THE STRING ASSOCIATED WITH THE NON-UNIVERSAL CONDITION HAS BEEN SAFED. PORT MODING WILL NOT BE ATTEMPTED ON A STRING WITH A NON-UNIVERSAL I/O ERROR UNLESS THE BUS WITH THE ERROR HAS BEEN SAFED OR CRITICAL RECOVERY IS BEING ATTEMPTED. @[121296-4564A]

When an element bypass occurs, if the I/O error condition is not logged equally in the I/O error logs by each GPC in the RS, then a nonuniversal I/O error has occurred. This could be caused by a GPC problem, an unterminated data bus, or a loquacious BTU. If only a single GPC in an RS logs an error associated with this condition, then that GPC will fail-to-sync. If more than one GPC, but not all GPC's log an error, then the condition is more properly called a nonuniversally detected error condition (as defined by the software developers). Upmoding of a bypassed element under conditions of nonuniversal I/O error by the use of port moding, restringing or I/O resets, can result in an FTS or in a redundant set split. Therefore, these actions should be avoided (user note 101757) until the string associated with the nonuniversal I/O error has been safed, unless critical capability recovery is being attempted. @[121296-4564A]

Safing of a string associated with a non-universal I/O error condition is guaranteed by deassigning the string from the NBAT and performing an OPS mode recall or OPS transition. Also, a string may be safed by ensuring that all LRU's (except GPC's) capable of transmitting on the affected bus are powered off. If this can be done, then the nonuniversal I/O error condition becomes a universally detected error since there is no longer any LRU remaining that can respond to a request from the GPC for data. For the entry phase of flight, the only active LRU's on the flight critical buses are the FF and FA MDM's. The MEC's and EIU's are also connected to flight critical buses, but these LRU's are powered off during entry. If the MDM associated with the bus having the nonuniversal I/O error condition is powered off, the error is made universal, and the bus has been safed. During ascent, the MEC's and EIU's are powered on. Since the MEC's and EIU's cannot be powered off during OPS 1 or 6, the only viable method of safing flight critical buses five through eight is to deassign the affected string. Flight critical buses one through four (used by FF MDM's while on primary ports) only have the FF MDM's (or FA MDM if port moded to secondary ports) that can transmit on the bus. Therefore, for ascent, only buses one through four could be safed by powering off the associated MDM. @[121296-4564A]

If fault messages indicate that not all GPC's are annunciating the error, then a nonuniversal I/O error has occurred and the crew will be aware of the condition. If the fault messages indicate universal annunciation of the error, there still may be a nonuniversal error condition, but the crew will not be able to detect it since the I/O error logs are the only absolute indicator of the condition.

Given no evidence of nonuniversal I/O errors or no advice from flight controllers, the crew will follow normal procedures which use I/O reset, port moding, and in some cases, restring, as part of the recovery attempts for bypasses.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-104 NONUNIVERSAL I/O ERROR ACTION (CONTINUED)

Because the port moding operation only upmodes the string being port moded, a port mode can be done to recover a bypassed element under nonuniversal I/O error conditions if the nonuniversal error is associated with a different string than the one being port moded.

If recovery of critical capability is needed, then I/O reset, port mode and restringing may be attempted even if nonuniversal error conditions exist in an attempt to recover the bypassed element with the knowledge that a FTS or set split may occur.

For cases where a nonuniversal I/O error condition exists prior to execution of an OPS transition, the string with the nonuniversal I/O error condition should not be assigned in the NBAT for the OPS being entered unless the string has been safed. ©[121296-4564A]

Rules {A7-102C}.1, PASS DATA BUS ASSIGNMENT CRITERIA; {A7-103}, I/O RESET; and {A7-105}, MDM PORT MODING, reference this rule.

A7-105 MDM PORT MODING

MDM PORT MODING WILL BE PERFORMED ACCORDING TO THE FOLLOWING GUIDELINES:

- A. MM 102 - PORT MODING OF FLIGHT-CRITICAL OR PAYLOAD MDM'S WILL NOT BE ATTEMPTED UNLESS IT IS NECESSARY TO REGAIN CRITICAL SYSTEM CAPABILITY.

For port dependent MDM failures, port moding may be attempted to regain the required MDM redundancy by giving up port redundancy in the bypassed MDM. During MM 102, system reconfiguration is not routinely done due to the dynamic nature of this flight phase. For multiple failures that impact critical systems capability, port moding may be done.

- B. POST-MM 102 TO PRE-MECO - PORT MODING OF FLIGHT-CRITICAL AND PAYLOAD MDM'S MAY BE PERFORMED TO REGAIN CRITICAL SYSTEM CAPABILITY OR AFTER ANY SECOND FAILURE. NONCRITICAL RECOVERY WILL NOT BE ATTEMPTED FOR CASES OF NONUNIVERSAL I/O ERROR (REF. RULE {A7-104}, NONUNIVERSAL I/O ERROR ACTION).

For noncritical recovery, port moding is not performed until another failure has occurred. The other failure is any other failure and does not have to be avionics related, but a failure that sufficiently adds complexity to the overall vehicle system to warrant taking action.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-105

MDM PORT MODING (CONTINUED)

- C. POST-MECO, FOR FLIGHT-CRITICAL OR PAYLOAD MDM FAILURES, RECOVERY ATTEMPTS BY PORT MODING MAY BE PERFORMED IN ANY MAJOR MODE OF ANY VALID OPS VIA DISPLAY ITEM ENTRIES ON THE DPS UTILITY DISPLAY EXCEPT FOR CASES OF NONUNIVERSAL I/O ERROR (REF. RULE {A7-104}, NONUNIVERSAL I/O ERROR ACTION).

FC or PL MDM's communicate on one of two redundant ports that are selectable via software. If an MDM is bypassed due to a port failure, communication on the redundant port may be attempted via an item entry to the available user SPEC to attempt recovery of the MDM.

- D. WHEN A CHOICE EXISTS BETWEEN THE LOSS OF AN FF OR FA MDM AND NO OTHER CRITICAL SYSTEM FAILURES EXIST, FA1, 2, OR 3 WILL BE GIVEN UP IN FAVOR OF FF1, 2, OR 3. FF4 WILL BE GIVEN UP IN FAVOR OF FA4.

For certain multiple MDM failure scenarios (i.e., FFX primary port failure and FAX secondary port failure) only one FC MDM per string can be selected at any given time. Using the port mode capability, system optimization can be achieved with respect to protecting for the next failure. FF1, 2, and 3 are selected for IMU capability. FA4 is desired for insight into OMS system/FCS channel capability, since giving up FF4 costs a minimum of capability. FA3 is given up even though it provides insight into the left OMS. It is believed that losing an IMU is more probable and critical than the loss of insight into an OMS system.

Rule {A2-5}, PORT MODING/RESTRINGING GUIDELINES, references this rule.

FLIGHT RULES

A7-106

MMU OPERATIONS

MMU OPERATIONS WILL BE ACCOMPLISHED USING THE FOLLOWING GUIDELINES :

- A. SM CHECKPOINTS WILL BE MAINTAINED ON ALL OPERATIONAL TAPE-DRIVEN MASS MEMORY UNITS AND SOLID STATE MASS MEMORY (SSMM) UNITS. @[012402-5017]
- B. IF ONE SSMM HAS FAILED, OPERATIONS ON THE REMAINING SSMM WILL NOT BE RESTRICTED.

The Modular Memory Unit (MMU) houses both the SSMM and the Solid State Recorders (SSR). The SSMM is a replacement for the tape-driven Mass Memory Unit. The SSR is a replacement for the Payload Recorder and OPS Recorders. This rule is only applicable to the SSMM portion of the Modular Memory Unit.

SSMM units are initially loaded with exactly the same data, and, procedurally, this redundancy is maintained throughout a flight. Since SSMM's are not mechanical devices, failure susceptibility of the remaining SSMM does not significantly increase when that SSMM is utilized for nominal shuttle operations. Therefore, if one SSMM fails or is inaccessible, the remaining SSMM will still have a complete copy of all data. A single failed or inaccessible MMU should not impact the utilization of the remaining SSMM.

- C. IF ONE MMU HAS FAILED, OPERATIONS ON THE REMAINING MMU WILL PRECLUDE ROUTINE SM CHECKPOINTS. IN ADDITION, USE OF SM ROLL-IN DISPLAYS AND TFL/DFL OPTIONS WILL BE MINIMIZED (NOT APPLICABLE FOR VEHICLES WITH SSMM'S).

If one tape-driven MMU fails or is inaccessible, the remaining MMU will still have a complete copy of all data. However, tape-driven MMU's (because of their mechanical nature and tape wear) are more susceptible to a subsequent failure of the remaining unit. Therefore, use of the remaining tape-driven MMU will preclude routine SM checkpoints and all other MMU transactions will be strictly minimized to help protect against the subsequent loss of the remaining MMU. Reducing MMU access will help to minimize the possibility of a subsequent loss of the remaining MMU. @[012402-5017]

FLIGHT RULES

A7-107

TIME MANAGEMENT

ONBOARD TIME MANAGEMENT WILL BE ACCOMPLISHED USING THE FOLLOWING GUIDELINES:

- A. MTU/GPC GMT ERROR WILL BE MAINTAINED AT OR BELOW 100 MS WHEN SPEC 2 "TIME" IS AVAILABLE. A 15-MS UPDATE WILL BE PERFORMED ANYTIME THE ERROR EXCEEDS THAT THRESHOLD.

The MTU provides a stable frequency output that, over the course of a 7-day mission, should never be in error more than 100 milliseconds. However, due to an MTU failure, GMT may be in error. A greater variance in GMT may impact navigation, thus the GMT will be maintained within ± 100 milliseconds of true GMT. Since the onboard computers are processing in a redundant and/or common set, a software limitation of a maximum of 15 milliseconds per update precludes a GPC failure caused by a time change. A time update can only be performed using the SPEC 2 "time" display. SPEC 2 is not available in the BFS or during PASS GNC OPS 1/6/3.

- B. THE ONBOARD TIME MANAGEMENT SYSTEM (MTU/GPC) WILL NOT BE UPDATED IN-FLIGHT TO INCORPORATE ADJUSTMENTS TO THE WORLD WIDE TIME BASE REFLECTED BY WWV.

Because of variations in the Earth's orbit, leap seconds are incorporated into true GMT. Leap seconds are added or subtracted from GMT and are reflected in WWV GMT. Since the vehicle is not connected to WWV GMT, the crew would have to make multiple 15-millisecond updates to correct onboard time. (Note: It takes 1 to 2 minutes for one update.) Therefore, orbiter GMT will not be updated for leap seconds.

- C. FOR YEAR END ROLLOVER OF MTU GMT, THE MTU WILL BE REINITIALIZED WITH GPC GMT.

The onboard GPC's do not roll over (reset to GMT day 1) at year-end; the MTU does. For the GPC's to accept the MTU time, they must be taken to STBY and reinitialized. This results in a period of no vehicle control, no navigation updates, and no payload support. Since this is unacceptable, the MTU is forced to accept GPC time. When this is done, the orbiter no longer reflects true GMT as reflected by WWV.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-107

TIME MANAGEMENT (CONTINUED)

- D. A MANUAL MTU OSCILLATOR SWITCH WILL BE PERFORMED POST-MECO UP UNTIL HAC INTERCEPT FOR EITHER OF THE FOLLOWING CONDITIONS:
1. THE MTU BITE BIT 4 (OSCILLATOR 1/2 FREQ DIFFERENCE) IS SET AND THE MCC OBSERVES STEADILY INCREASING MTU DELTA TIMES.
 2. IF THE BFS LOSES TRACK WITHIN 1 MINUTE OF THE MTU BITE BIT 4 BEING SET AND BFS I/O RESETS ARE UNSUCCESSFUL IN RECOVERING THE BFS.

If the MTU BITE bit 4 is set, this indicates a frequency difference between the two oscillators; this bit does not tell which oscillator is malfunctioning and is, therefore, not used by the auto switch logic. Therefore, the MCC must use the MTU 1 and MTU 2 delta times (the difference between the onboard MTU referenced GMT and the ground GMT) and/or the state of the BFS to determine if a manual oscillator switch needs to be made.

The BFS will lose track if the HFE listen command is late by more than 180 microseconds for 24 consecutive minor cycles. Because of perturbations in the HFE listen cycle, the engineering community feels the BFS may not lose track immediately. However, best engineering judgment dictates that the BFS will lose track within 1 minute. Therefore, if the BFS loses track of the PASS when the MTU BITE bit 4 is set, it is a good indication that the selected oscillator is drifting and is the cause of the BITE indication.

In the event of launch with the BITE bit indicator already set (either because of a false BITE indication due to a BITE circuitry failure or because of a failed oscillator), consideration should be given to performing a manual oscillator switch after BFS loses track before declaring the BFS failed and performing a BFS IPL.

If a manual oscillator switch is made to the bad oscillator, the worst outcome would be that the PASS would fault down to internal time (which testing has verified causes no serious degradation of performance). If this happened, the PASS could not be switched back to MTU time until SPEC 2 is available.

In general, reach and visibility constraints do not allow the crew to reach the MTU oscillator select switch until post-MECO. There is a time shortly after SRB SEP, however, when the G-forces have decreased enough for the crew to reach the switch. Therefore, a manual MTU oscillator switch post-SRB SEP could be attempted and will be a real-time call. Ref. Ascent/Entry Flight Techniques Panel #69 (7/20/90) minutes, and the 5/15/90 and 6/21/90 SARS minutes.

FLIGHT RULES

A7-108

DEU EQUIVALENT CRITERIA

(REFERENCE RULE {A2-111}, DPS COMMAND CRITERIA.) @[072595-1775A]

- A. ALL DEU EQUIVALENT LOADS SHOULD BE COORDINATED WITH THE CREW. DEU EQUIVALENT LOADS DURING CREW SLEEP MUST BE COORDINATED WITH THE CREW PRIOR TO THE START OF THE SLEEP SHIFT UNLESS THE LOADS ARE REQUIRED TO AVOID POTENTIAL NUISANCE ALARMS.

In order for the crew to maintain situational awareness of all orbiter activities, they need to be informed of all planned DEU equivalents loads. As long as the crew has been informed of a general plan prior to going to sleep, it is acceptable to alter the specifics of the plan without notifying the crew of the changes. If the need arises for a DEU equivalent load after the crew has gone to sleep, it will not be uplinked unless it is required to prevent waking up the crew.

- B. OPS TRANSITIONS, MAJOR MODE TRANSITIONS, AND OPS MODE RECALLS WILL NOT BE PERFORMED VIA DEU EQUIVALENT LOADS. THE ONLY EXCEPTION TO THIS IS FOR THE G1 TO G9 OPS TRANSITION DURING PAD ABORTS/HOLDS TO PROVIDE A BACKUP TO THE CREW OR KSC LDB COMMANDING. @[042502-5317B]

Although OPS transitions, major mode transitions, and OPS mode recalls can be performed via a DEU equivalent load, a program level decision was made to avoid such commands based on the high level of risk associated with them. Due to the complexity of performing these types of software operations, there exists the possibility of annunciating fault messages or, worse case, not successfully completing the transition. For pad aborts/holds, the LPS safing/recovery procedure allows the MCC to control the transition from G1 to G9 in the event KSC and the crew are both unable to perform the transition. Allowing MCC to perform this transition in the event of an LPS loss will potentially minimize vehicle turn-around time and risks from unexpected command outputs and/or system failures. @[072795-1775A] @[042502-5317B]

- C. DEU EQUIVALENT LOADS WILL NOT BE CHAINED. @[072595-1775A]

DEU equivalent loads will not be chained because the successful execution of one load cannot be verified before subsequent commands are executed. Although not necessarily recommended, it is acceptable to link multiple item entries on a specific page together via separator keys as long as a separate command is required to invoke the loaded data (i.e., arm and fire).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-108

DEU EQUIVALENT CRITERIA (CONTINUED)

- D. IF A SPEC OTHER THAN THE OPS DISPLAY IS REQUIRED FOR DEU EQUIVALENT LOADS, IT WILL NOT BE CALLED UP UNTIL REQUIRED. THE SPEC WILL THEN BE RESUMED AS SOON AS PRACTICAL.

In order to avoid the possibility of accidentally trapping a SPEC due to certain GPC and CRT failures, it is best to always RESUME SPEC's when not in use. The crew is trained to place the CRT's in a specific configuration prior to sleep, and they expect them to be in this same configuration when they wake up. Therefore, leaving the OPS display up on all CRT's will coincide with what the crew expects.

- E. DUE TO GROUND LIMITATIONS, THE FOLLOWING KEYSTROKES CANNOT BE USED IN ANY DEU EQUIVALENT LOAD.

1. FAULT SUMM
2. SYS SUMM
3. GPC/CRT
4. MSG RESET
5. CLEAR
6. ACK @[072795-1775A]

Although the onboard software allows the above keystrokes, the ground command processing software prohibits DEU equivalent loads from containing them. Since the FAULT SUMM and SYS SUMM displays do not contain any ITEM entries, the MCC does not benefit from uplinking these keystrokes. The other four keystrokes can interfere with the crew's CRT configuration or fault message recognition. Therefore, it was decided prior to STS-1 to prohibit the ground from uplinking these specific keystrokes. @[072795-1775A]

FLIGHT RULES

A7-109

IN-FLIGHT MAINTENANCE (IFM)

IN-FLIGHT REPLACEMENT OF LRU'S WILL BE PERFORMED FOR THE FOLLOWING EQUIPMENT FAILURE DEFINITIONS:

In-flight replacement (IFM) will be done to regain LRU redundancy and/or lost capabilities.

- A. IF A KEYBOARD FAILURE CAN BE ISOLATED TO A SPECIFIC KEY, THE KEY WILL BE REPLACED WITH THE AFT KEYBOARD "ACK" KEY; OTHERWISE, A FAILED FORWARD KEYBOARD WILL BE REPLACED BY THE AFT KEYBOARD.

Keyboard failures can occur on specific keys or the entire keyboard. IFM on such failures associated with the forward keyboard will be to replace it with the aft keyboard, since it is not used during entry.

- B. ANY FORWARD CRT MAY BE REPLACED BY CRT 4 IF THE SCREEN BLANKS OR IS UNREADABLE AND THE GROUND VERIFIES THE CRT IS THE FAILED ELEMENT VIA DISPLAY UNIT BITE (N/A FOR MEDS VEHICLES).
@[021397-4763] @[040899-2459B]

CRT 4 has been selected as a replacement CRT for any forward CRT because it is not used during entry.

- C. ANY FAILED MDU MAY BE REPLACED BY ANOTHER MDU. AT LEAST ONE CDR MDU AND ONE PLT MDU MUST BE MAINTAINED FOR ENTRY. AN MDU IS CONSIDERED FAILED IF IT HAS A BLANK DISPLAY, AN INOPERATIVE 1553 DATA PORT, OR AN INTERNAL PROBLEM THAT PREVENTS THE MDU FROM BEING USEFUL AS A DISPLAY DEVICE. @[111501-4949]

- a. *Failed forward MDU* @[031500-7172D]

An IFM to replace any failed forward MDU with an aft MDU will regain full redundancy for entry. When replacing a forward MDU with an aft MDU, AFD1 MDU is the preferred MDU since CRT4 MDU is used during entry.

- b. *Failed AFT MDU*

If it is desired to replace a failed aft MDU with a forward MDU, MFD2 MDU is the preferred MDU. MFD2 MDU is preferred based on the following: CRT MDU's should be left in place, CDR2 and PLT1 MDU's are used for the primary flight instrument displays, and removing CDR1 or PLT2 MDU's would make their respective side of the cockpit vulnerable to single-point electrical bus failures. Because of the large number of MDU's (11) and the simple and low risk MDU IFM (45 minutes), an IFM to replace a failed aft MDU with a forward MDU could aid the crew in critical aft station operations (RNDZ, dock/undock) without losing any capability in the forward cockpit. In addition, the MDU can be reinstalled in the forward cockpit after the critical aft operations are complete. @[031500-7172D]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A7-109****IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)**c. *MDU failures* @[111501-4949]

There are multiple failures that may cause an MDU to be declared failed. The most obvious is a blank or unusable display. Loss of one of the two 1553 data ports by itself is not a problem for non-CRT MDU's since switching to the alternate port provides full functionality. CRT MDU's have only one 1553 data bus connected. Therefore, loss of that data port to a CRT MDU renders it useless. Combinations of failures may cause a non-CRT MDU with a single failed port to be declared failed such as the case of a failed IDP on the other port. Other internal failures may still prevent the MDU from being a useful display device. A failed edge key could preclude the ability to navigate to the desired display. @[111501-4949]

D. DEU 1, 2, 3 MAY BE REPLACED WITH DEU 4 IF THE DEU FAILS TO FUNCTION FOLLOWING AN IPL AND THE GROUND VERIFIES THE DEU IS THE FAILED ELEMENT VIA DEU BITE (N/A FOR MEDS VEHICLES).
@[040899-2459B]

DEU's 1, 2, 3 will be replaced with DEU 4 because DEU 4 is not used during entry.

E. IDP 1, 2, 3 MAY BE REPLACED WITH IDP 4 IF THE IDP FAILS TO FUNCTION.

IDP's 1, 2, 3 will be replaced with IDP 4 because sacrificing IDP4 to regain IDP1, 2, or 3 regains full capability for the forward flight stations. If an IDP only loses interface to the flight critical buses, an IFM is not required due to IDP redundancy. @[040899-2459B]

F. A PL MDM WILL BE SWAPPED WITH THE OTHER PL MDM ONLY AFTER POWER CYCLING AND PORT MODING FAILS TO CLEAR A NON-GPC CAUSED "I/O ERROR PL" AND THERE HAS BEEN A FAILURE OF ANY PLBD MCA (EXCEPT MCA 2) CONTROLLED BY THE GOOD MDM. @[040899-2459B]

Payload MDM will be swapped to allow payload bay door closure. MCA 2 is an exception because swapping PL MDM will not recover all the necessary functions, and pin kit IFM procedures would still be required to close and latch the doors. For this case, Rule {A2-105C}.16, IN-FLIGHT MAINTENANCE (IFM), will be implemented.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-109

IN-FLIGHT MAINTENANCE (IFM) (CONTINUED)

G. AN FF MDM 1, 2, OR 3 MAY BE REPLACED BY FF4 ONLY AFTER POWER CYCLING AND PORT MODING FAILS TO CLEAR A NON-GPC CAUSED "I/O ERROR FFX" OR TOTAL OUTPUT CARD FAILURE AND IT RESULTS IN THE LOSS OF:

1. A SECOND IMU
2. A SECOND AA (AA4 MUST BE FAILED)

Where previous LRU failures would cause a loss of at least fail-safe redundancy in an entry-critical system, it is considered viable to replace FF1, 2, or 3 with FF4. This operation would be accomplished to recover an IMU for redundancy in onboard navigation for entry. The same is true for an AA to regain redundancy for entry control.

H. AN MMU CONTINGENCY POWERUP MAY BE PERFORMED TO RECOVER AN MMU THAT IS DOWN DUE TO POWER LOSS. @[101096-4516]

The IFM may be performed at a convenient time when it will not interfere with higher priority mission operations or crew activities. If the remaining MMU fails, this IFM will be performed ASAP. A successful IFM will return power to the MMU that in turn can be used for GNC/SM transitions, and GPC/DEU reload capabilities.

DPS EOM REQUIREMENTS/DEFINITIONS

A7-201

DPS REDUNDANCY REQUIREMENTS

THE MINIMUM DPS REDUNDANCY REQUIREMENTS TO CONTINUE TO EOM ARE:

This rule provides a guideline for continuing nominal mission activities with less than a fullup complement of DPS resources, equipment, and capabilities. The objective is to maintain sufficient resources such that one additional failure can be sustained without jeopardizing vehicle safety, while protecting against a generic failure in both the primary and redundant systems (either hardware or software).

A. NO MORE THAN ONE GPC HAS BEEN DECLARED UNRECOVERABLE. @[101096-4516]

If one GPC fails, the DPS system is still fail-operational. With one GPC failed, there is no reason to believe the failure is more than an isolated incident; there is no increased risk to the orbiter or crew safety associated with staying to the nominal end of mission. @[092195-1798] @[101096-4516]

A second GPC failure may indicate a generic problem with an increase in risk to orbiter and crew safety. For this reason, a second GPC failure is reason for not going to nominal end of mission even though the orbiter would still be fail-operational for entry. @[092195-1798] @[101096-4516]

B. DATA PATHS NECESSARY TO SUPPORT REQUIRED LRU AND DISPLAY REDUNDANCY.

Each discipline has LRU and display redundancy requirements for continuing nominal mission activities; consequently, this was written to provide data bus capability if they require it to maintain critical systems redundancy.

C. TWO INDEPENDENT SOURCES OF DEORBIT PASS SOFTWARE ARE REQUIRED AND ARE DEFINED AS ONE OF THE FOLLOWING:

1. TWO MASS MEMORY UNITS (MMU'S)
2. ONE GNC MAJOR FUNCTION GNC 3 ARCHIVE GPC (FREEZE DRIED GNC-3 GPC) AND ONE MMU

The PASS deorbit software (GNC OPS 3) is available from the following sources: MMU 1, MMU 2, a previously G3 archived GPC, or a freeze-dried GNC 3 GPC on orbit. The allowable combinations of sources always include one MMU.

Rules {A2-120B}, RNDZ/PROX OPS DPS SYSTEMS MANAGEMENT; and {A7-13E}.1.d, GPC MAJOR FUNCTION CONFIGURATION, reference this rule.

THIS RULE CONTINUED ON NEXT PAGE

- [7] IF TWO FORWARD CRT'S, PERFORM IFM ASAP.
- [8] IF TWO FORWARD IDP'S, PERFORM IFM ASAP. @[04082459A]
- [9] LOSS OF EITHER FUNCTION, DPS OR FLIGHT INSTRUMENT, IN ANY 3 SEPARATE IDP'S IS PLS. @[031500-7172D]

The DPS GO/NO-GO CRITERIA matrix reflects the MDF/PLS criteria (ref. Rules {A2-102B}.2, MISSION DURATION REQUIREMENTS, and {A2-1001}, ORBITER SYSTEMS GO/NO-GO).

MDF - Multiple failures in an avionics system, even though it remains single-fault tolerant, may be indicative of a generic failure; consequently, an MDF is invoked for loss of two GPC's, loss of two DEU/CRT's, or for MEDS flights, two IDP's. @[040899-2459B]

Although a nominal end of mission can be accomplished with no accessible mass memory units (MMU's), the loss of two MMU's would result in the inability to recover subsequent GPC and/or DEU failures, loss of TFL's and DFL's, and loss of system management (SM) roll-in displays. Loss of SM roll-in displays contributes to a loss of additional insight into systems status in the event of a significant failure. Therefore, because of the loss of the above capability, an MDF is invoked for failure of two MMU's.

Loss of flight-critical and payload MDM's is an exception to the single-fault tolerant rule because loss of a single MDM reduces redundancy in multiple systems increasing the risk that a single LRU failure in any one of several systems could put the orbiter at a zero-fault tolerant level.

A risk assessment presented at the AEFTP #131 concluded that the combination of LRU's lost with FF4 does not warrant early mission termination. There is no systems requirement for an MDF after the loss of FF4. In addition, mission length for the loss of FF1, 2, 3 and FA MDM's should correspond to the IMU and FCS mission length, respectively. Mission length for the first IMU and FCS failure was changed to NEOM. The probability of losing a second PL MDM, thereby requiring an IFM to close the PLBD's and latch gangs, is extremely low. Therefore, NEOM is acceptable after the loss of one PL MDM. @[121296-4595C]

PLS - A next PLS deorbit will be executed at the earliest practical time for failures which place the orbiter system at the zero-fault tolerant level or results in a condition where one more failure causes a severe orbiter configuration management condition.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A7-1001

DPS GO/NO-GO MATRIX (CONTINUED)

Loss of three GPC's may be indicative of a generic problem. If another GPC failure occurred, this would result in entry on a single PASS GPC. Therefore, a next PLS is invoked.

If two CRT's are lost in the forward station, for non-MEDS vehicles, a next PLS will be invoked because it will place the orbiter in a fail-critical situation for entry. The aft CRT may be used as a replacement CRT for the forward station. ©[121296-4595C] ©[040899-2459B]

One remaining keyboard (following an IFM) will place the orbiter in a zero-fault tolerant situation.

If two IDP's are lost in the forward station, a next PLS will be invoked because it will place the orbiter in a fail critical situation for entry. The aft IDP may be used as a replacement IDP for the forward station.

If two forward MDU's are failed, they can be replaced with the two aft MDU's. If additional MDU's fail, display flexibility allows the other MDU's to support DPS displays, Flight Instrument displays, and Subsystem Status displays. The loss of eight MDU's places the orbiter in a zero-fault tolerant entry configuration: one MDU for PASS software control, one for BFS insight, and one for ADI/AMI/AVVI/HSI capability. ©[040899-2459B] ©[031500-7172D]

FLIGHT RULES

SECTION 8 - GUIDANCE, NAVIGATION, AND CONTROL (GN&C)

GENERAL

A8-1 FCS DOWNMODE

- A. FOR CONTROL PROBLEMS, FCS DOWNMODE (CSS AND BFS ENGAGE) IS AN ONBOARD DECISION AND MAY RESULT FOR ANY OF THE FOLLOWING:
1. IMPENDING LOSS OF CONTROL (LOC).
 2. NO VEHICLE RESPONSE TO EXPECTED MANEUVERS.
 3. ANY UNEXPLAINED ATTITUDE/RATE EXCURSIONS OR UNDAMPED OSCILLATORY MOTIONS. WITH THIS IN MIND, THE FOLLOWING GUIDELINES ARE PROVIDED:
 - a. ASCENT - FIRST STAGE: ANY UNEXPLAINED VEHICLE RATE OR UNDAMPED OSCILLATION GREATER THAN 3 DEG/SEC.
 - b. ASCENT - SECOND STAGE: ATTITUDE ERRORS (3 DEGREES IN PITCH OR YAW; OR 10 DEGREES IN ROLL) WITHOUT CONVERGING RATES OR RATES GREATER THAN 3 DEG/SEC WITHOUT CORRESPONDING ATTITUDE ERRORS.
- B. CREW DOWNMODING PROCEDURE FOR LOSS OF CONTROL IN FIRST STAGE THROUGH LOAD RELIEF (90 SECONDS MET) SHOULD BE TO ENGAGE THE BFS. POST LOAD RELIEF AND THROUGHOUT SECOND STAGE, THE DOWNMODING SEQUENCE SHOULD BE, CONDITIONS PERMITTING, TO FLY CSS CONTROL FOLLOWED, IF NECESSARY, BY BFS ENGAGE.

FCS downmoding (CSS and BFS engagement) is an onboard decision. The crew is ultimately responsible for the safety of the vehicle and onboard personnel. The types of situations requiring downmode action include impending loss of control, lack of vehicle response to expected maneuvers or trajectory changes, or any unexplained vehicle attitude/rate excursions or undamped oscillations.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1

FCS DOWNMODE (CONTINUED)

Guideline limits are given which reflect our flight experience and simulation data base or, in the case of second stage, bound vehicle behavior such that an acceptable MECO target is achieved. The following sources were used to develop these criteria:

- a. R&E ascent flight control system certification tests show vehicle rates no greater than 2 to 3 deg/sec.*
- b. Flight Design and Dynamics Division range safety simulation cases of flight control disturbances (stuck SRB actuators, etc.) show, for survivable cases, that vehicle rates and oscillations typically did not exceed 3 deg/sec. In addition, these oscillations had periods on the order of 6 to 10 seconds and were fairly well damped.*
- c. Rockwell simulations cases (refer to RI Internal Letter FSD&P/IGN&C87, November 25, 1987) with an attitude error bias in the digital autopilot concluded that proper MECO targets could be met and good flight control maintained when a 3-degree attitude error in any axis was applied and when a 10-degree attitude error in roll was applied. These runs included RTLS, TAL, and ATO abort scenarios.*

As a result, downmoding action is warranted when vehicle response is outside this flight envelope.

For violation of any of the criteria in paragraph A, the downmoding action is dependent upon the phase of flight. During first stage, loss of control may occur rapidly due to the control authority of the SRB's. In addition, the crew cannot adequately control the vehicle in CSS during load relief. Moding to the BFS in this timeframe changes the entire flight software which may recover control of the vehicle. (Note, auto flight control is the only mode available during powered flight in the BFS.) Post load relief, dynamic pressure is diminished (and in second stage control authority is decreased) which allows the crew to attempt CSS control for unusual vehicle behavior and then engage the BFS if necessary. Typically, CSS provides greater rate command authority than auto. In any phase of flight, however, conditions may be such (e.g., rapid LOC) to preclude the use of CSS prior to BFS engage. Note, for vehicle rate excursions or oscillations, CSS without RHC inputs will command attitude hold (zero rate command with attitude error command coming from integrated RGA data) and eliminate guidance, auto steering (and effectively IMU data) from the command loop. Vehicle displays, however, will reflect guidance parameters.

FLIGHT RULES

A8-2

SSME THRUST VECTOR CONTROL (TVC) HARDOVER

AN SSME WITH A CONFIRMED, UNCOMMANDED HARDOVER TVC ACTUATOR WILL BE MANUALLY SHUT DOWN IN ACCORDANCE WITH THE FOLLOWING TABLE:

ACTUATOR, DIRECTION	FAILURE OCCURS:	
	FIRST STAGE	SECOND STAGE
LEFT -YAW, RIGHT +YAW * CENTER + PITCH * CENTER ±YAW LEFT & RIGHT ±PITCH	PRIOR TO 1:40	N/A
LEFT +YAW, RIGHT -YAW	PRIOR TO 1:40	SINGLE ENG PRESS
CENTER -PITCH	PRIOR TO 7:00	PRIOR TO 7:00

* BELL COLLISION CONCERN

“Confirmed” hardovers imply that multiple independent sources of information indicate that an actuator is stuck hardover. These sources include OI position indications for all actuators, multiple FCS channel bypasses (same actuator), and vehicle control problems. Only the MCC can confirm that an actuator is hardover, and the MCC will inform the crew immediately upon recognition of the failure.

Failure of the lower engines hardover inboard in yaw (left -Y, right +Y) result in immediate bell collision in first or second stage. The MCC will attempt to recommend shutdown of the affected engine prior to MET 1:40 after which SRB thrust tailoff would further increase the amount of bell collision. In second stage, the MCC will not offer a recommended action (listed as N/A) because of the expected immediate bell collision.

Failure of the center engine hardover in positive pitch (toward lower engines) in first stage results in bell collision during SRB tailoff. Engine shutdown prior to MET 1:40 will prevent collision. In second stage, the case is listed as N/A because of the expected immediate bell collision.

Hardovers of the center engine ±yaw and lower engines ±pitch are controllable in first stage until SRB thrust tailoff. Shutdown of the affected engine prior to MET 1:40 will prevent LOC. These same failures in second stage cause vehicle control to be lost immediately. These cases are listed as N/A because of the expected immediate LOC.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-2

SSME THRUST VECTOR CONTROL (TVC) HARDOVER (CONTINUED)

Failures of the lower engines outboard in yaw (left +Y, right -Y) during first stage result in vehicle sideslip (beta) angles of more than 25 degrees as SRB thrust tails off. This is well above the limits established to protect external tank (ET) heating constraints. Maximum ET heating occurs in the MET 100- to 120-second timeframe. The hardover engine should be shut down no later than MET 1:40 to allow control transients (specifically beta) to damp so as to not violate ET heating constraints. The same hardovers during second stage result in control transients (expected to be recoverable) at the time of the hardover. Depending on the time of the second stage failure, less than desirable MECO conditions can result if the affected engine is allowed to run until MECO. This occurs because control perturbations caused by failures later in second stage may not have sufficient time to damp out. Thus, the recommended action is to shut down the affected engine at single engine press to MECO.

Failure of the center engine hardover in negative pitch (bell up away from the lower engines) is controllable until late in ascent. As the vehicle center of gravity changes, the good actuators gimbal to maintain a trimmed vehicle. By approximately MET 7:00, the good actuators reach their software command limits and loss of control follows.

The actions presented in this rule summarize the results of SMS runs and an ascent thrust vector control hardover failure study using the Space Shuttle Functional Simulator. The study was performed using the STS-26 mission design. The recommended shutdown actions apply to all flights. (Ref. Lockheed Correspondence No. 46-88, 04/11/88, and Ascent Flight Techniques Panel Meeting #44, 05/17/88.)

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

A8-3

LOSS OF GNC SYSTEM

REGARDLESS OF GNC SYSTEMS PROBLEMS DURING ASCENT, THE MOST DESIRABLE ACTION IS TO CONTINUE TO ORBIT. FOR CONFIRMED, PERMANENT LOSS OF ALL FAULT TOLERANCE IN ANY ENTRY-CRITICAL GNC SYSTEM, A FIRST DAY PLS RETURN WILL BE INVOKED.

Failures in an entry-critical GNC system will not cause aborts (RTLS, TAL, ATO, AOA) during the ascent phase. However, for the confirmed loss of all fault tolerance in an entry-critical system during ascent, a first day PLS should be performed to reduce the time available for any subsequent system failures which may affect deorbit/entry. Continuing the mission with no system redundancy constitutes unreasonable risk and deorbit should be performed.

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A8-4

FAULT TOLERANCE PHILOSOPHY

- A. EARLY MISSION TERMINATION WILL BE SCHEDULED AT THE NEXT PLS OPPORTUNITY IF ANY ENTRY-CRITICAL GNC SYSTEM HAS LOST ALL FAULT TOLERANCE.

Continuing the mission with no fault tolerance in a critical system would result in unreasonable risk. By performing a next PLS deorbit, we reduce the exposure to a subsequent failure which would preclude a safe deorbit/entry (ref. Rule {A8-1001}, GNC GO/NO-GO CRITERIA).

Several GNC systems have zero-fault tolerance during entry with two LRU's remaining. The system can still support entry if one of these LRU's fails on orbit. For these systems, remaining on orbit is acceptable, since the next on-orbit failure does not preclude a safe entry. Reference EFTP #45, 06/17/88.

- B. THE FLIGHT WILL CONTINUE TO NOMINAL END OF MISSION FOR THE FIRST FAILURE WHICH IMPACTS AN ENTRY-CRITICAL SYSTEM. IF THE SYSTEM IS NO LONGER SINGLE-FAULT TOLERANT (FAIL-SAFE), A REVIEW OF THE FAILURE MODE AND REMAINING SYSTEMS CAPABILITY WILL BE CONDUCTED TO DETERMINE WHETHER NEOM IS APPROPRIATE.
@[121296-4610]

REFERENCE RULES {A8-1001}, GNC GO/NO-GO CRITERIA, AND {A2-102}, MISSION DURATION REQUIREMENTS.

In general, it is an acceptable configuration to continue to nominal EOM after a single failure in an avionics system which leaves that system with single-fault tolerance. The systems which fall into this category are the four-LRU systems (i.e., AA's, RGA's, and FCS channel position feedbacks). The risk of staying on orbit until nominal EOM is acceptable after one failure because these systems, after the second failure regardless of the cause for the failure (i.e., LRU, MDM, or GPC), are only vulnerable to the next LRU failure (third failure overall) while in MM 304 to 305. Prior to entry, a failure in the AA's, RGA's, or position feedbacks can be deselected via SPEC 53, ENTRY CONTROLS display.

The Flight Control System (FCS) command channels and the IMU system are single-fault tolerant (fail-safe) after the first failure, with the exception of certain "smart failures" during specific windows of deorbit and entry. Neither the IMU system nor the FCS command channels can sustain greater than two failures and still be able to fly entry. However, a risk assessment completed by the AEFTP in 1996 (Ref. AEFTP #131 and 6/96 AEFTP Splinter Meeting) concluded that the relative risk of remaining on-orbit to NEOM rather than returning at the minimum duration flight (MDF) point after the first failure (in the FCS or IMU system) is an order of magnitude less than the launch risks and orbital debris risks. For an IMU or FCS command channel failure, the risk will be re-assessed in real time based on the latest run-time and failure history. @[121296-4610]

In addition (per Rule {A2-102}, MISSION DURATION REQUIREMENTS), for multiple failures in an entry-critical system which results in loss of two-fault tolerance but still retains single-fault tolerance, an MDF will be declared. The MDF is performed due to the loss of confidence in the integrity of the system (ref. Rule {A2-102}, MISSION DURATION REQUIREMENTS).

FLIGHT RULES

A8-5 ACCELEROMETER ASSEMBLIES (AA) FAULT TOLERANCE

IF FAIL-SAFE REDUNDANCY (THREE OF FOUR) DOES NOT EXIST IN NORMAL AA'S, THEN THE PITCH AXIS AUTO MODE WILL NOT BE USED IN MM 305, MM 602 (Nz HOLD PHASE), OR MM 603. MCC CALL MAY BE REQUIRED.

Fail-safe redundancy of normal accelerometers is required to engage the pitch axis auto mode in MM 305, MM 602, and MM 603. MCC call may be required since RM terminates after first failure.

The flight control auto pitch channel receives normal acceleration commands from guidance in MM 305, MM 602, and MM 603. If two normal accelerometers have failed, then the AA selection filter will be midvalue selecting bad Nz data if a third normal axis accelerometer fails. If the first two accelerometer failures are due to commfaults, the selection filter will average the remaining two.

The pitch channel uses Nz feedback to close the auto flight control loop and, if bad data concerning vehicle response is fed back, loss of control can occur. CSS removes Nz feedback from the flight control loop.

During the Nz hold phase of MM 602, the ADI pitch error needle displays Nz error, and the ACCEL tape on the AMI displays Nz in g's. If a third normal axis accelerometer failure occurs, it may be difficult to maintain the target Nz (approximately 2.1 g's) while flying manually, since these displays will be driven with bad feedback. The crewmember may have only the G-meter and the energy profile on the ENTRY TRAJ display as cues for maintaining target Nz. Although it may be difficult to maintain the precise Nz in the event of a third failure, pitch CSS is required after two failures to prevent a loss of control. Testing in the SMS has shown that if the pitch axis AUTO mode is used and the third failure occurs, a loss of control can result during MM602 Nz hold.

Rule {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, references this rule.

A8-6 CONTROLLERS/FCS SWITCHING FAULT TOLERANCE

EXCEPT FOR RHC'S, REQUIRED FAILURE TOLERANCE FOR ALL CONTROLLERS OR FCS SWITCHING FUNCTIONS CAN BE SATISFIED FROM EITHER SIDE OR BOTH SIDES OF THE COCKPIT. RECONFIGURATION IN GNC 8 IS ALLOWED TO MEET CONTROLLER AND SWITCH REDUNDANCY REQUIREMENTS.

Existence of station processing and system redundancy ensures availability of functions from either side of the cockpit. However, because of their use during entry (especially the CDR's RHC), RHC's require a higher priority for system reconfiguration which can be done in OPS 2 or 8.

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A8-7

ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION

- A. A FAILURE IN ANY ENTRY-CRITICAL SYSTEM THAT WILL PRECLUDE SINGLE-FAULT TOLERANCE DURING ENTRY WILL BE VERIFIED PRIOR TO DEORBIT BURN. IF THE FAILURE IS RECOVERABLE (TRANSIENT), ENTRY WILL BE DELAYED ONE ORBIT, IF AVAILABLE, TO ALLOW RECONFIGURATION.

A one-orbit deorbit delay will be called to allow system failure compensation/reconfiguration to be performed since most can be handled in one orbit. Delaying an entire extra day unnecessarily increases the exposure to further system failures.

- B. THE DEORBIT BURN WILL BE DELAYED UP TO 1 DAY TO ALLOW RECONFIGURATION TO RECOVER THE FUNCTION OF EITHER RHC.

Due to the RHC requirements during entry, a 1-day delay will be performed if multiple failures cause the loss of function of one RHC. The 1-day delay will allow the implementation of an RHC/DDU IFM (ref. Rule {A2-105C.7}, IN-FLIGHT MAINTENANCE (IFM)) in order to recover the RHC capability. The 1-day delay is needed due to the amount of time required to perform the RHC or DDU IFM. Both hardware changes take at least 3 hours to perform.

Rules {A2-301}, CONTINGENCY ACTION SUMMARY; and {A8-8}, ENTRY SYSTEMS RM DILEMMA, reference this rule.

A8-8

ENTRY SYSTEMS RM DILEMMA

FOR FAILURES RESULTING IN LOSS OF AN ENTRY-CRITICAL FUNCTION DUE TO RM DILEMMA, ENTRY WILL BE DELAYED TO ALLOW THE SINGLE REMAINING SYSTEM TO BE PRIME SELECTED.

If an entry-critical function has been lost due to an RM dilemma, delaying entry allows the crew to perform any recovery procedures necessary to recover the function by prime-selecting the single remaining system. The systems which could announce a dilemma prior to deorbit burn are the hand controllers and IMU's. However, of the hand controllers, only the RHC would cause a deorbit delay to recover the function of the RHC (ref. Rule {A8-7B} ENTRY SYSTEMS SINGLE-FAULT TOLERANCE VERIFICATION). For most of the systems, prime selection can be done in OPS 2 or 3.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

FLIGHT RULES

A8-9 **AFT STATION GNC REDUNDANCY**

LOSS OF AFT STATION GNC SYSTEMS SHALL NOT BE A CAUSE FOR EARLY FLIGHT TERMINATION. NO IFM WILL BE DONE TO REPLACE AN AFT GNC SYSTEM WITH A FORWARD SYSTEM.

Aft station systems are not required for safe entry. There are no on-orbit activities that would require risking the loss of an entry-critical forward system.

Rule {A8-1001E}, GNC GO/NO-GO CRITERIA, references this rule.

A8-10 **POWER/DATA PATH REDUNDANCY**

LOSS OF POWER REDUNDANCY OR DATA PATH REDUNDANCY TO A GNC LRU IS NOT CONSIDERED LOSS OF THE LRU REDUNDANCY.

Loss of power or data path redundancy to an LRU does not indicate a generic systems failure. A single external failure should not imply impending LRU-related failures. The LRU should be considered operational as long as power and a communications path exist to the LRU.

A8-11 **LOSS OF BFS**

LOSS OF BFS BECAUSE OF LOSS OF GNC SYSTEMS WILL NOT BE CAUSE TO TERMINATE THE FLIGHT EARLY.

The role of the BFS GNC software is a protection against generic errors in the prime GNC software. The level of BFS GNC fault-tolerance is not considered a requirement for on-orbit stay time. Given the present early termination rules for GNC systems loss, only the loss of the BFS engage switches would invoke this rule. If the BFS GNC is lost by BFS hardware or software problems, then the generic protection is already lost and no extra risk is involved in staying on orbit until nominal end-of-flight.

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A8-12**HEAD UP DISPLAY (HUD) AND CREW OPTICAL ALIGNMENT
SIGHT (COAS) ALIGNMENT**

A CALIBRATED HUD/-Z COAS IS AN ADEQUATE BACKUP TO THE STAR TRACKERS FOR ENTRY IMU ALIGNMENT. @[111094-1723A]

A 3-sigma COAS IMU alignment and a HAINS IMU drifting at 1 sigma in all axes result in a total platform misalignment of 0.25 degrees at EI which meets the navigation requirement of no more than 0.5 degrees (ref. Rule {A4-151}, IMU ALIGNMENT). The KT-70 IMU represents the worse case, since the HAINS IMU 1 sigma drift rate is significantly low. The 0.25 degree misalignment is based on SODB data (SODB para. 4.5.1.2.3.e.3.d) for a COAS calibrated immediately following a star tracker IMU alignment and an entry alignment that is done 2.5 hours prior to the deorbit burn with a time of approximately 30 minutes from burn to EI. Based on flight calibration data, it is assumed that a HUD IMU alignment will be as good as, if not better than, a COAS IMU alignment. As backups to the star trackers for IMU alignments, the CDR HUD is the primary station and the PLT HUD/-Z COAS is the secondary station. The +X COAS performance during flights has not been adequate to support an entry IMU alignment and should not be used as a backup to the star trackers (ref. On-Orbit FTP meeting #133, October 9, 1992, HUD/COAS CALIBRATION, and On-Orbit FTP meeting #148, September 9, 1994, HUD/COAS CALIBRATION STATUS). @[111094-1723A]

Rule {A8-108}, HUD/COAS SYSTEM MANAGEMENT , references this rule.

FLIGHT RULES

A8-13

RTLS ET SEPARATION

FOR RTLS ET SEPARATION, CREW ACTION SHALL BE AS FOLLOWS:

- A. DURING MATED COAST, COMMAND A FAST SEPARATION IF ALPHA ? -4 ± 2 DEGREES AND DIVERGING OR BETA ? 0 ± 2 DEGREES AND DIVERGING.

During RTLS mated coast, MM 601, G/C steer is commanding attitude hold in all axes in either CSS (while the RHC is in detent) or auto flight control mode. Due to the time limitations of performing RTLS ET separation, a fast separation should be commanded anytime the vehicle attitude is diverging from the RTLS ET separation structural release constraints. All of the RTLS ET separation design staging conditions are documented in JSC-07700, volume X, figure 3.2.1.1.10.4.

- B. DURING -Z TRANSLATION, SELECT CSS IF ALPHA DECREASING OR ANY RATE ? 2 DEG/SEC WITH DIVERGING ATTITUDE ERRORS. THE CREW SHOULD DELAY 1 SECOND AFTER SEPARATION PRIOR TO DOWNMODING TO ENSURE ADEQUATE ORBITER/ET CLEARANCE.

During -Z translation, decreasing alpha may cause recontact with the ET. Rates greater than 2 deg/sec with a diverging attitude indicate a control problem in the auto mode which may lead to loss of control during recovery phase and entry. When performing an auto separation, the DAP will inhibit automatic rotational control for 1 second. CSS rotational commands are allowed anytime but should be avoided until adequate orbiter/ET clearance exists. One second was established as the optimum time to prevent propagation of initial disturbances resulting in loss of control but yet allow sufficient clearance from the ET (ref. Rockwell ET SEP Panel meeting, 12/2/82).

FLIGHT RULES

A8-14 **POWER MANAGEMENT**

- A. SYSTEMS REQUIRED FOR GNC 6 OR GNC 3 WILL BE ON FOR ASCENT AND LEFT ON UNTIL THE END OF AOA OPPORTUNITY.

Should an AOA be necessary, the crew will be busy preparing for the maneuver and should not be burdened with a requirement to power up equipment in this time-critical phase.

The MLS is the only GNC system not powered for the launch. However, the MLS will be powered for the abort (entry) per the FDF checklist.

- B. DURING ENTRY DAY, THE OPS 3 CRITICAL LRU'S (RGA'S, AA'S, AND ASA'S) WILL BE POWERED PRIOR TO MCC GO/NO-GO FOR OPS 3 TRANSITION. MCC TELEMETRY VERIFICATION IS HIGHLY DESIRABLE.

Additional time could be required for adequate MCC telemetry verification since it will not be obvious to the crew that all LRU's have been powered. The RGA's are powered prior to the OPS-3 transition in order to provide vehicle rate feedback to flight control (TRANS DAP). The ASA's are powered prior to the OPS-3 transition to preclude possible damage to the rudder/speed brake power drive unit (PDU) at APU start. The AA's are powered prior to the OPS-3 transition because of the proximity of these switches to the other LRU switches.

A8-15 **GNC PARAMETERS/LRU FAILURES**

GNC PARAMETERS/LRU'S THAT PERMANENTLY FAIL RM LIMITS OR GNC 8 SELF-TEST WILL BE INHIBITED FROM FURTHER USE.

Once an LRU has been identified as faulty by self-test or RM, it is no longer considered reliable.

A8-16 **GNC SYSTEMS FAILURES**

GNC SYSTEMS DECLARED FAILED BY RM WILL BE CONSIDERED FAILED UNLESS SUBSEQUENT VERIFICATION INDICATES THAT THE SYSTEM IS RECOVERABLE. WHEN TIME PERMITS, RECOVERY WILL BE ATTEMPTED FOR ANY GNC SYSTEMS TRANSIENT FAILURE.

FOR SOME SYSTEMS, THE CREW HAS VERY LITTLE VISIBILITY INTO THE REASON FOR RM DECLARED FAILURES. IN MOST CASES, THE FAILURES ARE CAUSED BY SYSTEM DEGRADATION WHICH CAN BE COMPENSATED BY THE MCC, THEREBY RECOVERING THE FUNCTION OF THAT LRU.

FLIGHT RULES

A8-17

EQUIPMENT REQUIRED FOR EMERGENCY AUTOLAND

THE FOLLOWING EQUIPMENT IS REQUIRED TO ALLOW USE OF AUTOLAND CAPABILITY TO TOUCHDOWN IN EMERGENCY SITUATIONS:

- A. ONE - NORMAL AA.
- B. ONE - MSBLS.
- C. ONE - ADTA.

Situations that may require emergency autoland include crew incapacitation, window contamination, or any contingency landing below weather minimums.

Normal axis accelerometer data is required for the Aerojet DAP auto mode in MM 305.

MLS is the only navigation LRU with sufficient accuracy to guide the orbiter to a precision runway landing in the auto mode. Autoland cannot be flown on default air data. The availability of these systems should not be considered as part of GO/NO-GO for deorbit.

Rule {A8-1001}, GNC GO/NO-GO CRITERIA, references this rule.

A8-18

LANDING SYSTEMS REQUIREMENTS

- A. FOR THE GIVEN CONDITIONS AND LANDING SITES, THE FOLLOWING ARE THE NUMBER OF ONBOARD MSBLS REQUIRED:

	LAKEBED	CONCRETE RUNWAY
DAYLIGHT LANDING:		
CEILINGS > 10K FEET	0	0
CEILINGS < 10K FEET	1	2
NIGHT LANDING:		
CEILINGS > 15K FEET	1	2
CEILINGS < 15K FEET	2	2

For lower ceilings (8,000 to 10,000 feet) or night operations, redundant MSBLS (single-fault tolerance) is required for landing on a concrete runway. This is due to the fact that longitudinal and lateral concrete runway environments are limited and less forgiving of navigation errors when adequate visual cues are not available (i.e., lower ceilings or night landings). MSBLS provides accurate azimuth, elevation, and range information that allow a precise approach to the runway.

MSBLS is also mandatory for daylight landings on the lakebed with reduced ceilings but is not required to be redundant due to the increased margin for error on the lakebed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-18

LANDING SYSTEMS REQUIREMENTS (CONTINUED)

For a night landing and the loss of redundant MSBLS, a lakebed runway is required. In addition, ceilings must be greater than 15,000 feet for a night landing to a lakebed runway without redundant MSBLS to allow early acquisition of PAPI lights and aimpoint should a single point failure causing loss of MSBLS occur. This increased ceiling requirement allows more time for glide slope and runway centerline corrections. The 15,000 feet altitude is based on extensive analysis conducted in the Shuttle Mission Simulator (SMS) and Shuttle Training Aircraft (STA) by Flight Design and Dynamics personnel and crew representatives (ref. Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]). ©[111094-1622B]

MSBLS redundancy is maintained with two onboard MSBLS remaining (one MSBLS failed) assuming the MCC is available to solve dilemmas. A dilemma occurs for an erroneous output failure of one of the remaining two units. The only information used to solve the dilemma (outside of MCC assistance) is built-in test equipment (BITE), which is limited in its ability to detect failures. The MCC requires ground radar along with telemetry data to isolate the bad MSBLS in the event of a dilemma.

Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC], references this rule. ©[111094-1622B]

- B. A DAYLIGHT LANDING WILL BE REQUIRED, IF AVAILABLE, FOR LOSS OF ANY OF THE FOLLOWING:
1. THREE MSBLS.
 2. TWO FORWARD ADI'S (N/A FOR MEDS VEHICLES). ©[040899-2459B]

MSBLS is required at night to maintain an accurate approach path to a lower altitude before transitioning to visual cues (PAPI's, ball bar, and runway markings). For the loss of all three onboard MSBLS, enter to a daylight landing, if available.

One ADI is required to commit to a night landing in order to fly bank angle around the HAC in the event of guidance problems.

A requirement for the HSI was considered for night landings due to the need for accurate heading and course information; however, such a requirement was not levied since MSBLS and the HUD were required and should supply sufficient information during the approach phase.

- C. FOR LOSS OF THE LEFT HUD, A DAYLIGHT LANDING IS HIGHLY DESIRABLE.

The left HUD is highly desirable for night landings in order to reduce approach and landing workload, monitor touchdown critical parameters, and offset the loss of outside visual references. Therefore, the left HUD is desired to commit to a night landing, situation permitting (e.g., weather, etc.). Reference Memorandum CB-89-265, and Rule {A2-105}, IN-FLIGHT MAINTENANCE (IFM). ©[072398-6646]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-18

LANDING SYSTEMS REQUIREMENTS (CONTINUED)

D. RA ALTITUDE DATA IS HIGHLY DESIRABLE FOR NIGHT LANDINGS.
@[072398-6646]

Due to the lack of visual depth perception during night landings, the RA's and ball bar become the primary source for altitude and altitude rate information from approximately 50 feet until main gear touchdown. If RA data is not available, the ball bar is considered sufficient under normal circumstances to allow the pilot to achieve acceptable touchdown conditions. In the event of an RA failure(s), consideration should be given to landing site conditions (e.g., winds, turbulence, ceiling, lighting conditions, visibility, landing ground speed, vehicle mass properties, touchdown point, runway lighting, mission duration, etc.) as they relate to pilot workload and usefulness of the ball bar. Of particular concern are conditions, which if combined with no RA data, will increase the probability of exceeding landing gear/tire limits. Consideration should be given to selecting the landing site that offers the more benign landing conditions. This consideration should focus on which of the sites' landing conditions would result in minimum pilot workload and/or impact to the usefulness of the ball bar. @[072398-6646]

Rules {A8-58}, ADI LOSS; and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A8-19

YAW JET DOWNMODE

- A. IF NO YAW JETS ARE AVAILABLE ON EITHER LEFT OR RIGHT SIDE, THE NO-YAW-JET DAP MODE WILL BE SELECTED IF ABOVE MACH = 1.

The no-yaw-jet mode for emergencies is a certified flight control mode from Q -bar = 20 psf through landing. This mode should be selected between Q -bar = 20 psf and Mach 1 (yaw jets inhibited) if no-yaw-jets are available on a side. In the low Q -bar regime (Q -bar < 20), vehicle response will be sluggish and pilot workload increased, but control will be better than with the baseline DAP. Once selected, it is not necessary to deselect the no-yaw-jet mode. Flight Rule {A6-305}, AFT RCS REDLINES, defines when to engage no-yaw-jet based on aft RCS quantity. Reference DA8-88-20 (FT), Entry Flight Techniques Meeting #41.

- B. IN OPS 3, IF THE AEROJET DAP BASELINE MODE IS SELECTED AND ADDITIONAL LATERAL CONTROL MARGIN IS REQUIRED, THE WRAPAROUND DAP MODE WILL BE ENABLED IF ABOVE MACH 1. @[021998-6485B]

The aerojet DAP wraparound mode is normally enabled for EOM, AOA/ATO, and contingency payload return entry but is not enabled for TAL abort entries, due to lack of certification for TAL aborts. The wraparound DAP is not available in OPS 6. If lateral control margin is reduced due to three yaw jets failed on one side or aileron trim saturation, a loss of control may occur. In addition, if LVAR 9 aerodynamic uncertainties are experienced (a low-probability potential below Mach 6), excessive jet firings and high RCS propellant usage may result. Enabling wraparound mode eliminates these problems by providing increased aileron authority. Reference DA8-88-20 (FT), Entry Flight Techniques Meeting #41, and Ascent/Entry Flight Techniques Panel meeting #141 minutes. @[021998-6485B]

Rules {A6-206}, RCS MANIFOLD/LEG LEAK REPRESSURIZATION, and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule. @[ED]

FLIGHT RULES

A8-20**ENTRY ELEVON SCHEDULE SELECTION CRITERIA**

THE AUTO ELEVON SCHEDULE WILL NOMINALLY BE SELECTED INDEPENDENT OF X-AXIS CENTER-OF-GRAVITY (X CG) LOCATION WITH THE FOLLOWING EXCEPTIONS:

- A. THE FIXED ELEVON SCHEDULE WILL BE SELECTED AS REQUIRED ON A FLIGHT-SPECIFIC BASIS IN ORDER TO SUPPORT AERODYNAMIC PTI'S. IF AERO PTI'S ARE SCHEDULED AND IT IS SUBSEQUENTLY DECIDED NOT TO EXECUTE THEM, THEN THE AUTO SCHEDULE WILL BE SELECTED.
- B. IF THE NO-YAW-JET MODE OF THE AEROJET DAP IS REQUIRED DURING ENTRY, THE FIXED SCHEDULE WILL BE SELECTED IF IT IS I-LOADED WITH THE AFT SCHEDULE. IF EITHER THE FORWARD OR MID SCHEDULE IS LOADED, THE AUTO SCHEDULE WILL BE SELECTED.

The smart body flap logic incorporated with OI-20 software eliminates the need for selecting elevon schedules based on the X CG for entry. The smart body flap is enabled anytime the auto schedule is selected and will maintain the elevons on a schedule that is similar to the previous mid-CG schedule but will allow the elevons to move off-schedule, within limits, in order to thermally protect the body flap and main engines.

The fixed elevon schedule maintains the body flap logic used prior to OI-20 and allows one of the three previously used schedules (fwd, mid or aft) to be loaded into this slot. It is planned to use this schedule to support aero PTI's as required on a flight-specific basis.

Low RCS propellant quantity or loss of yaw jets may require that the no-yaw-jet mode of the Aerojet DAP be selected during entry. Selecting a schedule with more positive elevon deflection (down) increases the control authority of the elevons by moving them into the airstream. For flights in which aero PTI's are not planned, the aft schedule will be loaded into the fixed slot and this schedule will be selected if the no-yaw-jet mode is required even though this may thermally impact the main engine nozzles (turnaround issue). The auto elevon schedule is certified for use with the no-yaw-jet mode; however, the aft schedule provides better control authority (ref. A/E FTP #76, held 3/15/91). The fwd schedule is not certified for use with the no-yaw-jet mode. The RCS critical entry cue card contains the procedural callout for selecting the correct schedule to be used with the no-yaw-jet mode.

A8-21 THROUGH A8-50 RULES ARE RESERVED

FLIGHT RULES

FAILURE DEFINITIONS

A8-51 PHILOSOPHY

A GNC PARAMETER WILL BE CONSIDERED FAILED WHEN IT DIFFERS WITH COMMON REDUNDANT OUTPUTS BY A VALUE GREATER THAN THE I-LOADED RM TRACKING TEST LIMITS. IF AN LRU DOES NOT PROVIDE REDUNDANT OUTPUTS (IMU, TACAN, MSBLS, ETC.), PARAMETER LOSS WILL CONSTITUTE LRU LOSS. FOR THOSE LRU'S WITH REDUNDANT OUTPUTS, (RHC, RPTA, SBTC, SWITCHES, ETC.), THE LRU WILL NOT BE CONSIDERED FAILED UNTIL MULTIPLE FAILURES HAVE CAUSED THE SELECTION FILTER TO OUTPUT BAD DATA. REDUNDANT LRU'S MAY BE REGAINED BY RECONFIGURING RM TO "PRIME SELECT" A SINGLE OUTPUT PARAMETER. SUBSEQUENT FAILURE OF THE PRIME SELECT PARAMETER WILL CONSTITUTE LOSS OF THE LRU.

An LRU with redundant outputs may still be usable as long as the SF outputs good data. Deselection of failed parameters, allowing the SF to prime select the good parameter, regains use of that LRU. When this final good parameter fails, the LRU is, therefore, unusable.

A8-52 SENSOR FAILURES

SENSOR FAILURES DETECTED BY COMPARISON WITH GROUND RADAR DATA:

- A. IMU - AFTER ONBOARD RM HAS DECLARED A DILEMMA, THE FAULT IS ISOLATED TO THE LRU WITH THE MOST NON-ZERO SLOPE ON THE RADAR/IMU VELOCITY PLOTS.
- B. TACAN:
 1. AFTER ONBOARD RM HAS DECLARED A DILEMMA, THE FAULT IS ISOLATED TO THE LRU WHOSE RANGE OR BEARING EXHIBITS THE LARGEST DELTA FROM GROUND RADAR.
 2. IF THE GROUND RADAR/TACAN COMPARISON INDICATES A SIMILAR ERROR ON ALL LRU'S GREATER THAN 0.3 NM (RANGE) OR 1.0 DEGREE (BEARING), THEN THE ALTERNATE TACAN GROUND STATION WILL BE SELECTED (IF AVAILABLE).
 3. AT THE TACAN 2-LRU LEVEL, IF THE AVERAGE GROUND RADAR/TACAN DELTA IS GREATER THAN 0.3 NM (RANGE) OR 1.0 DEGREE (BEARING), THEN THE LRU WITH THE LARGER ERROR WILL BE DESELECTED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-52

SENSOR FAILURES (CONTINUED)

- C. ADTA - AFTER ONBOARD RM HAS DECLARED A DILEMMA, THE FAULT IS ISOLATED TO THE LRU WHOSE ALTITUDE IS FURTHEST FROM THE RADAR-COMPUTED ALTITUDE ON THE RADAR/ADTA PLOTS.
- D. MLS - AFTER ONBOARD RM HAS DECLARED A DILEMMA, THE FAULT IS ISOLATED TO THE LRU WHOSE RANGE/AZIMUTH/ELEVATION EXHIBITS THE LARGEST DELTA WITH RESPECT TO RADAR-COMPUTED VALUES ON THE MCC MLS PLOTS.

This rule applies to ascent/entry only.

A dilemma occurs at the two-level when a disagreement greater than the RM threshold occurs. Onboard RM may not be able to correctly isolate a dilemma. The ground can determine more readily and accurately which unit has failed by comparing the orbiter parameters to the ground radar. The crew has no insight into radar data.

- a. *For the IMU, the onboard state vector (PASS and BFS) may be compared to ground vector to resolve the dilemma. Onboard velocity data is a function of platform alignment as well as accelerometer accuracy. When accelerations are large (i.e., during powered flight or entry), the onboard velocity data is compared with radar data to determine which unit is providing the most accurate data, thus breaking the dilemma. During orbit operations, accelerometer output is read directly to reveal the IMU with incorrect velocity output.*
- b. *A TACAN dilemma will occur for a range disagreement of 3000 feet or for a bearing disagreement of 6 degrees. Analysis shows that selected TACAN errors greater than 0.3 nm in range or 1.0 degree in bearing can result in violation of position delta state limits. Rule {A4-206}, NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF), references this rule. (Ref. Rule {A4-204}, DELTA STATE POSITION UPDATES, and Ascent/Entry Flight Techniques #80.)*
- c. *At the four-level, a side-to-side dilemma can occur if there is a data miscompare between the two sides.*
- d. *For the MLS, the data good flag will be reset for a disagreement of 0.329 nm in range, 0.5 degree azimuth, or 0.4 degree elevation. In this case, navigation will default to IMU data. For an azimuth or range dilemma, MLS data should not be processed. For an elevation dilemma, do not process elevation data, but process azimuth or range data if good. Processing of bad MLS data can be inhibited by powering off the appropriate LRU, by changing the channel thumbwheel selection, or by forcing TACAN data.*

Rule {A4-206A}, NAVIGATION FILTER MANAGEMENT AUTO/INHIBIT/FORCE (AIF), references this rule.

FLIGHT RULES

A8-53

OMS TVC LOSS

- A. AN OMS ENGINE IS CONSIDERED FAILED IF TVC CAPABILITY (BOTH PRIMARY AND SECONDARY) IS LOST IN EITHER AXIS AND THE ENGINE DOES NOT MEET THE REQUIREMENT AS SPECIFIED IN PARAGRAPH D.

TVC capability is required in both axes of the OMS gimbal for proper vehicle control. It is possible to burn an engine with TVC power off if the position mistrim with respect to the vehicle CG is acceptable. RCS usage will increase in proportion to the magnitude of the mistrim. The maximum amount of mistrim acceptable (determined by RCS constraints) is documented in paragraph D.

- B. THE PRIMARY OR SECONDARY OMS TVC IS CONSIDERED FAILED IF THE GIMBAL DRIVE CHECK INDICATES A DRIVE RATE OF LESS THAN 2.9 DEG/SEC BETWEEN A GIMBAL POSITION OF ± 3 DEGREES.

The limit of 2.9 deg/sec is sufficient to provide adequate vehicle control, but this rate is well below average rate of all actuators in the field. The spec (Aerojet Rocket Company ALRC 42483-J) is 2.9 deg/sec and thus the lower limit for drive rate was established in accordance with the spec.

- C. ENGINE BELL MOVEMENT DURING ASCENT:

1. AN OMS ENGINE WILL NOT BE FIRED IF IT HAS BEEN CONFIRMED, BY BOTH THE PRIMARY AND SECONDARY POSITION TRANSDUCERS, THAT THE ENGINE BELL MOVED INBOARD OR UP MORE THAN 1.5 DEGREES IN EITHER AXIS FROM THE PRELAUNCH NORMAL ENGINE STOW POSITION (ENGINE BELL DOWN AND OUTBOARD) DURING THE TIME BETWEEN LIFTOFF +40 TO 70 SECONDS.

During the time between liftoff plus 40 to 70 seconds, the vehicle experiences maximum dynamic pressure. Movement of the OMS engine into the airstream during this region of ascent could expose the engine to windstream pressures great enough to cause damage to the nozzle/throat. Both the primary and secondary position transducers must confirm that the engine moved 1.5 degrees in either axis into the airstream. If such movement occurs, the nozzle may be deformed and/or the throat may be cracked. Firing an engine in this condition is potentially catastrophic. The constraints in this rule apply to both the thin- and thick-walled engine bells. (Ref. SODB, volume III, paragraph 4.3.3.6, CA8-82-05 (FT), EH12-81-99, and EH12-82-030.)

2. FOR SUSPECTED MOVEMENT (ONE OF TWO TRANSDUCERS) INBOARD OR UP MORE THAN 1.5 DEGREES IN EITHER AXIS, THE ENGINE WILL ONLY BE FIRED DURING ABORT DUMPS IN ACCORDANCE WITH RULE {A6-101}, OMS ENGINE BELL MOVEMENT DURING ASCENT.

Suspected movement is movement indicated by only one transducer. PROP Rule {A6-101}, OMS ENGINE BELL MOVEMENT DURING ASCENT, explains the risks incurred by not firing an engine during ascent abort dumps.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-53

OMS TVC LOSS (CONTINUED)

- D. AN OMS ENGINE MAY BE USED FOR OMS BURNS WITH TVC POWER OFF IF THE NO-BACK DEVICE HELD POSITION, ± 0.2 DEGREES, FOR THE ASCENT PHASE OF FLIGHT AND ALL SUBSEQUENT OMS BURNS WITH THE TVC POWER OFF. THE PROPELLANT COST (ADDITIONAL POUNDS OF RCS PROPELLANT PER SECOND OF COMPUTED BURN TIME) FOR BURNING ENGINES WITH THE TVC POWER OFF (FIXED TVC) IS AS FOLLOWS:
1. FOR A TWO-ENGINE OMS BURN, ONE ENGINE FIXED TVC, A PROPELLANT COST OF 0.9 LB/SEC (100 PERCENT ARCS) WILL PROTECT FOR AN ENGINE TRIMMED THROUGH THE CG WITHIN 1.0 DEGREE IN PITCH AND WITHIN 0.5 DEGREES IN YAW.
 2. FOR A SINGLE ENGINE OMS BURN WITH FIXED TVC, THE PROPELLANT COST WILL BE (72 PERCENT ARCS, 28 PERCENT FRCS):
 - a. 1.5 LB/SEC, FOR TOTAL MISTRIM ($|P| + |Y|$) \leq 2.0 DEGREES
 - b. 0.75 LB/SEC PER DEGREE MISTRIM, FOR TOTAL MISTRIM $>$ 2.0 DEGREES

SODB paragraph 4.3.3.4.6.1.2e specifies that the minimum operating life of a no-back device is unknown. It further specifies, however, that if the no-back device holds ± 0.2 degrees for the boost phase of flight, it will hold an engine in position for subsequent OMS burns for the remainder of that mission and is acceptable for a subsequent mission.

The propellant cost figures for fixed TVC burns are taken from studies in which data from Trans DAP OMS TVC burns was gathered/generated and analyzed from the following sources: SSFS (1983), SAIL (1984, 1985), and Draper SLS Simulator (1987, 1988). The data was analyzed separately for the two-engine burns (one fixed TVC) and for the single-engine fixed TVC burns.

For the two-engine cases, the pre-deorbit burn mass properties were used from STS 61-C; delta-V total = 227.7 ft/sec and vehicle weight = 216,520 lb (ref. SODB, volume II). These cases involved combinations of cg mistrims on the fixed TVC of pitch = -1.0, 0.0, +1.0 and yaw = -0.5, 0.0, +0.5. It should be noted that uncertainties in the cg estimate contribute to the expected total mistrim error (RSS of 3-sigma mistrim estimates) of approximately 0.6 degrees (ref. Charles Stark Draper Laboratory, Inc. memo no. SSV-88-50). The data indicated that a propellant cost of 0.9 lb/sec of computed burn time would protect for all combinations of P and Y mistrims as stated above.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-53****OMS TVC LOSS (CONTINUED)**

For the single-engine cases, the pre-deorbit burn mass properties were used from STS-6, STS 41-D, and STS 61-C. The delta-V total ranged from 227.7 to 284.7 ft/sec, and the vehicle weight ranged from 197,500 to 216,520 lb (ref. SODB, volume II.). Other pertinent assumptions include the trimming of residuals and data normalization. In all cases, if the X and Z residuals were more than 2.0 ft/sec, the propellant cost to trim them to less than 2.0 ft/sec [+X (25 lb/fps), -X (30 lb/fps), +Z (24 lb/fps), -Z (35 lb/fps)] was included in the total propellant cost figure. In order to account for the differences in mass properties and delta V of the burns, the data was normalized using computed burn time.

The propellant cost for total mistrims ($|P| + |Y|$) less than or equal to 2.0 degrees is 1.5 lb/sec of computed burn time. However, even in this range where the cost is a constant, one can expect that the lower the total mistrim, the lower the propellant cost, especially for single axis mistrims. Therefore, mistrim should still be minimized. The data is noisy in this regime and it was necessary to assume a cost of 1.5 lb/sec for all cases less than 2.0 degrees in order to safely blanket all data points.

The cost for a total mistrim of greater than 2.0 degrees was determined to be 0.75 lb/sec of computed burn time, per degree of total mistrim. This is the linear function that safely covers all data points for total mistrims greater than 2.0 degrees. The 0.75 lb/sec per degree of mistrim is conservative and the actual amount of mistrim in each axis (and the direction of the mistrim) determines the more exact propellant cost. Due to the general dependence on the given combination of pitch and yaw mistrims and the differences in mass properties and burn delta V, it is recommended that, time permitting, the actual case is simulated to supplement the results shown here. This data and all other data from the mentioned studies is documented (ref. Lockheed Engineering and Management Services Co. memo LEMSCO-19176; Charles Stark Draper Laboratory, Inc., memos SSV-87-10, SSV-87-18, and SSV-88-14; and G&C Systems Briefs 12.0, OMS TVC).

Rules {A6-101A}, OMS ENGINE BELL MOVEMENT DURING ASCENT; {A8-113A.4, A.5 and B}, OMS TVC SYSTEM MANAGEMENT; and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A8-54

FIRST STAGE LOSS OF CONTROL DEFINITION

FOR THE PURPOSES OF RANGE SAFETY DECISIONS, LOSS OF VEHICLE CONTROL DURING FIRST STAGE POWERED FLIGHT IS DEFINED AS PITCH OR YAW RATES GREATER THAN 5 DEG/SEC SUSTAINED FOR MORE THAN 5 SECONDS.

This rule defines vehicle loss of control during first stage, for the purposes of range safety, as sustained rates in pitch or yaw of larger than 5 deg/sec. For large oscillations where the rates are returning to less than 5 deg/sec (within 5 seconds), the vehicle will not be defined as out of control in order to allow the flight control system the opportunity to arrest the perturbations.

Flight control system certification tests showed pitch and yaw rates no greater than 2 to 3 deg/sec. An additional limited set of simulation runs by FDDD of stuck SRB actuators showed that, for the cases where intact abort capability and vehicle structural integrity were maintained, the vehicle pitch and yaw rates did not exceed 3 deg/sec (ref. Range Safety Panel Minutes from August 27, 1987). Typical periods of these oscillations were on the order of 6 to 10 seconds. (In other words, the flight control system responded in only a few seconds.)

It is postulated that a disturbance resulting in vehicle rate oscillations of greater than 5 deg/sec may be arrested by the flight control system. Hence, the flight control system should be given the opportunity (up to 5 seconds) to arrest such a disturbance (ref. Rule {A4-256D}, CONTROLLABILITY, and Ascent Flight Techniques, 4/24/87).

A8-55

ET SEPARATION RCS REQUIREMENTS

JET GROUP	MINIMUM REQUIREMENTS	
	NOMINAL	RTL5
FWD DOWN	1	3
AFT LEFT	1	3
AFT RIGHT	1	3
AFT UP	1/SIDE	2/SIDE
AFT DN	1/SIDE	2/SIDE
FWD YAW	-	1/SIDE

These requirements represent the minimum jets required to maintain vehicle control during mated coast, prevent contact between the ET and the vehicle during ET separation, and to meet the required staging conditions post RTL5 ET separation. Nominal ET separation occurs at a lower dynamic pressure such that fewer jets are required to achieve satisfactory separation. These requirements were determined from JSC Engineering Directorate studies (ref. SODB, paragraph 4.5.1.1.6.1). (Ref. Rules {A2-63}, ASCENT STRING REASSIGNMENT; {A2-254}, ENTRY STRING REASSIGNMENT; and {A7-102C.4}, PASS DATA BUS ASSIGNMENT CRITERIA.)

Rules {A2-69} REGAIN RCS JETS FOR RTL5 ET SEPARATION; and {A6-61A.2}, RCS MANIFOLD/OMS CROSSFEED LINE REPRESSURIZATION [CIL], reference this rule.

FLIGHT RULES

A8-56

BFS LRU REQUIREMENTS

THE FOLLOWING DOUBLE LRU FAILURES (ERROR > PASS RM LIMIT) WHICH COULD RESULT IN LOSS OF CONTROL WILL CAUSE THE BFS TO BE NO-GO UNTIL THE LRU'S ARE DESELECTED BY THE CREW. DUAL NULL FAILURES ARE ACCEPTABLE FOR ALL LRU'S EXCEPT SRB RGA'S.

There is no FDI in the BFS. To determine if the LRU is failed in the BFS, the same criteria that is used by FDI in the PASS to declare an RM failure must be applied.

Interchangeable-mid-value-select (IMVS) is used for all AA's and RGA's, the same as in the PASS. The aerosurface feedback selection scheme utilizes IMVS that functions like quad-mid-value-select (QMVS) due to an I-load which is unique to the BFS. QMVS and IMVS protect against dual null failures, but neither protect against dual null failures greater than RM. In either case, the crew will deselect the failed LRU's in the BFS in order to maintain an engageable BFS. The BFS has the same manual deselect capability as the PASS for AA's, RGA's, and aerosurface feedbacks. There is no automatic downmoding for comm faults, so deselection is also needed for these cases. The SRB RGA selection filter uses a mid-value-select (MVS) scheme for LRU's 1, 2, and 3 only, with no deselect capability.

A. OPS 1:

1. ANY TWO LATERAL AA'S PRIOR TO THE END OF FIRST STAGE (LATERAL AA'S NOT USED IN OPS 1 POST-MM 102).
2. ANY TWO NORMAL AA'S PRIOR TO END OF LOAD RELIEF (90 SECONDS MET).

The lateral axis feedback is used in first stage from load relief through SRB tailoff, but the normal axis feedback is not used in OPS 1 after load relief is complete. The normal axis feedback is gained to zero at Vrel = 2628 fps, which correlates to approximately 90 seconds MET. Double failures of AA feedback in the same axis would cause the BFS selection filter to output bad data.

3. ANY TWO ORBITER RGA'S, SAME AXIS.
4. ANY TWO OF SRB RGA'S 1, 2, OR 3, SAME AXIS (MM 102 ONLY).

The RGA's are used all through ascent to provide vehicle rate data to guidance and flight control. Like the AA's, a double failure in RGA feedback in the same axis could cause the BFS selection filter to provide bad data to flight control. The SRB RGA selection filter uses a MVS scheme for LRU's 1, 2, and 3 only, with no deselect capability.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-56

BFS LRU REQUIREMENTS (CONTINUED)

B. OPS 3 OR 6:

1. ANY TWO LATERAL AA'S.
2. ANY TWO ELEVON OR BODY FLAP POSITION FEEDBACKS, SAME SURFACE.
3. ANY TWO RGA'S, SAME AXIS.

In general, it is assumed that the crew will not engage the BFS unless absolutely required. The philosophy is that, if it is considered usable, the BFS is GO for engage after committing to entry, even though it may require off-nominal crew procedures.

Double failures of RGA, lateral AA, body flap, or elevon position feedbacks could cause the BFS selection filter to provide bad data to flight control. This may result in loss of vehicle control.

AA lateral (Ny) feedback was originally added to the flight control system to control beta (sideslip) dispersions as a result of alpha errors. A post-STS-4 R&E study (which assumed no Ny feedback, LVAR 20 elliptical uncertainties, FAD 4 aero, and only two RCS yaw jets available per pod) concluded that alpha errors (as a result of IMU errors and winds) resulted in a beta buildup and subsequent reduction of stability margins.

Sensitivity to alpha errors was especially noted during bank maneuvers since these maneuvers are performed about the vehicle stability axis (alpha is used in flight control to determine the stability axis).

A reduction in both the aerodynamic variations and in the severity of wind environment since the STS-1 development program increase the capability of the flight control system with Ny feedback failed to null. A quick look R&E study performed in 1987 using the STS-26 conditions and nominal aero revealed that with Ny feedback failed to null, alpha errors up to 4 degrees were acceptable assuming all RCS yaw jets were available. As a result, the EFTP concluded that the BFS flight control system should be considered GO with null Ny feedback.

It is also important to note that the incorporation of air data into GNC essentially eliminates alpha error and reduces the requirement for Ny feedback. Reference EFTP #39, 12/11/87.

AA normal (Nz) feedback is not as critical in the BFS. It is removed from the command loop in CSS (BFS is CSS only). However, with bad Nz feedback, the crew displayed ADI pitch error will be erroneous. This presents an increased flying challenge since the crew is not well trained to fly in this configuration.

For body flap (BF) feedback failures, loss of control is a concern if the failures cause the BF to drive full DOWN and stay there. The elevons will be driven up to maintain pitch axis trim. This causes a degradation of aileron control authority which significantly impacts lateral/directional vehicle control. SES studies (September 4, 1990) showed that loss of control can occur with the BF stuck full DOWN. A full UP BF does not create flight control problems, but this may have significant thermal impacts.

FLIGHT RULES

Rule {A2-59B}, BFS ENGAGE CRITERIA, references this rule.

A8-57 PRELAUNCH IMU HOLD

PRELAUNCH IMU HOLD DOES NOT APPLY PRIOR TO T MINUS 4 MINUTES (EVENT 11 TIME) WHEN CONTINUOUS IMU ALIGNMENT IS COMPLETE AND THE IMU'S GO INERTIAL. AFTER T MINUS 4 MINUTES, THE FOLLOWING CRITERIA APPLY:

- A. THE JSC MISSION EVALUATION ROOM (MER) WILL PROVIDE THE IMU INERTIAL REFERENCE MISALIGNMENT LAUNCH GO/NO-GO RECOMMENDATION TO THE JSC FLIGHT CONTROL TEAM. KSC WILL SERVE AS A BACKUP TO THE MER.

The inertial reference alignment monitor system (IRAMS) is required to monitor individual IMU prelaunch misalignment. IRAMS is available at the JSC MER and at KSC. All MER calls relating to the IMU system will be coordinated with the GNC officer. The MER is responsible for coordination with all elements (KSC, RI, etc.) (ref. AFTP #40).

- B. THE LAUNCH WILL BE NO-GO FOR THE FOLLOWING:

1. THE INERTIAL REFERENCE MISALIGNMENT OF ANY IMU AXIS, AS MEASURED BY THE IRAMS, EXCEEDS THE APPLICABLE REDLINE AS SHOWN BELOW:

The redlines have been developed as limits on the IMU inertial reference misalignment as measured by IRAMS. Redlines are applicable for standard and direct insertion flights (ref. AFTP #40).

- a. FOR A 28.5-DEGREE INCLINATION (DUE EAST) LAUNCH, THE GENERIC REDLINES FOR A SAFE AOA TO EDWARDS ARE:
@[011295-1752A]

-243 ARC SECONDS ? ?N ? 330 ARC SECONDS

| 0.43?W + ?U | ? 821 ARC SECONDS

- b. FOR A 28.5-DEGREE INCLINATION (DUE EAST) LAUNCH, THE GENERIC REDLINES FOR A SAFE AOA TO NORTHROP ARE:
@[011295-1752A]

-203 ARC SECONDS ? ?N ? 279 ARC SECONDS

| 0.43?W + ?U | ? 841 ARC SECONDS

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

- g. FOR RENDEZVOUS MISSIONS (EXCEPT FOR MIR RENDEZVOUS), REDLINES ARE SPECIFIED IN THE FLIGHT-SPECIFIC ANNEX WHEN REQUIRED: ©[011295-1752A]

WHERE:

?_n = MISALIGNMENT ABOUT THE NORTH AXIS

?_w = MISALIGNMENT ABOUT THE WEST AXIS

?_u = MISALIGNMENT ABOUT THE UP AXIS

NOTE: REF. FLIGHT RULES ANNEX FOR FLIGHT-SPECIFIC MISALIGNMENT REDLINES.

The OI-22 software upgrades added the capability to continuously align IMU's in OPS 1, up to T-4 minutes. With this change, the probability of violating the above redlines is extremely low. The scenario to invoke this part of the rule would generally involve counting down past T-4 minutes, where the OPS 1 continuous align software is terminated, and then recycling back for a later launch attempt while remaining in OPS 1. (Note: at least 1 hour of holdtime is required for ET propellant conditioning and APU cooldown.) If the recycle requires returning to G9, then the IMU preflight alignment will have to be reaccomplished (time permitting, ref. paragraph E.1.a of this rule) and the likelihood of violating this part of the rule will be negligible. For 51.6-degree inclination missions (Mir and Station flights), the extremely small launch window makes the probability of violating the redlines (without failing an IMU) negligible. ©[011295-1752A]

Historically, the redlines were written to protect for a safe launch and abort (RTLS, TAL, ATO, AOA) (ref. AFTP's #35, #37, #39, #40, and #44). The constraining case is the AOA. With the OPS 1 continuous IMU alignment, it is very unlikely that the redlines could be violated. Effectively, this rule now protects for an IMU failure occurring after T-4 minutes (no BITE or RM FL annunciated) and thus precludes launching into an early mission termination. ©[011295-1752A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

The redlines protect for 99.74 percent (3 sigma) probability for a safe AOA based on the following assumptions and groundrules:

- a. A single IMU was assumed as the baseline configuration in redline determination.
- b. A 3-sigma IMU postlaunch performance based on previous flight experience is equal to 2/3 of the 3-sigma IMU specification.
- c. OPS 1/3 transition will be accomplished per procedure at least 10 minutes before OMS-2 ignition.
- d. An AOA requires EI-5 downtrack navigation to protect the following constraints:
 1. 375 psf Q -bar vehicle structural limit with worst case aerodynamics at TACAN update (constraint drives the negative north tilt misalignment redline for 28.5-degree inclination launch and contributes to the redlines for a 57-degree inclination launch).
 2. TACAN low energy stretch maneuver capability assuming TACAN is forced at 130k feet altitude (constraint drives the positive north tilt misalignment redline for a 28.5-degree inclination launch; not a driver for 57-degree inclination launch redlines).
 3. Leading edge temperature limit of 3100° F with no heat rate limit (constraint contributes to 57-degree inclination launch redlines; not a driver for 28.5-degree inclination launch redlines).
- e. A ground state vector uplink or GCA is not required.
- f. Launch is from KSC.
- g. AOA landing site is Edwards or Northrup for 28.5-degree or 39-degree inclination launch and Northrup for 57-degree inclination launch (ref. CSDL Memo Shuttle - 90-035). The AOA landing site is 51.6-degree inclination launch (ref. CSDL MEMO Shuttle-94-025). ©[011295-1752A]
- h. KT-70 IMU.
- i. 245 fps maximum MECO underspeed.
- j. Prelaunch and postlaunch IMU performance are independent.
- k. Maximum EI minus 5 crosstrack dispersion 16.7 nm to protect trajectory control and autoland transition criteria (constraint drives the west and up misalignment redlines for a 28.5-degree inclination launch; not a driver for 57.0-degree inclination launch redlines). ©[011295-1752A]
- l. The Onboard Navigation Systems Characteristics (ONSC) model was used in developing the redlines.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

- m. IRAMS 1-sigma azimuth measurement error is 40 arc seconds.
 - n. Worst case vehicle AOA mass properties of heavyweight and forward CG (240k lb, 1080 inches).
2. IF THE IRAMS MISALIGNMENT COMPUTATION IS NOT AVAILABLE AT EITHER JSC OR KSC, THE LAUNCH GO/NO-GO CALL WILL BE MADE BASED ON THE FOLLOWING GUIDELINES:

LAUNCH WILL BE NO-GO IF MCC IMU RELATIVE DRIFT COMPUTATIONS INDICATE THAT ANY IMU CLUSTER AXIS IS DRIFTING AT A RATE > 0.05 DEG/HR. IMU PREFLIGHT CALIBRATION AND ALIGNMENT WILL BE REQUIRED BEFORE A SUBSEQUENT LAUNCH ATTEMPT. @[011295-1752A]

Individual IMU misalignment cannot be observed if IRAMS is unavailable at both KSC and JSC. MCC relative drift computations (between IMU's) provide the only remaining method of monitoring IMU prelaunch drift. Since relative drift only indicates the rate at which IMU's are drifting apart and does not indicate individual IMU performance, it can only serve as a rough health check of the IMU's. An IMU axis drift rate greater than 0.05 deg/hr (HAINS) in the IMU cluster reference frame (ref. SODB 4.5.1.2.3.p.2) indicates an anomalous condition. Interpretation of relative drift data and implementation of this rule is dependent on engineering judgment. A preflight calibration is required before a subsequent launch attempt to calculate gyro drift compensation terms and correct excessive drift, or verify an IMU failure. This will require a minimum of approximately 3.6 hours and exceed the 3-hour crew hold-time limit (ref. Rule {A2-4A}, LAUNCH DAY CREW TIME CONSTRAINTS), causing the launch to be scrubbed. The limit serves only as a health check of the IMU (ref. AFTP #40). Derivation of the limit follows:

	<u>HAINS</u>
a. 1-Sigma Acceleration Sensitive Drift Specification At 1g	0.015 Deg/Hr
b. 1-Sigma Bias Drift Specification (Up To 17 Hours From Start Of Preflight Calibration)	0.006 Deg/Hr
c. 1-Sigma Total Prelaunch Drift (RSS Of Above)	0.016 Deg/Hr
d. 3-Sigma Total Prelaunch Drift	0.05 Deg/Hr

@[011295-1752A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

- C. A PERIOD OF 30 MINUTES AFTER THE IMU'S GO INERTIAL (T MINUS 4 MINUTES) IS REQUIRED PRIOR TO USING THE IRAMS LAUNCH HOLD PREDICTION CAPABILITY.

IRAMS requires 30 minutes to generate an accurate hold time. The time required for an accurate hold time prediction is dependent on actual IMU performance and may vary, but 30 minutes is used as a guideline. If a prediction is required before 30 minutes, it will be accompanied by an estimated accuracy of the prediction. In this case, the predicted hold time and the estimated accuracy of that prediction are heavily dependent on engineering judgment (ref. AFTP #40).

- D. THE IMU'S MAY BE REALIGNED IF EITHER OF THE FOLLOWING WILL OCCUR PRIOR TO T-0 (THE NEW T-0 FOR UNPLANNED HOLDS), OR PRIOR TO THE END OF THE LAUNCH WINDOW IF A NEW T-0 IS UNCERTAIN:
1. IMU RELATIVE DATA INDICATES THREE-SIGMA OR GREATER DRIFT RATES.
 2. IRAMS HOLD PREDICTION PROGRAM DETERMINES THAT A MISALIGNMENT REDLINE WILL BE VIOLATED.

NOTE: REFERENCE PARAGRAPHS B.1, B.2, AND E OF THIS RULE.

If it is predicted that the IMU relative drift will exceed three sigma or if the IRAMS prediction program indicates that a violation will occur, then the IMU's should be realigned, time permitting, to attempt a launch within the window. If the IMU's are not realigned and a redline violation occurs without sufficient time for realignment, then the launch may be scrubbed unnecessarily.

- E. PRELAUNCH IMU REALIGNMENT MAY BE ACCOMPLISHED BY THE FOLLOWING METHODS:
1. G9 IMU PREFLIGHT ALIGNMENT MAY BE USED SUBJECT TO THE FOLLOWING CONSTRAINTS:
 - a. THE LAUNCH WINDOW MUST SUPPORT THE 90 MINUTES REQUIRED TO RECYCLE TO G9 FOR IMU REALIGNMENT AND COUNTDOWN TO T-0.

After a recycle to G9, the IMU alignment and nominal G1 prelaunch timeline requires 90 minutes. Some additional time may be required in G1 prior to transition to G9.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-57

PRELAUNCH IMU HOLD (CONTINUED)

2. G1 GYRO BIAS UPLINK MAY BE USED FOR IMU REALIGNMENT SUBJECT TO THE FOLLOWING CONSTRAINTS:
 - a. IRAMS IS REQUIRED TO CALCULATE GYRO BIAS UPLINK TERMS.

IRAMS is required to monitor individual IMU prelaunch misalignment and calculate gyro bias uplink values to correct the misalignment.

- b. THE LAUNCH WINDOW MUST SUPPORT THE 15 MINUTES REQUIRED TO GENERATE AND VERIFY THE GYRO BIAS UPLINK. THE GYRO BIAS TERMS (AS COMPUTED BY THE IMU PREFLIGHT CALIBRATION) WILL BE ON-BOARD, AND THE PERFORMANCE WILL BE VERIFIED PRIOR TO LIFT-OFF. IT IS HIGHLY DESIRABLE TO VERIFY THE PERFORMANCE PRIOR TO RESUMING THE COUNT AT T MINUS 5 MINUTES.

Five minutes is required for the uplink decision and implementation process. This process consists of the MER/MCC decision that an uplink is required; coordination of required compensation values between MER and MCC; uplink load generation; uplink load verification; coordination between MER, MCC and KSC prior to uplink execution; uplink execution; and 1 minute for torquing out IMU misalignment. An additional 10-minute monitoring/verification period is required after the realignment is complete prior to committing to launch.

A8-58

ADI LOSS

AN ADI IS CONSIDERED FAILED ONLY IF THE ATTITUDE BALL IS FAILED (N/A FOR MEDS VEHICLES). @[040899-2459B]

The entry-critical parameters required by the crew can be monitored using the attitude ball (or sphere). While rate and error needles are desirable (especially for monitoring vehicle control), the attitude ball is sufficient in providing the required information. As a result, an ADI will be considered failed only if the attitude sphere is not providing accurate or stable attitude reference. This rule is needed for making decisions regarding early flight termination, night landings, and IFM. (Ref. Rules {A8-1001E}, GNC GO/NO-GO CRITERIA, for dedicated displays and {A8-18}, LANDING SYSTEMS REQUIREMENTS.) (Ref. Entry Flight Tech. Panel #34, 8/21/87.)

FLIGHT RULES

A8-59

IMU BITE FAILURE DEFINITION

FOR PURPOSES OF EARLY MISSION TERMINATION AND LANDING SITE DOWNMODING, AN IMU WITH A BITE SHOULD BE CONSIDERED FAILED WITH THE FOLLOWING EXCEPTIONS:

- A. TRANSMISSION WORD 2 BITE
- B. TRANSMISSION WORD 1 BITE
- C. TEMPERATURE SAFE BITE
- D. TEMPERATURE READY BITE @[011295-1752A]

IF REAL-TIME ASSESSMENT DETERMINES THE BITE TO BE FALSE OR NO IMPACT, THEN THE IMU WILL NO LONGER BE CONSIDERED FAILED.

At the three-level, redundancy management (RM) will not downmode an IMU with a BITE because there is no risk of incorporating bad data. At the two-level, RM will downmode the IMU with the BITE should the attitude or velocity disagree by more than the RM threshold.

A BITE is an indication that the IMU has experienced a failure and may be operating outside of spec. BITE will almost always indicate an actual problem with the IMU. In most cases, data can be used to determine whether or not the BITE is real. There is, however, the possibility of a failure in the BITE circuitry itself - termed false BITE. Also, it cannot necessarily be determined whether or not an IMU will continue to operate in a consistent manner while outside of spec. For several BITE's, performance will remain unknown until data is observed during entry. It is logical, therefore, to assume that the BITE logic has correctly identified a real failure and to consider the unit failed. Since RM provides for BITE's, there is no requirement for manual deselection of the affected IMU.

A next PLS should be declared after the second BITE (or the first BITE at the two-level) to reduce the risk of losing the last IMU. Reference Rule {A2-207}, LANDING SITE SELECTION, for runway priorities. @[102402-5804C]

The Transmission Word 2 Fail BITE (loss of slew) only impacts the IMU if an IMU/IMU alignment is required. Even if an IMU/IMU is required, other options exist to fully recover the IMU.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-59

IMU BITE FAILURE DEFINITION (CONTINUED)

A Transmission Word 1 Fail BITE (loss of pulse torquing) indicates that the IMU has detected an error in the GPC transmitted pulse torquing commands. The IMU will not use these commands and will drift at its uncompensated rate. Since, the internal compensations of the HAINS are not updated on a flight-to-flight basis, the uncompensated drift rates can vary. For a real Transmission Word 1 BITE, real-time assessment will be required to determine if drifts are within acceptable limits to support entry. Matrix alignments can be performed to keep the IMU aligned and not appreciably alter the relative skew between the IMU platforms. ©[011295-1752A]

A false BITE has no impact to IMU performance except in the case of a false Transmission Word 1 BITE. If the Transmission Word 1 Fail BITE is false, the GPC will overtorque the IMU. The impact of this false BITE can be minimized by zeroing the uplinked gyro drift compensation command, moding the IMU to standby and back to operate, and then performing a matrix alignment. ©[011295-1752A]

The Temperature Safe and Temperature Ready BITE's do not indicate temperature problems, but rather power supply failures. These discretes are driven directly by the +5 V dc isolated power supply on the input power conditioner (IPC) card and are used only to maintain transparency between the current HAINS and the previous KT-70 IMU's. If only one of these BITE's is annunciated, it is probably a false indication. If both BITE's are set together, then the +5 V dc isolated power supply is suspect. Failure of this power supply would also result in Platform Temperature Safe, Platform Temperature Ready, and Communication Good BITE's. The In-operate Mode and Operate command would also be set false, resulting in the IMU moding to standby. ©[011295-1752A]

A8-60

LOSS OF VERNIER RCS DAP MODE

THE VERNIER RCS DAP MODE IS CONSIDERED LOST IF:

- A. ANY SINGLE DOWN-FIRING VRCS JET (F5L, F5R, L5D, R5D) IS LOST.

For the loss of a down-firing VRCS jet, closed-loop (i.e., AUTO, INRTL-DISC, LVLH-DISC) DAP stability and controllability usually cannot be maintained, and the VRCS system will not be used in this mode. The DAP will downmode to free drift when any VRCS jet is lost, but the software will not prevent reselection of a VRCS closed-loop mode, even though this mode could result in an unstable DAP configuration. Open-loop VRCS control (INRTL-PULSE, FREE) will also be significantly degraded, and the use of this mode should be assessed on a case by case basis. ©[110900-7259]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-60

LOSS OF VERNIER RCS DAP MODE (CONTINUED)

- B. EITHER SIDE-FIRING VRCS JET (R5R, L5L) IS LOST WHILE A PAYLOAD IS ATTACHED TO THE ORBITER IN ANY NON-ENTRY CONFIGURATION.

EXCEPTIONS IN WHICH DAP PERFORMANCE IS KNOWN TO BE ACCEPTABLE FOR THE LOSS OF EITHER SIDE-FIRING JET INCLUDE:

1. ALL SPACELAB MISSIONS IN WHICH LOADED RMS OPERATIONS ARE NOT BEING PERFORMED.
2. ALL CONFIGURATIONS FOR INERTIAL UPPER STAGE (IUS) DEPLOYS.
3. THE PORTIONS OF THE HUBBLE SPACE TELESCOPE (HST) REVISITS IN WHICH THE PAYLOAD IS ATTACHED DIRECTLY TO THE PAYLOAD BAY.
4. ALL FLIGHTS FOR WHICH MISSION-SPECIFIC DAP STABILITY ANALYSES HAVE FOUND DAP PERFORMANCE TO BE ACCEPTABLE FOR THIS CONFIGURATION.

Stable VRCS DAP performance has been verified for the loss of L5L or R5R with either an empty payload bay or payloads berthed in the bay. The DAP will still downmode to free drift when any VRCS jet is lost, but the software will not prevent reselection of a VRCS closed-loop mode, even though this mode could result in an unstable DAP configuration. If payloads are attached to the orbiter in a non-entry configuration (e.g., on the remote manipulator system (RMS) or deployed on the stabilized payload deployment system (SPDS)), the stability and controllability of the orbiter/payload system must be uniquely verified for each payload position and each combination of operable VRCS jets. This type of study is necessitated by the influence on DAP performance of both payload CG offsets and the flexibility of the attached mechanisms. [110900-7259]

A study has already been performed on several payloads which are commonly flown (Spacelab and all payloads deployed using an IUS), as well as the portions of the HST maintenance missions in which HST is attached directly to the payload bay. It was found during the study that DAP stability will be adequate with these payloads in these configurations (ref. Draper Memo SSV-90-027, Controllability of Orbiter With Vernier Jet Failures During Attached Payload Operations). For any other non-entry orbiter/payload configuration, the loss of a side-firing vernier should be cause to NO-GO the VRCS DAP mode unless an applicable study has been performed which indicates that the given configuration will result in adequate DAP performance. If such a study is performed, it will be documented in Section A3.12 of the mission-specific Flight Rules Annex (JSC-18308). Rule {A6-154}, RCS VERNIER OPERATION TERMINATION, references this rule.

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES

THE FAILURE OF TWO HYDRAULIC SYSTEMS DURING ASCENT WILL RESULT IN THE LOSS OF TVC ON ONE SSME AND THE LOSS OF THROTTLE CAPABILITY ON TWO SSME'S. IF TWO HYDRAULIC SYSTEMS FAIL, THE FOLLOWING ACTION WILL BE TAKEN:

- A. WITH TWO ENGINES RUNNING (NOM/ATO/TAL/RTL), ONE OF THEM NONGIMBALLING, SINGLE ENGINE ROLL CONTROL (SERC) WILL BE INVOKED IMMEDIATELY BY THE CREW. THE NONGIMBALLING ENGINE WILL BE SHUT DOWN WHEN SINGLE-ENGINE PRESS CAPABILITY FOR THE CURRENT TRAJECTORY IS ACHIEVED, BASED ON THE THROTTLE LEVEL OF THE GIMBALLING ENGINE AND WITHOUT ABORT GAP CLOSURE TECHNIQUES APPLIED.

Simulator testing has verified that a loss of control is almost certain to occur, usually very quickly, when one of the two remaining engines has lost gimbal capability and SERC is not active. Even if SERC is invoked (TRAJ display, Item 6), a loss of vehicle control is still possible, especially during very dynamic vehicle maneuvers such as powered pitcharound (PPA) on an RTL. However, if SERC is invoked within a few seconds of the failure that results in this configuration, it will often provide good vehicle control until SSME gimbal saturation occurs. Gimbal saturation generally does not occur prior to single-engine capability, but will usually occur prior to MECO, resulting in rapid degradation of vehicle control. Shutting down the nongimballing engine at single-engine press eliminates the possibility of gimbal saturation occurring after that point. Single-engine capability calls ("single-engine press," "single-engine TAL," etc. depending on current trajectory) should be based on the throttle level of the gimballing engine with no abort gap closure techniques applied (ref. Rule {A4-56I}, PERFORMANCE BOUNDARIES). The risk of a few more seconds of exposure to potential gimbal saturation is considered small compared to the risks of flying gap closure techniques. If single-engine capability has already been achieved when this failure scenario occurs, the nongimballing engine should be shut down immediately. ©[082593-1464C]

- B. THREE ENGINES RUNNING:

1. NOMINAL/ATO - THE NONGIMBALLING ENGINE WILL BE SHUT DOWN AT SINGLE-ENGINE PRESS TO MECO.

SES testing has verified that vehicle control is acceptable with three engines running and one nongimballing (two-engine control laws are utilized). To minimize the time to single-engine press, the nongimballing engine will be allowed to continue to run. The risk incurred in this period is that a gimballing engine will shut down and immediate action (invoking SERC, ref. Paragraph A above) will be required to maintain vehicle control. ©[082593-1464C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES (CONTINUED)

After single-engine capability is achieved, the performance risk incurred due to a good engine failing following shutdown of the nongimballing engine is minimized. At the same time, the loss of control risk associated with allowing the nongimballing engine to continue to run remains. Therefore, the non-gimballing engine should be shut down at single-engine press to minimize the next failure impact.

If two engine throttles are stuck at a high power level, 3.5g may be exceeded near MECO. Shutting an engine down at an operationally convenient point such as single-engine press will eliminate this problem.

2. TAL - THE NONGIMBALLING ENGINE WILL BE SHUT DOWN AT SINGLE-ENGINE TAL. MANUAL THROTTLES WILL BE ENABLED PRIOR TO ABORT SELECTION IN ORDER TO MAINTAIN THE THROTTLES AT THE NOMINAL POWER LEVEL. @[082593-1464C]

For a three-engine TAL, the same rationale as paragraph 1 above applies for engine shutdown. There are several reasons why it is undesirable to throttle down the good engine: It may result in guidance transients, flight control would not be as good during the roll to heads up (although it would still be acceptable), little time would be gained to perform the abort dump, and the time to single-engine press would be increased. Therefore, manual throttles will be selected to prevent an automatic throttle down when TAL is declared. This action is not required if TAL is declared early enough that automatic throttling will not occur at abort selection. However, since there is no disadvantage to selecting manual throttles for this short period of time, manual throttles will always be selected, for consistency. AUTO throttle will be reselected after TAL is declared. @[082593-1464C]

3. RTLS:
 - a. IF ONE OR BOTH OF THE ENGINES WITH STUCK THROTTLES ARE AT 85 PERCENT OR LESS, THEN THE NONGIMBALLING ENGINE WILL BE ALLOWED TO RUN TO MECO.
 - b. IF BOTH ENGINES WITH STUCK THROTTLES ARE AT MORE THAN 85 PERCENT, THEN THE NONGIMBALLING ENGINE WILL BE SHUT DOWN 2 MINUTES PRIOR TO MECO.

NOTE: BEFORE SELECTING RTLS, MANUAL THROTTLES WILL BE ENABLED AND MINIMUM THROTTLES SELECTED. AT LEAST 10 SECONDS OF MINIMUM THROTTLE LEVEL IS DESIRED PRIOR TO RTLS SELECTION. AUTO THROTTLES WILL BE RESELECTED ANYTIME PRIOR TO PPA. @[082593-1464C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES (CONTINUED)

As with the NOM/ATO/TAL cases, it is preferable to leave the nongimballing engine running through single-engine press to MECO and accept the risk of the loss of a gimballing engine to this point. Due to the possibility of SSME failures resulting from valve drift on the engines in hydraulic lockup, the time to single-engine press should be minimized, since engine failures prior to this point can result in loss of vehicle and crew bailout. Unfortunately, shutting an engine down at single-engine press on an RTLS with two stuck throttles can lead to undesirable results.

For the contingency case in which two hydraulic system failures, in addition to another independent failure, result in a three-engine RTLS with two SSME throttles stuck high, it is possible for g forces to get as high as 3.9g. Therefore, if both stuck throttles are above 85 percent, an engine must be shut down before MECO-20 seconds in order to avoid the possibility of exceeding 3.5g. However, analysis has shown that shutting down the nongimballer with 85 seconds of MECO in this scenario leaves more than 2 percent propellant remaining in the ET at MECO, resulting in orbiter/ET recontact after ET SEP. Therefore, MECO-2 minutes was selected as an operationally convenient shutdown cue that would eliminate both the recontact and the g-load concerns. One drawback to shutting down at this point (or any later point) is that guidance commands a large pitch-up. Although the vehicle adequately follows the guidance commands, this pitch transient causes the dedicated displays to pass through the singularity point, degrading the crew's capability to monitor vehicle control. The only way to avoid this pitch transient would be to shut the engine down just after powered pitcharound (PPA), which would extend the time to single-engine press by more than 1 minute, compared to shutting down at MECO-2 minutes. Since the pitch transient is due to a guidance command and not a control problem and since the risk of engine failure due to valve drift was considered to be a greater concern than the momentary loss of crew monitoring capability, it was decided that MECO-2 minutes is the optimal shutdown time. (Reference Ascent/Entry Flight Techniques Panel #105, 10/22/93.)

For the case in which at least one throttle is stuck at or below 85 percent, there is no threat of exceeding 3.5g. Depending on the throttle levels of the stuck engines, it also may not be acceptable, from a performance standpoint, to shut down the nongimballing engine before single-engine press. Since shutting down after single-engine press can result in an undesirable pitch transient and is not required to protect for excessive g-loads, it is preferable to leave all three engines running to MECO for this case. The only risk incurred with this philosophy is that the window of exposure to the failure of a gimballing engine remains open until MECO for this case.

The 85-percent throttle level provides an operationally convenient breakpoint which ensures that a shutdown will never be performed if the engine is needed to achieve the desired MECO targets, while also ensuring that an engine will always be shut down if any threat of exceeding 3.5g exists. For scenarios in which engines are stuck at intermediate throttle settings, acceptable results can sometimes be obtained regardless of whether or not an engine is shut down.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-61

SSME SHUTDOWN DUE TO HYDRAULIC SYSTEM FAILURES
(CONTINUED)

For all RTLS cases with two stuck throttles, minimum throttles will be selected prior to abort selection. Doing so will allow guidance to converge on the correct average thrust level and will reduce the probability of a early PPA. For guidance to have enough time to converge, minimum throttle levels must be achieved at least 10 seconds prior to RTLS selection. If not, an early PPA may occur, resulting in MECO conditions that are not optimized. AUTO throttles should be reselected at some point prior to PPA, but are not mandatory prior to RTLS selection. ©[082593-1464C]

C. SHUTDOWN MATRIX:

FAILED HYDRAULIC SYSTEM	NONGIMBALLING ENGINE	ENGINES WITH STUCK THROTTLES
1 AND 3	CENTER	CENTER AND RIGHT
1 AND 2	LEFT	CENTER AND LEFT
2 AND 3	RIGHT	LEFT AND RIGHT

The failure of two hydraulic systems will cause two engines to lock up hydraulically and eliminate TVC capability on one of these two engines. The engine shutdown matrix identifies which engines have lost TVC and/or throttle capability.

Rules {A4-59}, MANUAL THROTTLE SELECTION; {A5-109}, MANUAL SHUTDOWN FOR TWO STUCK THROTTLES (NOT DUAL APU FAILURES); {A5-103}, LIMIT SHUTDOWN CONTROL; and {A2-301}, CONTINGENCY ACTION SUMMARY, reference this rule. ©[092195-1770A] ©[ED]

MANAGEMENT

A8-101 BEEP TRIM DEROTATION

- A. THE RHC BEEP TRIM SWITCH WILL NOMINALLY BE USED TO PERFORM ORBITER DEROTATION. THE RHC WILL BE USED AS A BACKUP IF THE BEEP TRIM IS INOPERABLE. @[120894-1722A] @[110900-3780]

The RHC beep trim switch provides a smooth and predictable orbiter pitch derotation rate. Use of this switch eliminates the derotation rate dispersions introduced during the initiation of derotation when using the RHC. The improved derotation characteristics provided by the beep trim switch reduces tire and main landing gear peak loads. This in turn allows derotation to be performed at higher airspeeds than it can be performed using the RHC. Derotating at higher airspeeds reduces the time in the two-point attitude where less lateral control authority is available.

Beginning with OI-28, PASS software was modified to provide effectively two-fault tolerance to an uncommanded rate input by using WOW and EAS as the enable function for the Beep Trim derotation (beep trim is a two-contact switch). This eliminated a requirement to reconfigure the PANEL power and RHC/PANEL enable switches at M 2.7, and closes a window of exposure where a failed contact/commfault combination resulted in an undesired rate command. On the first pass after WOW is set, the software polls the left and right beep trim contacts, and no-ops contacts indicating "1" (vote to initiate a negative pitch rate) by latching the failed high contacts to "0". If both contacts on one RHC indicate "1" during the first pass, only one contact is set to "0". Additionally, a commfaulted contact is considered to be "0" by the logic. Post WOW, while greater than 195 KEAS (I-load), both contacts of either the left or right beep trim are required to indicate "1" prior to a derotation command being honored. Less than or equal to 195 KEAS, only one contact is required to initiate a derotation. If both contacts are failed open or commfaulted, or if one contact is failed high prior to WOW and the other contact commfaulted, a manual derotation using the RHC is required. There are specific failures which will result in an auto-derotation anytime the orbiter airspeed is less than or equal to 195 KEAS. These are 1) failure of a single contact high after WOW, and 2) two contacts failed high pre-WOW.

- B. IF THE BFS IS ENGAGED, THE CDR'S PANEL TRIM POWER WILL BE TURNED OFF AND THE RHC/PNL TRIM INHIBIT/ENABLE SWITCH WILL BE PLACED IN ENABLE TO PROVIDE BEEP TRIM DEROTATION CAPABILITY.

This action will provide beep trim derotation capability for the CDR only; there is no PLT capability in the BFS. @[110900-3780]

FLIGHT RULES

A8-102

RGA SYSTEM MANAGEMENT [CIL]

IF FOUR ORBITER RGA'S ARE AVAILABLE AND A KNOWN FAILURE CONDITION EXISTS WHERE ONE ADDITIONAL FAILURE WOULD CAUSE TWO ORBITER RGA'S TO SIMULTANEOUSLY LOSE POWER, ONE OF THE AFFECTED RGA'S WILL BE DESELECTED IN THE BFS [CIL].

Test data indicates that when power is removed from an orbiter RGA or SRB RGA the RGA output electronics generate a false rate approximately equal to 18 deg/sec in roll and 10 deg/sec in pitch and yaw. This false rate signature decreases linearly to zero approximately 10 seconds after the power is removed from the RGA. Since interchangeable midvalue selection (IMVS) is used for the RGA selection filter in the BFS when four RGA's are available, a simultaneous power fail of two RGA's would feed the bad rate signature directly into BFS flight control. This is not a concern in the PASS, since PASS redundancy management automatically deselects power failed RGA's. The effect of this transient and subsequent bad rate feedback on flight control may be catastrophic during any dynamic flight phase. (Ref. Configuration Control Board, January 22, 1991, Power Loss Characteristics for FCS RGA's.)

If it is known that one electrical bus failure will remove power simultaneously from two RGA's (requires previous failure), one of those RGA's can be deselected in the BFS to protect for that bus failure. Deselecting an RGA will downmode the selection filter to a MVS scheme and thus regain full single-fault tolerance.

If less than four RGA's are available, deselecting an RGA to protect for the next bus failure would leave the system at risk to any RGA LRU or power failure (while averaging or prime selecting), so no action will be taken.

FLIGHT RULES

A8-103

PRIORITY RATE LIMITING (PRL) SYSTEMS MANAGEMENT

- A. MANUAL SYSTEMS MANAGEMENT WILL BE REQUIRED ANY TIME THE PRL SOFTWARE DOES NOT REFLECT THE CURRENT STATUS OF THE HYDRAULIC SYSTEMS.

Self-explanatory.

- B. DURING ENTRY, SINGLE APU PRL RATES ARE REQUIRED WHEN ONE HYDRAULIC SYSTEM IS DRIVING THREE OR MORE ELEVONS.

One hydraulic system cannot support the flow rate required to move three elevons at the maximum commanded rate of 30 degrees per second (ref. SODB 4.2.7.1.1). Short term pressure degradations (due to the high hydraulic fluid flow rate) would have an adverse effect on vehicle flight control due to sluggish or stalled elevon movement.

There are no concerns with the hydraulic flow required to support single APU rates with two hydraulic systems, regardless of how many elevons are being driven by one of the two systems.

The areas of concern for vehicle flight control are during the final flare maneuver and vehicle derotation, when actuator rates are at the highest. The risks associated with single APU drive rates during this timeframe are less than those associated with unequal elevon movement. Ascent load relief and entry prior to Mach 0.6 are not of concern for this case, since the nominal actuator rates are not high enough to cause significant pressure degradation. (Ref. A/E Flight Techniques Panel #69, July 20, 1990.)

FLIGHT RULES

A8-104

FCS CHECKOUT

THE FCS CHECKOUT PART 1 (SECONDARY ACTUATOR CHECK) WILL BE PERFORMED, IF POSSIBLE, PRIOR TO THE DEORBIT BURN (PREFERABLY IN OPS 8). IF THE ACTUATOR CHECK CANNOT BE PERFORMED PRIOR TO THE BURN, IT WILL BE PERFORMED, IF POSSIBLE, IN MM 303. THE ACTUATOR CHECK WILL BE DONE UTILIZING AN APU OR HYDRAULIC SYSTEM CIRCULATION PUMP ACCORDING TO THE FOLLOWING PRIORITY:

- A. AN APU PREBURN.
- B. A CIRCULATION PUMP PREBURN.
- C. AN APU POSTBURN.

The primary purpose of the secondary actuator check is to test the aerosurface servo amplifiers (ASA's) for null driver failures. Two undetected null failures on an elevon could cause loss of vehicle control because the two good channels could be bypassed during a request for high surface rate (CIL 05-1-FC60402-1). The secondary purpose of the check is to test the secondary pressure transducers and the fault-detection circuitry in the ASA that issues channel bypass commands. (This test requires hydraulic system pressure greater than 2025 psi to be completely accomplished.)

It is preferable to perform the complete FCS checkout pre-deorbit burn to allow time to fully troubleshoot any flight control system failures. The first priority is to use an APU if possible. If one or more APU's have failed, MMACS will determine if it is safe to attempt starting a failed APU. If an APU cannot be used for the actuator check, then a hydraulic system circulation pump will be used, if possible, to do the check preburn.

When using an APU, the checkout procedure has the crew bypass any port that does not bypass when the stimulus is applied. A port may not bypass because of either a null driver failure (1R/2) or a fault detection circuit failure (1R/3). Without insight into secondary delta pressures, the crew must assume the worst case driver failure and manually bypass the port. Given time to review the data (i.e., for checks done preburn), the MCC can confirm which failure exists. For a fault-detection circuitry failure, the channel is considered to be good and the port will be reset.

When using a circulation pump, two things are given up because the hydraulic system pressure is not great enough. The rudder and speedbrake drivers cannot be checked because brakes will not allow these surfaces to move, and the fault-detection circuitry for all surfaces cannot be tested. These two things considered, it is still preferable to accomplish the check for null elevon drivers before committing to entry rather than to wait until after the deorbit burn to accomplish a more complete check.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-104**FCS CHECKOUT (CONTINUED)**

If the situation does not permit the actuator check to be accomplished with either an APU or circulation pump prior to the burn, the check will be performed in MM 303 if it is possible to do so. An APU will be used with its hydraulic pump in normal pressure even if only one APU is available for entry.

One polarity stimulus is sufficient to test for null failures; both polarity stimuli are required to fully test the fault-detection circuitry. If the check is done using a circulation pump or if it is done postburn, it will be abbreviated in that only one stimulus will be used. The abbreviated check is appropriate postburn because it minimizes the time required to perform the check.

The priorities are the same for early mission termination scenarios (AOA, next PLS, MDF) with or without APU/hydraulic systems failures. Considerations of whether to perform the check when entering early include crew workload, other systems failures, and APU hot restart constraints.

Reference Rules {A10-21}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS; {A10-29}, FCS CHECKOUT APU OPERATIONS; and Ascent/Entry Flight Techniques Panel Meeting #47, Continuation, August 29, 1988.

Rules {A10-21}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS, and {A10-29}, FCS CHECKOUT APU OPERATIONS, reference this rule.

FLIGHT RULES

A8-105**CONTROLLERS**

IF TWO CHANNEL FAILURES OCCUR ON AN RHC, THE REMAINING TRANSDUCER WILL BE PRIME SELECTED, IF POSSIBLE, TO REGAIN THE CONTROLLER FUNCTION AND THE RHC WILL THEN BE POWERED OFF. THE RHC MAY BE POWERED AT ANY TIME IF REQUIRED FOR VEHICLE CONTROL. IF THE FAILED RHC IS ON THE CDR'S SIDE, THE CDR WILL FLY THE VEHICLE DURING APPROACH AND LANDING AS LONG AS THERE HAS BEEN NO MORE THAN ONE TRANSDUCER FAILURE.

If two channels of an RHC fail, prime-selecting the one remaining transducer permits use of that RHC. The RHC is powered off to preclude a failure of the remaining good transducer which could cause inadvertent jet firings, incorrect aerosurface commands, or loss of vehicle control. This implies that if the left (CDR) RHC is failed, then the vehicle must be flown using the right (PLT) RHC, either by the PLT or by the CDR after changing seats. Since the CDR and PLT are most proficient in systems knowledge and operation on their respective sides of the cockpit and the CDR is more highly trained to fly the vehicle, it is strongly desired that the CDR fly the vehicle whenever possible and only from the left seat. The only danger in using the remaining channel (pitch and roll transducer) is if it should fail when the orbiter is extremely close to the ground. This would be a third failure and would have to be a smart failure as well, since it would have to occur in a very narrow bandwidth of time after having successfully functioned for most of the approach. Since each member of the crew is highly trained to perform specific functions during the approach and landing, there is a much greater risk involved with altering these functions just to protect for a highly unlikely smart, third failure. If there is no reason to suspect the reliability of the remaining channel (pitch and roll transducer), i.e., its outputs are normal and both previous failures were not due to transducer problems, then there is an acceptable risk in using that RHC (two transducer failures could indicate a possible generic problem). Therefore, as long as the last remaining channel (pitch and roll transducer) on the CDR's RHC has good outputs and is believed to be reliable, the CDR will fly the vehicle during approach and landing.

Rules {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A8-106

TVC-SSME STOW/ACTUATOR FLUID FILL (REPRESSURIZATION)

- A. IF SSME STOW PROBLEMS OCCUR AT THE END OF ASCENT, THE APU'S WILL BE SHUT DOWN ON TIME AND THE STOW OPERATION WILL BE COMPLETED ON ENTRY DAY.

It is possible, under certain conditions, to not achieve SSME stow during ascent. Because the last commands issued are carried across OPS transitions, if the stow commands are not sent before the stow sequence is halted in OPS 1, the SSME's will not be commanded to stow in OPS 3. Thus, a transition to OPS 8 is required since the stow commands are issued upon transition. If the stow commands are sent before the sequence is halted, the stow commands will carry over across the OPS 3 transition.

- B. SSME ACTUATOR FLUID FILL USING FULL HYDRAULIC PRESSURE WILL BE PERFORMED ON ENTRY DAY ON ALL ACTUATORS OF ALL THREE ENGINES EXCEPT FOR THE FOLLOWING CONDITIONS:
1. THE DIFFERENCE BETWEEN ANY COMMAND (AVERAGE OF THE ACTIVE ATVC DRIVER OUTPUTS) AND THE INDICATED POSITION IS GREATER THAN 2 DEGREES. FOR ACTUATORS THAT ARE SUSPECTED TO HAVE A BIASED POSITION TRANSDUCER (SINGLE STRING), DATA FROM PAST FLIGHTS OF THAT ACTUATOR WILL BE USED TO ASSESS THE LIKELIHOOD OF ACTUALLY MOVING THE ACTUATOR MORE THAN 2 DEGREES.
 2. MAIN ENGINE POSITION DATA IS NOT AVAILABLE AND DATA BEFORE THE LOSS INDICATES THAT A STEP OF 2 DEGREES OR MORE IS POSSIBLE.

EVERY ATTEMPT WILL BE MADE TO AVOID VIOLATING THE 2-DEGREE STEP CONSTRAINT, INCLUDING STARTING AN APU ON ORBIT TO PERFORM SSME FLUID FILL.

Fluid fill and engine repositioning is required due to hydraulic fluid shrinkage after cooling down which may result in engine movement of 2 to 3 degrees in each axis. A 2- to 3-degree movement from the stow position would result in exceeding the design nozzle temperature limits (aerodynamic heating) on engines 2 and 3 (left and right ME's). Two APU's will repressurize all three engines. One APU will repressurize two ME's (ref. Rule {A10-21B}, LOSS OF APU/HYDRAULIC SYSTEM (S) ACTIONS).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-106

TVC-SSME STOW/ACTUATOR FLUID FILL (REPRESSURIZATION) (CONTINUED)

SSME steps greater than 2 degrees (indicated) under full hydraulic pressure risk damage (possible rupture) to the hydraulic lines and subsequent loss of that hydraulic system. The average of the active ATVC driver outputs are used in the differencing scheme (as opposed to the software command) to eliminate the uncertainties in the command path. The 2-degree constraint takes into account the transducer uncertainty (ref. SODB 3.4.5.1h.1). Since some SSME TVC actuator position transducers have shown biases and scale factors in the position output, a false indication of the command/position delta could lead to multiple APU starts and SSME represses. For a suspected bias in the transducer (single transducer through MDM OAI), data from the post-MECO stow position and past hydraulic represses of that actuator will be used to assess the likelihood of actually moving the actuator more than 2 degrees. The flight history data will be obtained from the SSME actuator and hydraulics subsystem managers through a SPAN-MER chit.

Main engine position data are used by the MCC to ensure the 2-degree constraint will not be violated. If position data is lost, an attempt will be made to determine if a 2-degree step is likely. The command/position delta at the time of loss of data, the drift rate at the time of loss of data, and previous flight history are factors that will be used to aid in this determination.

Wind tunnel testing indicates that movement of a main engine nozzle from its stow position during entry increases aerodynamic heating on that nozzle. Not performing SSME fluid fill increases the possibility that nozzle damage will occur during entry.

This rule is referenced by Rule {A8-107}, FCS CHANNEL MANAGEMENT.

FLIGHT RULES

A8-107

FCS CHANNEL MANAGEMENT

- A. FOR RESTRING CASES DUE TO GPC FAILURES, ASA AVAILABILITY (VIA FCS CHANNEL SWITCHES) WILL BE MANAGED SO THAT EACH GPC IN THE REDUNDANT SET WILL BE ASSIGNED AN EQUAL NUMBER OF ASA'S. WITH NO ADDITIONAL FAILURES, THE GPC/FCS CHANNEL ASSIGNMENTS WILL BE:

FOUR GPC'S - FOUR CHANNELS IN AUTO, ONE CHANNEL PER GPC.

THREE GPC'S - THREE CHANNELS IN AUTO, ONE CHANNEL PER GPC, ONE CHANNEL OFF.

TWO GPC'S - FOUR CHANNELS IN OVERRIDE, TWO CHANNELS PER GPC.

ONE GPC - FOUR CHANNELS IN AUTO.

If each GPC does not control an equal number of FCS channels, subsequent failure of the GPC that has the larger number of channels could cause good ports to be bypassed resulting in a loss of vehicle control. Ports are taken offline by taking the FCS channel power to OFF.

To equalize channels for the three GPC-four FCS channel case, one FCS channel must be turned off. It is desirable to turn off FCS channel 4 since both the bodyflap and the BFS use channels 1-3. On OV-102, this will result in the loss of high rate ACIP data, but low rate data is considered acceptable. For the two-GPC case, having all channels in override will prevent loss of good ports for the next GPC failure. In this case, rapid crew action will still be required to turn off the channels on the failed GPC, but this is the safest configuration of all of the options. With one GPC, the next GPC failure cannot be accepted, but the auto system will operate properly for FCS channel problems.

- B. FOR AN FA MDM OR GPC FAILURE DURING ASCENT OR ENTRY, THE CORRESPONDING FCS CHANNEL WILL BE TURNED OFF.

When an FA MDM fails or a GPC fails to halt or sync, its actuator commands are no longer valid. The FCS channel, if left powered, would cause a force fight with the other good channels. It is appropriate to turn the FCS channel OFF, which will bypass that channel. It will also eliminate the possibility of a subsequent failure causing a two-on-two force fight.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-107****FCS CHANNEL MANAGEMENT (CONTINUED)**

- C. DURING OPS 1, 3, OR 6 IF ANY OF THE FIRST THREE FCS CHANNELS ARE TURNED OFF, THE CORRESPONDING POSITION FEEDBACKS WILL BE DESELECTED. IF FCS CHANNEL 4 IS TURNED OFF, THE CORRESPONDING FEEDBACKS WILL NOT BE DESELECTED UNLESS THERE IS A POSITION FEEDBACK FAILURE ON ONE OF THE FIRST THREE FCS CHANNELS.

Deselection of feedbacks is performed on CONTROLS SPEC 53, which is available in OPS 1, 3, and 6. Crew item deselection removes all feedbacks on the associated FCS channel. For the first three FCS channels, feedbacks should be deselected any time the channel is turned off. This action allows FCS channel 4 feedbacks to be used and protects against failing the position feedbacks on the unpowered channel if the failure that caused the channel to be turned off is subsequently recovered. If there are no other FCS channel position feedback problems, position feedbacks should not be deselected on FCS channel 4 when it is turned off. This action will allow FDIR to isolate a problem on FCS channels 1, 2, or 3 without requiring the position feedbacks to be deselected on all aerosurfaces of the affected channel. It is not critical to protect the rudder or speedbrake position feedbacks. The rudder feedback is only used for crew display on the surface position indicator (SPI). The speedbrake position is used to set a pitch trim rate gain in the AEROJET DAP and for crew display on the SPI. Since the bodyflap uses a QMVS selection filter, no action is required for the bodyflap position feedbacks. Feedbacks are deselected in OPS 1 to ensure a good feedback configuration is available should an abort be required.

- D. IF A SINGLE CHANNEL IS FAILED BUT NOT BYPASSED, THE REMAINING CHANNELS WILL BE PLACED IN "OVERRIDE".

This action protects for the next GPC/MDM/LRU failure. If the channels are left in auto, the next failure could cause both good channels to be bypassed resulting in loss of vehicle control. By placing the remaining channels in override, we inhibit port popping of the good channels. The FCS system must now be managed manually, using ground calls. Reference RI-Downey Internal Letter 283-430-81-075.

- E. WHEN ONLY TWO GOOD FCS CHANNELS REMAIN ON A SINGLE ACTUATOR, BOTH WILL BE PLACED IN "OVERRIDE".

This action protects for the next GPC/MDM/LRU failure. If the channels are left in AUTO, the next failure could cause the good channel to be bypassed resulting in loss of vehicle control. In override, the next failure will result in a one-on-one force fight which is preferred because it may allow the crew time to secure the bad channel and engage BFS to recover good channels. One channel control is not certified. The FCS channels in override must be managed manually. Reference RI-Downey Internal Letter 283-430-81-075.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-107

FCS CHANNEL MANAGEMENT (CONTINUED)

- F. WHEN MOVING MULTIPLE FCS CHANNEL SWITCHES FROM "AUTO" TO "OVERRIDE" OR "OVERRIDE" TO "AUTO", A 2-SECOND DELAY BETWEEN INDIVIDUAL SWITCH ACTUATIONS WILL BE MAINTAINED.

The FCS switches are of the break-before-make type. When moved from one position to another, power to the FCS channel is temporarily interrupted. When power is interrupted, logic inside the ASA causes power to remain off for at least 510 msec and for as long as 1370 msec regardless of how fast the FCS switch is moved (ref. RI-Downey Internal Letter 283-220-86-009). The affected channel is bypassed during the time that the ASA power is off. If multiple channel switches are actuated at the same time, an aerosurface may have no active ports controlling it because all ports have been bypassed due to previous failures and/or switch actuations. This could cause the surface to go hardover which would cause a transient in the flight control system.

- G. IN OPS 3 OR 6, AN AEROSURFACE PORT WILL BE MANUALLY BYPASSED IF IT IS FORCE FIGHTING OTHER CHANNELS WITH A SECONDARY DELTA PRESSURE OF 1400 PSI OR GREATER.

The ASA hardware has built-in fault detection that will bypass a port if its secondary delta pressure is greater than 2025 psi. This limit is a compromise; it is high enough to avoid transient failures of good channels yet low enough that a bad channel will likely be isolated. Also, the ASA has a redundant channel equalization function designed to compensate for variation of hardware tolerances. By design, equalization should prevent a port with no hardware failure from being bypassed. The effect of equalization is fully realized when the secondary delta pressure for the affected port has reached about 1400 psi (ref. SODB volume III, par. 4.5.1.1.1).

The intent of this rule is to allow for manual isolation of a port that has a failure below the hardware fault detection limit of 2025 psi, but above equalization (1400 psi). This action protects for the next worst failure which could result in a two-on-two force fight. A two-on-two is an uncertified FCS configuration and could cause bypass of the two good FCS channels resulting in loss of control during entry. No action is required in OPS 1 because aerosurfaces are not used for control. (The capability to manually bypass a port exists in OPS 1, 3, 6, and 8.)

- H. DURING OPS 3, FCS CHANNEL MANAGEMENT TO REGAIN ATVC REDUNDANCY WILL NOT BE PERFORMED IF IT RESULTS IN A LOSS OF ASA SINGLE FAULT TOLERANCE.

FCS channel management to optimize ATVC's in OPS 3 would only be performed to provide fault tolerance for drag chute repositioning. Aerosurface control redundancy will not be jeopardized to reposition SSME bells for drag chute deployment since the drag chute can be deployed, if required, without SSME repositioning. Reference Ascent/Entry Flight Techniques Panel meeting #84, November 15, 1991, DRAG CHUTE IMPACTS.

@[041196 1883]

FLIGHT RULES

This rule references Rule {A8-106B}, TVC-SSME STOW/ACTUATOR FLUID FILL (REPRESSURIZATION).

A8-108 HUD/COAS SYSTEM MANAGEMENT

- A. IF EITHER STAR TRACKER IS SUSPECTED OF BEING FAILED, THE CALIBRATION PROCEDURE FOR THE CDR HUD WILL BE PERFORMED WITHIN 24 HOURS. IF AN UPDATE IS REQUIRED, THE PROCEDURE WILL BE RUN AGAIN WITHIN 24 HOURS TO VERIFY THE CALIBRATION
 ©[111094-1723A]

If a star tracker is lost and the CDR HUD is not calibrated, the capability to perform an entry alignment is zero-fault tolerant. The calibration procedure should be run for the CDR HUD to ensure the SODB specified COAS IMU alignment accuracy for entry is met. During the procedure, if the delta bias is large enough that an update is required, the procedure should be run again within 24 hours to verify the accuracy of the calibration. Although the HUD flight data has shown no significant in-flight line-of-sight (LOS) shifts, it is prudent to ensure it will provide the best possible IMU alignment capability if required. (Ref. Rule {A8-12}, HEAD UP DISPLAY (HUD) AND CREW OPTICAL ALIGNMENT SIGHT (COAS) ALIGNMENT). (Ref. On-Orbit FTP meeting #133, October 9, 1992, HUD/COAS CALIBRATION and On-Orbit FTP meeting #148, September 9, 1994, HUD/COAS CALIBRATION STATUS.)

- B. THE SECONDARY STATION CALIBRATION WILL BE PERFORMED AS SOON AS PRACTICAL UPON LOSS OF THE PRIMARY STATION IF A STAR TRACKER IS FAILED.

A calibrated device at one station is required. If it has been determined that the calibrated device has been lost (e.g., loss of power or an obstructed window), the other station will be calibrated to meet the requirements in paragraph A of this rule. As backups to the star trackers for IMU alignments, the CDR HUD is the primary station and the PLT HUD/-Z COAS is the secondary station. (Ref. On-Orbit FTP meeting #148, September 9, 1994, HUD/COAS CALIBRATION STATUS.)

- C. THE SECONDARY STATION WILL BE CALIBRATED IF THE CABIN IS AT A PRESSURE DIFFERENT FROM THE PRIMARY STATION CALIBRATION AND A STAR TRACKER IS FAILED.

There is insufficient data to state that a decrease in cabin pressure to 10.2 psi will or will not cause a HUD/COAS line-of-sight shift large enough to violate the 0.5 degree EI IMU alignment accuracy requirement for entry (ref. Rule {A4-151}, IMU ALIGNMENT). Therefore, if a star tracker is lost, a HUD/-Z COAS calibration is required for fail-safe redundancy to perform an entry IMU alignment. Using the CDR or PLT HUD and the alternate software location for the calibrated vector is acceptable to meet the intent of this rule which is to provide a calibrated device at both cabin pressures. ©[111094-1723A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-108 HUD/COAS SYSTEM MANAGEMENT (CONTINUED)

- D. IT IS HIGHLY DESIRABLE THAT HUD/COAS CALIBRATIONS BE IMMEDIATELY PRECEDED BY A STAR TRACKER IMU ALIGNMENT.
@[111094-1723A]

HUD/COAS calibration accuracy is directly dependent on IMU misalignment. This is a controllable error source and should be minimized.

- E. IF BOTH STAR TRACKERS ARE SUSPECTED OF BEING FAILED, THE SECONDARY STATION WILL BE CALIBRATED AS SOON AS POSSIBLE.

If both star trackers are failed, the CDR HUD will be the primary device for performing IMU alignments. Since the HUD is zero fault tolerant (e.g., power failure), a PLT HUD/-Z COAS calibration is required for fail-safe redundancy to perform an entry IMU alignment. The PLT HUD/-Z COAS calibration should be performed as soon as possible to minimize IMU misalignment error and improve the accuracy of the calibration. @[111094-1723A]

A8-109 STAR TRACKER SYSTEM MANAGEMENT [CIL]

- A. BOTH STAR TRACKERS WILL BE CONTINUOUSLY POWERED FOR THE ON-ORBIT PORTION OF THE FLIGHT TO OBTAIN STAR-OF-OPPORTUNITY DATA. TRACKERS MAY BE POWERED OFF IF A PARTICULAR LONG DURATION ATTITUDE PRECLUDES GATHERING STAR-OF-OPPORTUNITY DATA.
- B. ONE STAR TRACKER DOOR WILL BE CLOSED IF A KNOWN FAILURE CONDITION EXISTS WHERE ONE ADDITIONAL FAILURE WOULD CAUSE BOTH DOORS TO BE FAILED OPEN. [CIL]

Star-of-opportunity alignments can decrease or eliminate the need to repeatedly perform maneuvers for IMU alignment, saving crew effort, time, and propulsion consumables.

Rockwell thermal studies (ref. SAS-TA-TPS-87-238, IL 294-400-87-071, and IL SAS-TA-RCC-78-160) have shown that entry with one star tracker door open results only in minor local damage due to stagnation conditions in a single opening cavity. In the absence of further studies showing that a two-door-open entry is also safe, conservative engineering judgment must assume that a plasma flow between the two doors could cause potentially catastrophic damage to the airframe, crew cabin, and/or navigation base.

Therefore, if the next electrical failure results in the loss of the last motor function on both doors, one door will be closed immediately to eliminate the potential for a two-door-open entry. Additionally, if one door is already stuck open, the other door will be closed immediately (even if redundant motor capability is available) in order to protect for a mechanical failure (e.g., door jam) that could result in a two-door-open entry (ref. CIL 02-4F-032001-1).

FLIGHT RULES

A8-110

IMU SYSTEM MANAGEMENT

- A. A PRE-DEORBIT IMU-TO-IMU ALIGNMENT WILL BE PERFORMED AT DEORBIT TIG - 70 MINUTES TO RESET THE IMU RM THRESHOLDS.

The pre-deorbit IMU/IMU alignment is required to reset the IMU RM thresholds. If the thresholds are not reset, then the IMU RM two-level attitude failure coverage during entry is drastically reduced. For no pre-deorbit IMU/IMU alignment, the probability of isolation for XY plane IMU errors at the two-level is 64 percent to 46 percent (decreasing with time) between EI and touchdown. The probability of isolation for Z-axis IMU errors (corresponds to critical orbiter vertical and down-range position and velocity errors) is 0 percent between EI and touchdown. In contrast, having performed the pre-deorbit IMU/IMU alignment, the probability of isolation for XY plane IMU errors at the two level is approximately 68 percent (reaching a max of 70 percent) between EI and touchdown. The probability of isolation for Z-axis (critical) IMU errors is 100 percent between EI and touchdown.

For deorbit wave-off cases, the pre-deorbit IMU/IMU alignment can be waved and performed one time only at the TIG - 70-minute point of the actual deorbit. For a wave-off declared after the IMU/IMU alignment has been performed, the alignment will be performed again at the next TIG - 70-minute point.

- B. THE PRE-DEORBIT STAR ALIGNMENT ON ENTRY DAY IS DEFINED AS CRITICAL.

IMU accuracy needs to be determined during the entry alignment and verification to assure that the IMU's will be within 0.5 degrees of desired attitude (RSS at EI) in order to protect the vehicle and crew during the entry phase (ref. Rule {A4-151}, IMU ALIGNMENT). The pre-deorbit alignment is currently the only identified critical alignment.

- C. ONBOARD ALIGNMENT VERIFICATION IS REQUIRED FOLLOWING ANY CRITICAL ALIGNMENT. DEORBIT WILL BE DELAYED ONE ORBIT, IF AVAILABLE, TO ALLOW THE OPS 3 STAR ALIGNMENT VERIFICATION TO BE COMPLETED.

The time element here is crucial. Any noncritical alignment results can be observed over some extended time period and verified by the MCC. Any problems discovered can then be corrected. However, a critical alignment must be as accurate as possible at that point in time, as the future provides little or no opportunity for correction.

- D. ONBOARD VERIFICATION IS NOT REQUIRED FOLLOWING NONCRITICAL ALIGNMENTS. VERIFICATION WILL BE ACCOMPLISHED BY THE MCC USING TELEMETERED STAR-OF-OPPORTUNITY AND RELATIVE MISALIGNMENT DATA.

Rationale same as for paragraph C.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-110

IMU SYSTEM MANAGEMENT (CONTINUED)

- E. IMU GYRO DRIFT TERMS WILL BE UPDATED WHEN THE DRIFT EXCEEDS 3 SIGMA IN ANY AXIS. COMPENSATIONS LESS THAN 3 SIGMA WILL BE DONE AS REQUIRED TO MINIMIZE LONG TERM, STABLE DRIFT.

Correcting large (3 sigma) gyro drift errors will maintain the IMU's in the best possible position to support contingency deorbit and orbiter and payload operations. An IMU drifting at 3 sigma (0.02 deg/hr) will not jeopardize the 0.5 degree entry misalignment constraint for over 25 hours but does indicate significant out-of-spec performance, which should be corrected. Gyro drifts of this magnitude need not be compensated immediately but should wait for reliable drift measurements. Gyro drifts of less than 3 sigma, but which are stable and of long duration (typically 8 hours or more), should be corrected to place the IMU's in the best possible configuration to support orbiter and payload activities, sleep periods, IMU align wave-offs, entry, and any contingencies. The 1-sigma drift value is 0.006 deg/hr (ref. SODB 4.5.1.2.3.q.2.a-2). ©[011291752A] ©[081497-4060A]

- F. IMU ACCELEROMETER BIAS TERMS WILL BE UPDATED WHEN THE ERROR EXCEEDS 3 SIGMA IN ANY AXIS. COMPENSATIONS LESS THAN 3 SIGMA WILL BE DONE AS REQUIRED TO MINIMIZE LONG TERM, STABLE ERRORS.

Correcting large (3 sigma) accelerometer errors will maintain the IMU's in the best possible position to support orbiter and payload activities and entry. A 3-sigma error indicates significant out-of-spec performance which should be corrected when a reliable error measurement is available. Accelerometer errors of less than 3 sigma, but which are stable and of long duration (typically 4 hours or more), should be corrected to place the IMU in the best possible position to support entry as well as to provide an extra margin of safety on orbit. The 1-sigma value is 50µG's (ref. SODB 4.5.1.2.3.q.1-b). ©[011295-1752A] ©[081497-4060A]

- G. THE IMU'S NEED NOT BE REALIGNED WITH STAR DATA TO SUPPORT A DEORBIT ON ORBITS 2 OR 3.

A worse case IMU (3 sigma in all axes) results in a total platform misalignment of 0.125 degrees (RSS) at EI for an orbit 3 deorbit which meets navigation's requirement of 0.5 degrees (RSS) (ref. Rule {A4-151}, IMU ALIGNMENT). An orbit 2 or 3 deorbit would be an emergency action, and an IMU alignment using stars would impact the crew timeline. This rule does not preclude the use of an IMU/IMU alignment to regain a failed IMU.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-110 IMU SYSTEM MANAGEMENT (CONTINUED)

H. IMU ALIGNMENTS WILL BE PERFORMED FOR LAUNCH DAY DEORBITS AFTER ORBIT 3 TO OPTIMIZE ENTRY NAVIGATION.

A 3-sigma HAINS IMU drift (in all axes) results in a total platform misalignment of 0.312 degrees (RSS) at EI for orbit 7 deorbit. This meets navigation's requirement of 0.5 degree (RSS) but is worse than the desired 0.25 deg at EI (ref. Rule {A4-151}, IMU ALIGNMENT). Using the scheduled alignment for these deorbit opportunities has no impact on the crew timeline workload and the align will be performed as required to optimize entry navigation. ©[011295-1752A]

I. THE CRITICAL ENTRY IMU STAR ALIGNMENT WILL BE REACCOMPLISHED AS REQUIRED IN ORDER TO PROTECT THE 0.5 DEGREE (RSS) ATTITUDE ERROR LIMIT (REF. RULE {A4-151}, IMU ALIGNMENT). IF A "NO-GO" FOR DEORBIT IS GIVEN PRIOR TO THE IMU ALIGNMENT, THEN, TIMELINE PERMITTING, THE ALIGNMENT WILL SLIP TO THE SAME RELATIVE PLACE AS NOMINAL WITH RESPECT TO THE NEW BACKUP DEORBIT OPPORTUNITY.

From the time of critical alignment for entry to the one orbit late backup orbit deorbit time, the IMU drift is still within requirements to support an entry without a realignment. If a NO-GO for deorbit is called prior to the entry alignment, it is best to move the alignment to the nominal pre-entry time to maximize IMU accuracy for entry (ref. A/E Flight Techniques #5, Sept. 9, 1983). ©[011295-1752A]

J. IMU STAR ALIGNMENTS WILL BE PERFORMED AS REQUIRED TO MAINTAIN THE ENTRY INTERFACE (EI) IMU ALIGNMENT CRITERIA. STAR ALIGNMENTS WILL BE SCHEDULED APPROXIMATELY ONCE PER FLIGHT DAY. ©[011295-1752A]

IMU star alignments will be performed periodically on orbit to ensure that the 0.5 degree (RSS) EI IMU alignment criteria is satisfied for contingency situations (ref. Rule {A4-151}, IMU ALIGNMENT). For nominal circumstances, the desired 0.25 degree alignment criteria will be maintained to ensure the best possible navigation performance during entry. IMU star alignments will be performed using either star-of-opportunity (SOO) data or star data acquired from dedicated orbiter maneuvers.

Scheduling star alignments once per flight day accounts for the expected IMU performance to ensure that the EI criteria is satisfied, while minimizing crew time and RCS propellant usage for alignments. ©[011295-1752A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-110

IMU SYSTEM MANAGEMENT (CONTINUED)

- K. IMU GYRO CALIBRATION WILL BE BASED ON A SET OF TORQUING ANGLES MEASURED AT LEAST 3 HOURS FROM THE TIME THE PREVIOUS SET OF TORQUING ANGLES WAS MEASURED.

For several hours postalignment, the misalignment uncertainty is as large as the actual platform misalignment. Therefore, reliable drift rates cannot be computed from torquing angles generated shortly after an alignment. As IMU misalignment grows with time, one can more accurately determine the true drift rate of the platform.

- L. CALIBRATION DATA WILL BE UPLINKED TO THE BFS, IF REQUIRED, AS SOON AS PRACTICAL ON ENTRY DAY. @[011295-1752A]

As the BFS has not been running on orbit, the gyro drift and accelerometer changes have only been made in the PASS. Thus, the BFS machine needs to be brought up to date with the PASS machine bias alterations by uplink as soon as practical on entry day.

- M. G-SENSITIVE TERMS WILL BE UPDATED IN-FLIGHT VIA UPLINK, BASED ON ANALYSES OF ASCENT PERFORMANCE AND PREDICTED CHANGES AS REQUIRED TO MAINTAIN 3 SIGMA LRU PERFORMANCE. @[011295-1752A]

Analysis of ascent data may indicate a scale factor problem (G-sensitive term) in an IMU. An uplink will be done to maximize performance. Due to the granularity of MCC programs, it will not be possible to guarantee any level of LRU performance.

@[111501-4906]

FLIGHT RULES

A8-111

GNC AIR DATA SYSTEM MANAGEMENT [CIL]

- A. AIR DATA WILL BE INCORPORATED INTO G&C BASED ON A REASONABLENESS ASSESSMENT OF h , M , AND ALPHA ONBOARD, AND A REASONABLENESS ASSESSMENT OF THE ALTITUDE (H-GROUND COMPUTED) AND RAW PRESSURES ON THE GROUND.

The crew is able to read h , M , and alpha onboard on their override SPEC. They can compare this to navigation data as we can on the ground. If the data agrees, within reason (reasonableness assessment), then the crew will pass the air data information into the flight control system. This assessment opportunity is used in solving dilemmas as well.

- B. IF ONLY ONE GOOD ADTA REMAINS, AIR DATA INPUT TO G&C WILL BE INHIBITED AND VEHICLE WILL BE FLOWN WITH "DEFAULT/NAVDAD" AIR DATA EXCEPT FOR THE FOLLOWING CONDITIONS WHEN A SINGLE GOOD ADTA WILL BE INCORPORATED INTO G&C:
1. BFS ENGAGE.
 2. BAD NAV STATE.
 3. HIGH WINDS ON THE HAC (? 80 KNOTS).
 4. ANYTIME THE ADDITIONAL BURDEN OF FLYING THETA LIMITS PRESENTS AN UNSATISFACTORY RISK OF LOSING CONTROL OR THE ABILITY TO MAINTAIN A SATISFACTORY GROUNDTRACK (CDR'S DISCRETION).

Incorporating air data (AD) to G&C when only a single ADTA remains may result in loss of vehicle control if that last remaining ADTA should fail. Numerous AD parameters (dynamic press, TAS, EAS, M , and alpha) are being used by the flight control system. Should the last remaining ADTA fail, no fault detection exists to identify or isolate this bad ADTA and loss of vehicle control could result before the crew or MCC can react. While a high piloting task, use of default AD/NAVDAD (flying "theta limits") is considered an acceptable flight control mode and should be used when only a single good ADTA remains.

The BFS, however, does not have default AD and, thus, resorts to NAVDAD alone for no AD. Also, the BFS itself is only single string. Therefore, when the BFS is engaged, incorporating the last ADTA into G&C is preferred.

In the event of a bad navigational state, air data incorporation would be required to G&C. Since NAVDAD/default air data utilizes navigation parameters (Vrel, altitude, drag decel, alpha, and vehicle mass), a bad navigation state, and in particular a bad Vrel, would be reason to incorporate AD to G&C when only a single ADTA remains.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-111

GNC AIR DATA SYSTEM MANAGEMENT [CIL] (CONTINUED)

High winds on the HAC would be another circumstance for which air data will be incorporated into G&C. For winds on the HAC ? 80 knots, the risk of LOC or excessive loss of energy due to the difficulty of the theta limits task exceeds the risk of utilizing the last remaining ADTA.

A single ADTA will be incorporated into G&C, at the CDR's discretion, in the event conditions arise which would significantly increase the possibility of loss of vehicle control or result in an unsatisfactory groundtrack if theta limits were flown. The crew task of flying "theta limits" should be avoided when circumstances arise such that the crew is not able to devote the attention required for this task. These circumstances include, but are not limited to, numerous other systems failures, health problems, etc. As a result, under these conditions, the risk associated with using a single ADTA will be accepted.

Reference Entry Flight Techniques Panel meetings #39 and #43.

- C. IF AIR DATA IS BEING INPUT TO G&C BELOW TAEM INTERFACE (< MACH 2.5), THE PITCH AXIS "CSS" MODE WILL BE SELECTED. "AUTO" MAY BE RESELECTED FOLLOWING INCORPORATION.

Dynamic pressure (Q-bar) and dynamic pressure rate (Q-bar dot) are currently not reinitialized for all ADTA SOP dynamic pressure source selection changes. Large, falsely derived Q-bar dot rates can occur during NAVDAD-to-air-data mode changes. In TAEM (M ? 2.5), an increase in Q-bar of the order that can occur during the NAVDAD-to-air-data mode change will result in a step in the normal acceleration command (Nzc). Pitch axis CSS mode will prevent the step Nzc change.

- D. WHEN ALL AIR DATA IS LOST OR NOT INCORPORATED INTO FLIGHT CONTROL, THETA LIMITS WILL BE ENFORCED. [CIL] @[041196 1870A]

If air data is not incorporated into G&C, flight control defaults to use a fixed value of alpha (7.5 degrees). Q-bar is derived from an I-loaded table as a function of navigation ground relative velocity (V_{rel}). Since guidance no longer limits alpha by protecting the low Q-bar boundary, it is necessary for the crew to follow theta limits on the vertical situation display. In this situation, the displayed alpha is not reliable. Keeping theta between the NOSE HI and NOSE LO region will ensure that the vehicle alpha is within acceptable limits. Allowing theta to exceed NOSE HI increases the chances of stall while allowing theta to fall below NOSE LO could cause Q-bar to increase to unacceptable limits. Keeping theta within limits also reduces energy dispersions. Although the speedbrake setting during Approach and Landing is affected by the lack of air data to G & C, off-line simulations have shown that when the speedbrake is left in auto, performance is generally better than when it is set to a predetermined position (reference AEFTP #128, 12/8/95). Therefore, the speedbrake will be left in auto and the setting evaluated for reasonableness. If the speedbrake setting is unreasonable, the crew may select manual speedbrake and set it as necessary. @[041196 1870A]

Rules {A2-261}, ENTRY DTO/AUTO MODE/CROSSWIND DTO GO/NO-GO, and {A8-1001}, GNC GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A8-112 AEROSURFACE ACTUATOR PROTECTION

TO PRECLUDE DAMAGE TO AEROSURFACE ACTUATORS, APU'S WILL NOT BE STARTED IN OPS 2. ALSO, ALL AVAILABLE AEROSURFACE AMPLIFIERS MUST BE "ON" PRIOR TO APU START (REF. RULE {A10-22G}, APU START/RESTART LIMITS).

By turning the APU's on while in OPS 2, we run the risk of damaging the aerosurface actuators by applying hydraulic pressure to the systems. Since OPS 1, the aerosurfaces may have drifted from their last commanded position such that, if the position delta is great enough at APU start, it could be possible to generate such a command force on the actuator that damage may occur. If the APU's have to be started on orbit, it is prudent to turn the ASA's on prior to transition to OPS 8 and APU start. The OPS 8 software for aerosurface control will be active so that at transition to OPS 8 the aerosurface commands will be made equal to their present position.

Rule {A10-22G}, APU START/RESTART LIMITS, references this rule.

A8-113 OMS TVC SYSTEM MANAGEMENT

A. FOR LOSS OF AN OMS TVC:

1. DURING PERIODS OF INACTIVITY, THAT OMS ENGINE WILL BE PARKED THOUGH THE NOMINAL EOM DEORBIT BURN CG AND THE TVC WILL BE POWERED OFF AS SOON AS PRACTICAL.

Parking the affected OMS engine through the cg and powering off the TVC protects against loss of that OMS engine for numerous single-point failures in the OMS TVC, failure of an FA MDM, or power failure. (Note: Loss of an FA MDM can result in loss of the remaining TVC on that engine, ignition redundancy on the other engine, and two +X RCS jets.) Given that the other OMS engine is usable, the procedure for parking that engine should be performed when practical.

2. OMS-1, OMS-2, AND THE DEORBIT BURN WILL BE PERFORMED TWO-ENGINE WITH TVC ACTIVE ON BOTH ENGINES.

As long as the other OMS engine is usable, sufficient redundancy exists to permit use of the remaining TVC for OMS burns. This is especially true for OMS-1, OMS-2, and the deorbit burn due to the criticality and time constraints of these burns.

3. IT IS PREFERABLE TO PERFORM ALL ON-ORBIT BURNS SINGLE ENGINE, USING THE OMS ENGINE WITH REDUNDANT TVC.

Given that OMS TVC redundancy is lost on one engine, it is preferable to perform all on-orbit burns single engine, using the OMS engine with redundant TVC. It is desired to leave the OMS engine with only a single TVC parked and powered off as much as possible to preserve it as a safe deorbit capability.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-113

OMS TVC SYSTEM MANAGEMENT (CONTINUED)

4. IF THE REMAINING TVC ON THE OMS ENGINE WITH THE FAILED TVC IS SUSPECT, POST-OMS-2 THAT OMS ENGINE WILL BE PARKED THROUGH THE NOMINAL EOM DEORBIT BURN CG ASAP AND POWERED OFF UNTIL AFTER THE DEORBIT BURN.

The purpose of this rule is to preserve the engine as a safe deorbit method. The engine should remain parked and powered off through the deorbit burn. The deorbit burn will be accomplished with that engine parked through the CG and TVC powered off. Post-deorbit burn, the engine should be powered on and driven to the entry stow position. (Ref. Rule {A8-53}, OMS TVC LOSS.)

5. IF THE AFFECTED OMS ENGINE IS THE LAST REMAINING OMS ENGINE :
 - a. OMS-1 WILL BE PERFORMED SINGLE ENGINE WITH TVC ACTIVE.
 - b. POST-OMS-1 THE OMS ENGINE WILL BE PARKED THROUGH THE CG ASAP AND POWERED OFF. OMS-2 AND ALL SUBSEQUENT OMS BURNS WILL BE PERFORMED SINGLE ENGINE, TRIMMED THROUGH THE CG WITH TVC OFF.

If the last OMS engine has only one TVC remaining, that engine should be parked through the CG and powered off as soon as possible to preserve it as a safe deorbit method. The first opportunity to park the engine is post-OMS-1 due to the time constraints and criticality of that burn. Since that engine is the last remaining engine, all OMS burns post-OMS-1 should be performed with the engine parked through the CG and TVC powered off. Even if RCS deorbit capability exists, parking the engine protects against the requirement for a next PLS entry for failure of the TVC. (Ref. Rule {A8-53}, OMS TVC LOSS.)

- B. FOR TWO-ENGINE BURNS WHERE ONE ENGINE IS TO BE BURNED WITH THE TVC POWER OFF, THE BURN WILL BE PERFORMED USING CG TRIMS.

For two-engine burns where one engine is to be burned with TVC power off, CG trims are required to protect for the loss of the engine with TVC on. Using CG trims places the OMS engine without TVC through the CG and enables the use of that engine if the engine with active TVC fails during the burn. (Ref. Rule {A8-53}, OMS TVC LOSS.)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-113 OMS TVC SYSTEM MANAGEMENT (CONTINUED)

C. OMS TVC GIMBAL CHECKS

1. THE NOMINAL OMS GIMBAL CHECK PLAN IN OPS 1 AND OPS 3 WILL CONSIST OF PERFORMING ONE GIMBAL CHECK OF BOTH PRIMARY AND SECONDARY SYSTEMS POST-OMS-2 AND IN MM 301 (PRE DEORBIT BURN) .

IN OPS 2, POSTBURN GIMBAL CHECKS WILL BE PERFORMED ON THE GIMBALS THAT ARE PLANNED TO BE USED DURING THE NEXT BURN. ONLY GIMBALS THAT WILL BE USED FOR TWO-ENGINE CRITICAL BURNS OR ANY SINGLE-ENGINE BURN NEED BE CHECKED.

A full system gimbal check performed post-OMS-2 and prior to deorbit burn will always be performed in order to assess the status of the TVC system. The gimbals, nominally, will not be checked prior to OMS-2 due to the time constraints and ground coverage available.

It is desirable to minimize gimbal checks on orbit to increase the lifetime of the TVC's. Hence, for any single-engine or two-engine critical burn, only the system(s) that have not been checked since their last active use will be checked. During single-engine burns, the nonburning engine TVC is still active (unless powered off) and being driven and so must be checked before subsequent selection as an engine to be burned, per the criteria above (two-engine critical or single-engine burn). Checking the gimbals immediately after the previous burn provides the maximum amount of time to troubleshoot any problem uncovered during the check.

2. UNSCHEDULED GIMBAL CHECKS WILL BE PERFORMED AS REQUIRED BY MCC FOR SYSTEM ANALYSIS TO TROUBLESHOOT ANY INDICATED OMS SYSTEMS ANOMALIES.

Gimbal checks will be performed on a system anytime the MCC believes there may be a problem with a gimbal system.

A8-114 ENTRY BODY BENDING FILTER SELECTION

THE PAYLOAD BODY BENDING FILTER WILL BE SELECTED FOR RETURNING PAYLOADS GREATER THAN 10,000 LB.

Selection of the payload body bending filter for returning payloads greater than 10,000 lb precludes the flex body high frequency oscillations which creates greater elevon deflections and increased APU fuel consumption. The 10,000-lb weight is representative of the weight for primary payloads (i.e., PAM's, IUS, Syncom, etc.).

FLIGHT RULES

A8-115

GPS SYSTEM MANAGEMENT

CERTIFIED SINGLE STRING GPS WILL BE CONSIDERED TO BE FUNCTIONING PROPERLY AND AVAILABLE FOR USE DURING ON-ORBIT AND ENTRY OPERATIONS GIVEN THE FOLLOWING CRITERIA: ©[092602-5643]

- A. NO COMMFAULT, HARDWARE, OR POWER FAILURES
- B. NO EXTENDED PERIODS OF HIGH FOM
 - 1. ORBIT FOM LIMITS - CAN BE > 175 FT (FOM > 2) FOR NO MORE THAN 5 MIN.
 - 2. ENTRY FOM LIMITS - CAN BE > 650 FT (FOM > 5) FOR NO MORE THAN 3 MIN.
- C. PERIODS OF TRACKING LESS THAN FOUR SATELLITES LIMITED TO NO MORE THAN 5 MIN.

GPS is certified to be used for on orbit as well as an additional entry navaid with the consideration given to the above criteria for evaluating the status and availability of GPS. The above limits for FOM and periods of tracking less than four satellites were established to meet the requirements for on-orbit state vector maintenance as well as loss of service requirements for entry certification. Antenna pointing, structural blockage, and other constellation and environmental surroundings should be considered as having a possible impact on the GPS's ability to track satellites and maintain low FOM conditions. These specifications will be used to consider mission duration impacts, single-fault tolerance, and zero-fault tolerance for orbit and entry operations. (Ref. AEFTP #176 July 27, 2001, #185 June 28, 2002)

Reference Rule {A2-102}, MISSION DURATION REQUIREMENTS.

Rules {A8-4}, FAULT TOLERANCE PHILOSOPHY; {A2-301}, CONTINGENCY ACTION SUMMARY; and {A8-58}, ADI LOSS, reference this rule.

When failure(s) require a next PLS entry but do not require a first day PLS entry, the rationale is that the risks associated with performing a first day PLS entry are greater than those associated with remaining on orbit until the next PLS opportunity.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

A. CONTROLLERS and SWITCHES

If necessary or desirable, most entry-critical controllers and switches can be reconfigured in OPS 8 and/or OPS 2 (ref. Rule {A8-6} CONTROLLERS/FCS SWITCHING FAULT TOLERANCE).

LH, RH RHC

For the loss of two RHC channels on the same controller, MDF is required. Subsequent failures can be tolerated on orbit, either by RM or by channel reconfiguration. For four or more RHC channels failed, the next failure results in the loss of at least one RHC, and possibly both. For five channels failed, a next PLS is required since the RHC's are zero-fault tolerant for manual flight of the vehicle. There are no first day PLS requirements for RHC channel failures, since an IFM will be done to recover the failed RHC.

LH THC

There are no first day PLS requirements for the left THC since an IFM will be performed to regain RCS deorbit capability, if required.

AFT RHC, THC

Loss of aft station capability does not require early mission termination since these systems are not available for entry (ref. Rule {A8-9}, AFT STATION GNC REDUNDANCY).

LH, RH RPTA

There are no mission duration impacts. Although manual control capability is desirable, RPTA control is not required for a safe entry.

LH, RH SBTC

For three SBTC channels failed on one side (loss of that SBTC) and one failed on the other side, MDF is required. The next failure, unless a commfault, will result in the loss of manual speedbrake operations. Reference A/E FTP #128, 12/8/95. ©[102402-5804C]

LH, RH BF UP and DN SW

There are no mission duration impacts since the body flap can be manually driven UP for any number of body flap UP/DOWN switch failures. Manual control is only required for off-nominal CG or aero conditions, to use the body flap as a trim device and allow better elevon control authority.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

LH, RH PANEL and RHC TRIM SW

These switches are not considered critical for entry and do not impact mission duration.

LH, RH BFS ENGAGE SW

Failures associated with the BFS engage switches do not require early mission termination (ref. Rule {A8-11}, LOSS OF BFS).

LH, RH FCS MODE AUTO SWITCH

For three or more FCS MODE AUTO switch (PITCH and ROLL/YAW) contacts failed (at least two failed one side, one failed other side), a next PLS is required. The system is zero-fault tolerant since the next failure results in no capability to mode the flight control system to AUTO.

LH, RH FCS MODE CSS SW

Failures in these switches are not considered critical and do not require early mission termination. RHC hot stick (to manual control) is available any time in OPS 3.

LH, RH FCS MODE BF A/M SW

The body flap will be in AUTO under most flight conditions, but manual (MAN) may be required (off-nominal CG or aero conditions). For two BF AUTO/MAN (A/M) switch contacts failed, changing the body flap flight control mode is single-fault tolerant, and MDF is required. For three or more contacts failed (at least two failed one side, one failed other side), a next PLS is required. At least two contacts on each side, or all three contacts on one side, are required to maintain single-fault tolerance on these switches.

LH, RH FCS MODE SB A/M SW

The SB A/M switch is used to mode the speedbrake from MAN to AUTO only, since MAN is achieved with the SBTC takeover switch. If the crew is required to take over MAN speedbrake and subsequent failures result in the loss of capability to mode back to AUTO, the crew can remain in manual with no added workload.

LH, RH SBTC TAKEOVER SW

Reference rationale for LH, RH SBTC rationale.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 **GNC GO/NO-GO CRITERIA (CONTINUED)**

ENTRY MODE

This switch is not considered critical for entry. For a failure of the switch during entry (LO GAIN or NO-YAW-JET), the AUTO position can be selected on SPEC 51, OVERRIDE, in MM 304/305.

ABORT MODE SW

This switch is used to select the bailout function and early mission termination is not required.

ORBIT DAP PBI's

If the COAS is required for entry IMU alignment, then MDF is required by definition of COAS/STAR TRACKER requirements. If any of the required switches is zero-fault tolerant (and the COAS is required for entry IMU alignment), then a next PLS will be declared.

B. TVC and DRIVERS

SSME ACT CHNL and SSME SEC DELTA P

These systems are not required for performing a safe entry (impacts to postlanding configuration and turnaround activities only).

SRB ACT CHNL and SRB SEC DELTA P

These systems are not used for entry, and mission duration impacts do not apply.

L, R OMS PITCH and YAW TVC

The two OMS engines and the four +X RCS jets constitute three means of deorbit capability. If failures of the left and/or right OMS TVC in combination with failures of the +X RCS jets result in the loss of two out of three deorbit methods, then a next PLS (or first day PLS) is required (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL], and Rule {A8-3}, LOSS OF GNC SYSTEM).

FORWARD RCS JETS

The forward RCS jets are not considered critical for entry. Reduction of mission duration is not required for failures of these jets.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)****L, R RCS JETS LEFT and RIGHT (YAW JETS)**

For one yaw jet failed and the orbiter CG outside of the nominal EOM boundary (ref. Rule {A4-153}, CG PLANNING), a next PLS is required due to the potential for elevon saturation. A full complement of yaw jets is required to ensure vehicle control within the contingency CG envelope. The loss of three yaw jets on the same side results in significantly degraded flight control in the low Q -bar regime (Q -bar < 20 psf). Therefore, a next PLS is required after two yaw jet failures, without regard to vehicle CG. There are no first day PLS requirements for the loss of these jets because the no-yaw-jet mode is certified (Q -bar > 20 psf) for flight control (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]; Rule {A8-19}, YAW JET DOWNMODE; and EFTP, 1/15/88).

L, R RCS VERNIER JETS

The loss of these jets has no impact on mission duration.

L, R RCS JETS UP and DOWN

For the loss of any two jets on the same side that fire in the same direction (two LEFT UP firing, for example), a next PLS (or first day PLS) is required. These jets are critical for vehicle pitch and roll control during entry, and entering next PLS reduces the risk for the next failure which could impact vehicle control (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]).

L, R RCS JETS AFT (+X JETS)

If failures of the left and/or right OMS TVC in combination with failures of +X RCS jets result in the loss of two out of three deorbit methods, then a next PLS (or first day PLS) is required. There are no mission duration requirements for loss of these jets alone (ref. Rule {A6-1001}, OMS/RCS GO/NO-GO CRITERIA [CIL]).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

C. AEROSURFACES

FCS CHANNELS

For one channel failed (any surface) the FCS is single-fault tolerant, with the exception of certain “smart failures” during specific windows of entry, and there are no mission duration impacts (ref. Rule {A8-4}, FAULT TOLERANCE PHILOSOPHY). The risk of sustaining a second failure in the FCS affecting the same aerosurface (ASA, MDM, or actuator) while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, MISSION DURATION REQUIREMENTS. After the first failure, there are certain failures in the FCS command channels (ASA, servo valve, actuator) which could reduce flight control margins (2-on-1 force fight) for short periods during entry until the MCC and crew can isolate the bad channel. However, the risk of sustaining one of these failures at the three-level on the FCS command channels during entry is the same regardless of when entry occurs (i.e., the window-of-exposure is the same regardless of flight duration). For two channels failed on the same aerosurface, a next PLS (or first day PLS) will be declared. PLS landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. Loss of three command channels on any aerosurface is an uncertified flight mode. ©[121296-4610] ©[102402-5804C]

BF ACT CHNL

For one of three bodyflap (BF) channels failed, BF control is single-fault tolerant, and there are no mission duration impacts (ref. Rule {A8-4}, FAULT TOLERANCE PHILOSOPHY). The risk of sustaining a second BF channel failure while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, MISSION DURATION REQUIREMENTS. For two channels failed, next PLS is required since BF control is zero-fault tolerant. It is required to maintain control of the BF in order to avoid off-nominal flying configurations and to prevent damage to the main engine bells and/or the body flap itself. There are no first day PLS requirements for BF channel failures. ©[121296-4610]

ELEVON/BF POS FDBK

For two elevon or body flap position feedbacks failed on the same surface, MDF is required since the system is single-fault tolerant. For three feedbacks failed on the same surface, the system is fail critical and a next PLS (or first day PLS) is required. However, if the affected port is bypassed, then the FCS channel loss criteria will apply (ref. A/E FTP #45, 6/17/88).

RUDDER and SPDBK POS FDBK

The position feedbacks for these surfaces are not used in the aerojet DAP but are used for surface position indications on the SPI. Although desirable, these indications are not considered critical for entry and there are no mission duration impacts associated with them. However, if the affected port is bypassed, then the FCS channel loss criteria will apply (ref. A/E FTP #45, 6/17/88).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001 GNC GO/NO-GO CRITERIA (CONTINUED)

ELEVON PRI DELTA P

For two elevon primary delta pressure indications failed on the same surface, MDF is required since the system is single-fault tolerant. For three failed, a next PLS is required because the system is zero-fault tolerant. The effector system requires at least one primary pressure feedback loop in an actuator since the ASA relies on these pressure indications to provide command stability (ref. SODB, volume I, paragraph 3.4.5.1-4).

SECONDARY DELTA P

The aerosurface and SSME/SRB actuator secondary delta pressure transducers provide fault detection (RM) in the ASA's and ATVC's, respectively. If RM is lost, the system can still be managed (MCC required) and any failed channels can be manually bypassed if required. FCS channel loss criteria will apply for transducer failures that degrade the FCS performance/redundancy.

D. SENSORS

LATERAL AA

For two lateral axis AA's failed, an MDF is required and, for three failed, a next PLS (or first day PLS), is required. Landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. The lateral axis AA feedback is used in the aerojet DAP for turn coordination by preventing rolloff during bank maneuvers. The lateral feedback is also used for NWS control during rollout (ref. A/E FTP #45, 6/17/88). ©[102402-5804C]

NORMAL AA

The normal AA feedback is used for ADI pitch error and alpha error indications only prior to MM 305. In MM 305, the normal AA feedback is used by guidance to provide Nz commands to the flight control system. However, failures in these feedbacks do not require reduction in mission duration because the crew can fly CSS in the pitch axis in MM 305, thereby removing the normal feedback from the command loop.

ORBITER RGA

For two orbiter RGA's failed, MDF is required because the system is single-fault tolerant on orbit. For three failed, a next PLS (or first day PLS) is required because the system is zero-fault tolerant on orbit. Landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. (ref. A/E FTP #45, 6/17/88). ©[102402-5804C]

SRB RGA

These systems are not used for entry, and mission duration impacts do not apply.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)IMU

For the loss of one IMU, the system is single-fault tolerant, with the exception of certain “smart failures” during specific windows of deorbit and entry, and there are no mission duration impacts (ref. Rule {A8-4}, FAULT TOLERANCE PHILOSOPHY). The risk of sustaining a second IMU failure while on-orbit for the remainder of the mission (NEOM) will be assessed in real time as required per Rule {A2-102}, MISSION DURATION REQUIREMENTS. Also, high-speed C-band radar is mandatory for entry at the IMU two-level (ref. Rule {A3-1}, GROUND AND NETWORK DEFINITIONS). There are single-point failures that can result in either an unresolvable dilemma at the two-level, or bad selected data due to a transient output which is not present long enough for IMU RM to operate and declare a failure. For these cases, the onboard state vector and/or vehicle flight control could be significantly impacted during critical deorbit or entry phases. However, the risk of sustaining one of these failures at the two-level during entry is the same regardless of when entry occurs (i.e., the window-of-exposure is the same regardless of flight duration). Additionally, it is expected that the IMU entry two-level redundancy management (RM), including the use of BITE, will correctly isolate and reconfigure the system (prime selecting the good IMU) for at least 98 percent of all failures. For two IMU’s failed, a next PLS (or first day PLS) is required. The system is zero-fault tolerant because navigation and flight control require one IMU for entry. Landing site selection will be determined per Rule {A2-207}, LANDING SITE SELECTION. ©[041196-1914] ©[121296-4610] ©[ED] ©[102402-5804C]

STAR TRACKER/COAS/HUD ©[111298-6750]

If only one instrument for aligning the IMU’s remains, enter next PLS. It is important to note that in considering the availability of manual alignment instruments, an instrument can only be considered available if it has been calibrated and verified. An instrument that is not calibrated and verified should not be used to perform IMU alignments. Only the CDR HUD is considered calibrated at launch (except on OV-104). This calibration should be verified before using the HUD to perform IMU alignments. Refer to Flight Rule {A8-108}, HUD/COAS SYSTEM MANAGEMENT.

The only exception to the PLS rule is the case where the -Z COAS is the only instrument remaining for performing IMU alignments. Since the probability of a COAS failure is considered extremely remote (COAS is a simple mechanical apparatus), the mission can be extended beyond next PLS to MDF.

If a manual alignment instrument is required, it is necessary to have the appropriate digital auto pilot (DAP) modes available. The DAP modes are required to allow the crew to mark accurately on a star.
©[111298-6750]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)**ATT REF PB**

The ATT REF PB is required for IMU alignments using the COAS or HUD. If the COAS and/or HUD is required for the entry and only a single ATT REF PB remains, a next PLS is required. It should be noted that only the forward station ATT REF PB's are supported in OPS 3; and, if only the aft PB remains, the alignment will have to be performed in OPS 2. ©[111298-6750]

TACAN AND SINGLE STRING GPS

*For three of four Entry Nav aids (TACAN's and/or Single String GPS) failed, the system is single-fault tolerant (assuming command delta state capability exists), and MDF is required. For three of four LRU's failed, enter next PLS if high-speed C-band radar is not scheduled and not available to be scheduled for entry (ref. Rule {A3-1}, **GROUND AND NETWORK DEFINITIONS**). For all four Entry Nav aids failed, a next PLS is required to protect for the loss of CONUS site capability. Entry with no TACAN's or GPS could require a GCA and/or a command delta state uplink to correct navigation errors, and declaring next PLS minimizes exposure to landings that do not have these options. Consideration must be given to Data and Power Bus configurations to ensure that fault tolerance exists for remaining TACAN and GPS LRU's. If fault tolerance does not exist, then a PLS landing is required (ref. EFTP #28, #29, #30, #176, #185). ©[041196-1914] ©[092602-5718]*

TACAN MODE SW, ANT SEL, CHNL SEL

The TACAN mode switch, antenna select, and channel select are not critical for entry. If the switch failures render the TACAN(s) unusable, then the TACAN loss criteria will apply.

ADTA

*For two ADTA's failed, the system is zero-fault tolerant and MDF is required. With the next failure (three ADTA's failed), air data (AD) will not be incorporated into G&C except for specific off-nominal circumstances, and a next PLS (or first day PLS) is required. Landing site selection will be determined per Rule {A2-207}, **LANDING SITE SELECTION**. The incorporation of AD to G&C is required for auto flight control and very desirable for manual. It is highly desirable to protect against the last ADTA failure so that it can be used if necessary. Without AD, the crew will fly theta limits for pitch control (ref. A/E FTP #45, 6/17/88, ENTRY FTP #34, 8/21/87, and A/E FTP #187, 9/20/02). ©[102402-5894C] ©[102402-5804C] ©[102402-5804C]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)

MSBLS

There are no requirements for early mission termination for MLS failures, since in most cases a safe landing can be performed without the use of MLS (ref. Rule {A8-18}, LANDING SYSTEMS REQUIREMENTS). However, for one MLS failed and MLS redundancy required (ref. Rule {A3-202}, MLS), high-speed C-band radar should be scheduled as required (ref. Rule {A3-1}, GROUND AND NETWORK DEFINITIONS). ©[041196-1914] ©[ED]

RA

The radar altimeters are used for altitude source from 5k feet to the ground and are highly desirable for night landings and/or low ceilings. However, there are no mission duration impacts for RA failures. (Ref. Rule {A8-18}, LANDING SYSTEMS REQUIREMENTS.) ©[072398-6646]

E. DEDICATED DISPLAYS

LH & RH ADI

Declare MDF when only one forward ADI remains since only a single display source of bank angle (phi) and vehicle rates and errors remains. Bank angle is required during MM 304 for controlling drag and H-dot in the event of bad guidance. Similarly, vehicle rates and attitude errors are required in the event of guidance or flight control problems. Given the availability of replacement units for both the ADI and DDU (aft station), two failures are required in order to have only a single remaining ADI in the forward station.

AFT ADI

There is no requirement for this display during entry. (Ref. Rule {A8-9}, AFT STATION GNC REDUNDANCY.)

HUD/AMI

Equivalent air speed (EAS), displayed on the HUD and AMI, is a critical parameter from TAEM to touchdown. As a result, declare PLS for loss of three of the four sources for this parameter, and MDF for loss of two of the four sources for this parameter.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A8-1001

GNC GO/NO-GO CRITERIA (CONTINUED)HUD/AVVI

Altitude (H), displayed only on the HUD and AVVI from TAEM to touchdown, is a critical parameter required by the pilot during the approach and landing phases of the entry. Thus, declare PLS for loss of three of the four sources for this parameter, and MDF for loss of two of the four sources for this parameter.

While H -dot, displayed only on the AVVI in MM 304, is an important parameter, early flight termination will not be declared for the loss of one AVVI. It is not reasonable to declare early flight termination to protect for the extremely remote scenarios (if they exist at all) where H -dot would be required to fly a manual MM 304 entry.

HUD/FWD ADI

Phi (bank angle) and one of gamma (flight path angle) or theta (pitch) are required from TAEM through the approach phase of entry. These parameters are only available to the pilot on the HUD and forward ADI. Thus, declare PLS for loss of three of the four sources for these parameters, and MDF for loss of two of the four sources for these parameters.

HUD

The HUD is highly desirable but not mandatory for night landings; therefore, an MDF is not required.
©[111298-6750]

HSI

For low ceilings (<10k feet) or night landings, the HSI is desirable, but not required, for accurate heading and course information. Since MLS is required under both of these situations, accurate approach information is available. In addition, rough course alignment and heading is provided by the Horizontal Situation Display (HSD). As a result, early flight termination is not required for loss of HSI(s). (Ref. Rules {A8-18}, LANDING SYSTEMS REQUIREMENTS; {A3-202}, MLS; and {A2-6}, LANDING SITE WEATHER CRITERIA [HC].)

SPI and G-METER

Though desirable, these displays are not required.

FLIGHT RULES

SECTION 9 - ELECTRICAL

LOSS/FAILURE DEFINITIONS

A9-1 FUEL CELL (FC) LOSS [CIL]

A FUEL CELL (FC) IS CONSIDERED LOST IF:

- A. AN ABNORMAL OR UNEXPLAINED VOLTAGE VERSUS CURRENT PERFORMANCE LOSS OF ? 0.5 VOLT FOR A SINGLE FC BASED ON PREDICTED PERFORMANCE DATA. [ED]

For a three substack FC, the loss of 1 of 96 cells will result in a performance drop of approximately 0.5 volt. This assumes the FC is thermally stable with no internal heaters on. For each flight, predicted nominal performance curves are provided for each FC by Rockwell International Corp. via R&E subsystem manager. In-flight nominal performance is defined by the cue card curve selected after the first purge (reference back of the FC cue card).

DOCUMENTATION: SODB 3.4.4.1.6.b.

- B. THE COOLANT PUMP OR H₂ PUMP/H₂O SEPARATOR IS LOST. [CIL]

Loss of coolant pump results in loss of FC cooling and cryogenic O₂/H₂ preheating capability. With ascent electrical loads, excessive heating of the FC power section can occur within 9 minutes of pump failure. Excessive heating of the FC results in loosening of the stack due to loss of tie-rod tension resulting in the uncontrolled mixing of O₂ and H₂ that is a catastrophic failure. Since the FC coolant loop is no longer circulating, the cryogenic preheaters are no longer warming the cold reactants. This results in excessive cooling of the dual-gas regulator and possible loss of pressure regulation. Loss of H₂ pump results in loss of water removal capability from the FC. A FC without water removal capability has a predicted lifetime of about 110 amp-hrs. (See paragraph E for 110 amp-hr explanation.) [ED]

DOCUMENTATION: SODB, 3.4.4.1.15.

Rules {A9-1001}, ELECTRICAL GO/NO GO CRITERIA, and {A9-160}, CAUTION AND WARNING (C&W) [CIL], reference this rule. [ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-1 FUEL CELL (FC) LOSS [CIL] (CONTINUED)**

- C. THE FC STACK COOLANT TEMPERATURE IS > 250 DEG (242.5 DEG) F OR < 175 DEG (182.5 DEG) F. [ED]

At a stack temp > 250 deg F, FC tie-rods lose tension causing loosening of the FC stack and seat/seal softening occurs allowing direct O₂/H₂ reactant mixing, or possible FC failure due to reactant gas crossover through a dry electrolyte matrix resulting from excessive water removal. At a stack temp < 175 deg F, water removal capability is degraded sufficiently to allow FC failure due to dilution of KOH electrolyte to the point where it will no longer support adequate reaction within the cell. This flooding is caused by the reduced vapor pressure of H₂O at lower temperatures. Normally the water is removed from the power section as a vapor. It cannot be removed as a liquid. [ED]

DOCUMENTATION: SODB, 3.4.4.1.11. [ED]

- D. THE COOLANT PRESSURE IS > 75 (71.4) PSIA AND INCREASING. [ED]

Normal coolant pressure range is 55 to 70 psia. All insight into coolant pressure is lost at 100 psia. No real constraint at up to 100 psia has been identified. The upper limit comes from O₂/H₂ dual-gas regulator relief valve crack pressures plus instrumentation error. Likely causes of increased coolant pressure are preheater leak which would probably be confirmed by coolant pump cavitation causing delta P to fluctuate and eventually remain low, O₂/H₂ dual-gas regulator shift high, regulator stage failed open, or thermal expansion of an overfilled coolant loop (STS 61-A).

DOCUMENTATION: SODB, 4.4.1.6.i.

- E. THE FC IS UNABLE TO DISCHARGE WATER. [CIL]

Inability to relieve product water from a FC results in loss of the FC due to flooding within approximately 110 amp-hr. The 110 amp-hr figure assumes a healthy FC with a KOH concentration of 32 percent at the time water removal capability is lost. With a water production rate of 0.02371 lb H₂O/amp-hr, the KOH concentration falls to 26 percent (flooded condition) within approximately 110 amp-hrs. Actual FC lifetime after loss of water removal capability depends on KOH concentration at the time of the failure. Even temporary water line blockage can result in an H₂ pump/water separator motor stall due to water buildup. Once stalled, the motor may not restart even if the blockage is removed. In a flooded cell, water electrolysis and O₂ generation in the H₂ system can occur. Therefore, a flooded fuel cell must be shut down and safed. [ED]

DOCUMENTATION: SODB, 4.4.1.3.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-1 FUEL CELL (FC) LOSS [CIL] (CONTINUED)**

- F. LOCAL KOH CONCENTRATION IS > 48 PERCENT (45 PERCENT) DRY OR < 24 PERCENT (29 PERCENT) WET AS INDICATED BY FC STACK TEMPERATURE, CONDENSER EXIT TEMPERATURE, AND CURRENT RELATIONSHIP. ©[ED]

A KOH concentration > 48 percent indicates that a FC is drying out. This condition can lead to uncontrolled mixing of O₂ and H₂ (crossover) through a dry electrolyte matrix, which is a hazardous situation. A KOH concentration < 24 percent indicates a wet FC which leads to a flooded condition; i.e., fluid covering the O₂ and H₂ reaction sites to the point that it will no longer support adequate reaction within the FC. If the H₂/H₂O separator is running, flooding a FC can lead to the leaching of KOH from the FC matrix and expulsion into the FC manifold and the orbiter potable H₂O supply. This contaminated H₂O is unsuitable for crew consumption and FES usage. KOH in the FC manifold is a possibly catastrophic situation inside the FC since the disassociation of H₂O could occur, generating O₂ in the H₂ manifold. ©[ED]

DOCUMENTATION: SODB, 3.4.4.1.8.a.

- G. A FC REACTANT VALVE FAILS CLOSED. ©[ED]

FC is unable to produce electricity without reactants.

- H. THE FC CANNOT BE CONNECTED TO A MAIN BUS. [CIL]

An FC capable of producing power cannot be utilized if it cannot be connected to main bus A, B, or C.

- I. CONFIRMED PRESENCE OF KOH IN THE FC PRODUCT WATER DOES NOT CLEAR IN 1 HOUR. ©[070899-6892A]

KOH in the fuel cell product water is a hazardous situation. KOH can be transported to the H₂ manifold in the humidified H₂ stream that can create a conductive path providing a mechanism for the disassociation of H₂O into O₂ and H₂ through electrolysis, producing a potentially explosive environment in the fuel cell. KOH is a highly corrosive material, exposure of the FES to KOH can lead to FES core damage resulting in leakage and/or blockage. Purging a FC in which this leaching has occurred can deposit KOH into the common H₂ purge line causing possible clogging of the line and preventing over pressure relief and H₂ purge capability from all three fuel cells. A FC should be safed for this failure. ©[070899-6892A] ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-1****FUEL CELL (FC) LOSS [CIL] (CONTINUED)**

The 1-hour limit is based on flight experience and engineering judgment. Flight experience has shown that, on occasion, some fuel cells have residual KOH (either from a new stack build or from being in storage for extended periods of time) that is expelled into the product water. Small amounts of residual KOH in FC product water will not lead to a hazardous O₂ concentration in the H₂ manifold; therefore, the 1-hour time will allow for the intermittent pH condition to clear. During STS-79, KOH was expelled from a fuel cell (new stack build) for a period lasting approximately 20 minutes. In addition, STS-2 flight experience and vendor tests have shown that if hazardous amounts of KOH are being expelled from the FC, other signs of degradation will be present. ©[070899-6892A]

Methods of confirming KOH in the product water after an initial fuel cell pH indication include: an indication from the pH sensor in the common product H₂O line, litmus test of the product water confirming pH>9, unexplained FC performance degradation, or by FC flooding. Confirming cues for FC flooding may be seen in FC performance degradation, FC temperatures, H₂ pump status and associated AC currents, and the Delta Amps when FC is bus tied. Substack delta volts and the Fuel Cell Monitoring System (FCMS) may also be useful in confirming flooding or performance degradation in a fuel cell.

DOCUMENTATION: SODB, 3.4.4.1.13., STS-2 flight experience, STS-79 flight experience, engineering judgment, and vendor testing.

J. THE FC SUBSTACK DELTA VOLTS CHANGES BY 150 MV FROM THE BASELINE PREFLIGHT VALUE, IS INCREASING, AND MEASUREMENT OF SINGLE CELL VOLTAGES HAS NOT BEEN PERFORMED. [CIL] ©[070899-6893A]

The failure that the cell performance monitor (CPM) is designed to detect; i.e., reactant crossover, can be hazardous if allowed to progress uncontrolled. If time permits, the FCMS will be activated, data recorded, downlinked, and analyzed to verify FC health. If health cannot be verified before a change of 150 mv has occurred, the FC will be safed. If single cell voltages clearly show that crossover is not present (i.e., small degradation in multiple cells or CPM malfunction) fuel cell operation can continue. Since the FCMS requires use of Portable General Support Computers (PGSC's), it will not be available during Ascent/Entry and may not be available during other mission critical timeframes. Baseline prelaunch values are obtained once the fuel cells have been started, reached thermal equilibrium, and are operating at the nominal prelaunch load of 150 amps. ©[070899-6893A]

DOCUMENTATION: SODB, 3.4.4.1.6.a.

A9-1

FUEL CELL (FC) LOSS [CIL] (CONTINUED)

K. ITS VOLTAGE CANNOT BE MAINTAINED ? 27.5 VOLTS. ©[ED]

This voltage is required to assure that orbiter equipment requiring dc power is maintained at a voltage no lower than 24 volts. Below 27.5 volts, the capability to maintain voltage at all equipment above 24 volts is not possible due to line losses.

DOCUMENTATION: SODB, 3.4.5.6.2.

L. ANY SINGLE CELL OPEN CIRCUIT VOLTAGE IS BELOW 1100 MV.
©[070899-6893A]

It is the engineering judgment of the FC vendor and has been confirmed through testing that individual cells with voltages below 1100 mv at open circuit are most probably experiencing reactant crossover. It should be kept in mind that CPM readings are not valid for fuel cells that are at open circuit. There are single point wiring failures that could affect both the CPM and FCMS measurements. Single cell voltages < 1100 mv may be measured on cells whose voltage measurement pin connection has high resistance. High resistance in a cell pin connection manifests itself as a low voltage reading on a single cell and a high voltage reading on an adjacent cell. Verification of the health of cells with high resistance in the pin connection may not be possible.

DOCUMENTATION: Engineering judgment and Fuel Cell Lifetime testing (serial # 122) at International Fuel Cells. ©[070899-6893A]

FLIGHT RULES

A9-2

FC ALTERNATE H₂O SYSTEM LOSS

THE FC ALTERNATE H₂O SYSTEM IS CONSIDERED LOST IF:

- A. BOTH SYSTEM A AND B HEATER SYSTEMS ON THE FC ALTERNATE H₂O SYSTEM ARE LOST.

Loss of both heater systems will allow the stagnant H₂O in the alternate H₂O lines to freeze, resulting in a disabled alternate system.

- B. TWO OR MORE FC'S RELIEVING OVERBOARD.

Any FC relieving H₂O overboard indicates either a possible alternate and primary H₂O system failure or an overboard relief valve failed open. More than one FC relieving H₂O overboard indicates a probable generic FC H₂O system problem.

- C. ALTERNATE H₂O SYSTEM PRESSURE NOT TRACKING THE EVCSS (EMU WATER SUPPLY PRESSURE) H₂O SUPPLY PRESSURE (WHILE TANK B INLET AND OUTLET VALVES ARE OPEN).

Normal on-orbit alternate H₂O pressure will track the EVCSS H₂O supply pressure. Alternate H₂O pressure not tracking indicates a probable alternate common path failure.

FLIGHT RULES

A9-3

ELECTRICAL POWER DISTRIBUTION AND CONTROL (EPDC) SYSTEM [CIL]

- A. MAIN BUS IS CONSIDERED LOST IF THE BUS VOLTAGE CANNOT BE MAINTAINED > 27.0 (27.2) V DC AND < 32.0 (31.8) V DC. [CIL].
@[ED]
- B. FORWARD PCA BUS IS CONSIDERED LOST IF THE BUS VOLTAGE CANNOT BE MAINTAINED > 26.2 (26.4) V DC AND < 32.0 (31.8) V DC.
@[ED]
- C. AFT PCA BUS IS CONSIDERED LOST IF THE BUS VOLTAGE CANNOT BE MAINTAINED > 26.1 (26.3) V DC AND < 32.0 (31.8) V DC. @[ED]
- D. CONTROL BUS IS CONSIDERED LOST IF THE BUS VOLTAGE CANNOT BE MAINTAINED > 24.8 (25.0) V DC AND < 32.0 (31.8) V DC, OR THE CONTROL BUS IS DETERMINED TO HAVE A SHORT BY THE MCC. @[ED]
- E. ESSENTIAL BUS IS CONSIDERED LOST IF THE BUS VOLTAGE CANNOT BE MAINTAINED > 25.5 (25.7) V DC AND < 38.0 (37.8) V DC. @[ED]

Orbiter equipment is qualified to operate at 23 V dc for intermittent loads and at 24 V dc for continuous loads. Considering line losses from the orbiter buses to the user equipment, the lower voltage limits for the buses listed above guarantee 24 V dc at the equipment interface. The upper voltage for most orbiter equipment is 32 V dc; however, the equipment on the essential buses is qualified to 38 V dc due to the requirement to operate at near FC open circuit voltage. If a control bus is shorted, it will be unpowered even though its voltage measurement may be > 24.8 V dc. @[ED]

Rule {A9-101}, DC BUS VOLTAGE LIMITS, references this rule.

Reference rule {A9-106}, CONTROL BUS, for additional control bus loss rationale. @[ED]

DOCUMENTATION: SODB, 3.4.5.6.2; Lockheed memo #EP5-M10-215, Shuttle Control Bus Kapton Wire Arc Tracking Test Summary, 10-12-90; and LEMSCO-25658, Summary of the Control Bus Re-power Test, May 1988.

FLIGHT RULES

A9-3

ELECTRICAL POWER DISTRIBUTION AND CONTROL (EPDC)
SYSTEM [CIL] (CONTINUED)

F. AN AC SINGLE-PHASE BUS IS CONSIDERED LOST IF:

1. THE BUS VOLTAGE IS < 110 (110.7) V AC OR > 120 (119.3) V AC. [ED]

Orbiter ac equipment was designed to operate between 110 and 120 V ac.

DOCUMENTATION: SODB, 3.4.5.6.3.a.

2. THE POWERED SINGLE-PHASE BUS CURRENT EXCEEDS:
 - a. 14.4 (13.4) AMPS - (GROUND CALL ONLY) LAUNCH THROUGH MPS POWERDOWN .
 - b. 7.7 (6.7) AMPS - CONTINUOUS LOAD FROM MPS POWERDOWN PROJECTED THROUGH ENTRY.

NOTE: AC BUS CURRENT VALUES BASED ON BUS LOAD POWER FACTOR OF 0.8 LAGGING.

These numbers represent the output power capability of the inverter under both a continuous normal 100 percent load, 7.7 amps, and at 200 percent rated load for 2 minutes, 14.4 amps with cooling. An inverter operated above these limits could fail due to overheating.

DOCUMENTATION: SODB, 4.5.6.3.1.8.

G. AN AC THREE-PHASE BUS IS CONSIDERED FAILED IF THE BUS CANNOT SATISFY USER REQUIREMENTS.

Self-explanatory.

H. MCA THREE-PHASE AC BUS IS CONSIDERED LOST IF ANY TWO PHASES ARE FAILED, OR IF ANY SINGLE AC PHASE IS SHORTED.

MCA buses power three-phase motors that cannot operate with two phases lost. Also, the MCA three-phase buses use "ganged" circuit breakers, so all three phases are lost when the single cb is opened to isolate a short circuit.

Rule {A9-101}, DC BUS VOLTAGE LIMITS, references this rule.

FLIGHT RULES

A9-4 CAUTION AND WARNING (C&W)

- A. ALL C&W LIGHTS AND TONES ARE CONSIDERED LOST (PRIMARY, BACKUP, AND SM) IF POWER SUPPLIES A AND B ARE LOST.

Without power, the hardwire C&W, C&W tones, and SM tones are inoperable.

- B. PRIMARY C&W IS CONSIDERED LOST IF:
1. POWER SUPPLY A IS LOST.
 2. FAILS SELF-TEST.
 3. FALSE ALARMS ARE GENERATED TO EXTENT IT IS UNUSABLE.
 4. NEITHER LIGHT NOR TONE WILL ANNUNCIATE.

For any of the above failure modes, the system is either totally inoperable or suspect to the point of being unreliable.

- C. BACKUP C&W IS CONSIDERED LOST IF:
1. NEITHER LIGHT NOR TONE WILL ANNUNCIATE.
 2. FALSE ALARMS ARE GENERATED TO EXTENT IT IS UNUSABLE.

For any of the above failure modes, the system is either totally inoperable or suspect to the point of being unreliable.

A9-5 THROUGH A9-50 RULES ARE RESERVED

FLIGHT RULES

FUEL CELL SYSTEMS MANAGEMENT

A9-51

FC POWER LEVEL CONSTRAINTS

- A. THE FC'S CAN BE OPERATED AT ANY POWER LEVEL BETWEEN 2 AND 12 KW CONSISTENT WITH SATISFACTORY DC BUS VOLTAGE AND FC TEMPERATURE MAINTENANCE. TO SATISFY MISSION OBJECTIVES AND FC LIFETIME CONSTRAINTS, FC POWER LEVELS SHOULD BE MANAGED AS FOLLOWS:
1. 2-10 KW - CONTINUOUSLY
 2. 10-12 KW - NOT MORE THAN 15 MINUTES EVERY 3 HOURS
- B. IN THE EVENT OF A FC FAILURE, FC LOADING IMBALANCE BECAUSE OF UNEVEN FC PERFORMANCE CHARACTERISTICS, OR OTHER SYSTEM FAILURE, THE REMAINING FC'S MAY BE OPERATED AT: [ED]
1. 2-12 KW - CONTINUOUSLY
 2. 12-13 KW - FOR LESS THAN 4 HOURS
 3. UP TO 16 KW FOR 10 MINUTES CONSISTENT WITH SATISFACTORY BUS VOLTAGE AND FC TEMPERATURES

At < 2 kW the FC voltage may exceed 32 volts. Most orbiter equipment is only certified to 32 volts. At > 12 kW, the FC thermal control system capability may become unable to maintain the FC at safe operating temperatures. Due to lifetime considerations, FC power should be limited to less than 8 kW for normal operations. However, continuous operation between 8 and 10 kW is allowable as long as accelerated lifetime decay is accepted. [ED]

DOCUMENTATION: SODB, Volume I, 3.4.4.1.2, and Volume III, 4.4.1.1.15. [ED]

FLIGHT RULES

A9-52

FC PURGE

- A. THE FC'S WILL BE PURGED SEQUENTIALLY WITH O₂ AND H₂ ON A SCHEDULED BASIS NOT TO EXCEED 96 HOURS BETWEEN PURGES. THE FREQUENCY OF PURGES WILL BE BASED UPON FC PERFORMANCE LOSS OF 0.2 VOLTS BETWEEN EACH PURGE. FC LOAD SHOULD NOT EXCEED 10 KW OR 350 AMPS DURING PURGES. HOWEVER, FOR CONTINGENCY CASES, A NORMAL 2-MINUTE PURGE CAN BE DONE AT 12 KW OR 430 AMPS. @[090894-1681]

Both the O₂ and H₂ paths through an FC must be purged to rid the FC of inerts that dilute reactant, thereby reducing FC performance. Fuel cell degradation of 0.2 volts is based on engineering judgment as the minimum performance change that can be accurately assessed in real time. The 96-hour duration is based upon flight experience of the average maximum time before fuel cell degradation reaches 0.2 volts. Should the onboard cryogenic O₂ and H₂ contain excessive inerts, faster than normal voltage degradation would occur necessitating more frequent purges. @[090894-1681]

During a purge, the preheater capability to warm the cryogenic reactants coming into the dual-gas regulator is marginal. Regulator freeze-up and subsequent lockup of the regulator is possible if purged too long at > 350 amps (430 amps for contingency operations provided purge is continuous for only 2 minutes). @[ED]

DOCUMENTATION: SODB, 3.4.4.1.4.c. @[080894-1681]

- B. FC'S WILL NOMINALLY BE PURGED USING THE AUTOMATIC SEQUENCE (SM OPS 2). THE MANUAL SEQUENCE WILL BE USED AS A BACKUP. ONE MANUAL PURGE WILL BE PERFORMED PER FLIGHT. AUTO PURGES WILL NORMALLY BE INITIATED BY MCC TMBU. @[050400-7188A]

MCC initiation of purges via TMBU allows real-time detailed analysis of fuel cell purge data by the MCC while relieving the flightcrew from housekeeping duties. The manual purge will normally be performed early in the flight to verify operational backup capability and to satisfy ground turnaround activities. @[050400-7188A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-52

FC PURGE (CONTINUED)

- C. A FC THAT HAS LOST O₂ PURGE CAPABILITY AND ITS PREDICTED PERFORMANCE WILL NOT SUPPORT NOMINAL EOM PLUS 2 DAYS WILL BE BUS TIED TO A HEALTHY FC, AND THEN EITHER PLACED IN STANDBY OR SHUTDOWN IN ORDER TO SUPPORT NOMINAL EOM PLUS 2 DAYS. THE DECISION TO PLACE THE FC IN STANDBY OR SHUTDOWN WILL DEPEND ON LIFETIME PREDICTIONS BASED ON DEGRADATION TO THAT POINT AND THE RESULTING FC TERMINAL VOLTAGE. IF THE FC IS SHUT DOWN, RESTART CAPABILITY MUST BE DEMONSTRATED TO CONTINUE PAST MDF. @[ED]

Except during purge operations the FC O₂ system is not a flowthrough design. O₂ gas flows directly to the reaction sites where it is consumed. Contained within the O₂ reactant gas are minute quantities of other gases which accumulate in the reaction chambers. With time, inerts begin to dilute the O₂ gas, effectively reducing the partial pressure of O₂ in the area of the electrolyte/catalyst reaction sites. As FC performance is a direct function of reactant partial pressure, FC output decays as inert content builds. The O₂ system is more sensitive to performance loss than the H₂ system since the H₂ system has a large volume circulating loop to distribute the inerts. Remaining lifetime depends upon gas purity, FC load, and initial FC performance.

DOCUMENTATION: SODB, 4.4.1.3r., 4.4.1.4.o, and flight data.

- D. FOR THE LOSS OF THE CAPABILITY TO PURGE EITHER THE O₂ OR H₂ REACTION CHAMBERS FOR ALL THREE FC'S, A NEXT PLS IS REQUIRED.

The single-point failure causing the loss of all O₂ or all H₂ purge capability from all FC's is a blockage in the common purge vent line. With the blockage in the common purge ventline, all FC's are no longer fail-safe (see paragraph E rationale). In addition, all FC's have no means to recover from performance degradation, so their useful lifetime remaining is limited; therefore, the prudent action is to prepare for a PLS at the next opportunity.

DOCUMENTATION: SODB, 4.4.1.3r, 4.4.1.4.o, and flight data.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-52

FC PURGE (CONTINUED)

E. A FC THAT HAS LOST EITHER O₂ OR H₂ PURGE CAPABILITY DUE TO A SUSPECTED BLOCKED VENT/PURGE LINE WILL NOT BE SHUTDOWN UNLESS DICTATED BY PERFORMANCE DEGRADATION (REF. PARAGRAPH C).

⑥[ED]

With a blocked vent/purge line the dual-gas regulator in the fuel cell can no longer vent overboard should a failure occur in the regulator. This can result in overpressurization of the fuel cell. The worst-case scenario, undetected rapid pressure increase, could cause fuel cell rupture. For vent/purge line blockage, shutting down the fuel cell would appear to be the appropriate action. However, this would result in a two-FC entry which exposes the program to potentially greater risks; therefore, the rule is to leave the fuel cell running. These risk trades were made when arriving at this decision:

- a. *Evaluation of regulator failure history for 18 units with a total of 30,000 hours of operation (through STS 51-L) have indicated that the only failures involving internal leakage/pressurization were seal or seat leakage at a rate well below normal flow (consumption).*
- b. *Seal leakage would not be significant during normal operation because the reactant being leaked is consumed as part of the normal flow.*
- c. *Shutting down the fuel cell for seal leakage could result in a pressure increase as the consumption goes to zero, assuming the upstream reactant valve also leaks when closed. For this case continued operation of the fuel cell would be the proper action.*
- d. *Postulating a significant decrease in fuel cell load (50 amps) with a regulator that sticks at the higher demand setting, a pressure increase of approximately 20 psi/min could result. For this case the crew would have greater than 5 minutes to respond to the COOP P alert and shut down the fuel cell.*
- e. *Shutting down a fuel cell for a blocked vent line and flying a two-fuel cell entry exposes the program to any number of failures during entry on either of the remaining fuel cells that could result in a single fuel cell operation.*

Rule {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A9-53

FC H₂O SYSTEM HEATERS

ONE SET OF FC H₂O RELIEF SYSTEM HEATERS AND WATER LINE HEATERS WILL BE ENABLED AT ALL TIMES.

Capability to dump FC product water overboard must be immediately available in the event the FC can no longer deliver product water into the potable water tanks. Without this backup H₂O removal capability, the FC's will be lost due to flooding. To preclude any blockage in the nonredundant dump line due to freezing, thermal control of this dump line and nozzle is required continuously. Similarly, the FC alternate water lines are normally nonflowing and require thermal control to preclude freezing and line blockage.

DOCUMENTATION: SODB, 3.4.4.1.9.a. Also see System Thermal Control Design and Analysis (RI), SD 77-SH-0284, Dec. 1977, and Electrical Power Generation Water Relief Nozzle Development Test Final Report (RI) EPST-03, 6 Oct. 1976.

Rule {A18-301A}, TCS HEATER CONFIGURATION, references this rule.

A9-54

FC STANDBY DEFINITION

FC IN STANDBY IS DEFINED AS DISCONNECTION FROM ITS MAIN AND ESSENTIAL BUSES. THE ELECTRONIC CONTROL UNIT (ECU) REMAINS POWERED AND THE REACTANT VALVES REMAIN OPEN.

With the FC in standby, the disconnection of the FC from the buses removes all external load from the FC. By leaving the ECU powered and the reactant valves open, the FC remains thermally controlled by the internal sustaining heater and the coolant loop, which maintains it for immediate use.

FLIGHT RULES

A9-55

FC SHUTDOWN DEFINITION [CIL]

- A. FC SHUTDOWN IS DEFINED AS DISCONNECTION FROM BUSES, FC TO "STOP", AND REACTANT VALVES CLOSED. IF THE FC IS STILL CONSIDERED USABLE IN-FLIGHT, THE REACTANT VALVES NEED NOT BE CLOSED AFTER THE FC IS STOPPED.

In the shutdown procedure, disconnection of the FC from the buses removes all external electrical load from the FC. FC to STOP removes any normal load on the FC caused by the thermostatically-controlled FC heaters and unpowers the coolant and H₂ pumps. Closing the reactant valves precludes the possibility of providing the reactants in a possible crossover, internal short, or failed-on heater situation.

- B. ANY FC THAT IS SHUT DOWN, BUT CONSIDERED AVAILABLE FOR REUSE, WILL BE MAINTAINED > 40 DEG F (48 DEG F). THE SHUTDOWN FC WILL BE CONSIDERED "GO" FOR GO/NO-GO PURPOSES PROVIDED RESTART CAPABILITY IS DEMONSTRATED WHEN THE FC HAS REACHED THERMAL EQUILIBRIUM WITH ITS ENVIRONMENT. (RESTART APPROXIMATELY 48 HOURS AFTER SHUTDOWN FOR -ZLV ATTITUDE.)
@[071494-1659]

On-orbit restart capability of the FC's was a design consideration; however, this capability has not been verified at thermal equilibrium. Therefore, in order to confirm this capability, it is necessary to attempt a restart during which the FC will be put through as realistic of a thermal transient as it will see when it is called upon later in the flight to support entry. For planning purposes, the FC will be considered GO until this restart capability can be verified. It is the intent of this rule, that should a FC at ambient temperature be successfully restarted on orbit, the requirement to verify restart capability for any future FC shutdowns will not be required and that this rule will be modified accordingly.

The thermal data in parentheses is based on FC shutdown data from STS-2, STS-54, and STS-51 (All -ZLV attitude). On STS-2, FC1 was shut down due to internal flooding and not restarted. The cooling characteristics of the STS-2 fuel cell was different than the existing 3-substack fuel cells because it had only 2 substacks and less thermal blanketing. On STS-54, FC2 was shut down for 9 hours and then successfully restarted (DTO). The thermal data is based on accessory section of the FC since no direct power section insight exists.

DOCUMENTATION: JSC-26545, FC ON-ORBIT SHUTDOWN/RESTART DTO. @[071494-1659]

FLIGHT RULES

A9-56

FC SAFING

FC SAFING WILL BE PERFORMED UNDER THE FOLLOWING CIRCUMSTANCES:

- A. CONFIRMED PRESENCE OF KOH IN FC PRODUCT WATER THAT DOES NOT CLEAR IN 1 HOUR. @[070899-6891A]
- B. CROSSOVER OF REACTANTS WITHIN THE FC
- C. A SHORT CIRCUIT WITHIN THE FC
- D. CONFIRMED COOLANT PRESSURE > 75 (71.4) PSIA

FC SAFING IS DEFINED AS EVACUATION OF THE FC REACTANT CHAMBERS BY OPERATING THE FC WHILE ITS REACTANT VALVES ARE CLOSED. FC SAFING IS COMPLETE WHEN THE FC COOLANT PRESSURE IS < 15 PSI. ONCE SAFING IS COMPLETE, THE FC WILL BE DISCONNECTED FROM THE ASSOCIATED ESSENTIAL AND MAIN BUSES AND THEN TAKEN TO STOP. IF THE FC CURRENT EQUALS 0 AMPS BEFORE THE COOLANT PRESSURE IS < 15 PSI, THE FC WILL BE DISCONNECTED FROM THE ASSOCIATED ESSENTIAL AND MAIN BUSES TO ALLOW THE SUSTAINING HEATERS TO COMPLETE FC SAFING.

The onboard FC safing procedures close the reactant valves, and for all cases except a short within the FC, use the Main Bus loads to rapidly consume the reactants. This shortens the time a crossover situation or a FC internal short could sustain itself. Also, for the case of KOH in the manifold (pH high), safing evacuates the manifold of reactants to prevent electrolysis due to thin films of KOH across two or more cells. With KOH and water in the reactant chamber, electrolysis can occur that would disassociate H₂O into H₂ and O₂, allowing for recombination and resultant heat. At < 15 psi, the density of the reactants is so small that a catastrophic event is unlikely. Getting much below 15 psi may be difficult due to the continuing outgassing of reactants and H₂O vapor pressure. Also, the dual-gas regulator is designed such that the O₂ side always remains 5 psi above the H₂ side. In case of high coolant pressure, FC safing will relieve the FC stack overpressure. During on-orbit safing scenarios, it is unlikely, but possible, that FC current will reach 0 amps before the coolant pressure reaches 15 psi. At a FC current telemetry output of 0 amps, the healthy fuel cell, in parallel with the failed fuel cell, could drive cells in the failed fuel cell in the negative direction, resulting in the evolution of free O₂ and H₂ molecules. These free O₂ and H₂ molecules could end up on either the O₂ or H₂ side of the cell resulting in extra heat and H₂O production. Therefore, when FC safing is complete, the fuel cell will be disconnected from the associated essential and main buses and then taken to stop. @[ED]

Documentation: STS-2 and STS-83 flight experience, vendor electrochemical analysis, and engineering judgment. @[070899-6891A]

FLIGHT RULES

A9-57

REUSABLE FC

A FC WILL BE SHUT DOWN AND WILL BE CONSIDERED REUSABLE FOR THE FOLLOWING CASES: [ED]

A. INABILITY TO MAINTAIN BUS VOLTAGE <32 VOLTS.

All orbiter equipment requiring dc power is qualified to a maximum of 32 volts. A main bus voltage is > 32 only when the FC is lightly loaded (i.e., due to a powerdown). The FC is reusable when it is sufficiently loaded to drop its voltage below 32 V dc. [ED]

DOCUMENTATION: SODB, 3.4.5.6.2.b.

B. ANY FC WITH A COOLANT PRESSURE THAT IS NOT AT LEAST 10 PSIA ABOVE THE SUPPLY H₂O TANK PRESSURE WILL BE SHUT DOWN IMMEDIATELY. THE FC MAY BE RESTARTED AFTER H₂O TANK A HAS BEEN VENTED PROVIDED THE COOLANT PRESSURE IS AT LEAST 6 PSIA ABOVE THE SUPPLY H₂O TANK PRESSURE IF ONLY TANK A VENTED, OR 10 PSIA ABOVE THE SUPPLY H₂O TANK PRESSURE IF ALL TANKS VENTED, AND ULLAGE EXISTS IN THE VENTED TANK(S). [090894-1680] [ED]

A FC with a low coolant pressure that is not at least 10 psia above the supply H₂O tank pressure cannot be guaranteed to have its product H₂O removed. Without the H₂O removal capability, the FC H₂ pump will be irrecoverably lost within a few minutes resulting in FC flooding. If the FC is shut down quickly, it may be used after supply water tank A has been vented to allow the FC coolant pressure to be at least 6 psia greater than supply H₂O pressure if tank A is the only tank vented, or at least 10 psia greater than supply H₂O pressure if all tanks are vented. The 10 psia differential pressure requirement is due to the measurement error of the pressure transducer (3.6 psia) plus worst case tolerances on three check valves between the FC's and the ECLSS supply H₂O tanks (2 psia each). With supply H₂O tank A vented, all three FC's will be filling tank A since it has the lowest tank pressure. Therefore, tank A ullage must be managed. [090894-1680] [ED]

C. UNABLE TO PURGE O₂ OR H₂ REACTANT SYSTEM AND PREDICTED FC PERFORMANCE WOULD NOT BE ABOVE THE LAUNCH COMMIT V-I CURVE AT NOMINAL EOM.

It is advisable to save the FC for critical mission phases such as entry.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-57****REUSABLE FC (CONTINUED)**

- D. LOSS OF FC PUMP PACKAGE THAT IS RECOVERABLE BY AN IFM REQUIRING CONTINUOUS POWER FROM AN ASSOCIATED PREFLIGHT TEST BUS. IN ADDITION TO THE PREFLIGHT TEST BUS CONSTRAINTS (REF. RULE {A9-110}, PREFLIGHT TEST BUS MANAGEMENT), THE FOLLOWING CONSTRAINTS WILL BE USED FOR THE IFM IMPLEMENTATION:
1. THIS IFM IS NOT CONSIDERED FEASIBLE FOR LOSS OF THE MAIN DISTRIBUTION BOX ESSENTIAL BUS.
 2. ORBIT - USE TO RECOVER FC ON FIRST FAILURE. THE FC WILL BE CONSIDERED LOST FOR GO/NO-GO PURPOSES AND WILL BE POWERED DOWN FOR ENTRY UNLESS REQUIRED TO PROVIDE SFT. MISSION IMPACT - MDF.
 3. IFM USED ONLY TO RESTORE ENTRY SFT (TWO FC ENTRY).

The IFM procedure to restore power to the FC pump package takes 1 hour to perform. The FC can be operated a maximum of 9 minutes without the coolant pump; therefore, the FC must be shut down while the IFM procedure is performed. Each essential bus has three power sources. The single failure that would cause loss of a main distribution box essential bus is a bus short. Since the preflight test bus powers the essential bus, the short would probably cause the pre-flight test bus fuse to open. On orbit, the IFM will be performed for the first FC failure, since single failures associated with powering the preflight test bus are recoverable without placing the crew/vehicle in a critical situation. To be consistent with the preflight test bus Flight Rule {A9-110}, PREFLIGHT TEST BUS MANAGEMENT, concerning entry operations, only SFT entry critical functions are recovered since use of the preflight test bus may expose the crew to problems not as easily recoverable as during orbit operations. The mission impact for first FC failure will be MDF since the FC will not be used for entry. ©[ED]

Reference Rule {A9-110}, PREFLIGHT TEST BUS MANAGEMENT, for additional rationale. ©[ED]

FLIGHT RULES

A9-58

FC SUSTAINER HEATER

A SUSTAINER HEATER FAILED ON IS NOT CAUSE TO SHUT DOWN THE AFFECTED FC. HOWEVER, IF FC SHUTDOWN IS REQUIRED FOR OTHER REASONS, IT WILL BE SAFED BY CLOSING ITS REACTANT VALVES PRIOR TO UNPOWERING THE FC PUMPS.

Thermal analysis by International Fuel Cells (IFC) indicates that a failed-on sustainer heater does not overheat a FC and that the FC would be usable for the normal mission duration. If the FC is shut down, the failed-on sustainer heater will remain powered as long as there are reactants to power the FC. To prevent excessive localized heating, the reactants will be depleted prior to unpowering the coolant pump.

©[ED]

DOCUMENTATION: SODB, 4.4.1.1.1.

A9-59

FC - CELL PERFORMANCE MONITOR [CIL]

FOR A FUEL CELL THAT HAS LOST ANY CELL PERFORMANCE MONITOR (CPM) TELEMETRY OR HAS EXPERIENCED A CPM CHANGE OF GREATER THAN 50 MV FROM THE BASELINE PRELAUNCH VALUE, THE AFFECTED FC WILL:

©[070899-6893A]

- A. TIE BUS TO ANOTHER FC. A PERFORMANCE SHIFT SUFFICIENT TO CAUSE A DELTA AMPS CHANGE OF > 12 AMPS AND DIVERGING THAT IS NOT RELATED TO REACTANT PRESSURE CHANGE, THERMAL CONTROL, INERTS, OR NORMAL V-I PERFORMANCE DIFFERENCES (DERIVED FROM BASELINE PERFORMANCE CURVES), COULD BE INDICATIVE OF AN INTERNAL CELL FAILURE, AND UNLESS THE FC HEALTH CAN VERIFIED, THE FUEL CELL WILL BE SAFED. IF FC PERFORMANCE HAS NOT VIOLATED THE ABOVE CRITERIA, THE BUSES WILL BE UNTIED PRIOR TO THE DEORBIT BURN.
- B. HAVE ITS SINGLE CELL VOLTAGES RECORDED, DOWNLINKED, AND ANALYZED AT LEAST ONCE PER DAY. IF ANY INDIVIDUAL CELL VOLTAGE IS LESS THAN 910 MV WITH FC LOAD BETWEEN 4 AND 8 KW, THE FUEL CELL WILL BE TAKEN OPEN CIRCUIT, AND SINGLE CELL VOLTAGES WILL BE RECORDED, DOWNLINKED, AND ANALYZED. FOR AN OPEN CIRCUIT SINGLE CELL READING OF LESS THAN 1100 MV, THE FC WILL BE SAFED. ©[070899-6893A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-59****FC - CELL PERFORMANCE MONITOR [CIL] (CONTINUED)**

For loss of CPM, a viable procedure to regain insight into possible crossover in a FC is to tie the affected FC to an adequately instrumented healthy FC and note any change in the delta amps between the FC's once an equilibrium delta amp has been identified. A performance shift of 12 amps is equivalent to an approximate 300 mV degradation in one of the 96 cells of the FC. It is the engineering judgment of the FC vendor that this degree of performance change might indicate an internal cell problem and, if allowed to continue, could lead to a crossover condition. The time period between deorbit TIG and touchdown is considered short enough not to require the insight afforded by the bus tie. Also, it is advisable to isolate the three main buses whenever possible for EPDC redundancy. ®[ED]

Using the FCMS provides insight into individual cell voltages. Testing at International Fuel Cells on FC serial number 122 showed that during the beginning stages of crossover, changes to individual cell voltages will be small and may be difficult to detect while the fuel cell is under load. During testing, cells known to have crossover were consistently below 910 mv while under load. When taken to open circuit, the voltage degradation due to crossover was clearly evident and the cell voltages were consistently below 1100 mv. A change of 50 mv from the established baseline prelaunch value indicates that something off nominal may be occurring in the fuel cell and the FCMS will be utilized to ensure safety of the crew and vehicle. In addition, the FCMS may provide additional insight whenever the health of the fuel cell is in question. There are single point wiring failures which could affect both the CPM and FCMS measurements. Single cell voltages < 1100 mv may be measured on cells whose voltage measurement pin connection has high resistance. High resistance in a cell pin connection manifests itself as a low voltage reading on a single cell and a high voltage reading on an adjacent cell. Verification of the health of cells with high resistance in the pin connection may not be possible. ®[070899-6893A]

DOCUMENTATION: Rule {A9-107}, MAIN BUS TIE [CIL], references this rule. ®[070899-6893A]

FLIGHT RULES

A9-60

FC COOLANT PUMP FAILURE MANAGEMENT [CIL]

- A. THE FC MUST BE SHUT DOWN WITHIN 9 MINUTES (AT 7 KW) FOR LOSS OF COOLING. FC SAFING IS NOT REQUIRED.

After the loss of cooling, the FC must be shut down to preclude catastrophic failure due to overheating. Overheating will result in expansion of the stack, leaking of reactants into the PBD, and uncontrolled mixing of O₂ and H₂ resulting in potential explosion. Testing and analysis indicate that the FC will reach the redline stack temperature of 250 deg F in approximately 9 minutes at 7 kW.

DOCUMENTATION: SODB, 3.4.4.1.15.

- B. FUEL CELL OPERATION WITHOUT COOLING MAY BE EXTENDED BEYOND 9 MINUTES IF THE MCC CALCULATED FC STACK TEMPERATURE IS PREDICTED TO BE LESS THAN 250 DEG F. FC OPERATIONS BEYOND 9 MINUTES WILL ONLY BE ALLOWED DURING CRITICAL MISSION PHASES TO:
1. MAINTAIN TWO FUEL CELLS, OR
 2. MAINTAIN THREE MAIN BUSES (I.E., BUS TIE CAPABILITY LOST)

At the FC power load of 7 kW, a FC can be operated for 9 minutes before the FC stack temperature reaches 250 deg F. However, if the power level can be reduced quickly after the loss of FC cooling, FC operation may be extended beyond 9 minutes since a lower power level lowers the heating rate. FC operations would be extended when absolutely necessary to maintain two FC's or three main buses to allow critical equipment to remain powered, provide extra time to reconfigure safely, or to get past a critical event (i.e., ascent/entry). The 250 deg F limit of the FC stack temperature is required to maintain integrity of the FC power stack. Based upon analysis and testing conducted by IFC and JSC E&D, the predicted FC stack temperature can be calculated from the FC stack temperature at the time of the failure and the affected FC subsequent power levels (reliable FC stack temperature measurement is lost following the loss of coolant flow).

DOCUMENTATION: RI Internal Letter, 287-EPS-88-074, FC Operating Time Following Loss of Coolant, May 24, 1988; JSC-23091, Internal Note for FC X708 Thermal System Off-Limits Test, November 25, 1988; and SODB, 3.4.4.1.15.

FLIGHT RULES**A9-61****ACTIONS FOR FUEL CELL PH INDICATIONS** @[121296-4737B]

A FUEL CELL THAT HAS RECEIVED A "PH" INDICATION WILL BE HANDLED IN THE FOLLOWING MANNER:

- A. THE FUEL CELL'S ASSOCIATED MAIN BUS WILL BE BUS TIED TO A GOOD FUEL CELL'S MAIN BUS. THE SUPPLY H₂O TANKS WILL BE MANAGED TO ISOLATE KOH FROM UNDESIRE TANKS. IF CONFIRMING INDICATIONS OF FUEL CELL FLOODING OR CROSSOVER ARE RECEIVED AT ANY TIME, THE FUEL CELL WILL BE SAFED AND CONSIDERED LOST.
@[070899-6892A]

Reception of a fuel cell pH indication can be the result of a new stack build or from being in storage for extended periods, flooding, crossover, or other mechanisms that cause the KOH to escape from a fuel cell. If KOH is escaping, fuel cell failure may occur. The bus tie is performed to protect the fuel cell's associated main bus should the fuel cell completely fail and also to monitor the fuel cell's performance. Aside from a new stack build, fuel cell flooding is the most probable cause of KOH in the product water. Flooding may be the result of improper condenser temperature maintenance, coolant pressure imbalance, or degraded or failed water removal system. Confirming cues for FC flooding may be seen in FC performance degradation, FC temperatures, H₂ pump status and associated AC currents, and the Delta Amps when the FC is bus tied. Confirming indications of crossover may be changing substack delta volts or unexplained performance degradation. The Fuel Cell Monitoring System (FCMS) may also be useful in confirming crossover, flooding, or performance degradation in a fuel cell.

H₂O tank management should consider effects of KOH on crew drinking supply, FES usage, water transfers, and any other potential uses of the fuel cell product water.

DOCUMENTATION: SODB Volume 1, Section 3.4.4.1 (13), STS-2 and STS-79 flight experience, and Rule {A9-1}, FUEL CELL (FC) LOSS [CIL], references this rule.

- B. FOR RECEPTION OF THE FUEL CELL AND/OR COMMON H₂O LINE PH INDICATION, A LITMUS TEST OF THE FUEL CELL PRODUCT WATER WILL BE PERFORMED WITHIN 1 HOUR TO VERIFY THE PRESENCE OF KOH.

It is imperative that the litmus test be expedited. Continued operation of a fuel cell with KOH discharge could result in a hazardous condition. The fuel cell pH and common H₂O line pH sensors measure conductivity of the fuel cell product water and are not specifically measurements of KOH content. A litmus test of the water must be performed to conclusively determine if KOH is present. As much as 20 minutes transport time from the affected fuel cell to the galley QD may be required (8-9 minutes between the affected fuel cell pH indication and the common H₂O line indication).

@[070899-6892A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-61 ACTIONS FOR FUEL CELL PH INDICATIONS (CONTINUED)**

1. IF BOTH FUEL CELL AND COMMON H₂O LINE PH INDICATIONS ARE PRESENT AND THE LITMUS TEST CANNOT BE PERFORMED WITHIN 1 HOUR, THE FUEL CELL WILL BE SAFED AND CONSIDERED LOST.
@[070899-6892A]

With both FC and common pH sensors indicating a high pH, the likelihood that the fuel cell is releasing KOH is high. Continued operation of a fuel cell with a KOH discharge could result in a hazardous condition. The 1-hour operational constraint is based upon engineering judgment. It was chosen to allow the pH indications (from residual KOH) to clear, thus preventing premature fuel cell safing (fuel cell historical flight data STS-79 FC2 pH indication only lasted about 20 minutes). Sustained pH indications for 1 hour would represent a continuing problem and an eminently hazardous condition requiring the FC to be safed.

2. FUEL CELL OPERATION FOR CONFIRMED KOH RELEASE PH > 9 (BY A LITMUS TEST) WITHOUT SIGNS OF FLOODING OR CROSSOVER IS ALLOWABLE FOR 1 HOUR. IF THE INDICATIONS ARE SUSTAINED FOR GREATER THAN 1 HOUR, THE FUEL CELL WILL BE SAFED AND CONSIDERED LOST.

The 1-hour limit is based on flight experience and engineering judgment. Flight experience has shown that, on occasion, some fuel cells have residual KOH (either from a new stack build or from being in storage for extended periods of time) that is expelled into the product water. Small amounts of residual KOH in FC product water will not lead to a hazardous O₂ concentration in the H₂ manifold; therefore, the 1-hour time will allow for the intermittent pH condition to clear.

3. FUEL CELL OPERATION MAY CONTINUE WITH BOTH SENSORS ON IF PH < 9 (BASED UPON A LITMUS TEST) AND THERE ARE NO INDICATIONS OF FLOODING OR CROSSOVER. THE BUS TIE WILL BE MAINTAINED TO MONITOR FUEL CELL PERFORMANCE. THE BUS TIE WILL BE BROKEN FOR ENTRY. AN FCMS DATA TAKE AND AN H₂O LITMUS TEST WILL BE PERFORMED DAILY.

A fuel cell whose pH sensors continue to indicate a high pH but whose product water is verified to have a pH level < 9 and whose performance is nominal, will be allowed to continue operation. Flight experience has shown that some fuel cells may have residual KOH, either from a new stack build or from being in storage that is intermittently expelled into the product water. The sensor indications are possibly due to very minute amounts of KOH that the litmus test cannot verify. Because this is still an off-nominal situation, the bus tie will be maintained so that fuel cell performance can be monitored. If performance degradation or indications of flooding are received, the fuel cell will be safed. An FCMS data take and an H₂O litmus test will be performed daily to verify FC health.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-61 ACTIONS FOR FUEL CELL PH INDICATIONS (CONTINUED)

DOCUMENTATION: SODB Volume 1, Section 3.4.4.1 (13) and STS-79 flight experience. Rule {A9-1}, FUEL CELL (FC) LOSS [CIL], references this rule. ©[121296-4737B] ©[070899-6892A]

- C. A FUEL CELL PURGE WILL NOT BE PERFORMED WHEN EITHER A FUEL CELL INDIVIDUAL OR COMMON H₂O LINE PH INDICATION IS PRESENT, UNLESS FUEL CELL PRODUCT WATER PH IS CONFIRMED < 9.0 USING A LITMUS TEST. ©[070899-6892A]

Purging a FC that is expelling KOH can result in KOH being deposited in the common H₂ purge line causing possible clogging of this line and preventing over-pressure relief of all three fuel cells. With the common H₂ purge line plugged, the H₂ purge capability from all three fuel cells is also lost.

DOCUMENTATION: SODB Volume 1, Section 3.4.4.1 (13). Rule {A9-1}, FUEL CELL (FC) LOSS [CIL], references this rule. ©[070899-6892A]

A9-62 FUEL CELL MONITORING SYSTEM DATA TAKE

A MINIMUM OF ONE FCMS DATA TAKE WILL BE PERFORMED EACH FLIGHT. ©[070899-6893A]

The FCMS data take will nominally be scheduled as early as is practical in the mission timeline to establish a fully operational on orbit baseline and to verify system capability. Performing a data take each flight adds to the historical data base of inflight single cell voltages. In the event of a fuel cell problem, this data base will be used to help evaluate fuel cell health. The only time to verify operation of the entire FCMS, including data interfaces, onboard PGSC's, and downlink capability, is during flight. Since the PGSC configurations are constantly being upgraded, it becomes imperative to do a data take every flight to ensure FCMS capability is available when required. ©[070899-6893A]

A9-63 THROUGH A9-100 RULES ARE RESERVED

FLIGHT RULES

DC POWER DISTRIBUTION AND CONTROL SYSTEMS MANAGEMENT

A9-101 DC BUS VOLTAGE LIMITS

DC BUS VOLTAGE WILL BE MAINTAINED AS FOLLOWS:

- A. MAIN BUS VOLTS > 27.0 (27.2) V DC AND < 32.0 (31.8) V DC.
- B. CONTROL BUS VOLTS > 24.8 (25.0) V DC AND < 32.0 (31.8) V DC.
- C. ESSENTIAL BUS VOLTS > 25.5 (25.7) V DC AND < 38.0 (37.8) V DC.
- D. FORWARD PCA VOLTS > 26.2 (26.4) V DC AND < 32.0 (31.8) V DC.
- E. AFT PCA VOLTS > 26.1 (26.3) V DC AND < 32.0 (31.8) V DC.

Rationale same as for Rules {A9-3}A through E, ELECTRICAL POWER DISTRIBUTION AND CONTROL (EPDC) SYSTEM [CIL].

A9-102 ESSENTIAL BUS

EACH ESSENTIAL BUS WILL BE CONNECTED TO ALL THREE OF ITS POWER SOURCES.

The highest level of power redundancy will be maintained to the essential buses. They power orbiter critical equipment such as GPC's.

A9-103 POWER REDUCTION GUIDELINES

IF AN ELECTRICAL POWER SYSTEM PROBLEM REQUIRES AN IMMEDIATE POWER REDUCTION, POWER TO MADS AND/OR PAYLOAD EQUIPMENT MAY BE TERMINATED.

Those electrical loads not required for orbiter systems operations while in a situation requiring immediate reduction in electrical load to prevent FC overloading and/or equipment undervoltage will be terminated.

FLIGHT RULES

A9-104

MAIN BUS SHORT

IF A CONFIRMED MAIN BUS SHORT RESULTS IN A TOTAL BUS CURRENT GREATER THAN 500 AMPS (OFF-SCALE HIGH) AND DOES NOT CLEAR AUTOMATICALLY:

- A. PRE-MECO, THE MAIN BUS WILL REMAIN POWERED AS LONG AS THE ASSOCIATED AC BUS VOLTAGE IS > 95 V AC OR UNTIL MCC CONFIRMS SSME CONTROLLER SWITCHOVER HAS OCCURRED.

The orbiter EPDC system is designed for self-isolation of shorted circuitry. In reality, a sustained short of this magnitude is highly unlikely. Should it occur, however, main engine controller power requirements will not be jeopardized. The crew has no insight into SSME controller switchover. Once the ground confirms switchover or MECO has occurred, the uncleared short will be isolated. As long as the ac voltage remains above 95 volts, controller switchover will not take place.

- B. DURING OMS MANEUVERS CRITICAL FOR CREW SAFETY, DEORBIT BURN, AND TAEM, THE MAIN BUS WILL REMAIN POWERED AS LONG AS BUS VOLTAGE DOES NOT DROP BELOW 26.4 (26.6) V DC.

During OMS maneuvers critical for crew safety (as defined in the Flight Rule Annex), deorbit burn, and TAEM, it is highly desirable that the maximum level of electrical power redundancy to orbiter equipment be maintained and that single power source equipment not be lost. The crew should take action at the C&W limit of 26.4 V dc.

FLIGHT RULES

A9-105

CB/RPC RESET

- A. A CB OR RPC WILL NOT BE RESET IMMEDIATELY UNLESS THE FUNCTION OR SYSTEM LOST IS CRITICAL TO MAINTAIN SAFE ORBITER OPERATIONS. THE MCC WILL REVIEW ASSOCIATED DATA FOR CAUSE OF THE OPEN CIRCUIT.
1. IF A SHORT OR OVERLOAD CAUSED THE TRIP, IT WILL NOT BE RESET UNLESS THE AFFECTED LRU(S) WOULD BE THE LAST METHOD TO PERFORM A CRITICAL FUNCTION. IT WILL NOT BE RESET TO REGAIN REDUNDANCY FOR A CRITICAL FUNCTION OR TO REGAIN MISSION SUCCESS ITEMS.
 2. IF THERE IS CONCLUSIVE EVIDENCE THAT NO SHORT/OVERLOAD EXISTS, IT CAN BE RESET (DURING MCC COVERAGE). RESET SHOULD ONLY BE PERFORMED IF THE LRU IS NEEDED. CONCLUSIVE EVIDENCE IS TELEMETRY INDICATING THE EXACT TIME OF POWER LOSS AND ADEQUATE RESOLUTION AND SAMPLE RATE FOR THE BUS CURRENTS AT THAT TIME. IF THE LRU IS REGAINED DURING A CB RESET AND NO SHORT IS SEEN, BUT THE CB FAILS TO HOLD, THE IFM CB RETENTION DEVICE CAN BE INSTALLED IMMEDIATELY FOR CREW SAFETY ISSUES ONLY. INSTALLATION OF THE RETENTION DEVICE FOR MISSION SUCCESS SHOULD BE AVOIDED, BUT INDIVIDUAL CASES WILL BE CONSIDERED BASED UPON IMPACT OF LRU LOSS, LENGTH OF TIME THAT RETENTION DEVICE IS NEEDED, MOST PROBABLE FAILURE MODE, ETC.
 3. IF DATA IS INCONCLUSIVE (E.G., INADEQUATE RESOLUTION OR TIME NOT KNOWN) CB/RPC RESET WILL BE BASED UPON IMPACT OF LRU LOSS, WIRE TYPE (KAPTON TWISTED PAIR IS HIGHEST RISK), DEGREE OF UNCERTAINTY IN DATA ANALYSIS, ETC.

Laboratory tests on Kapton wiring indicate that "arc tracking" can cause extensive damage to wire harnesses. Loss of a wire harness in itself could be catastrophic. Reset of the circuit protection in many cases caused more damage than the original occurrence. However, if it is known that the open circuit was not caused by a short, the cause is most likely mechanical failure or the control was inadvertently bumped. Installation of the cb retention device should be avoided since there have been instances where the cb is damaged in such a manner that it will not latch, nor would it be able to trip if held closed. Under some circumstances, it will be impossible to verify that no short occurred. Examples include: loss of data, circuit protection trip characteristics in noise level of bus currents, low data sample rates, unable to determine exact time of event, etc. Since these present varying degrees of uncertainty and since wire type plays an important role in the risk of reset, cases falling into this category will be addressed based on real-time conditions.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-105 CB/RPC RESET (CONTINUED)

DOCUMENTATION: Testing performed at KSC Malfunction Analysis Laboratory and at the JSC EPDC Laboratory. Also CAR # AC1737-010.

- B. A CIRCUIT OR LRU WHICH IS PROTECTED BY A CB (NOT TRIPPED) AND WHICH HAS FAILED TO FUNCTION FOR AN UNDETERMINED REASON, MAY HAVE ITS CB CYCLED ONCE. IF NO SHORT IS SEEN, IT MAY BE CYCLED FIVE TIMES.

Corrosion can form on the contacts of cb's. Troubleshooting experience has shown that this corrosion can be removed by cycling the cb while under load. Five cycles have been sufficient. In case the cb has popped internally due to a short, MCC must review data after the first cycle.

DOCUMENTATION: CF NOI53 (STS-3 and subs), CF7/82-19, Orbiter Circuit Breaker Contact Oxidation.

A9-106 CONTROL BUS

- A. A. A CONTROL BUS THAT IS DETERMINED TO HAVE A SHORT BY THE MCC WILL BE UNPOWERED USING THE FOLLOWING GUIDELINES.
1. IF A SHORT CAUSES THE LOSS OF A CONTROL BUS RPC, THE CONTROL BUS CENTER POWER SOURCE CIRCUIT BREAKER (ON PANEL R15) WILL BE OPENED AND THE REMAINING RPC WILL BE DISABLED BY CONTINUOUSLY HOLDING THE CONTROL BUS RPC RESET SWITCH (ON PANEL R1) IN THE RESET POSITION WHILE AN IFM IS PERFORMED TO UNPOWER THE DESIRED RPC.
 2. IF A SHORT DOES NOT CAUSE LOSS OF ANY CONTROL BUS RPC'S, BOTH OF THE ASSOCIATED CONTROL BUS RPC RESET SWITCHES WILL BE ACTUATED CONTINUOUSLY TO DISABLE BOTH CONTROL BUS RPC'S UNTIL AN IFM IS PERFORMED TO UNPOWER THE DESIRED RPC'S. IF, AFTER DISABLING BOTH RPC'S, THE CREW REPORTS VISIBLE ARCING OR SMOKE, THE R15 CENTER SOURCE CB WILL BE PULLED. THIS WILL DISABLE THREE CONTROL BUSES (E.G., CNTL AB1/2/3) UNTIL THE IFM CAN BE PERFORMED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-106 CONTROL BUS (CONTINUED)

- B. A CONTROL BUS WHICH HAS FAILED DUE TO A SHORT MAY HAVE ONE OF ITS RPC'S RESET (DURING GROUND COVERAGE ON MCC REQUEST) TO ATTEMPT POSITIONING OF VALVES OR RELAYS (POWERED BY THE CONTROL BUS THROUGH MOMENTARY SWITCHES) WHEN THE ATTEMPT IS CONSIDERED MANDATORY FOR FLIGHT SAFETY.

*Breadboard testing in May 1988 determined that a control bus short would not open all three circuit protection devices due to bus wire size and length. The result would be a partial control bus loss with the short still being supplied power. (The maximum power possible from a 5-amp RPC source is $7.5A * 30V = 225$ watts).*

If a control bus is determined to have a short, it will be unpowered as soon as possible to prevent further damage due to localized heating and/or possible arc tracking. Kapton wire arc-tracking tests performed in 1990 indicate that initiation of arc tracking on a single conductor wire (as used for control buses) is unlikely. However, if it did occur, testing indicates that the entire bundle/ harness could be damaged. Since control bus wires are routed in bundles and harnesses containing other control buses and critical functions, damage affecting multiple wires could be catastrophic.

If a control bus is shorted, one of the power sources will most likely be lost.

- a. *If a control bus RPC is lost due to a short, the quickest way to remove the other two power sources is to use the RPC reset switch and open the center source circuit breaker. This action will cause four other control buses to lose one of three power sources, and two other control buses to lose two of three power sources. After the IFM is performed to unpower the "reset RPC," two RPC's will be regained by releasing the RPC reset switch. This will result in one control bus (the one with the short) with no power sources, four control buses with two of three power sources, and all others with all three power sources.*
- b. *If a control bus short does not cause the loss of an RPC, the center source 5-amp fuse (downstream of the 10-amp cb) is probably open. The only quick method of removing the other two power sources is to use the two associated RPC reset switches. This action will cause six other control buses to lose one of three power sources, and two other control buses to lose two of three power sources. After the IFM is performed to unpower the associated "reset RPC's," four RPC's will be regained by releasing the RPC reset switches. This results in one control bus (the one with the short) with no power sources, two control buses with two of three power sources, and all others with all three power sources. Continued arcing and smoke may require the center feed cb to be pulled to ensure no power is available to the shorted bus.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-106 CONTROL BUS (CONTINUED)

The IFM unpowers individual RPC's using the appropriate LF MDM cable pins. The IFM does not power the LF MDM or the preflight test bus.

With respect to resetting a control bus RPC to attempt positioning of valves or relays, depending on the location and magnitude of the short, tests have indicated that it may be possible to power momentary (2 to 3 seconds) loads by resetting one of the control bus RPC's.

DOCUMENTATION: SODB 3.4.5.6.2; Lockheed memo #EP5-M10-215, Shuttle Control Bus Kapton Wire Arc Tracking Test Summary, 10-12-90; and LEMSCO-25658, Summary of the Control Bus Repower Test, May 1988.

A9-107 MAIN BUS TIE [CIL]

- A. NORMALLY THE MAIN BUSES WILL BE ISOLATED FROM EACH OTHER. TWO OR THREE MAIN BUSES WILL BE TIED:
1. TO REGAIN INSIGHT INTO AN FC PERFORMANCE DUE TO SUSPECT OR FAILED INSTRUMENTATION (I.E., CPM) AND WILL BE UNTIED PRIOR TO DEORBIT TIG. FOR PAYLOAD DEPLOYS OR PROX OPS, A MAXIMUM OF TWO MAIN BUSES WILL BE TIED. WHILE TIED, FC MANAGEMENT WILL BE PERFORMED PER RULE {A9-59}, FC - CELL PERFORMANCE MONITOR [CIL].

It has been determined that a viable alternative to adequate FC instrumentation is to tie the FC to a healthy, adequately instrumented FC. For critical flight phases during which the temporary loss of all GPC's would be unacceptable, only two buses will remain tied.

DOCUMENTATION: SODB, 4.4.1.1.1.

2. FOR CELL FAILURE OR DEGRADATION IN ORDER TO MAINTAIN THREE POWERED MAIN BUSES.

It is highly desirable to always maintain the highest level of power redundancy to all orbiter equipment.

3. IN PERFORMANCE OF MALFUNCTION PROCEDURES TO MINIMIZE LOAD TRANSIENTS ON THE FC'S.

It is highly desirable that no FC be stressed unnecessarily by excessive loading. Therefore, for total vehicle electrical loads of >18 kW, all three buses will be tied during periods of troubleshooting. The FC malfunction procedures reflect this philosophy.

DOCUMENTATION: SODB, 3.4.4.1.2.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-107

MAIN BUS TIE [CIL] (CONTINUED)

4. FOR EXTENDED ON-ORBIT OPERATION OF PAYLOADS REQUIRING >4 KW (TWO BUSES TIED.)

It is used to preclude one FC from being overstressed by excessive electrical load caused from supporting a main bus and the high power requirement of the payload. ©[092701-4872]

After a powerdown of orbiter equipment to accommodate the payload power requirements, the orbiter will still require approximately 4 kW power per FC. With the addition of a payload power demand of 4 kW on a single fuel cell, about 1 kW of the total load will shift to the other FC due to the dioded load sharing. The total load remaining on the fuel cell will be approximately 7 kW that is the SODB maximum limit for continuous power from a fuel cell. Therefore, payload power demands greater than 4 kW require two buses tied so that additional load can be shared between two FC's.

DOCUMENTATION: SODB, 3.4.4.1.2 and engineering judgment.

- B. BUS TIEING DURING ASCENT/ENTRY WILL ONLY BE PERFORMED IF THE TOTAL FC ELECTRICAL LOAD IS ?27 KW OR 930 AMPS AND THE REMAINING FC PERFORMANCE (V-I) HAS BEEN NOMINAL.

A bus tie to a decaying FC during powered flight is acceptable provided the remaining FC's have adequate performance margins available to support two buses.

- C. BUS TIEING TO A DEAD BUS (I.E., BUS VOLTS <20 V DC) PRIOR TO SRB SEPARATION WILL NOT BE PERFORMED.

The voltage transient on a good bus while tieing to an unpowered bus may cause an undervoltage condition on the SRB buses resulting in the loss of two of three power sources to the SRB's. All critical equipment will remain powered with loss of one main bus (volts < 20). Therefore, only the switching absolutely necessary should be performed pre-SRB separation, and the bus tie steps when main volts are < 20 Vdc should not be performed.

A9-108

CRITICAL PHASE BUS MANAGEMENT

ELECTRICAL BUSES NOT REQUIRED FOR ASCENT AND/OR ENTRY (E.G., PAYLOAD BUSES NOT REQUIRED FOR THESE PHASES) WILL NORMALLY BE POWERED OFF PRIOR TO THE CRITICAL PHASE.

Unpowered circuitry cannot provide a site for a short. This affords more protection to the orbiter during critical mission phases.

This rule is referenced by Rule {A9-262}, EDO PALLET MANAGEMENT.

FLIGHT RULES

A9-109

PRIMARY PAYLOAD BUS MANAGEMENT

ELECTRICAL POWER TO MAJOR PAYLOADS IN THE ORBITER PLB IS PROVIDED VIA THE ORBITER PRIMARY PAYLOAD BUS. THE PRIMARY PAYLOAD POWER SOURCES TO THE ORBITER PLB WILL BE MANAGED AS FOLLOWS:

- A. PRIMARY PAYLOAD MNC - 8 KW CONTINUOUS, 12 KW PEAK FOR 15 MINUTES EVERY 3 HOURS.
- B. PRIMARY PAYLOAD FC3 - 8 KW CONTINUOUS, 12 KW PEAK FOR 15 MINUTES EVERY 3 HOURS.
- C. PRIMARY PAYLOAD MNB - 7 KW CONTINUOUS, AND PEAK @071494-1658A]

By design, the power level constraints noted above must be observed. The orbiter MNC bus feed is the normal source of power to the primary payload bus to maximize the amount of power delivered to a payload. Although the FC3 feed has the same power constraints as the orbiter MNC bus feed, it has always been the philosophy to feed the payloads from orbiter buses rather than directly from the FC, when possible. The MNC and FC3 feeder constraint is based upon FC power limitations. The existing fuel cells cannot supply the full power capabilities of the four feeders (each with 200 amp fuses) without violating the FC power constraints. The orbiter MNB feed does not have the power capabilities of the other feeds due to the fuse sizing between the orbiter MNB bus and the primary payload bus. The MNB feeder constraint was based on a detailed analysis completed by the subsystems managers. It was determined for a worst case of 26.8 volts and a 10 percent difference between the two feeders, that 7 kW continuous and peak was to be the highest level that the MNB bus should operate at and still maintain the integrity of the feeder and provide a slight margin of safety. Payload power includes all ac and dc power provided to the payload. Primary payload power is measured at the FC output terminals.

©[071494-1658A]

DOCUMENTATION: SODB 4.5.6.8.1.

FLIGHT RULES

A9-110

PREFLIGHT TEST BUS MANAGEMENT

IF NECESSARY TO REGAIN A CRITICAL FUNCTION, THE PREFLIGHT TEST BUS MAY BE POWERED MOMENTARILY OR CONTINUOUSLY FOR ORBIT OR ENTRY. THE PRELAUNCH MDM'S WILL NOT BE POWERED. SPECIFIC LRU'S OR SITUATIONS THAT USE THE PREFLIGHT TEST BUS WILL BE IDENTIFIED IN THE RULES SECTION FOR EACH DISCIPLINE.

- A. USAGE OF THE PREFLIGHT TEST BUS WILL BE CONSTRAINED AS FOLLOWS:
1. ORBIT - RESTORE CRITICAL EQUIPMENT AFTER FIRST FAILURE.
 2. ENTRY - RESTORE CRITICAL EQUIPMENT FOR ENTRY SINGLE-FAULT TOLERANCE (SFT).
- B. THE FOLLOWING CONSTRAINTS MUST BE FOLLOWED IF THE PREFLIGHT TEST BUS IS POWERED CONTINUOUSLY.
1. ORBIT - A MAIN BUS TIE WILL BE PERFORMED TO PROTECT AGAINST AN INADVERTENT MAIN BUS DISCONNECT PRIOR TO PREFLIGHT TEST BUS POWERUP:
 - a. FOR PREFLIGHT BUS 1 USAGE - BUS TIE MNA TO MNB.
 - b. FOR PREFLIGHT BUS 2 USAGE TO RECOVER FC3 - TO PRECLUDE POSSIBLE LOSS OF TWO MAIN BUSES, BUS TIE MNA TO MNC WHILE THE PREFLIGHT BUS IS POWERED AND FC3 IS NOT YET RECOVERED. ONCE FC3 IS RECOVERED, RECONFIGURE THE BUS TIE MNB TO MNC AND CONNECT FC3 AND MNC TO THE PRIMARY PAYLOAD BUS.
 - c. FOR PREFLIGHT BUS 2 USAGE IN ALL OTHER CASES - BUS TIE MNB TO MNC AND CONNECT FC3 AND MNC TO THE PRIMARY PAYLOAD BUS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-110

PREFLIGHT TEST BUS MANAGEMENT (CONTINUED)

2. ENTRY - FOR FUEL CELL (ECU) RECOVERY, THE PREFLIGHT TEST BUS WILL BE USED TO PROVIDE A TWO FC ENTRY (REF. RULE {A9-57D}, REUSABLE FC). TO PRECLUDE POSSIBLE LOSS OF TWO MAIN BUSES DUE TO A PREFLIGHT TEST BUS DRIVER FAILURE, THE FOLLOWING MAIN BUS TIE/PRIMARY PAYLOAD BUS CONFIGURATION SCHEDULE WILL BE IMPLEMENTED:
- a. FC1 RECOVERED, FC2(3) FAILED: BUS TIE MNB TO MNC
 - b. FC2 RECOVERED, FC1 FAILED: BUS TIE MNC TO MNA
CONNECT FC3 TO PRI PL BUS
CONNECT MNC TO PRI PL BUS
 - c. FC2 RECOVERED, FC3 FAILED: BUS TIE MNC TO MNA
 - d. FC3 RECOVERED, FC1(2) FAILED: BUS TIE MNA TO MNC (MNB)
CONNECT FC3 TO PRI PL BUS
CONNECT MNC TO PRI PL BUS

FOR ALL OTHER USES, FOLLOW THE MAIN BUS TIE GUIDELINES IN PARAGRAPH B.1.

NOTE: A CREWMEMBER MUST BE ABLE TO UNPOWER THE PREFLIGHT TEST BUS WHILE SECURED IN SEAT.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-110

PREFLIGHT TEST BUS MANAGEMENT (CONTINUED)

C. MOMENTARY USE OF THE PREFLIGHT TEST BUS CONSTRAINTS ARE AS FOLLOWS:

IF MOMENTARY USE IS POSSIBLE DURING ENTRY, ON-ORBIT PREFLIGHT TEST BUS POWERUP IS REQUIRED TO VERIFY NO DRIVER FAILURES. IF POSSIBLE, THE MOMENTARY FUNCTION WILL BE EXERCISED ON ORBIT.

Powering the preflight test bus enables circuits that use the single-string launch MDM's and data bus system to operate most orbiter systems equipment during ground turnaround. Due to the design, a single driver failure could cause equipment to be inadvertently commanded whenever the preflight test bus is powered. A study prepared by the Electrical Systems Section, Systems Division, Mission Operations Directorate, showed that the results of each driver failure is recoverable and would not place the orbiter or crew in a critical situation. Therefore, while on orbit, the preflight test bus may be used to restore critical redundancy beyond SFT. Due to entry being a critical phase of flight, use of the preflight test bus is limited to restore only single-fault tolerance to entry-critical systems. Note that at no time would the prelaunch MDM's be powered during a mission since a single card failure could send multiple, conflicting commands to orbiter systems and alter vehicle configuration severely (e.g., simultaneous FC/main bus disconnect/connect, etc.). The three most significant single driver failures that were noted were the FC/main bus disconnect, three-phase ac inverter and bus disconnect, and APU fuel valve closure.

During the orbit phase, if the preflight bus is to be powered continuously, a bus tie is performed to prevent loss of a main bus due to an inadvertent disconnect caused by a preflight test bus driver failure. For the recovery of FC3, total prevention of the loss of a main bus cannot be met. However, to avoid losing two main buses, the bus tie configuration is modified so MNC is tied to MNA during the relatively brief time when the preflight test bus is powered, but FC3 is not yet recovered. This configuration covers the case for the untied FC2/MNB bus system having a failed driver when the preflight test bus is first powered which results in the temporary loss of MNB. The prevention of the loss of a main bus can be met once FC3 is recovered and connected to its main bus by reconfiguring the bus tie between MNB and MNC. In addition, while FC3 is operating, the primary payload bus can be used to provide a redundant electrical path between FC3 and MNC which will prevent FC3 from inadvertently disconnecting from its main bus.

During entry, the bus tie configuration depends upon the reason the preflight test bus is being used. For the case where it is used to recover a FC, the bus tie configuration depends upon which FC is recovered and which FC has failed. The reason for this is to protect the electrical system from losing more than one main bus due to a driver failure. Again, the primary payload bus can be used to provide a redundant electrical path between FC3 and MNC which will prevent FC3 from inadvertently disconnecting from its main bus.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-110**PREFLIGHT TEST BUS MANAGEMENT (CONTINUED)**

A disconnect of either ac inverter power or ac buses can be corrected during either orbit or entry phase of flight by unpowering the preflight bus and using the panel switches to restore the affected ac system. Unpowering the preflight test bus will result in the loss of the system it recovered.

Since avionics bay fire suppression can be inhibited by an undetectable DISCHARGE CMD driver failure (one driver per avionics bay), as well as other undesirable driver failures affecting vehicle configuration, the crew must be able to unpower the preflight test bus while seated for entry. If fire suppression is required for an avionics bay while on orbit, either the preflight test bus can be unpowered momentarily to recover the AV bay built-in system or a handheld bottle can be discharged. Preflight test bus 1 can affect avionics bay 3 fire suppression, and preflight test bus 2 can affect avionics bays 1 and 2 fire suppression.

Momentary use of the preflight test bus would require only a few seconds of operations (<5 seconds) to accomplish most switching or reconfiguration tasks, so exposure to driver failures is limited. The only constraint is that on-orbit verification of preflight test bus capability be performed which will ensure the integrity of the test bus and the IFM procedure prior to its use during entry.

DOCUMENTATION: On-Orbit/Entry Usages of Preflight Test Bus, Electrical Systems Section - Mission Operations Directorate. Presented to Orbit Flight Techniques on November 18, 1988.

Rule {A9-57D}, REUSABLE FC, references this rule.

A9-111 THROUGH A9-150 RULES ARE RESERVED

FLIGHT RULES

AC POWER DISTRIBUTION AND CONTROL SYSTEMS MANAGEMENT

A9-151 AC INVERTER MANAGEMENT

NORMALLY, ALL AC INVERTERS AND BUSES WILL BE POWERED DURING FLIGHT. IF AN INVERTER FAILS, IT WILL BE DISCONNECTED FROM BOTH THE AC AND DC BUSES.

All nine ac inverters are utilized by orbiter equipment. The dc power to a failed inverter will be disconnected since the inverter could act as a load. Also, the output capacitor acts as a load of 2.95 amps on the other two phases of the ac bus supplying power to coupled three-phase loads (ac motors).

A9-152 AC BUS SENSORS SWITCH MANAGEMENT

TO PRECLUDE INADVERTENT AC BUS DISCONNECT, THE AC BUS SENSORS WILL BE PLACED IN THE "MONITOR" POSITION DURING ASCENT (UNTIL MM 105). ALSO, DURING ASCENT PRIOR TO MECO, IF ANY AC PHASE BUS FAILS, OR IF A MAIN ENGINE SHUTS DOWN, OR IF AN SSME CONTROLLER LOSES REDUNDANCY, THEN ALL THREE AC BUS SENSOR SWITCHES WILL BE PLACED TO "OFF". POST OMS-1, THE AC BUS SENSORS WILL NOMINALLY BE PLACED IN "AUTO TRIP" AND REMAIN IN THAT POSITION FOR THE REMAINDER OF THE FLIGHT (THROUGH WHEEL STOP). @[110900-3510]

AC sensors are put to MONITOR during powered flight to prevent an inadvertent tripoff that would cause SSME controller auto switchover from the affected bus to a secondary SSME controller on another ac bus. If a main engine shuts down, or SSME controller redundancy is lost, or a failure occurs in the AC system, the ac sensor switches will be put to OFF so that no failure in the ac bus sensor could cause further complications. If a failure occurs in an AC system during the entry timeframe, the affected AC bus sensor can be taken "OFF" to protect for critical equipment redundancy. @[110900-3510]

Rule {A5-111A}, AC BUS SENSOR ELECTRONICS CONTROL [CIL] references this rule. @[ED]

A9-153 AC BUS LOADING

WHEN POSSIBLE, AC BUS LOADING WILL BE SELECTED TO PROVIDE SEPARATE POWER SOURCES TO REDUNDANT EQUIPMENT AND TO BALANCE BUS LOADS.

The highest level of power redundancy should be maintained. It is advisable to maintain near equal loading on all buses in the event that, if a single FC powers two main buses, it will not be overstressed.

FLIGHT RULES

A9-154

AC LOAD MANAGEMENT DURING ASCENT

- A. ONLY THE FOLLOWING AC SWITCHABLE LOADS, WHOSE RECOVERY CANNOT BE DELAYED UNTIL POST-MECO, MAY BE RECONFIGURED PRE-MECO:
1. FREON PUMPS (IF ONLY ONE FREON LOOP AFFECTED, SWITCH WITHIN 6 MINUTES; IF BOTH FREON LOOPS AFFECTED, SWITCH ASAP)
 2. RAD BYPASS VALVES (ONLY FOR LOSS OF FES OR FREON LOOP(S) AFFECTED)
 3. RAD ISOLATION VALVES (FOR AN UNEXPLAINED LEAKING LOOP ATTEMPT ISOLATION ASAP; IF LEAK RATE CAN SUPPORT MECO AND AC CRITICAL, DELAY ACTION UNTIL POST-MECO) @[040899-2568A]
 4. AVIONICS BAY FANS (SWITCH WITHIN 3 MINUTES IF A POWERED GOULD TACAN IS LOCATED IN AFFECTED AV BAY. IF AV BAY 3A UPGRADED FOR ENHANCED COOLING, THE FAN WILL NOT BE SWITCHED.)
 5. OMS/RCS VALVES
 6. APU/HYD WSB CONTROLLER (ONLY AFTER HIGH TEMP FDA ALERT)
 7. H₂O LOOP PUMPS (ONLY IN THE EVENT OF AVIONICS AIR TEMP FDA)
 8. CREW SEAT OPERATIONS (ONLY IF CONSIDERED MANDATORY BY THE CREW) @[040899-2568A]
- B. AC CIRCUIT BREAKERS WHICH HAVE OPENED WILL NOT BE RESET PRE-MECO UNLESS THE FUNCTION IS CRITICAL AND:
1. THE MCC HAS CONFIRMED THAT THE CB(S) DID NOT OPEN BECAUSE OF A SHORT, OR:
 2. THE MCC CONFIRMS THAT BOTH SSME CONTROLLERS ON THE AFFECTED BUS HAVE BEEN LOST, OR:
 3. LOSS OF THE FUNCTION IS CONSIDERED TO BE A GREATER RISK THAN LOSS OF THE TWO AFFECTED SSME CONTROLLERS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-154 AC LOAD MANAGEMENT DURING ASCENT (CONTINUED)

- C. FOR A SHORTED OR STALLED AC LRU, WHEN RECONFIGURATION IS DELAYED UNTIL POST-MECO, THE POWER WILL BE REMOVED PRE-MECO.
- D. AC EQUIPMENT WITH MULTIPLE POWER SOURCES WILL NOT BE RECONFIGURED TO AN ALTERNATE SOURCE PRE-MECO.
- E. IF PRE-MECO AND A SSME HAS LOST SSMEC REDUNDANCY, SWITCHING OF REDUNDANT HARDWARE ON TO A CRITICAL AC BUS WILL BE DELAYED AS LONG AS POSSIBLE.
- F. IF NEEDED, ANY UNSHORTED EQUIPMENT THAT HAS BECOME UNPOWERED MAY BE REPOWERED PRE-MECO.

Under normal circumstances, the startup transients of three-phase motors will not introduce a voltage transient on an ac bus that would affect a Space Shuttle main engine controller (SSMEC). However, switching such equipment increases the risk of causing severe voltage transients since an unknown short circuit may be present on the previously unpowered circuitry. By limiting the reconfiguration of ac loads to those absolutely required, this risk can be minimized.

Those loads that may be reconfigured prior to MECO include the Freon pumps since they provide vehicle cooling, radiator bypass valve motors to obtain radiator flow for cooling if total FES fails or to determine if there is blockage in the bypass leg of the Freon loop when Freon flow is low, avionics bay fans since they are required to provide cooling to the Gould TACAN's (an ac powered LRU that has been shown to short-circuit within 5 minutes following loss of cooling), OMS/RCS valves since they are required in malfunction cases, leak isolation or propellant dump operations, and the crew seat motors since they may be needed due to reach or visual problems. Reconfiguration of these items cannot wait until MECO.

With one Freon loop down and one good Freon loop, corrective actions can be delayed for 6 minutes (at ascent power loads) without any violation of any orbiter thermal limits (ref. RI Analysis SEH-ITA-80-055T).

However, if both Freon loops are affected, troubleshooting of the Freon loops will occur ASAP. The loss of both Freon loops is an RTLS/TAL abort. Switching of Freon pumps and moving the Rad bypass valves or RAD isolation valves may be required to determine the status of the Freon loops before an abort call can be made. Additionally, a Freon loop leak that is observable during ascent is a large leak and will require first day PLS if no action is taken. The radiator isolation valve may isolate the leak and allow mission extension to MDF. ©[040899-2568A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-154**AC LOAD MANAGEMENT DURING ASCENT (CONTINUED)**

The SODB indicates the Gould TACAN's are the only avionics bay equipment that may be expected to fail because of the loss of an avionics bay fan during the powered flight time period. When the Gould TACAN fails due to the loss of cooling, the ac transient generated could cause loss of SSMEC redundancy on two SSME's. The TACAN's could be unpowered for ascent since ample time exists, even during an RTLS, for their activation before they are required. However, access to TACAN's would require an MS to unbuckle to reach the switches since they are located beyond the reach of the crew while seated. The redundant avionics bay fans are checked about 12 hours prior to launch. Therefore, switching to the redundant avionics bay fan appears to be of less risk than having a crewmember unrestrained in an attempt to turn on the TACAN's during an abort. The avionics fan will be switched within 3 minutes after loss of original fan (ref. SODB Table 34.32-1, note h).

The Enhanced Middeck Cooling modification will place cabin fans in Av Bay 3A vice the normal avionics fans. Because of the large startup AC transient associated with these type fans, the Av Bay 3A fans will not be switched, in powered flight, if the modification is in place. Vehicles with cabin fans installed in Av Bay 3A will also have Collins TACAN's which are free air cooled. Switching fans pre-MECO will not be necessary. ©[040899-2568A]

Following the loss of a water loop pump or APU/HYD WSB controller, reconfiguration can wait until post-MECO without great risk to the equipment. Should real-time data indicate that the temperatures are out of limits, then action will be taken in order to preserve the necessary equipment prior to MECO. Reconfiguring of affected ac equipment prior to MECO may be attempted since this action may reduce the risk of further problems. Temperature violations are not expected pre-MECO. Cabin fan, IMU fan, and humidity separator reconfiguration is not required until post-MECO.

If a circuit breaker has opened, it could very well be due to a short circuit. If both SSME controllers have been lost (due to the short), or if a short was not the problem, then the cb(s) may be reset if needed to regain a critical function. Resetting a cb that has opened due to a short would further expose SSME controllers (if not already lost) while the chance of a successful reset would be minimal.

AC LRU's with alternate power sources should not be reconfigured since an electrical short in the LRU will place the short on the affected ac bus; and, by switching the source power, the short will be transferred to another ac bus. During ascent, this could result in the loss of one SSME and total loss of redundancy for the two remaining SSME's.

If Pre-MECO and a SSME has lost controller redundancy, switching of redundant hardware on to a critical ac bus will be delayed as long as possible. By delaying switching to after "Press to MECO" or "Single Engine Press" (if possible), even in the unlikely event the alternate fan or pump is stalled and causes a transient on a critical bus, the orbiter could still make it to orbit with the loss of a SSME.

If an LRU is not shorted and was operating nominally, but somehow became deactivated, then it can be repowered pre-MECO, if it is required. Since the shutdown and startup of the LRU would be on the same ac bus, multiple SSMEC's could not be affected.

DOCUMENTATION: SODB 3.4.5.2-1.

FLIGHT RULES

A9-155**AC INVERTER THERMAL LIFE**

- A. THE INVERTER/AC BUS WILL BE DISCONNECTED IMMEDIATELY IF:
1. THE AC VOLTAGE IS CONFIRMED >130, OR
 2. THE AC VOLTAGE IS <95 AS CAUSED BY A SHORT/OVERLOAD, OR
 3. BOTH MAIN ENGINE CONTROLLERS POWERED BY THAT BUS ARE NONFUNCTIONAL (POST-MECO OR MCC VERIFIED FAILED PRE-MECO) AND:
 - a. THE AC VOLTAGE IS CONFIRMED <108, OR
 - b. THE AC VOLTAGE IS CONFIRMED >123, OR
 - c. A SHORT/OVERLOAD CONDITION EXISTS.

AC equipment is only guaranteed to operate from 110 to 120 volts. If the voltage is > 123 (C&W high limit), the potential exists to damage LRU's on the bus. If the voltage is < 108 (C&W low limit), leaving the inverter connected to the bus can result in a load on the remaining two phases, or maintaining power to a short circuit if an overload exists. These risks will be accepted for a short duration of time (until MECO) providing that at least one of the affected main engine controllers is still functioning. Only the MCC can verify controller operation. If the voltage is > 130, then the main engine controllers should not be functional and damage could occur to other equipment on the bus. If the voltage is <95 and caused by a short/overload condition, then the engine controllers will probably not be functional, and leaving the inverter on line and feeding the short creates a fire hazard. This rule is consistent with the philosophy expressed in Rule {A9-104A}, MAIN BUS SHORT.

DOCUMENTATION: SODB 4.5.6.2.a, ICD-13M15000, engineering judgment.

- B. MECO THROUGH EOM LANDING WITH COOLING:
1. 7.7 (6.76) AMPS CONTINUOUS
 2. 9.6 (8.6) AMPS (130 PERCENT) 5 HOURS
 3. 11.1 (10.1) AMPS (150 PERCENT) 30 MINUTES

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-155

AC INVERTER THERMAL LIFE (CONTINUED)

4. 14.4 (13.4) AMPS (200 PERCENT) 2 MINUTES

POWERDOWN WILL BE PERFORMED AS REQUIRED TO MEET THE
7.7 (6.7) AMPS CONTINUOUS LOAD CRITERIA.

These values represent the output power capability of the inverters under various load conditions with nominal orbiter cooling.

DOCUMENTATION: SODB, 4.5.6.3.1.8.

C. WITHOUT COOLING:

1. 3.2 (2.3) AMPS (60 PERCENT) CONTINUOUS
2. 5.1 (4.2) AMPS (70 PERCENT) 5 HOURS
3. 6.4 (5.5) AMPS (85 PERCENT) 1.5 HOURS
4. 8.3 (7.4) AMPS (115 PERCENT) 30 MINUTES

These values represent the output power capability of the inverters under various load conditions without cooling (extrapolated from test data).

DOCUMENTATION: Westinghouse Elec. Corp., Aerospace Elec. Div., Lima, Ohio, Engineering Development Lab, Report No. LY21018, April, 1980, Test Report on 150 percent Overload and no Coolant Tests, Space Shuttle 750 VA Power Static Inverter.

NOTES: 1. AC BUS CURRENT VALUES ARE BASED ON BUS LOAD POWER FACTORS OF 0.8 LAGGING WITH COOLING AND 0.85 LAGGING WITHOUT COOLING.

The use of 0.8 power factor with cooling was to be able to give inverter output capability at a specific power factor so the values could be easily compared. The SODB gives the output capability at various loads at various power factors. The test data for inverter capability with no cooling used a power factor of 0.85.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-155

AC INVERTER THERMAL LIFE (CONTINUED)

2. AC INVERTER PHASE CURRENTS WILL BE USED TO PREDICT INVERTER THERMAL LIFE. INVERTER CURRENT WILL BE CALCULATED BY VECTORIALLY SUMMING ITS AC BUS CURRENT WITH A 2.95 AMP CAPACITOR LOAD.

THE INVERTER CURRENTS WILL BE CALCULATED USING THE FOLLOWING EXPRESSION:

$$I_{INV}^2 = 8.7 I_{BUS}^2 + 5.9 I_{BUS} \frac{PF}{|PF|} \sqrt{1 - (PF)^2}$$

WHERE: I_{INV} = INVERTER CURRENT

I_{BUS} = AC BUS CURRENT

PF = PREDICTED BUS POWER FACTOR (MINUS FOR LAGGING)

The ac current transducer is located downstream from the inverter output capacitor. Inverter thermal constraints are based on its output amperage upstream of the capacitor (no temperature readout is available). Due to the ac V-I phase shift with reactive loads, the measured amps must be vectorially summed with the output capacitor load to determine the actual inverter load. This calculation differentiates a theoretical inverter load which is covered by specifications from a bus load by a 10-microfarad capacitor located on the output of the inverter.

DOCUMENTATION: Information provided by Westinghouse Elect. Corp.

FLIGHT RULES

A9-156

LOSS OF SINGLE-PHASE AC

- A. IF ANY SINGLE-PHASE BUS IS SHORTED, IT WILL BE ISOLATED FROM BOTH THE INVERTER AND ITS THREE-PHASE AC LOADS. THE AFFECTED THREE-PHASE "GANGED" CB'S WILL BE OPENED TO ISOLATE THESE LOADS FROM THE SHORTED BUS. THE SUB-BUSES POWERED BY THESE CB'S WILL BE CONSIDERED LOST.

Single-phase shorts will be isolated from the three-phase loads so that the remaining two phases will not be loaded by the short by motor transformer coupling.

- B. IF ANY SINGLE-PHASE BUS IS LOST, BUT NOT SHORTED, ONLY THE AFFECTED SINGLE-PHASE LOADS WILL BE ISOLATED FROM THE BUS. ALL THREE-PHASE LOAD CB'S WILL REMAIN CLOSED.

Single-phase loads will be isolated from the lost ac bus so that the remaining two phases will not be loaded by motor transformer coupling.

- C. IF A SINGLE-PHASE BUS IS LOST FROM AC2 OR AC3 AND A DEACTIVATED CABIN FAN IS AFFECTED, THEN IT MUST BE DEMONSTRATED ON THE AFFECTED CABIN FAN THAT IT CAN SUCCESSFULLY START ON THE REMAINING TWO PHASES IN ORDER TO CONTINUE TO NOMINAL EOM. OTHERWISE, THE CABIN FAN IS CONSIDERED TO BE LOST.

Ground tests of the start capability of the cabin fan on two phases was marginal. Therefore, start capability on two phases should be demonstrated on orbit before continuing to nominal EOM.

- D. AFTER ALL REQUIRED BUS ISOLATION HAS BEEN PERFORMED, THREE-PHASE EQUIPMENT WILL BE ALLOWED TO OPERATE ON THE TWO REMAINING PHASES, WITH THE EXCEPTION OF THE H₂O AND FREON PUMPS WHICH WILL BE SWITCHED TO AN ALTERNATE POWER SOURCE OR PUMP.

The two-phase operation of the Freon and H₂O pumps results in loss of flow capability that is significant enough to warrant switching pumps or power sources. All other motors are capable of operating on two phases.

Rule {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A9-157 LOSS OF TWO-PHASE AC

IF TWO PHASES OF A THREE-PHASE ARRAY ARE LOST, MULTIPLE PHASE AC LOADS WILL BE DISCONNECTED SO THAT THE REMAINING SINGLE AC PHASE CAN REMAIN POWERED.

Attempted operation of three-phase equipment with only one good phase results in stall currents on the good remaining phase. The multiphase loads will be removed so that normal operation of single-phase loads can be resumed.

A9-158 AC POWER TRANSFER CABLE

- A. THE AC POWER TRANSFER CABLE WILL BE USED TO REPOWER A THREE-PHASE BUS WHEN TWO OR MORE OF ITS INVERTERS ARE FAILED. ALL INVERTERS WILL BE DISCONNECTED FROM THE FAILED THREE-PHASE BUS BEFORE CONNECTING THE CABLE. CRITICAL EQUIPMENT WILL BE POWERED THROUGH THE CABLE; HOWEVER, AC CURRENT PER PHASE WILL BE LIMITED TO 3 AMPS. A THREE-PHASE AC BUS REGAINED BY USE OF THIS CABLE WILL BE CONSIDERED ACCEPTABLE FOR MDF PROVIDED CRITICAL LRU'S CAN BE POWERED.

The IFM procedure describes the concept of using an "extension cord" from a reliable ac bus utility outlet to power another ac bus through its utility outlet. A maximum of 3 amps per phase is due to the size of the utility outlet circuit breakers. This load will always include the FC pumps (coolant and H₂) and may include any other required equipment as long as the total continuous load does not exceed 3 amps. An MDF will be declared for this failure since the next worst failure (loss of the FPC bus powering the inverters used to recover the lost ac system) would result in the loss of two ac systems and the associated fuel cells. (The ac power transfer cable would be used to regain one ac system, if the second failure occurred on orbit.)

- B. FOR LOSS OF TWO OF THREE PHASES ON AN AC BUS (UNSHORTED), A ONE ORBIT DELAY PRIOR TO A DEORBIT BURN WILL BE INVOKED, IF NECESSARY, TO INSTALL THE AC TRANSFER CABLE, REGAINING THE AC BUS. A 1-DAY DELAY IS ACCEPTABLE IF INSTALLATION OF THE AC TRANSFER CABLE IS REQUIRED TO MAINTAIN TWO-FC ENTRY CAPABILITY.

Loss of the ac bus causes loss of a fuel cell and some critical ac loads. It is preferable to delay to install the cable and regain the fuel cell and critical ac loads.

DOCUMENTATION: FDF, IFM Checklist, All Vehicle, AC Power Transfer Cable Installation, pg. A-3. Also, a list of possible loads to repower is in the FPC bus loss SSR's in the Orbiter Malfunction Procedures Book.

Rule {A-1001}, ELECTRICAL GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A9-159 MOTOR CONTROL ASSEMBLY (MCA)

INDIVIDUAL MCA BUS POWER MAY BE CYCLED AS REQUIRED TO PROTECT A BUS FROM SHORTED MOTOR LOADS OR TO REMOVE A "FAILED ON" MOTOR LOAD FROM A BUS.

Shorts will always be isolated from the rest of the electrical power and distribution system. It also may be necessary to remove power to a failed-on motor to protect the motor for future use during the flight.

A9-160 CAUTION AND WARNING (C&W) [CIL]

- A. PRIMARY C&W SYSTEM PARAMETERS THAT ARE NOT OPERATIONALLY FUNCTIONING WILL BE INHIBITED TO EXTINGUISH ANNUNCIATION LIGHTS.

Primary C&W system parameters that are not operationally functioning will be inhibited to extinguish annunciation lights so that they will not mask other parameters using the same light for alarm annunciation or interfere with recognition of new malfunctions.

- B. BACKUP C&W PARAMETERS THAT GENERATE NUISANCE ALARMS WILL BE INHIBITED.

Backup C&W parameters that generate nuisance alarms will be inhibited because by definition the nuisance alarms provide no new information for system operations and distract the flight crew from other activities.

- C. THE PRIMARY AND BACKUP C&W LIMIT VALUES WILL BE MAINTAINED THE SAME.

The primary C&W limits and backup C&W limits will be the same to ensure fail-safe operations in alerting the flight crew to perform necessary safing reconfiguration.

- D. A FAILED PRIMARY C&W SYSTEM MAY REMAIN POWERED AND ENABLED TO RETAIN TONE CAPABILITY PROVIDED NO NUISANCE ALARMS ARE GENERATED.

A failed primary C&W system may remain powered and enabled to retain tone capability if no nuisance alarms are generated in order to provide redundancy in audio tones for the backup C&W system. Redundant alarm tones are not required when they are a nuisance and distract the flight crew from other activities.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-160 CAUTION AND WARNING (C&W) [CIL] (CONTINUED)**

- E. FOLLOWING THE LOSS OF C&W POWER SUPPLY A OR B, ONE OF THE FOLLOWING ACTIONS WILL BE PERFORMED:
1. REDUNDANTLY POWER THE REMAINING C&W POWER SUPPLY SO THAT LOSS OF ANY ESSENTIAL BUS WILL TRIGGER AN AUDIBLE ALARM.
 2. DEDICATE A CREWMEMBER TO CONTINUOUSLY MONITOR CRT MESSAGES FOR LOSS OF ESS2CA DA2 AFTER LOSS OF C&W SYSTEM A OR ESS1BC DA1 AFTER LOSS OF C&W SYSTEM B (NO AUDIBLE ALARMS).
 3. PLACE AFFECTED FC IN STANDBY AFTER LOSS OF C&W SYSTEM A (FC 2) OR AFTER LOSS OF C&W SYSTEM B (FC 1).

Failure of ESS1BC DA1 (ESS2CA DA2) after loss of C&W power supply B(A) will not be aurally annunciated. The FC 1(2) coolant pump will stop, and the flight crew must, within a few minutes, shut down the fuel cell to prevent a catastrophic failure due to overheating. The flight crew must continuously monitor displays so that a failure will be detected and appropriate actions to safe the orbiter can be taken. Restoration of power to a lost C&W power supply or establishment of redundant power to the remaining power supply may be accomplished by performing C&W ELECTRONICS UNIT CONTINGENCY POWER IFM procedure and will allow audible alarms if an essential bus is lost. Standby operation of the associated FC will preclude the time-critical ESS bus/coolant pump failure mode. (Ref. Rules {A9-1B}, FUEL CELL (FC) LOSS [CIL]; {A2-104} A.5.b and {A2-104A}.6, SYSTEMS REDUNDANCY REQUIREMENTS.)

A9-161 HYDRAULIC CIRCULATION PUMP OPERATION

NORMALLY, A HYDRAULIC CIRC PUMP WILL NOT BE STARTED ON A MAIN BUS THAT POWERS THE PRIMARY PAYLOAD BUS WHILE SPACEHAB IS ACTIVATED. AN EXCEPTION WOULD BE IF REACTION TO PREVENT LOSS OF A HYDRAULIC SYSTEM DID NOT PERMIT TIME FOR POWER RECONFIGURATION, IF REQUIRED. @[092701-4872]

The voltage ripple caused by the startup of a hydraulic circ pump is greater than the Spacehab interface control document (ICD) requirements. Critical orbiter systems take precedence over payload systems if those orbiter systems are in jeopardy.

Reference: Spacehab PIP. @[ED] @[092701-4872]

A9-162 THROUGH A9-200 RULES ARE RESERVED

FLIGHT RULES

CRYOGENIC LOSS/FAILURE DEFINITIONS

A9-201

O₂ (H₂) MANIFOLD

AN O₂ (H₂) MANIFOLD IS CONSIDERED LOST IF UNABLE TO ISOLATE A PRSD SYSTEM LEAK OF > 10 LB/HR (O₂) OR 1 LB/HR (H₂) TO THE MANIFOLD ASSOCIATED TANK(S), FUEL CELL, OR PCS SYSTEM.

The O₂ manifold leak rate at which the manifold would be considered failed was derived to cover the worst case in which a tank near residual quantities of approximately 10 percent could be required to supply the leak and two fuel cells at entry power levels. Entry power levels will require about 5 lb/hr per fuel cell or 10 lb/hr total. The flow capacity of an O₂ tank (with single heater) near 10 percent quantity is approximately 20 lb/hr. Therefore the maximum leak rate that can be tolerated on top of the required fuel cell flow is 10 lb/hr.

DOCUMENTATION: SODB figure 4.4.2-16 and engineering judgment.

The H₂ manifold leak rate at which the manifold would be considered failed was derived from a study which concluded that the isolation or reduction of an H₂ leak to less than 2 lb/hr before entry is mandatory to eliminate a possible hazardous concentration during entry/landing. Additionally, H₂ leaks less than 1 lb/hr result in nonflammable H₂ concentrations throughout entry. Therefore, 1 lb/hr leak rate was chosen to provide a margin of safety.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A9-202

CRYO TANK

A CRYO TANK IS CONSIDERED LOST IF:

A. ALL CRYO HEATERS IN THE AFFECTED TANK ARE DEFINED AS LOST.

The addition of heat into the cryogenic reactant is the method used to extract fluid from the tank. With the loss of tank heaters, the only flow available from a tank is that corresponding to tank heat leak which is negligible compared to normal requirements. Therefore, the tank is considered lost for all practical purposes.

DOCUMENTATION: SODB, H₂ figure 4.4.1-6, 4.4.2-9 and O₂ figure 4.4.1-11, 4.4.2-17.

B. ELECTRICAL POWER DEMAND CANNOT BE SUPPORTED BY THE TANK.

If the cryo tank cannot be depended on to support normal electrical power levels, declaring it lost guards against the next tank failure for GO/NO-GO rule implementation purposes. The management philosophy that consumables will determine mission duration for a single tank loss still applies; therefore, the tank can be used to extend the mission as long as practical, but a subsequent tank failure would be considered two tanks lost for entering the GO/NO-GO matrix to determine the appropriate action. This rule is intended to cover the blocked filter and the failed closed check valve scenarios.

DOCUMENTATION: Engineering judgment.

C. CRYO TANK PRESSURE CANNOT BE MAINTAINED ABOVE THE TWO-PHASE SATURATION PRESSURE OF THE FLUID.

If the pressure goes significantly below the saturation pressure, there is a possibility that the fluid would go two-phase (under normal operating pressures the fluid is always single phase). The tank can be repressurized with the tank heaters; however, the danger is that, if the fluid is two-phase, some areas of the heater surface may be in the gaseous region and localized overtemperatures could occur that would not necessarily be indicated by the heater surface temperature. Overtemperature in the O₂ tank could result in ignition of Teflon in the tank. Overtemperature in the H₂ tank could result in damage to the tank structure.

DOCUMENTATION: SODB, paragraph 3.4.4.2, and EGIL Console Handbook, SCP 2.8.6.

Rule {A2-205}, EMERGENCY DEORBIT, references this rule.

FLIGHT RULES

A9-203

CRYO TANK ANNULUS VACUUM

A CRYO TANK ANNULUS VACUUM IS CONSIDERED LOST IF:

A. A TANK LEAK OF ANY SIZE HAS BEEN IDENTIFIED.

Leakage from the pressure vessel into the annulus vacuum will cause the burst disk to open on the girth ring of the tank assembly when the pressure difference exceeds 60 ± 25 psid. Very small leaks into the annulus resulting in total gas in the annulus of as little as 0.1 lbm H₂ or 0.7 lbm O₂ (at gas temperature of 70 deg F) will result in this pressure differential. Since the exact location of a pressure vessel leak cannot be identified, it must be assumed for worst-case purposes that the leak is from the pressure vessel into the annulus.

DOCUMENTATION: Engineering judgment.

B. EXCESSIVE HEAT LEAK INTO THE TANK HAS BEEN IDENTIFIED WHEN THE HEATERS ARE UNPOWERED.

In atmospheric flight, air entering the annulus will increase the heat transfer into the tank. In orbit, small pressure vessel leaks into the annulus, prior to the burst disk opening, will result in increased heat leak into the tank from the outer shell because of conduction through the gas in the annulus. This heat leak into the tanks may not always be readily detectable.

DOCUMENTATION: Orbiter Hazard Reassessment ORBI 281, Qualification Test Report for PRSD Vacuum Lost Test, Ball Aerospace Division (TM06,BR16425), and engineering judgment.

Rule {A9-252G}, CRYO HEATER MANAGEMENT FOR ORBIT [CIL], references this rule.

FLIGHT RULES

A9-204

CRYO HEATER

A CRYO HEATER IS CONSIDERED LOST IF:

- A. O₂/H₂ CRYO HEATER TEMPERATURE CANNOT BE MAINTAINED BELOW 350 DEG/200 DEG F (INSTRUMENTATION ERROR INCLUDED).

The O₂ heater temperature was set on the basis of the auto ignition temperature of Teflon (700 deg F) contained in the quantity probe. The 350 deg includes a 200 deg F margin and takes into account sensor lag (50 deg F), analytical and instrumentation error (50 deg F), and the delta T between the temperature sensor and the maximum point (50 deg F). The H₂ tank maximum heater temperature is 200 deg F to prevent potential damage to the tank structure. [ED]

DOCUMENTATION: SODB, paragraph 3.4.4.2; and NASA memo, Oxygen tank heater temperature limit, 02/04/71.

Rule {A9-252F}, CRYO HEATER MANAGEMENT FOR ORBIT [CIL], references this rule.

- B. AN O₂ DELTA CURRENT SENSOR TRANSITIONS TO "TRIP" WHILE ITS HEATER IS RECEIVING POWER.

If a delta current sensor trips while a heater is receiving power, it is considered highly possible that a short had developed in the heater. The consequences of repowering a shorted heater element are so grave that it would not be considered for mission success.

DOCUMENTATION: Flight experience, Apollo 13, and engineering judgment.

- C. BOTH O₂ DELTA CURRENT SENSORS TO THE HEATER ARE LOST.

Without a delta current sensor, a heater short would be a single point catastrophic failure. This is not an acceptable risk to accomplish mission objectives.

DOCUMENTATION: Flight experience, Apollo 13, and engineering judgment.

FLIGHT RULES

A9-205

O₂ DELTA CURRENT SENSOR

AN O₂ DELTA CURRENT SENSOR IS CONSIDERED LOST IF:

- A. THE O₂ DELTA CURRENT SENSOR DOES NOT INHIBIT THE A OR B HEATER WHEN TESTED.

If a sensor test does not inhibit the heater when tested, it is assumed that the sensor would not function if an actual heater short were to occur. ©[061297-6005]

DOCUMENTATION: Engineering judgment.

- B. THE O₂ DELTA CURRENT SENSOR TRANSITIONS TO "TRIP" WHEN NO POWER IS BEING APPLIED TO THE HEATER ELEMENT, AND A RESET DOES NOT REMOVE THE "TRIP" STATUS.

A "trip" due to an actual heater short cannot occur unless a heater is being powered. The inability to reset the "trip" status indicates a failed sensor.

DOCUMENTATION: Engineering judgment.

- C. THE O₂ DELTA CURRENT SENSOR LATCHING LOGIC WILL NOT REMAIN TRIPPED ONCE THE SENSOR HAS TRANSITIONED TO "TRIP".

The delta current sensor will automatically shut down the defective heater circuit in less than 5 milliseconds if a differential current of greater than 0.91 ampere is sensed, but once the sensor has tripped, the short has been removed and the sensor will allow heater reactivation. The function of the latching logic is to ensure that the heater remains disabled after it has been shut down or tripped offline. A heater element with a short that could not be automatically shut down would be a single point catastrophic failure. This is not an acceptable risk to accomplish mission objectives.

DOCUMENTATION: Engineering judgment.

A9-206 THROUGH A9-250 RULES ARE RESERVED

FLIGHT RULES

CRYOGENIC SYSTEMS MANAGEMENT

A9-251

CRYO HEATER MANAGEMENT FOR ASCENT

- A. THE A HEATERS IN CRYO TANKS 1 AND 2 WILL BE ENABLED FOR LIFT-OFF. THE B HEATERS IN CRYO TANKS 1 AND 2 WILL BE ENABLED POST-OMS-1.

Tank heaters will be enabled for launch in an attempt to maintain system pressurization. Only one heater per tank is used to minimize power load transients. In the event of a fuel cell/main bus loss during ascent, electrical power usage is critical. Since cryo heaters are normally not required, it is desirable to lose as many cryo heaters as possible with loss of a fuel cell or main bus during ascent. Since the A heaters are more susceptible to bus failures (loss of either of two main buses causes loss of heater) than the B heaters (requires loss of particular main bus to lose heater), the A heaters will be used for launch.

DOCUMENTATION: Engineering judgment.

- B. SHOULD AN RTLS BE REQUIRED FOR A CABIN LEAK, BOTH HEATERS IN CRYO O₂ TANKS 1 AND 2 SHOULD BE ACTIVATED.

In an RTLS case, the O₂ tanks have to supply flow to both the LES and fuel cell demand. Since the LES's are used through touchdown, all heaters in O₂ tanks 1 and 2 are activated to assure adequate flow capability in this circumstance. (Refer to Rule {A17-201A}, CABIN PRESSURE INTEGRITY.)

FLIGHT RULES

A9-252

CRYO HEATER MANAGEMENT FOR ORBIT [CIL]

- A. CRYO HEATER AND CONTROLLER OPERATION, IN ALL TANKS, WILL BE VERIFIED AS SOON AS PRACTICAL, BASED UPON BALLAST/CG REQUIREMENTS AND STANDARD CRYOGENIC MANAGEMENT PLAN.
@[071494-1653A]

A system health check on all tanks is required to determine flight duration and to formulate any off-nominal cryo management plan. Should a cryo controller be discovered to be failed, and AUTO cryo heater control capability be lost in a tank, MANUAL heater operations would be required. This may place constraints on crew activities. Therefore, it is desirable to discover controller failures early in the mission when latitude is available for timeline replanning. There is no safety of flight requirement to check out cryo controllers. Normally, Orbiter Tank Sets 1 - 5 will be checked out during the first 24 hours of the flight. Heaters in the EDO Tank Sets will be enabled per the cryo management plan.
@[071494-1653A]

DOCUMENTATION: Engineering judgment and flight data.

- B. A DELTA CURRENT SENSOR CHECK WILL BE PERFORMED ONCE PER FLIGHT EXCEPT IN A TANK WHERE A REAL CURRENT SENSOR TRIP (HEATER SHORT) HAD OCCURRED. IF A SENSOR FAILS, A SENSOR CHECK WILL BE PERFORMED ON THE REDUNDANT SENSOR EACH DAY THAT THE AFFECTED HEATERS ARE USED. @[061297-6005]

The purpose of the delta current sensors is to protect against heater shorts internal to the tank. The delta current sensors are tested to ensure that a trip and heater inhibit will occur if a heater is shorted. If the sensors fail the test, the affected heater(s) will not be used. @[061297-6005]

Flight Rule {A9-255A}, O₂ DELTA CURRENT SENSOR, states that a delta current sensor that had transitioned to "trip" while its associated heater is receiving power will not be reset, ensuring that the heater will not be operated. If the remaining heater in that tank is required for use, it will not be possible to test and reset the delta current sensor in the operating heater without also resetting the tripped sensor (one switch tests and resets all delta current sensors in a tank). Therefore, no current sensor tests will be conducted in that tank.

DOCUMENTATION: Engineering judgment.

- C. IF AUTO CRYO HEATER CONTROL IS LOST, THE HEATERS IN THE AFFECTED TANK OR TANK SET WILL BE MANUALLY CYCLED DURING CREW AWAKE PERIODS. TANK QUANTITY BALANCING WILL BE MAINTAINED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-252

CRYO HEATER MANAGEMENT FOR ORBIT [CIL]
(CONTINUED)

If auto heater control is lost, the crew must manually cycle the heaters in order to use the tank. The management plan is followed in order to balance quantities in the tanks and to minimize the impact of a single failure on consumables and mission duration.

DOCUMENTATION: Engineering judgment.

- D. A CRYO HEATER THAT IS DEFINED AS LOST WILL BE DEACTIVATED BY PLACING ITS CORRESPONDING SWITCH IN THE "OFF" POSITION. IF POSSIBLE, CRYO MANAGEMENT WILL BE MODIFIED TO EXPEDITE DEPLETION OF THE AFFECTED TANK. THE EXPEDITED TANK DEPLETION WILL BE TERMINATED WHEN THE NOMINAL MISSION DURATION PLUS TWO EXTENSION DAYS CAN BE ACCOMPLISHED IF THE REMAINING HEATER FAILS (LOSS OF TANK). IN ANY CASE, THE TANK WILL NOT BE DEPLETED PAST THE FOLLOWING POINTS:
1. FOR TANK 1 AND 2: MINIMUM QUANTITY TO GUARANTEE USAGE TO SUPPORT ITS ASSOCIATED FC/MN BUS FOR A NEXT PLS IN THE EVENT THAT ITS MANIFOLD BECOMES ISOLATED.
 2. MINIMUM QUANTITY WHICH WILL ALLOW CLOSURE OF ONE MANIFOLD VALVE FOR EACH SLEEP PERIOD FOR THE NOMINAL MISSION DURATION PLUS TWO EXTENSION DAYS, IF REQUIRED. IF TANK 1 OR 2 IS THE AFFECTED TANK, ITS ASSOCIATED MANIFOLD VALVE WILL NOT BE CLOSED FOR SLEEP PERIODS, IF POSSIBLE, TO PROTECT AGAINST A FAILED MANIFOLD VALVE.

The reference to the switch position is made so an O₂ delta current sensor "trip" will not be considered as a way of heater deactivation without further action. If the failure occurs in tank 1 or 2, the affected tank will be used until the total quantity remaining in the unaffected tanks will support the nominal mission duration plus two extension days. However, tank 1 or 2 will not be depleted because the next worst failure (center manifold leak) could result in loss of two fuel cells. If the failure occurs in any one of tanks 3 through 9, the same next failure would result in loss of one fuel cell. If the failure occurs in tanks 3 through 9, the affected tank will be immediately depleted. Also, sufficient quantity must remain in the tank so that a manifold valve may be closed during crew sleep. However, if other tanks can be used (e.g., modified cryo management), then the sufficient quantity requirement is met by the other tanks.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-252

CRYO HEATER MANAGEMENT FOR ORBIT [CIL]
(CONTINUED)

- E. AN O₂ CRYO HEATER WITH ONE OF TWO DELTA CURRENT SENSORS LOST WILL BE DEACTIVATED BY PLACING ITS CORRESPONDING SWITCH IN THE "OFF" POSITION, UNLESS DOING SO WOULD RESULT IN LOSS OF THE TANK.

If mission success can be performed without the use of the affected heater, then it is an unnecessary risk to continue to operate that heater with loss of the current sensor redundancy. With loss of a current sensor on each string in a tank (failure of the cb powering both current sensors), normal operation will continue since there is one current sensor left on each string and this sensor will be verified operational at least once a day (ref. paragraph B). The old ideology of depleting the tank is considered to be an unnecessary increase of risk, due to operation of the heaters more often than normal.

Rule {A9-205}, O₂ DELTA CURRENT SENSOR, references this rule.

- F. A CRYO HEATER THAT CONTINUES TO BE POWERED AFTER PLACING ITS CORRESPONDING SWITCH IN THE "OFF" POSITION WILL BE DEACTIVATED BY PERFORMING THE FOLLOWING: [CIL]
1. AN ATTEMPT WILL BE MADE TO DEACTIVATE AN O₂ HEATER BY PERFORMING A CURRENT LEVEL DETECTOR TEST. IF REQUIRED, THE HEATER CAN STILL BE USED MANUALLY BY OPERATION OF THE CURRENT LEVEL DETECTOR SWITCH (TEST/RESET FOR HEATER OFF/ON).

An O₂ heater that fails on for more than 9 hours after depletion of the tank to residual levels will risk exceeding the thermal limits of the tank. Prior to this though, the heater surface temperature will exceed the flight rule limit of 350 deg F for O₂ (ref. Rule {A9-204A}, CRYO HEATER).

DOCUMENTATION: FMEA/CIL No. M5-6MB-2029M1-2.

2. IF REQUIRED, AN H₂ HEATER OR AN O₂ HEATER WILL BE DEACTIVATED BY DROPPING THE MAIN BUS THAT POWERS THE HEATER. THE MAIN BUS MAY BE BROUGHT UP FOR ENTRY IF THE TANK QUANTITY ALLOWS CONTINUOUS HEATER OPERATION WITHOUT VIOLATING HEATER TEMPERATURE LIMITS.

If the use of the current level detector function for O₂ or any potential IFM for either O₂ or H₂ is not successful, dropping a main bus is the only option.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-252

CRYO HEATER MANAGEMENT FOR ORBIT [CIL] (CONTINUED)

An H_2 heater that fails on for more than 35 hours after depletion of the tank to residual levels will risk exceeding the thermal limits of the tank. Prior to this, however, the heater surface temperature will exceed the flight rule limits of 350 deg/200 deg F for O_2/H_2 (ref. Rule {A9-204A}, CRYO HEATER). Based on quantity and fuel cell flowrate, the heater could pressurize the tank and manifold until relieved by the overboard relief valve. Cracking of the relief valve could cause ingestion of cryo into the midbody, which is a hazardous condition. However, the alternative is performing entry with two main buses that could put the orbiter/crew at greater risk.

DOCUMENTATION: Engineering judgment, FMEA/CIL No. M5-6MB-2027M1-2, and SODB paragraph 4.4.2.6.2/4.4.2.7.2.

G. AN O_2 (H_2) TANK THAT HAS LOST ITS ANNULUS VACUUM WILL BE DEPLETED PRIOR TO ENTRY.

Loss of annulus vacuum in a PRSD O_2 (H_2) (ref. Rule {A9-203}, CRYO TANK ANNULUS VACUUM) tank would result in overboard venting of O_2 (H_2) through the relief ports near compartment vent doors. In atmospheric flight, atmosphere will enter the annulus and increase the heat transfer to the tank. An uncontrollable pressure rise would result until the overboard relief opens. Ingestion of vented H_2 through open vent doors may result in the accumulation of a flammable/explosive environment in orbiter compartments during entry. The possible H_2 flowrates, as determined by testing, vary from 120 lb/hr (100 percent quantity) to 240 lb/hr (40 percent quantity) to 2.5 lb/hr (10 percent quantity). Depletion of the affected H_2 tank will reduce the H_2 available to be vented and minimize venting flowrates. If the relief valve is opened during entry due to an O_2 tank vacuum loss, verification of that valve will have to be performed during ground turnaround. Depletion of the affected O_2 tank prior to entry will reduce the chance of opening the relief valve.

DOCUMENTATION: Orbiter Hazard Reassessment ORBI 281, Qualification Test Report for PRSD Vacuum Lost Test, Ball Aerospace Systems Division (TM06, BR16425), FMEA/CIL No. 04-1B-TK010-2, 04-1B-TK0 30-2.

FLIGHT RULES

A9-253

CRYO TANK HEATER TEMPERATURE MANAGEMENT

CRYO HEATERS WILL BE MANAGED TO PRECLUDE HEATER TEMPERATURES EXCEEDING 350 DEG FOR O₂ (INSTRUMENTATION ERROR INCLUDED) AND 200 DEG F FOR H₂. O₂/H₂ FLUID TEMPERATURES WILL BE MANAGED TO PRECLUDE EXCEEDING 160 DEG. @[052401-4643]

The O₂ heater temperature was set on the basis of the auto ignition temperature of Teflon (700 deg F) (in the quantity gauging probe). The 350 deg includes a 200 deg F margin and takes into account sensor lag (50 deg F), analytical and instrumentation error (50 deg F), and the delta T between the temperature sensor and the maximum point (50 deg F). The H₂ tank maximum heater temperature is 200 deg F to prevent potential damage to the tank structure.

DOCUMENTATION: SODB, paragraph 3.4.4.2, and NASA memo, Oxygen Tank Heater Temperature Limit, 02/04/71.

A9-254

CRYO HEATERS DEACTIVATION

AT APPROXIMATELY 50 (53) PERCENT QUANTITY, ONE SET OF 2 CRYO HEATERS WILL BE DEACTIVATED IN THE AFFECTED TANK.

With both heater sets activated in an O₂ tank, the heater surface temperature will begin to increase exponentially at lower quantities and could exceed 350 deg F. Therefore, below about 50 percent quantity, one-half of the heaters in each tank are disabled to minimize heater temperature.

DOCUMENTATION: SODB, 3.1.4.2-7, and flight data.

FLIGHT RULES

A9-255

O2 DELTA CURRENT SENSOR

- A. IF AN O₂ DELTA CURRENT SENSOR TRANSITIONS TO "TRIP" WHILE ITS HEATER IS RECEIVING POWER, IT WILL NOT BE RESET AND THE HEATER WILL NOT BE USED UNLESS REQUIRED FOR PREVENTION OF LOSS OF CREW AND VEHICLE.

THE REDUNDANT HEATER IN THE TANK WILL BE UNPOWERED AND USED ONLY TO: COMPLETE THE NOMINAL MISSION DURATION, PROVIDE AUTO HEATER CONTROL WHEN THE MANIFOLD VALVE(S) CLOSES, OR ALLOW USE OF TANKS 1 AND 2 FOR ENTRY.

The purpose of the heater delta current sensors is to provide automatic protection against O₂ tank internal electrical shorts that could cause explosions. In the event of a sensor trip, a reset of the sensor will not be attempted and the heater will be deactivated for safety. A reset and heater use would be allowed if the vehicle encountered extreme circumstances.

The unaffected heater in the tank will be unpowered because, although it is not considered likely, a short on one of two heater elements in an O₂ heater assembly could potentially damage an adjacent heater. It is prudent to unpower all heaters which could be affected if loss of the tank does not impact the mission duration. The unaffected heater may also be used to allow manifold valves to be closed during crew sleep and for entry, if required.

DOCUMENTATION: Flight experience and Apollo 13.

- B. RESET OF A TRIPPED DELTA CURRENT SENSOR ON AN UNPOWERED CIRCUIT CAN BE PERFORMED. THE ASSOCIATED HEATER WILL BE LEFT OFF UNLESS REQUIRED TO PREVENT LOSS OF THE TANK. IF THE HEATER MUST BE POWERED, THE SUSPECT SENSOR WILL BE UNPOWERED.

Two reasons exist for the reset: to allow determination of failure status (hard fail or inadvertent trip); and performing the daily sensor test (no reset would lock out rest of tank). It is undesirable to use a heater string with a failed sensor (see Rule {A9-252E}, CRYO HEATER MANAGEMENT FOR ORBIT [CIL]). Loss of the tank is considered to be a greater impact than operation of a heater string with only one delta current sensor.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A9-256

CRYO O2/H2 TANK QUANTITY BALANCING

TANK MANAGEMENT WILL BE PERFORMED IN A MANNER WHICH WOULD MINIMIZE THE IMPACT OF A TANK OR MANIFOLD LOSS.

- A. FOR THREE TANK SET MISSIONS, TANK HEATERS AND MANIFOLD VALVES WILL BE CONFIGURED DURING THE PRE/POSTSLEEP PERIODS TO MAINTAIN QUANTITY BALANCE AMONG ALL TANKS. @[082593-1532]
- B. FOR MISSIONS WITH FOUR OR MORE TANK SETS, ONE TANK IN THE CENTER MANIFOLD (PREFERABLY TANK 3) WILL BE HELD IN RESERVE, AND THE ADDITIONAL CENTER MANIFOLD TANKS (TANKS 4, 5, AND 6-9) WILL BE DEPLETED AS SOON AS PRACTICAL.
 1. FOR OV-102 WHERE TANK 5 IS PRESENT, TANKS 4 AND 5 WILL BE DEPLETED FIRST, FOLLOWED BY EQUAL DEPLETION OF ANY EDO TANKS (6-9).
 2. FOR OV-105, OR OV-102 WITHOUT TANK 5, THE ADDITIONAL CENTER MANIFOLD TANKS WILL BE MANAGED TO PROVIDE QUANTITY BALANCE AMONG THEMSELVES AS THEY ARE DEPLETED.
- C. FOR FORWARD CG PROBLEMS PREDICTED DURING NEOM OR EARLY ENTRY, CONSIDERATION WILL BE GIVEN TO THE FOLLOWING:
 1. FOR MISSIONS WITH ADDITIONAL MARGIN, CONSIDERATION WILL BE GIVEN TO LEAVING CRYO IN THE CENTER MANIFOLD TANKS (4-9) AS OPPOSED TO DEPLETING THE TANKS. THE AMOUNT AVAILABLE TO REMAIN IN THE TANKS (4-9) IS THE DIFFERENCE BETWEEN THE CURRENT TOTAL QUANTITY MINUS THE MISSION REQUIREMENTS AND REDLINE QUANTITIES. THIS DIFFERENCE SHOULD BE THE CURRENT MARGIN AVAILABLE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-256

CRYO O₂/H₂ TANK QUANTITY BALANCING (CONTINUED)

2. FOR MISSIONS WITHOUT MARGIN, TANKS 1, 2, AND 3 WILL BE USED AS NECESSARY, EARLIER THAN NORMALLY PLANNED, IN COMBINATION WITH THE CENTER MANIFOLD TANKS TO MAINTAIN THE REQUIRED CG. MINIMUM TANK QUANTITY AS DEFINED IN RULE {A9-252D}.1, 2, CRYO HEATER MANAGEMENT FOR ORBIT [CIL], WILL NOT BE VIOLATED.

When flying with four or more tank sets, a manifold leak could cause loss of all tanks in the center manifold (as many as seven tanks). Depletion of these tanks first minimizes the time exposure where a large number of tanks could be lost. While depleting these tanks, their quantity will be balanced to minimize the impact of a single tank loss. The exception to this philosophy is OV-102, where a five-tank configuration leaves O₂ tanks 4/5 with single heaters, and H₂ tanks 4/5 with a common check valve. This makes it desirable to deplete these tanks, followed by equal depletion of any EDO tanks. Tank 3 is the preferred center manifold tank to hold in reserve since its switches are accessible during entry.

For the forward CG missions, the mission margin may be used to adjust the CG. This will be accomplished by leaving the margin in the center manifold tanks, which are normally depleted. Tanks 1 and 2 will be held in reserve for entry. For extension requirements, if the margin is required, the quantity reserved in the center tanks will be used and the tanks will be depleted. A cryo management plan that allows quantity balancing between the forward cryo tanks and the center manifold tanks will alleviate the necessity to carry additional ballast to control forward CG.

DOCUMENTATION: Engineering judgment.

Rule {A9-262}, EDO PALLET MANAGEMENT references this rule.

FLIGHT RULES

A9-257

POWER REACTANT STORAGE AND DISTRIBUTION (PRSD) H₂ AND O₂ REDLINE DETERMINATION

THE REDLINE (AMOUNT CONSIDERED UNAVAILABLE FOR NORMAL MISSION OPERATIONS) CONSISTS OF:

- A. TANK RESIDUALS (H₂ = 4 PERCENT IN EACH OF TWO TANKS, 2.5 PERCENT IN REMAINING H₂ TANKS, O₂ = 6.5 PERCENT IN ALL TANKS).
- B. MEASUREMENT ERROR RSS'ED FOR THE NUMBER OF TANKS. INDIVIDUAL TANK ERROR IS 2.6 PERCENT.
- C. A 2-DAY MISSION EXTENSION PAST THE PLANNED LANDING. THE ON-ORBIT POWER LEVEL DURING THESE 2 DAYS WILL BE BASED ON A PRIORITY POWERDOWN GROUP C CONFIGURATION (REF. RULE {A2-108}, CONSUMABLES MANAGEMENT), PLUS ANY PAYLOAD SURVIVAL POWER. ONE DEORBIT PREP ON EACH EXTENSION DAY (IN ADDITION TO THE TWO NORMAL EOM DEORBIT OPPORTUNITIES) WILL BE BUDGETED DURING THESE 2 DAYS. @[092800-7247A]

The 2.5 percent and 6.5 percent numbers are the minimum quantities guaranteed to be obtainable prior to reaching maximum tank heater temperature limits. The 4 percent requirement in two H₂ tanks protect for entry fuel cell flow demands. This assumes dual heaters in each of two tanks (400 watts total) which yields a flow capacity of $400 \times 3.41/750 = 1.8$ lb/hr, or approximately 20 kW. 750 is the approximate dQ/dM for the 4 percent density fluid at 200 psia.

DOCUMENTATION: Flight Design Level B Groundrules and Constraints (NSTS 21075); S0DB 3.4.4.2, 4.4.2, Table 4.4.2-6; Rockwell Internal Letter #287-100-91-MMS-019; and NBS Technical Note 617.

FLIGHT RULES

A9-258

CRYO O₂ AND H₂ PRESSURE MANAGEMENT

CRYO O₂ AND H₂ PRESSURES WILL BE MANAGED ACCORDING TO THE FOLLOWING CONSTRAINTS:

- A. MANIFOLD PRESSURE UPPER LIMIT OF 950 (890) PSIA FOR O₂ AND 270 (250) PSIA FOR H₂.

Maximum absolute pressure should be such that the manifold relief valves do not crack. If the manifold relief valves open in flight, a retest is required before the next flight. This is not normally a planned test. Crack pressures are 975 psig for oxygen and 290 psig for hydrogen. The recommended maximum operating pressures are chosen to allow some margin for pressure overshoot and transducer error.

DOCUMENTATION: Engineering judgment and SODB 4.4.2.

- B. PEAK-TO-PEAK PRESSURE EXCURSIONS SHALL NOT EXCEED 375 PSI FOR OXYGEN AND 150 PSI FOR HYDROGEN.

Pressure excursions of greater than these values represent a structural pressure cycle on the tank. The tanks are designed to accommodate a lifetime total of 300 such pressure cycles. With a total lifetime requirement of 100 flights, only three structural cycles can be experienced per flight. One cycle is used during initial loading and pressurization. The other two cycles per flight are intended for any required ground testing or checkout.

DOCUMENTATION: SODB 3.4.4.2.9.

- C. OPERATION OF THE CRYO TANK HEATERS IN A TWO-PHASE FLUID WILL BE AVOIDED.

1. FOR MANUAL HEATER OPERATIONS, THE TANK PRESSURE WILL BE MAINTAINED ABOVE THE O₂/H₂ CRITICAL PRESSURES OF 731.4/187.5 PSIA.

Flight data from STS-51D shows that a two-phase condition existed in a tank during manual operation of the heaters. The expected condition of the fluid in the tank, based on quantity and pressure measurements, indicated a single-phase condition. This situation possibly existed because the heaters boiled the liquid around the elements faster than the pressure rise could keep the fluid liquefied. The danger of this is that some areas of the heater surface may be in the gaseous region and localized overtemperature could occur that would not necessarily be indicated by the heater temperature transducer. For this reason, operating heaters in this condition for long periods of time is unacceptable. Overtemperature in the O₂ tank could result in ignition of Teflon in the tank. Overtemperature in the H₂ tank could result in structural tank damage. Maintaining super-critical pressurization ensures that the fluid is single-phase at any temperature or density.

DOCUMENTATION: SODB, paragraph 3.4.4.2, and flight data.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-258

CRYO O2 AND H2 PRESSURE MANAGEMENT (CONTINUED)

2. FOR SITUATIONS IN WHICH THE TANK PRESSURE GOES BELOW THE CRITICAL PRESSURE BUT IS STILL ABOVE THE TWO-PHASE SATURATION PRESSURE, HEATERS MAY BE USED (DUAL HEATERS ARE PREFERRED) TO RAISE THE PRESSURE BACK ABOVE THE CRITICAL PRESSURE.

A two-phase condition may still exist depending on the degree of stratification in the tank. Dual heater operation will increase the pressure of the tank at a faster rate and lessen the possibility of creating a two-phase condition. This was evident from the flight data of STS-51D. Initially, when operating manual heaters, dual heaters were used and no phase change was observed. Later in the flight, single heaters were used and the pressure plateaued at the critical pressure of the fluid. Once the phase change was complete, the pressure continued to rise at a slower rate than before.

DOCUMENTATION: Engineering judgment and flight data.

3. IF THE TANK PRESSURE FALLS BELOW THE TWO-PHASE SATURATION PRESSURE, THE HEATERS WILL BE DISABLED UNTIL NORMAL HEAT TRANSFER INTO THE TANK RAISES THE PRESSURE ABOVE THE TWO-PHASE SATURATION PRESSURE. THE HEATERS MAY BE OPERATED ONLY IN A CONTINGENCY SITUATION.

When the pressure falls below the two-phase saturation pressure, two-phase fluid is located throughout the tank. The amount could be considerably more than the situation created in paragraph 2. The reason for the deactivation is the same as paragraph 2, except that greater risk is thought to be involved.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A9-259

CRYO O2/H2 MANIFOLD VALVES

MANIFOLD VALVE CONFIGURATION WILL BE MANAGED AS FOLLOWS:

- A. AT LEAST ONE MANIFOLD VALVE (PER SYSTEM) WILL REMAIN OPEN, EXCEPT DURING ISOLATION PROCEDURES FOR LEAKS EXCEEDING THE CURRENTLY CONFIGURED TANK HEATER FLOW CAPACITY. FOR THESE MAJOR LEAKS, BOTH MANIFOLD VALVES WILL BE CLOSED. IF NECESSARY, THE REACTANT VALVES ON THE AFFECTED FUEL CELL WILL BE CLOSED TO TROUBLESHOOT THE LEAK. A MANIFOLD VALVE WILL BE REOPENED AS SOON AS POSSIBLE ONCE MANIFOLD INTEGRITY IS RESTORED OR VERIFIED.

The PRSD system was designed without a relief valve in the crossover manifold. Closure of both manifold valves induces a potential hazard if reactant flow to fuel cell 3 is stopped (e.g., reactant valve fails closed). This is due to pressure buildup from environmental heat flow into a dense fluid contained within a fixed volume. An open manifold valve will provide relief through its associated hardware.

It is not considered acceptable to induce this potential hazard with a normal manifold valve configuration. However, in the event of a major system leak, it is desirable to isolate as many fuel cells from the leak as quickly as possible. If the leak is in manifold 1 or 2, no risk is induced by closure of the associated fuel cell reactant valves. If the leak is in the crossover manifold, then closure of the fuel cell 3 reactant valves for a short time period is considered to be a smaller risk than exposing a second fuel cell to the leak, or performing an unorthodox fuel cell shutdown procedure. Analytical and test data indicate that more than 1 minute could elapse before the pressure in the closed manifold reaches the advertised PRSD component burst pressure. Manifold valve testing at JSC indicated that the valves do relieve overpressures. However, relief pressure was in excess of the advertised manifold valve and check valve burst.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-259

CRYO O2/H2 MANIFOLD VALVES (CONTINUED)

B. ASCENT/ENTRY: ALL MANIFOLD VALVES WILL NORMALLY BE OPEN.

The risk of pressure buildup is not considered to be an acceptable trade-off for protecting (by closing both manifold valves) against a major PRSD system leak. The crew response time to the leak is considered to be roughly the same as the response time required for the overpressure concern (30 to 60 seconds). Since closure of any manifold valve can result in loss of a fuel cell due to a tank leak, both valves open is considered to be the best configuration.

C. ORBIT: ONE MANIFOLD VALVE PER SYSTEM WILL NORMALLY BE CLOSED FOR CREW SLEEP PERIODS (SINGLE SHIFT OPS).

During sleep, a major PRSD system leak could cause loss of fuel cell pressurization before the crew could respond. Closure of one valve will protect at least one fuel cell, while not inducing a safety hazard. The vehicle can be safed and reconfigured on orbit starting with a single main bus.

DOCUMENTATION: Rockwell informal desktop analysis on tank pressure blowdown, SODB volume I, tables 4.4.1-2, 4.4.1-3, and 4.4.1-5; and engineering judgment.

FLIGHT RULES

A9-260

CRYO SYSTEM LEAKS [CIL]

THE PRSD SYSTEM WILL BE MANAGED AS FOLLOWS FOR SYSTEM LEAKS:

A. ASCENT (PRE-MECO) - ISOLATION PROCEDURES WILL BE INITIATED IF A LEAK CAUSES THE PRESSURE TO DECAY BELOW THE HEATER CONTROL RANGE. THE PRSD SYSTEM WILL BE CONFIGURED TO MAINTAIN FULL CELL POWER OUTPUT BY:

1. CLOSING BOTH MANIFOLD VALVES.
2. ACTIVATING ALL TANK HEATERS IN THE LEAKING LEG.
3. CLOSING THE AFFECTED PCS O₂ SUPPLY VALVE (IF AN O₂ LEAK).

By the time that leak isolation procedures could be accomplished, the vehicle is no longer in atmospheric flight. Therefore, feeding the leak only amounts to a loss of consumables and is not a flammability concern. The above actions are considered to be the best compromise to prevent loss of pressurization to two fuel cells, while still trying to maintain pressure to the fuel cell in the leaking leg.

B. ENTRY (POST-DEORBIT TIG) - ISOLATION PROCEDURES WILL BE INITIATED IF A LEAK CAUSES THE PRESSURE TO DECAY BELOW THE HEATER CONTROL RANGE. FOR H₂ LEAKS WHERE NO FUEL CELLS HAVE PREVIOUSLY FAILED, THE PRSD SYSTEM WILL BE CONFIGURED TO ISOLATE OR REDUCE THE LEAK RATE BY:

1. CLOSING BOTH MANIFOLD VALVES.
2. USING ONLY THE STANDARD HEATER CONFIGURATION IN THE LEAKING LEG TO MAINTAIN PRESSURE.
3. SHUTTING DOWN THE AFFECTED FUEL CELL.

FOR O₂ LEAKS OR FOR H₂ LEAKS WHERE ONE FUEL CELL HAS PREVIOUSLY FAILED, THE PRSD SYSTEM WILL BE CONFIGURED TO MAINTAIN FUEL CELL POWER OUTPUT IN ACCORDANCE WITH THE ASCENT GROUND RULES.

Since a hydrogen leak during entry can result in fire or explosion, it is considered less of a risk to shut down the first fuel cell than to attempt hydrogen leak isolation. Consequently, extra heat will not be used in the leaking leg (as done for ascent) to overpower the leak. However, after TIG, if isolation of the leak requires a fuel cell shutdown leaving the orbiter with only one fuel cell, then the leak will be allowed to continue and extra heaters activated. This is because the risk of recovering from the loss of one main bus and further powerdown (for loss of the second fuel cell) is considered greater than the chance of fire or explosion in the midbody.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-260

CRYO SYSTEM LEAKS [CIL] (CONTINUED)

Increased oxygen concentrations from leaks are not considered a significant enough risk to warrant fuel cell shutdown to attempt leak isolation.

DOCUMENTATION: Engineering judgment and FMEA/CIL 04-1B-A01FSH-1/FSO-1.

C. ORBIT (MECO TO DEORBIT TIG):

1. TANK LEAKS - CONSUMPTION OUT OF THE LEAKING TANK WILL BE MAXIMIZED. THE CONFIGURATION OPTIONS ARE CONTINGENT ON HEATER FLOW CAPACITY (FUNCTION OF TANK QUANTITY) AND THE SIZE OF THE LEAK. IN ORDER OF PREFERENCE, THEY ARE:
 - a. DEACTIVATE ALL OTHER TANK HEATERS (LEAVE TANKS 1 AND 2 ACTIVE IF LEAK IS IN TANK 3/4/5) AND FEED ALL FUEL CELLS FROM THE LEAKING TANK. IF NECESSARY, DEORBIT WILL BE DELAYED IN ORDER TO DEplete A LEAKING H₂ TANK (FOR ANY SIZE LEAK). MANUAL HEATERS CAN BE USED TO CRACK THE TANK RELIEF VALVE IF NECESSARY TO EXPEDITE DEPLETION FOR A DEORBIT OPPORTUNITY.
 - b. FOR A TANK 1 OR 2 LEAK, IF SUPERCRITICAL PRESSURE CANNOT BE MAINTAINED WITH OPTION A, ISOLATE TANK TO ITS MANIFOLD AND FEED ITS ASSOCIATED FUEL CELL.
 - c. IF SUPERCRITICAL PRESSURE CANNOT BE MAINTAINED WITH OPTIONS A OR B, DEACTIVATE THE TANK HEATERS AND ALLOW THE PRESSURE TO BLEED DOWN. THIS MUST BE PERFORMED PRIOR TO ENTRY. IF INSUFFICIENT TIME EXISTS PRIOR TO DEORBIT TIG TO REDUCE AN H₂ LEAK TO < 1 LB/HR, THEN ENTRY WILL BE DELAYED IF ADEQUATE CONSUMABLES ARE AVAILABLE.

Maximizing consumption from the leaking tank will minimize the amount of consumables lost due to the leak. H₂ leaks > 1 lb/hr create flammable concentrations in the midbody during portions of entry and are considered to be of more risk than delaying entry. Depleting the tank and allowing its pressure to bleed down can aid in minimizing the leak rate and flammability concern during entry. If the leak rate/heater flow capacity will allow depletion, then deorbit can be waived off, if required, for any size leak. This is because the smallest of leaks can fill the vacuum annulus, pop the burst disk, and allow convective heat transfer during entry to cause extremely high venting overboard (200-300 lb). It is possible that the vented H₂ could be ingested into the midbody through the vents, creating a flammable condition.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-260

CRYO SYSTEM LEAKS [CIL] (CONTINUED)

DOCUMENTATION: Engineering judgment, FMEA/CIL 04-1B-A01FSH-1/FSO-1, and JSC Structures and Mechanics Division informal analysis.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

2. MANIFOLD OR FUEL CELL LEAKS:

- a. ORBIT RECONFIGURATION - AT LEAST ONE GOOD MANIFOLD/FUEL CELL WILL BE PROTECTED FROM THE LEAK BY CLOSURE OF A MANIFOLD VALVE OR THE LEAKING FUEL CELL REACTANT VALVES. FOR MANIFOLD LEAKS, THE ASSOCIATED TANK(S) WILL BE DEPLETED AS SOON AS PRACTICAL. IF ADEQUATE CONSUMABLES ARE NOT AVAILABLE TO FEED THE LEAK FOR AN MDF + 24 HOURS (PLS + 24 HOURS IF ONE FUEL CELL HAS PREVIOUSLY FAILED), OR IF SUPER-CRITICAL PRESSURIZATION CANNOT BE MAINTAINED, THEN THE LEAK WILL BE ISOLATED (REQUIRING FUEL CELL SHUTDOWN).
- b. ENTRY RECONFIGURATION - SEVERAL OPTIONS ARE AVAILABLE, BASED ON THE SIZE OF THE LEAK AND WHICH SYSTEM (O₂ OR H₂) IS AFFECTED:

FOR AN H₂ LEAK < 1 LB/HR OR O₂ LEAK OF ANY SIZE, ENTRY WILL BE PERFORMED WHILE FEEDING THE LEAK, PROVIDING THAT SUPER-CRITICAL PRESSURIZATION CAN BE MAINTAINED USING NORMAL HEATER MANAGEMENT. AT LEAST ONE GOOD MANIFOLD/FUEL CELL WILL BE PROTECTED FROM THE LEAK BY CLOSURE OF A MANIFOLD VALVE.

FOR AN H₂ LEAK > 1 LB/HR WHERE NO FUEL CELL HAS PREVIOUSLY FAILED, THE LEAK WILL BE ISOLATED (REQUIRING FUEL CELL SHUTDOWN) AND ENTRY PERFORMED ON TWO FUEL CELLS. IF INSUFFICIENT TIME EXISTS PRIOR TO DEORBIT TIG TO REDUCE THE LEAK RATE TO <1 LB/HR, THEN ENTRY WILL BE DELAYED IF ADEQUATE CONSUMABLES ARE AVAILABLE.

FOR AN H₂ LEAK > 1 LB/HR WHERE ONE FUEL CELL HAS PREVIOUSLY FAILED, THE LEAK WILL BE ISOLATED (AND FUEL CELL SHUT DOWN) ONLY IF SUPER-CRITICAL PRESSURIZATION CANNOT BE MAINTAINED. THE REMAINING FUEL CELL WILL BE PROTECTED FROM THE LEAK BY CLOSURE OF A MANIFOLD VALVE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A9-260****CRYO SYSTEM LEAKS [CIL] (CONTINUED)**

Since the plumbing in the affected manifold or fuel cell is no longer reliable, it must be isolated from the other manifolds and fuel cells to protect against rapid loss of pressurization affecting all fuel cells. Since the tanks themselves do not have isolation valves, then the only method of stopping or minimizing a manifold leak is to isolate it by closing one or both manifold valves, and then depleting its associated tank(s). After this is done, the manifold can be repressurized/isolated by opening/closing a manifold valve.

Since shutdown of a fuel cell requires the mission to be shortened to an MDF (PLS for loss of the second fuel cell), and if consumables will support the abbreviated mission plus a 24-hour extension while feeding the leak, then no gain is achieved by shutting down the fuel cell while on orbit.

Hydrogen leaks of > 1 lb/hr create flammable concentrations during portions of entry and are considered to be a greater risk than loss of the first fuel cell, but not the second.

DOCUMENTATION: Engineering judgment, FMEA/CIL 04-1B-A01FSH-1/FS0-1, and JSC Structures and Mechanics Division informal analysis.

A9-261**IMPENDING LOSS OF ALL CRYO**

IN THE EVENT THAT ALL RECONFIGURATION PROCEDURES HAVE BEEN PERFORMED FOR CRYOGENIC SYSTEMS FAILURES AND THAT A CONDITION STILL EXISTS WHERE ALL TANK AND MANIFOLD PRESSURES ARE DECREASING, THE EARLIEST ASCENT ABORT MODE AVAILABLE WILL BE SELECTED (REF. RULE {A2-54}, RTLs, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]).

If the pressure cannot be maintained in at least one cryo tank and manifold, the fuel cells will eventually stop producing electrical power, no matter what the quantity is in the cryo tanks. Since the amount of time available before "blowdown" of the tanks is dependent on a large number of variables, specific numbers cannot be defined for the purpose of selecting the most preferred abort mode. Therefore, this condition warrants the selection of the earliest abort opportunity.

DOCUMENTATION: Engineering judgment.

Rules {A2-54A}.4, RTLs, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]; and {A2-205A}.2.b, EMERGENCY DEORBIT. ©[ED]

FLIGHT RULES

A9-262

EDO PALLET MANAGEMENT

- A. ACTIVATION/DEACTIVATION - THE MAIN DC POWER TO THE PALLET WILL BE ACTIVATED SHORTLY AFTER POST INSERTION AND DEACTIVATED IN DEORBIT PREP. INSTRUMENTATION POWER WILL BE ACTIVE FOR LAUNCH AND ENTRY FOR THE PURPOSES OF TANK QUANTITY GAUGING AND LEAK DETECTION.

Since the pallet tanks are not required for ascent/entry, the main power will be removed to eliminate an unnecessary path for an electrical short. Reference rule {A9-108}, CRITICAL PHASE BUS MANAGEMENT. The pressure and quantity instrumentation was intentionally placed on a separate power source to allow quantity gauging and leak detection.

- B. TANK HEATER MANAGEMENT - TANK QUANTITY BALANCING WILL BE PERFORMED PER RULE {A9-256}, CRYO O₂/H₂ TANK QUANTITY BALANCING. IF THE SPARE MDCA-1 (100-AMP FUSE SIZE) IS USED, NORMALLY ONLY ONE SET OF HEATERS WILL BE ACTIVATED WHEN USING A TANK.

The original design modification to MDCA-1 included a 100-amp fuse to the EDO bus A power feed. A subsequent design change was performed which made it possible to exceed 100 amps if all the tank heaters were activated simultaneously. The second of two units built has a 200-amp fuse to correct this problem. The first unit (used as a spare) will retain the 100-amp fuse until the unit requires further modification. Single-string tank heaters will be used to provide a margin of safety if that box is ever flown.

FLIGHT RULES

SPACEHAB ELECTRICAL POWER SUBSYSTEM (EPS) MANAGEMENT

A9-351 ELECTRICAL POWER SUBSYSTEM (EPS) CONSTRAINTS

- A. POWER MANAGEMENT - ON-ORBIT SPACEHAB POWER LEVELS WILL BE MANAGED BY THE SPACEHAB OPERATIONS DIRECTOR (SHOD) AND WILL BE MAINTAINED WITHIN PREFLIGHT ALLOCATED QUANTITIES. @[111501-4975A]

Spacehab is allotted a specific quantity of energy preflight in the Carrier Integration Plan (CIP) and may use this energy as long as the Spacehab operations do not compromise normal orbiter operations.

- B. WHEN SPACEHAB IS REQUIRED TO BE POWERED DURING ASCENT/ENTRY, THE ASCENT/ENTRY ORBITER CONFIGURATION WILL INCLUDE:
1. FUEL CELLS CONNECTED TO THEIR RESPECTIVE BUSES
 2. PRIMARY PAYLOAD POWER - ON (PROVIDING POWER TO SPACEHAB)
 3. PAYLOAD AUX A - ON AND PAYLOAD AFT MN B - ON (PROVIDING EMERGENCY POWER IN THE SPACEHAB FOR SMOKE DETECTION/SUPPRESSION)
 4. PAYLOAD CABIN - MN A (B) (PROVIDING POWER TO THE STANDARD SWITCH PANEL (SSP))

Payload Primary provides power to the Spacehab power subsystem; this subsystem then provides power to subsystems and experiments requiring power on ascent/entry as negotiated in the CIP. The Payload AUX A and Payload AFT MN B orbiter buses provide redundant power to Spacehab's emergency buses. The emergency buses are required on ascent/entry for fire/smoke detection, fire suppression, and the Caution and Warning (C&W) system. @[111501-4975A]

- C. THE ON-ORBIT ORBITER CONFIGURATION FOR THE ORBITER TO SPACEHAB WILL BE: @[111501-4975A]
1. FUEL CELLS CONNECTED TO THEIR RESPECTIVE BUSES
 2. PAYLOAD PRIMARY POWER - ON (PROVIDING POWER TO SPACEHAB)
 3. AUX A AND PAYLOAD AFT MN B - ON (PROVIDING EMERGENCY POWER IN THE SPACEHAB FOR SMOKE DETECTION/FIRE SUPPRESSION)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-351 ELECTRICAL POWER SUBSYSTEM (EPS) CONSTRAINTS (CONTINUED)

4. PAYLOAD CABIN - MN A (B) (PROVIDING POWER TO THE SSP)
5. PAYLOAD AC 3 POWER - ON (PROVIDING POWER TO SPACEHAB)
6. (RDM ONLY) PAYLOAD AC 2 POWER - ON (PROVIDING POWER TO SPACEHAB)

Payload Primary provides power to the Spacehab power subsystem; this subsystem then provides DC power to subsystems and experiments. The payload AUX A and payload AFT MN B orbiter buses provide redundant power for fire/smoke detection, C&W sensors, and fire suppression. Items 1 through 5 are applicable to all Spacehab module configurations. Item 6 is only applicable to the RDM configuration. @[111501-4975A]

A9-352 SPACEHAB MAIN BUS MANAGEMENT @[111501-4986A]

ELECTRICAL POWER TO THE SPACEHAB MAIN BUS IS PROVIDED VIA THE PRIMARY PAYLOAD BUS. THE LOADS ON THE PRIMARY PAYLOAD BUS MUST BE MANAGED TO KEEP TOTAL POWER WITHIN THE CONSTRAINTS SPECIFIED IN ALL FLIGHTS RULE {A9-109}, PRIMARY PAYLOAD BUS MANAGEMENT.

Total payload bus power limitations are due to the Fuel Cell limitations and not on the individual SMCH fuse and wire ratings. The ICD specifies a power limit on each SCMCH feed to 2 kW continuous and allow a 3 kW peak for 15 minutes every 3 hours (a total excess energy of 0.25 kWh). The ICD is written to ensure that total payload power constraints are not violated on a mission where there are four independent payloads, each using its own dedicated SCMCH feed. Manifested payloads generally meet the ICD requirement. This drives the operational constraint to be based on the total payload power and not on the physical wire and fuse ratings of the individual SMCH feed. In the case where multiple SMCH feeds fail, the power on each SMCH will be managed to stay within its physical wire and fuse ratings.

Reference: All Flights Rule {A9-109}, PRIMARY PAYLOAD BUS MANAGEMENT; ICD-A-21095 and ICD-A-21426-RDM. @[111501-4986A]

FLIGHT RULES

A9-353

SPACEHAB EMERGENCY BUS LOSS @[111501-4986A]

- A. IF EITHER ORBITER DC SOURCE, PL AUX A OR PL AFT B, SUPPLYING POWER TO THE SPACEHAB EMERGENCY BUS IS LOST, SPACEHAB ACTIVITIES WILL CONTINUE.

PL AUX A and PL AFT B provide redundant power to the Spacehab emergency bus. The emergency bus sources are cross-strapped and the Spacehab emergency bus is still powered.

- B. IF THE SPACEHAB EMERGENCY BUS IS LOST, THE SPACEHAB WILL BE DEACTIVATED AND ALL POWER REMOVED.

All fire detection/suppression capability has been lost as well as power to the water line heaters. Therefore, orbiter attitude control will be required to prevent water line freezing.

Reference Rule {A18-555}, WATER LINE HEATER MANAGEMENT. @[111501-4986A]

FLIGHT RULES

A9-354

SPACEHAB AC MANAGEMENT @[111501-4986A]

- A. THE SPACEHAB INVERTER WILL BE THE MODULE'S NOMINAL AC POWER SOURCE DURING ASCENT AND ENTRY.

Orbiter AC power is not available to payloads during the ascent mission phase in order to protect critical orbiter systems (i.e., Space Shuttle Main Engine Controllers). Orbiter AC may be used during entry for a Spacehab AC system failure provided the total AC load (Orbiter + Spacehab) can be managed to stay within limits specified in All Flights Rule {A9-155}, AC INVERTER THERMAL LIFE.

- B. FOR LOSS OF SPACEHAB INVERTER(S), AC EQUIPMENT SHALL BE MANAGED AS FOLLOWS:

1. ASCENT

- a. AC EQUIPMENT POWERED BY THE FAILED INVERTER(S) WILL BE POWERED OFF VIA INCO COMMAND POST MECO.
- b. AC EQUIPMENT WILL BE CONFIGURED TO ORBITER POWER AND REPOWERED AS SOON AS PRACTICAL POST MECO PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN RULE {A9-155}, AC INVERTER THERMAL LIFE.

If the Spacehab inverter fails during ascent, module heat rejection and smoke detection are lost. To protect critical orbiter systems (i.e., Space Shuttle Main Engine Controllers) during ascent, orbiter AC power is not available to payloads prior to MECO (AC PL 3? circuit breaker(s) open). Therefore, orbiter AC power cannot be applied to Spacehab until the crew closes the AC PL 3? circuit breaker and the SM GPC is available to change the power source from Spacehab inverter to orbiter AC (the exception is the Spacehab subsystem water pump 2 which does have contingency commands to change the power source and therefore, does not require the SM GPC). If telemetry indicates thermal limits will be violated before power can be restored post MECO, consideration will be given to issuing the Main Power Kill command by arming the FSS. This will remove all power to the Spacehab, except PL AFT MN B, which is required to power the Spacehab water line heaters. @[111501-4986A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-354

SPACEHAB AC MANAGEMENT (CONTINUED)

2. ON-ORBIT @[111501-4986A]

AC EQUIPMENT POWERED BY THE FAILED INVERTER(S) WILL BE POWERED OFF, RECONFIGURED TO ORBITER POWER, AND REPOWERED AS SOON AS PRACTICAL PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN ALL FLIGHTS RULE {A9-155}, AC INVERTER THERMAL LIFE.

Orbiter AC power can be utilized if the Spacehab inverter(s) fail as long as AC loads can be managed within orbiter power capabilities.

3. ENTRY

- a. AC EQUIPMENT POWERED BY THE FAILED INVERTER(S) WILL BE POWERED OFF VIA INCO COMMAND.
- b. BACKUP AC EQUIPMENT CONFIGURED TO ORBITER POWER WILL BE POWERED AS SOON AS PRACTICAL PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN ALL FLIGHTS RULE {A9-155}, AC INVERTER THERMAL LIFE.

During entry, if there is a failure in the Spacehab AC system that precludes its use, orbiter AC may be used provided the total AC load can be managed within limits, the AC PL 3? circuit breaker is closed, and backup subsystem equipment (pump or fan) was configured to orbiter AC during Spacehab Entry Prep (the exception is the Spacehab subsystem water pump 2 which does not need to be pre-configured to orbiter AC since contingency commands are available to change the power source). A contingency command can then be sent by INCO to reconfigure and activate the backup fan or pump on orbiter AC power. If telemetry indicates thermal limits will be violated before power can be restored during entry when the crew is unable to respond to the failure, the Main Power Kill command will be issued by arming the FSS to remove all power to the Spacehab, except PL AFT MN B, which is required to power the Spacehab water line heaters. @[111501-4986A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-354

SPACEHAB AC MANAGEMENT (CONTINUED)

- C. IF ORBITER AC POWER IS THE NOMINAL POWER SOURCE AND BECOMES UNAVAILABLE, AFFECTED SPACEHAB AC EQUIPMENT WILL BE POWERED OFF AND RECONFIGURED TO SPACEHAB INVERTER POWER IF SPACEHAB AC LOADS PERMIT. @[111501-4986A]

On orbit, both the Spacehab inverter and orbiter AC power are used.

- D. SUBSYSTEM AC EQUIPMENT WHICH CAN BE SWITCHED BETWEEN SPACEHAB INVERTER AND ORBITER AC POWER SOURCES WILL NORMALLY BE DEACTIVATED BEFORE SWITCHING SOURCES.

Hot switching equipment will lead, over time, to degraded relay contacts in the Power Distribution Unit (PDU) and APDU (RDM only); however, in an off-nominal condition, hot switching can be performed without significantly damaging Spacehab hardware.

- E. APPLYING POWER TO UNPOWERED SPACEHAB SUBSYSTEM AC EQUIPMENT CONFIGURED ON, BUT NOT OPERATING, IS ACCEPTABLE, PROVIDED NO MORE THAN A SINGLE SUBSYSTEM COMPONENT IS CONFIGURED TO DRAW ORBITER AC POWER AT INITIAL BUS ACTIVATION.

In order to protect for failures (i.e., SM GPC not available for commanding) that could delay or inhibit Spacehab Activation or crew initial ingress into the module, some Spacehab subsystem components can be configured to turn ON when the orbiter AC PL 3? circuit breaker is closed. This configuration is normally used for Spacehab RDM or when the Spacehab SM/LDM is unpowered for ascent. Having only one subsystem component activated at a time minimizes start-up transients that could exceed orbiter inverter capabilities.

- F. WHEN POWER IS INTERRUPTED TO SUBSYSTEM AC EQUIPMENT, THE EQUIPMENT WILL BE DEACTIVATED BEFORE POWER IS REAPPLIED.

If Spacehab subsystem AC equipment using orbiter or Spacehab AC power are not deactivated after losing power, the orbiter's or Spacehab's inverter capabilities may be exceeded if power is reapplied simultaneously to all of the previously operating AC equipment. @[092800-7114] @[111501-4986A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A9-354

SPACEHAB AC MANAGEMENT (CONTINUED)

- G. IN ORDER TO PREVENT EXCEEDANCE OF THE SPACEHAB INVERTER'S CAPABILITIES: @[111501-4986A]
1. NO LOADS SHALL BE APPLIED UNTIL THE INVERTER HAS BEEN VERIFIED OPERATIONAL.
 2. TURN ON FANS BEFORE THE WATER PUMP IF TWO FANS ARE TO BE POWERED BY INVERTER AC.
 3. MCC APPROVAL MUST BE OBTAINED BEFORE USING THE AC VACUUM CLEANER. @[092800-7114]

Verifying that the Spacehab inverter is operational before applying AC loads minimizes possible failure of the inverter or damage to Spacehab hardware.

Turning two fans on before the pump avoids potential in-rush problems, since the fans have a higher in-rush current. In the SM/LDM, the Spacehab inverters are capable of providing power to the ARS fan, cabin fan, and Subsystem Water Pump. In the RDM, the forward inverters are not a concern since the ARS fan is the only fan that can be powered via the forward inverters. The RDM aft inverters are capable of providing power to the two HFA fans, CEWL pump, and WSA. Two fans can be powered on with the WSA operational since the WSA has a low power draw (approximately 40 watts). @[111501-4986A]

The orbiter vacuum cleaner has a high in-rush current of 4.5 amps/phase. Due to the mission unique experiment configuration and other ac power concerns that are timeline dependent, the MCC must be contacted to perform an ac analysis to ensure inverter capability.

FLIGHT RULES

A9-355

FUSE/CIRCUIT BREAKER MANAGEMENT

- A. APPLICABLE EXPERIMENTS AND SUBSYSTEM EQUIPMENT WILL BE DEACTIVATED PRIOR TO REPLACING A FUSE OR RESETTING A CIRCUIT BREAKER.

This action is required to prevent in-rush current or the original cause of the failure from opening the fuse or tripping the breaker again during the reset/replacement activity.

- B. A CIRCUIT BREAKER SHALL ONLY BE RESET OR FUSE REPLACED AFTER MCC REVIEW OF THE ASSOCIATED DATA. IT IS MANDATORY TO HAVE MCC REAL-TIME COVERAGE WHEN A CIRCUIT BREAKER RESET ATTEMPT OR FUSE REPLACEMENT IS MADE. REPEATED CIRCUIT BREAKER RESETS OR FUSE REPLACEMENTS WILL NOT BE ALLOWED.

A known short will not be repowered due to safety concerns. Real-time coverage is required in order to provide systems experts the opportunity to monitor the action and the associated response. Repeated circuit breaker trips or fuse failures indicate a hardware problem and for safety reasons, the repeated actions will not be allowed.

- C. A CIRCUIT BREAKER MAY BE RESET, IN ACCORDANCE WITH PARAGRAPH B, TO REGAIN SUBSYSTEM OR EXPERIMENT EQUIPMENT FUNCTIONS AFTER REMOVING UNNECESSARY LOADS AND THE EQUIPMENT CAUSING THE FAILURES. @[111501-4986A]

Circuit breakers often feed more than one piece of equipment; therefore, if unnecessary loads or troublesome equipment is removed, the circuit breaker may be successfully reset and the remaining loads used.

- D. NO CIRCUIT BREAKER RETENTION DEVICE SHALL BE USED IN THE SPACEHAB ELECTRICAL SUBSYSTEM.

The circuit breaker retention device is only used to recover emergency or crew safety related items. Mission success does not justify use of the retention device. Failure modes exist where the retention device can override circuit protection.

Reference: NASA/DF Note Of Interest, DF7/83-45, June 14, 1983.

FLIGHT RULES

A9-356 **FUEL CELL FAILURE MANAGEMENT**

- A. FOR THOSE MISSIONS REQUIRING A POWERED SPACEHAB MODULE DURING ASCENT/ENTRY, IF A FUEL CELL FAILS DURING ASCENT, THE SPACEHAB WILL NOT REMAIN POWERED EXCEPT PL AFT MN B.
@[111501-4986A]

There is not adequate power margin for Spacehab operations with only two orbiter fuel cells available during ascent. During orbit and entry, power margins may potentially allow payload power. PL AFT MN B provides power to Spacehab water line heaters.

- B. FOR A FUEL CELL FAILURE ON ORBIT, THE SPACEHAB POWER WILL BE MANAGED WITHIN THE 18 KW LIMIT FOR TOTAL ORBITER POWER.

In the event of a fuel cell failure, the 18 kW limit prevents overloading of the last remaining fuel cell.
@[111501-4986A]

A9-357 **SPACEHAB SURVIVAL POWER CONFIGURATION** @[111501-4986A]

SPACEHAB SURVIVAL POWER IS DEFINED AS THE POWER LEVEL REQUIRED TO MAINTAIN THE SPACEHAB IN A CONFIGURATION THAT ENSURES CREW SAFETY, INTEGRITY OF SCIENCE RESULTS/SAMPLES ALREADY OBTAINED, AND PROTECTION OF HARDWARE. REFERENCE FLIGHT SPECIFIC ANNEX FOR SURVIVAL POWER REQUIREMENT.

A known minimum power level is required to provide for a case in which the crew's full attention would have to be turned to an orbiter problem. The Spacehab/experiments would need to be placed in a condition which would draw the least amount of both crew time and orbiter resources. The survival configuration for the Spacehab/experiments needs to be clearly defined pre-mission so that this configuration can be achieved quickly and without ambiguity. @[111501-4986A]

A9-358 **CAUTION AND WARNING (C&W)**

CAUTION AND WARNING SYSTEM AND SYSTEM MANAGEMENT PARAMETERS WHICH GENERATE FALSE OR NUISANCE ALARMS WILL BE INHIBITED.

Inhibiting the alarms prevents reaction/response to nuisance and/or erroneous failure indications.

FLIGHT RULES**A9-1001 ELECTRICAL GO/NO-GO CRITERIA (CONTINUED)**

- [1] IF A FIVE-TANK SET IS FLOWN, TANKS 4 AND 5 ARE CONSIDERED AS ONE TANK.
- [2] FOR SINGLE TANK FAILURES, CONSUMABLES DETERMINE FLIGHT DURATION.
- [3] MAY REQUIRE FUEL CELL SHUTDOWN PRIOR TO ENTRY.
- [4] SINGLE FAULT TOLERANT. REF. RULE {A2-102B}, MISSION DURATION REQUIREMENTS. @[101796-4561A]
- [5] ZERO FAULT TOLERANT. REF. RULE {A2-102C}, MISSION DURATION REQUIREMENTS.
- [6] LOSS OF PRIMARY SYSTEM FOR MULTIPLE FC'S MAY HAVE RESULTED FROM FREEZING OF H₂O RELIEF PANEL WHICH COULD ALSO CAUSE LOSS OF OVERBOARD RELIEF AND LEAVE ONLY THE ALTERNATE SYSTEM FOR H₂O REMOVAL. REF. RULE {A2-102C}, MISSION DURATION REQUIREMENTS. @[101796-4561A]
- [7] LOSS OF PURGE CAPABILITY ON ALL THREE FC'S. ALSO, ALL THREE FC'S UNABLE TO VENT O₂ (H₂) FOR A DUAL GAS REGULATOR FAILURE. ALL THREE FC'S NO LONGER FAIL-SAFE. REF. RULES {A9-1J}, FUEL CELL (FC) LOSS [CIL]; AND {A9-52C}, D, AND E, FC PURGE.
- [8] FUEL CELL PREDICTED PERFORMANCE DETERMINES MISSION DURATION.
- [9] LOSE ALL MNA SUB-BUSES AND ASSOCIATED EQUIPMENT.
- [10] IF AC BUS NOT SHORTED, AN MDF MAY BE COMPLETED BY THE USE OF THE AC POWER TRANSFER CABLE TO REGAIN CRITICAL AC LRU'S. NEXT PLS REQUIRED IF AC BUS NOT REGAINED. REF. RULE {A9-158}, AC POWER TRANSFER CABLE. @[ED]
- [11] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 1 PUMPS. REF. RULES {A9-1B}, FUEL CELL (FC) LOSS [CIL], AND {A10-209H}, PLBD RULE REFERENCE MATRIX.
- [12] LOSE ONE MOTOR IN MULTIPLE PLBD CENTERLINE/BULKHEAD LATCH GANGS. REDUNDANCY MAY BE REGAINED BY PERFORMING THE PLBD SYS ENABLE RECOVERY IFM. REF. RULE {A10-209}, PLBD RULE REFERENCE MATRIX. @[011801-3851] @[032802-4814A]
- [13] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 1 PURGE VALVES. REF. RULES {A9-52C} AND D, FC PURGE, AND {A10-209H}, PLBD RULE REFERENCE MATRIX.
- [14] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY. REDUNDANCY MAY BE REGAINED BY PERFORMING THE PLBD SYS ENABLE RECOVERY IFM, ASSUMING THERE ARE NO OTHER SYSTEMS GO/NO-GO CRITERIA VIOLATED. REF. RULE {A10-209}, PLBD RULE REFERENCE MATRIX.
- [15] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY. REF. RULE {A10-209}, PLBD RULE REFERENCE MATRIX.
- [16] LOSE OMS X-FEED AND REPRESS CAPABILITY. A G-MEM CAN BE SENT TO RECOVER THESE FUNCTIONS.
- [17] FAILURE OF ANOTHER BUS RESULTS IN LOSS OF CAPABILITY TO OPEN FUEL TANK VALVES ON ANAPU AND CAPABILITY TO DEPRESS ANOTHER HYD SYSTEM. REF. RULE {A10-21A}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS. @[082593-1530] @[032802-4814A]
- [18] LOSE ALL MNB SUB-BUSES AND ASSOCIATED EQUIPMENT.
- [19] LOSE FUEL CELL 2 PUMPS, PLBD CLOSE FUNCTION MOTOR REDUNDANCY, S-BAND SYSTEM 1 (INCLUDES NSP 1), CABIN FAN B. REF. RULES {A9-1B}, FUEL CELL (FC) LOSS [CIL]; {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA; {A10-209H}, PLBD RULE REFERENCE MATRIX; AND {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA. @[ED]
- [20] LOSE S-BAND SYSTEM 1 (INCLUDES NSP 1). REF. RULE {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA.
- [21] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 2 PURGE VALVES. REF. RULES {A9-52C} AND D, FC PURGE, AND {A10-209H}, PLBD RULE REFERENCE MATRIX.
- [22] LOSE ONE MOTOR IN MULTIPLE PLBD CENTERLINE/BULKHEAD LATCH GANGS. REF. RULE {A10-209}, PLBD RULE REFERENCE MATRIX. @[011801-3851]
- [23] LOSE ALL MNC SUB-BUSES AND ASSOCIATED EQUIPMENT.
- [24] LOSE FUEL CELL 3 PUMPS, PLBD CLOSE FUNCTION MOTOR REDUNDANCY, S-BAND SYSTEM 2 (INCLUDES NSP 2), CABIN FAN A. REF. RULES {A9-1B}, FUEL CELL (FC) LOSS [CIL]; {A9-1001}, ELECTRICAL GO/NO-GO CRITERIA; {A10-209H}, PLBD RULE REFERENCE MATRIX; AND {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA.
- [25] LOSE S-BAND SYSTEM 2 (INCLUDES NSP 2). REF. RULE {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA. @[ED]

A9-1001 ELECTRICAL GO/NO-GO CRITERIA (CONTINUED)

- [26] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 3 PURGE VALVES, RGA 3. REF. RULES {A8-1001D}, GNC GO/NO-GO CRITERIA; {A9-52C} AND D, FC PURGE; AND {A10-209H}, PLBD RULE REFERENCE MATRIX. @[ED]
- [27] LOSE ADTA 3 AND 4. REF. RULE {A8-1001D}, GNC GO/NO-GO CRITERIA.
- [28] LOSE S-BAND SYSTEM 1 (INCLUDES NSP 1). RGA 2. REF. RULES {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA; AND {A8-1001D}, GNC GO/NO-GO CRITERIA. @[ED]
- [29] LOSE FUEL CELL 1 ECU PUMP PRIMARY RELAYS. REF. RULE {A9-1B}, FUEL CELL (FC) LOSS [CIL].
- [30] LOSE FUEL CELL 2 ECU PUMP PRIMARY RELAYS. REF. RULE {A9-1B}, FUEL CELL (FC) LOSS [CIL].
- [31] LOSE FUEL CELL 3 ECU PUMP PRIMARY RELAYS. REF. RULE {A9-1B}, FUEL CELL (FC) LOSS [CIL].
- [32] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 2 PUMPS, CABIN FAN B. REF. RULES {A9-1B}, FUEL CELL (FC) LOSS [CIL]; SECTION B; AND {A10-209H}, PLBD RULE REFERENCE MATRIX.
- [33] LOSE PLBD CLOSE FUNCTION MOTOR REDUNDANCY, FUEL CELL 3 PUMPS, CABIN FAN A. REF. RULES {A9-1B}, FUEL CELL (FC) LOSS [CIL]; SECTION B; AND 1 {A10-209H}, PLBD RULE REFERENCE MATRIX.
- [34] IF BUS SHORT-CIRCUITED, INVOKE CRITERIA FOR FMC, MMC, AMC SUB-BUSES, UNLESS SHORTED PHASE CAN BE ISOLATED FROM GANGED CB ASSEMBLY. REF. RULE {A9-156}, LOSS OF SINGLE-PHASE AC. @[ED]
- [35] LOSE 1 AC ? OF CABIN FAN B. CONTINUE IF DEMONSTRATED IN FLIGHT THAT CABIN FAN CAN BE STARTED ON TWO REMAINING AC?'S.
- [36] LOSE 1 AC ? OF CABIN FAN A. CONTINUE IF DEMONSTRATED IN FLIGHT THAT CABIN FAN CAN BE STARTED ON TWO REMAINING AC?'S.
- [37] LOSS OF ALL C&W ALARM TONES AND LIGHTS. FLIGHT CREW MUST MONITOR CRT MESSAGES FOR CRITICAL SYSTEM FAULT ANNUNCIATION. REF. RULES {A2-102C}, MISSION DURATION REQUIREMENTS; AND {A2-104A}.6, SYSTEMS REDUNDANCY REQUIREMENTS. @[101796-4561A]
- [38] LOSE POWER TO PCS O2 CROSSOVER VALVE 1 MDF UNTIL IFM TO RESTORE FULL MANIFOLD CAPABILITY IS INSTALLED OR UNTIL REAL-TIME TEST VERIFIES ADEQUATE O2 SUPPLY TO CREW. REF. RULE {A17-1001D}, LIFE SUPPORT GO/NO-GO CRITERIA. @[050400-7189]
- [39] LOSE POWER TO PCS O2 CROSSOVER VALVE 2 MDF UNTIL IFM TO RESTORE FULL MANIFOLD CAPABILITY IS INSTALLED OR UNTIL REAL-TIME TEST VERIFIES ADEQUATE O2 SUPPLY TO CREW. REF. RULE {A17-1001D}, LIFE SUPPORT GO/NO-GO CRITERIA. @[050400-7189]
- [40] NEXT WORST FAILURE (CNTLAB2 AND APC5 COMBINATION) RESULTS IN LOSS OF CAPABILITY TO OPEN THE TANK VALVES ON APU 2 AND LOSS OF BOTH WSB 1 CONTROLLERS. REF. RULE {A10-21A}, LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS. @[032802-4814A]

CRYO

a. Continue Nominal Ascent

If all but one of the cryo tanks fails during ascent, an abort is not required because the remaining tank will support a first day PLS entry.

b. Invoke Minimum Duration Flight

If a single tank fails, the amount of consumables will determine the length of the mission. After a single tank failure, at least two more failures are required before loss of crew/ vehicle.

c. Enter Next PLS

If two tanks fail, a PLS is called because the risk has increased that similar failures will occur in the remaining tanks. Loss of cryo is loss of crew/vehicle.

SECTION 10 - MECHANICAL

AUXILIARY POWER UNIT (APU) LOSS FAILURE/DEFINITION ©[ED]

A10-1 APU LOSS DEFINITIONS

A. AN APU IS CONSIDERED LOST IF:

1. THERE IS A CONFIRMED OR SUSPECTED HYDRAZINE LEAK. LEAKS MUST BE CONFIRMED BY THE GROUND. HYDRAZINE LEAKS CAN BE DETECTED BY ANY OF THE FOLLOWING:
 - a. UNEXPLAINED DECAY IN FUEL TANK OR FUEL FEED LINE PRESSURE. ©[040899-6824]
 - b. UNEXPLAINED COOLING OF HYDRAZINE TANKS, LINES, AND VALVES, OR ON-ORBIT HEATER DUTY CYCLES.
 - c. WHILE THE FUEL ISOLATION VALVES ARE OPEN, A PUMP SEAL CAVITY PRESSURE INCREASE TO ABOVE 40 PSIA FOLLOWED BY A DROP IN PRESSURE (INDICATING THAT THE BURST DISK HAS RUPTURED) AND EITHER:
 - (1) REPEATED PUMP SEAL CAVITY EXCURSIONS TO THE RELIEF VALVE CRACKING PRESSURE OF APPROXIMATELY 28 TO 42 PSIA, OR
 - (2) SUSTAINED FUEL PUMP SEAL CAVITY PRESSURE ABOVE THE VALVE RESEAT PRESSURE OF 16.8 TO 25.2 PSIA.
 - d. UNEXPLAINED DECAY IN SEAL CAVITY DRAIN LINE PRESSURE WHEN FUEL PUMP SEAL LEAKAGE HAS BEEN DETECTED.

A hydrazine leak into the aft compartment is a fire and corrosion hazard that could lead to loss of crew/vehicle.

There are cases where a hydrazine leak cannot be confirmed. For example, a decay in fuel tank pressure could be the result of a GN₂ leak. The only way to distinguish between a fuel leak and a GN₂ leak (without other confirming cues) is to run the APU until the fuel is depleted. The fuel tank pressure will stabilize around 80 psia for a hydrazine leak (the GN₂ precharge pressure) and 0 psia for a GN₂ leak. The flight rules assume the worst case scenario of a fuel leak. ©[040899-6824]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-1****APU LOSS DEFINITIONS (CONTINUED)**

Due to a combination of transducer placement and the large thermal mass of the tank and fuel, a fuel tank heater cycle causes the tank temperature to rise much faster than the corresponding rise in tank pressure. Before equilibrium is established, the onboard and ground fuel quantity computations show a decrease in quantity similar to a leak, followed by a rise in quantity to the original pre-heater cycle value. Since the crew cannot always distinguish between an actual leak and a heater cycle or transducer failure, the ground must confirm whether or not a leak exists. ©[040899-6824]

A cooling effect may be seen if fuel is leaking near a temperature transducer. During STS-9 entry, an APU injector stem leak was indicated by a 20 degree F drop in GGVM temperature. However, a drop in GGVM temperature shortly after liftoff can be the result of normal H₂O condensation in the aft compartment (the temperature decrease will be present for only about 1 minute; this signature was seen on STS 41-C).

An increased heater duty cycle could result from the cooling effect of leaking fuel or the loss in fuel line thermal mass caused by the vacated fuel. However, attitude effects and thermostat debonding can show a similar signature.

An internal hydrazine leak occurs when the fuel pump seal degrades and hydrazine leaks into the fuel pump seal cavity drain system. This is indicated by an increase in drain line pressure. With continuing leakage, the pressure will increase to the point that the burst disk ruptures (at 45 +5 psid) and the relief valve opens (at 28 to 42 psia), causing hydrazine to be spilled overboard. A leak of this type occurred on an ALT flight (without the burst disk; this modification first flew on STS-88). The relief valve will remain open until the reset pressure of 16.8 to 25.2 psia is reached (the relief valve will not reset for high enough leak rates).

Fuel pump seal leakage can be detected by an increase in drain line pressure (not due to heater cycles) while the APU is running (dynamic leak), or by a decrease in feed line pressure with a corresponding increase in drain line pressure while the APU is not running (static leak). However, fuel pump seal leakage by itself is not sufficient reason to declare an APU lost because the hydrazine is contained within the drain system. For the case of a decay in both feed line and drain line pressures, or a decay in drain line pressure following a dynamic leak, a small amount of hydrazine (up to 1.4 lbs, from between the fuel isolation valves and the shutoff valve, for the static leak case; reference SODB, vol. I, 4.4.3.2.d.3) has leaked into the aft compartment and the APU should be considered lost.

Hydrazine may also leak past multiple seals into the APU gearbox. This would be detected as an increase in both gearbox and drain line pressures since, in order to leak in to the gearbox, the fuel has to first leak into the seal cavity. No leakage of this type has been seen since the dual lip seals were incorporated as part of the IAPU design (first flight STS-45). ©[040899-6824]

Reference Rule {A10-27B}, APU FUEL LEAKS [CIL], and SODB, vol. I, 4.4.3.6.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-1 APU LOSS DEFINITIONS (CONTINUED)**

2. UNABLE TO MAINTAIN TURBINE SPEED BETWEEN 95 (95) PERCENT AND 121 (121) PERCENT WHILE THE APU IS RUNNING.

The primary fuel valve controls turbine speed at 103 ± 8 percent (95 to 111 percent) and is the one normally in control. If HI SPEED is selected, the secondary valve will control turbine speed at 113 ± 8 percent (105 to 121 percent).

If turbine speed cannot be maintained > 95 percent, the capability of that APU to support high demand is questionable and is considered lost.

If turbine speed cannot be maintained < 121 percent, then the normal speed control circuit has failed and an automatic shutdown for overspeed is likely. Since the length of time the APU will run is unknown, the APU is considered lost for mission rule purposes.

3. THE LUBRICATION OIL OUTLET PRESSURE IS > 150 (143) PSIA WHILE THE APU IS RUNNING. ©[032802-5345A]

A high lubrication oil outlet pressure is indicative of severely restricted lube oil flow. The oil pump and associated plumbing are not qualified for pressures above 150 psia, so component rupture is a concern. Also, since oil flow is restricted, little or no cooling of the gearbox will take place, resulting in bearing overheat and possible failure. Reference SODB, Vol. I, 3.4.4.3.

Reference Rule{A10-24D}, APU OIL/GEARBOX TEMPERATURE/PRESSURE.

4. THE DELTA PRESSURE BETWEEN THE GEARBOX GN₂ PRESSURE AND THE LUBRICATION OIL OUTLET PRESSURE IS < 20 PSID WHILE THE APU IS RUNNING.

A low delta P across the gearbox is indicative of a severely degraded oil pump. If the delta P is less than 20 psid, then not enough oil is flowing to provide adequate lubrication/cooling to the gearbox. If allowed to continue, the gearbox will overheat, resulting in possible bearing failure. Reference SODB, Vol. I, 3.4.4.3. ©[032802-5345A]

Reference Rule{A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-1****APU LOSS DEFINITIONS (CONTINUED)**

5. GEARBOX PRESSURE < 2.0 (3.1) PSIA PRIOR TO APU START.
 @[032802-5345A]

If the gearbox pressure is less than 2 psia, the oil pump may cavitate at APU startup. The low pressure may be caused by a GN₂ leak or an oil leak in the gearbox, which are indistinguishable prior to APU start. If the low pressure is due to a GN₂ leak, starting the APU will repressurize the gearbox from the GN₂ bottle, thus preventing pump cavitation. Once the APU is running, this GN₂ will also begin to leak from the gearbox, and volumetric inefficiency with resulting degradation in lubrication can result. However, an APU start attempt is safe as long as the oil pressure is carefully monitored during startup so the unit can be shut down if there is no oil pressure. The APU should be considered lost in the meantime. Reference SODB, Vol. I, 3.4.4.3.

Reference Rules {A10-23B}.5, APU ENTRY START TIME, and {A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE.

6. THE LUBRICATION OIL OUTLET TEMPERATURE > 425 (418) DEG F
 OR GEARBOX BEARING TEMPERATURE > 450 (439) DEG F WHILE APU
 IS RUNNING.

At high lube oil and bearing temperatures, the oil begins to break down (low viscosity) resulting in degraded lubrication/heat transfer capability, with high bearing and gear wear. Once all lubrication is lost, the bearings will seize and the APU will experience an underspeed shutdown. Although a start on an APU that has previously exceeded these limits may be attempted on entry, its condition is suspect and should be considered lost for planning purposes. Reference Ascent/Entry Flight Techniques #50, October 20, 1988.

Rule {A10-24A}, APU OIL/GEARBOX TEMPERATURE/PRESSURE, references this rule.

7. UNABLE TO MAINTAIN THE FOLLOWING APU TEMPERATURES WITHIN LIMITS:
- a. FUEL TANK > 35 (38) DEG F
 - b. FUEL LINES > 35 (40 DEG, GGVM SUPPLY LN 45, BYPASS LN 49) DEG F
 - c. FUEL PUMP > 35 (41) DEG F
 - d. LUBRICATION OIL > 0 (INLET TEMPERATURE 10 DEG, OUTLET TEMPERATURE 7) DEG F @[011295-1736C] @[ED]
 - e. GGVM > 35 (41) DEG F @[011295-1736C] @[ED] @[032802-5345A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-1****APU LOSS DEFINITIONS (CONTINUED)**

Hydrazine freezes at 35 deg F (ref. SODB, Vol. I, tables 3.4.4.3-1 and 4.4.3-4). If the fuel is frozen, then obviously the APU will not operate. If the fuel cannot be thawed, the APU will be considered lost. As hydrazine freezes, it contracts; when it thaws, it expands. Analysis has not been performed for APU components subjected to freeze/thaw cycles. Because of the possibility that a fuel system component could rupture, the APU is considered lost if any of the fuel system drops below 35 deg F. Below 0 deg F the lube oil will have such a high viscosity that it cannot adequately lubricate the gearbox. If the APU is started, gear bearing temperature will rise much faster than the oil temperature, and bearing or gear damage may occur before the oil can reach temperature for proper lubrication. Since the APU may be very limited in run time, it is considered lost for mission rule purposes. ©[011295-1736C] ©[032802-5345A]

Because the GGVM temperature and GGVM supply line temperature instrumentation errors are so large, the temperatures should be compared to other transducers in the area.

Reference Rule {A10-31}, APU FREEZE/THAW.

8. AN APU FUEL LINE HAS SUSTAINED TWO OR MORE FREEZE/THAW CYCLES.

McDonnell Douglas and JSC have performed analyses that indicate that a fuel line may rupture if it sustains as few as 3 freeze/thaw cycles (McDonnell Douglas Report TM-950002-02, December 23, 1994). The theoretical analysis addressed a straight section of 1/2 inch diameter fuel line that has yielded as a result of the freeze/thaw cycle. The fuel line radius has permanently expanded due to the yield. The line freezes again, and during thaw the resulting pressures further yield the line. This process continues until the ultimate strain of the line has been exceeded resulting in rupture. RI/Downey performed an analysis on fuel line bends that coupled TTA test data with a theoretical analysis. The engineering community decided, after a review of the analysis, that the fuel line bends could withstand two freeze/thaw cycles. A qualitative review of the fuel line welds and T's found them to be less critical for freeze/thaw than the tube bend section. The pressures resulting from thaw are directly related to the density of the frozen hydrazine. As hydrazine freezes the density increases linearly as a function of temperature decrease. The analysis assumed a worst case temperature of the solid hydrazine at -45 Deg F which then warms up to 70 Deg F. ©[032802-5345A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-1****APU LOSS DEFINITIONS (CONTINUED)**

9. FUEL TANK PRESSURE < 90 (99) PSIA PRIOR TO ON-ORBIT START. @[011295-1736C] @[032802-5345A]

APU startup time is a function of tank pressure. In order for the turbine speed to reach 80 percent in 10.5 seconds (to avoid an underspeed shutdown), the fuel tank pressure must be at least 90 psia. If INHIBIT is used to defeat the 10.5-second timer, the APU may start at a lower tank pressure, and a start attempt may be made unless the pressure is < 70 psi. Below 70 psia, start attempts become dangerous. However, as far as the flight rules are concerned, the APU must be considered lost because it may not start if the pressure is less than 90 psia. Reference SODB, Vol. I, 3.4.4.3 and figure 4.4.3.

Rules {A10-22D}, APU START/RESTART LIMITS; {A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE; and {A10-30A}, LOSS OF APU HEATERS/INSTRUMENTATION [CIL], reference this rule.

10. THE FUEL PUMP INLET PRESSURE IS < 15 (34) PSIA PRIOR TO OPENING THE FUEL ISOLATION VALVES. LOSS OF INSTRUMENTATION WILL NOT BE CAUSE FOR DECLARING AN APU LOST. @[021998-6491A]

If a large delta pressure exists across the FIV's, a surge pressure could result when the valves are opened. Under normal conditions, residual hydrazine in the fuel lines provides a damping force that reduces this surge pressure. At low pressures, the rapid compression results in frothing which may significantly reduce this damping force. When the pressure in the fuel lines is less than 15 psia prior to opening the FIV's, surge pressures over 2500 psia could result (WSTF Report 96-30335, 11/14/96). White Sands straight tube and U-tube testing showed that hydrazine becomes unstable above 2500 psia and Adiabatic Bubble Compression Detonation (ABCD) could occur (RD-WSTF-0002, 2/20/90). Reference SODB, Vol. I, 3.4.4.3, and Rule {A10-22}, APU START/RESTART LIMITS. @[032802-5345A]

Loss of the FPIP transducer results in loss of pressure monitoring of the portion of fuel line between the FIV's and the SOV. Loss of instrumentation alone is insufficient cause to declare an APU lost, but other factors (rising drain line pressure, history of leakage, leakage trend prior to transducer loss, etc.) in conjunction with loss of instrumentation may be enough to declare loss of a system.

The 34 psia limit accounts for transducer inaccuracies. Actual transducer biases are given for each mission based on data from KSC and should be taken into account for each system. @[021998-6491A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-1 APU LOSS DEFINITIONS (CONTINUED)

B. GG INJECTOR COOLING CAPABILITY IS CONSIDERED LOST IF GG INJECTOR COOLING WATER TANK PRESSURE IS < 55 (62) PSIA AT 70 DEG F (GROUND DETECTION ONLY) OR TANK OR LINE TEMPERATURES ARE < 32 (38) DEG F. @[ED] @[032802-5345A]

As long as at least one restart capability remains, injector cooling is still usable. From the SODB curve, with one restart remaining (five used already) and using worst case temperature of 70 deg F, the minimum pressure is 55 psia. Below this pressure, no hot restarts remain and injector cooling is considered lost. Reference SODB, Vol. I, 4.4.3.5. @[032802-5345A]

A10-2 THROUGH A10-20 RULES ARE RESERVED

FLIGHT RULES

APU SYSTEMS MANAGEMENT

A10-21 LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS

- A. EARLY MISSION TERMINATION FOR APU/HYDRAULIC SYSTEM LOSS(ES) WILL BE AS FOLLOWS:
1. FOR LOSS OF A SINGLE APU/HYDRAULIC SYSTEM, FLIGHT WILL CONTINUE TO NOMINAL EOM UNLESS A REVIEW OF THE FAILURE MODE AND THE REMAINING APU/HYDRAULIC SYSTEMS' CAPABILITY DETERMINES EARLY MISSION TERMINATION IS APPROPRIATE. ©[041097-4611B]

The APU/hydraulic systems are essentially quiescent while on-orbit. Because a subsequent failure of another APU/hydraulic system will likely only occur when these systems are operated for entry, there are no significant risks to continuing the flight until nominal EOM. A review of the failure mode and the remaining APU/hydraulic systems capability is required to determine that there are no generic or other failure concerns.

Rules {A2-102B}, MISSION DURATION REQUIREMENTS; and {A2-301}, CONTINGENCY ACTION SUMMARY, reference this rule.

2. FOR LOSS OF REDUNDANCY IN THE APU/HYDRAULIC/WSB SYSTEMS WHERE THE NEXT FAILURE RESULTS IN SINGLE APU/HYDRAULIC SYSTEM OPERATION AT ANY POINT FROM EI TO WHEELSTOP, A NEXT PLS WILL BE PERFORMED.

It is prudent to shorten the mission to minimize the time of exposure to any additional on-orbit failure that would result in a single APU entry. Only detectable on-orbit failures, including electrical bus failures, which may be affected by increased time on orbit will be considered as basis for early mission termination. Examples of redundancy for APU/hydraulic/WSB systems include, but are not limited to, the following:

APU	Controller RPC, MPU, fuel tank isolation valve, fuel line heaters
HYD	Accumulator (leak), circ pump, main pump depress RPC
WSB	Controller, steam vent heater

Each of the above components has experienced failure at least once during the history of the program.

This rule is referenced by Rule {A10-122B}, LOSS OF WSB(S) ACTIONS. ©[041097-4611B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-21

**LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS
(CONTINUED)**

3. FOR LOSS OF TWO APU/HYDRAULIC SYSTEMS, ENTRY WILL BE PERFORMED AT THE NEXT PLS OPPORTUNITY THAT ALLOWS FOR EXPEDITED PAYLOAD DEPLOY/JETTISON. FOR NONDEPLOY FLIGHTS, ENTRY WILL BE PERFORMED AT THE NEXT PLS OPPORTUNITY (FIRST DAY PLS IF APPLICABLE). @[041097-4611B]

The loss of two APU/hydraulic systems results in a situation where a single APU entry has to be made. It is desirable to stay on orbit in order to deploy payloads because this will improve the vehicle capability to maneuver and land safely. Jettison of deployable payloads that for some reason cannot be deployed should be considered and used as a means of last resort to improve the vehicle entry and landing capability. Once attempts have been made to deploy the payloads, the mission should not be extended beyond the next PLS opportunity. Staying on orbit increases the vehicle exposure time to the loss of the last APU. For flights where nondeployable payloads are onboard, the risk of staying on orbit outweighs the gain of continuing the flight; therefore, the mission should be terminated.

The PLS opportunity should be selected which provides the best possible conditions (i.e., trajectory, landing site, crew and vehicle health, weather conditions, etc.) for a single APU entry. Reference WX placards in Rule {A10-23A}, APU ENTRY START TIME.

4. FOR IMPENDING LOSS OF ALL APU/HYDRAULIC SYSTEM CAPABILITY, AN ABORT AT THE EARLIEST OPPORTUNITY WILL BE PERFORMED. THE PREFERRED ABORT MODE PRIORITY IS RTLS, TAL, AOA, FIRST DAY PLS, PLS, AND ELS. @[041097-4611B] @[040899-6857]

Since at least one operating APU/hydraulic system is required for entry, a landing as soon as possible is required if all APU/hydraulic system capability is failing. If this failure situation develops during ascent, an abort mode should be selected that minimizes entry time. This rule assumes that at least one APU/hydraulic system will be operating at any point throughout entry to wheelstop. @[040899-6857]

Rules {A2-54A}.1, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL], and {A2-205A}.2.c, EMERGENCY DEORBIT, reference this rule.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-21

LOSS OF APU/HYDRAULIC SYSTEM(S) ACTIONS (CONTINUED)

- B. DURING ENTRY, IF ONLY ONE GOOD APU/HYDRAULIC SYSTEM IS AVAILABLE THE APU WILL NOT BE SHUT DOWN IF RUNNING AND ITS HYDRAULIC PUMP WILL BE IN "LOW PRESS" UNTIL MM 304. IF NOT RUNNING, THE APU WILL BE STARTED AT TIG MINUS 5 MINUTES. AN ABBREVIATED ACTUATOR CHECK MAY BE PERFORMED IF REQUIRED. NO HYDRAULIC THERMAL CONDITIONING OR SSME REPRESSURIZATION WILL BE PERFORMED. IF THE APU/HYDRAULIC SYSTEM IS NOT NOMINAL, IT WILL BE SHUT DOWN AND RESTARTED, IF REQUIRED, TO MAINTAIN THE SYSTEM FROM MM 304 THROUGH WHEELSTOP. @[021199-6814]

If an APU is shut down, there is always the risk that it may not restart. This risk, however small, is simply not warranted in light of the criticality of the single APU that remains. The hydraulic pump is depressurized not only to save fuel, but also to put minimum stress on the system until absolutely required (MM 304-EI). However, if an abbreviated secondary actuator check is to be performed, the system will be taken to normal pressure in MM 303 post-deorbit burn just prior to the start of the check. If the APU is not already running (other two APU's known to be failed prior to TIG minus 5 minutes), it will be started at TIG minus 5 minutes. This ensures the APU will be fully operational before committing to the deorbit burn.

Reference Rules {A8-104}, FCS CHECKOUT, and {A10-1}, APU LOSS DEFINITIONS.

FLIGHT RULES

A10-22

APU START/RESTART LIMITS

- A. AN APU START/RESTART MAY BE ATTEMPTED AT ANYTIME IF THE BRANCH PASSAGE TEMPERATURE IS WITHIN ACCEPTABLE LIMITS. BRANCH PASSAGE TEMPERATURE IS ENSURED TO BE WITHIN ACCEPTABLE LIMITS IF ANY OF THE FOLLOWING IS TRUE: @[072398-6685A]
1. NO MORE THAN 1 SECOND HAS ELAPSED AFTER TERMINATION OF A MINIMUM OF 3.5 MINUTES OF CONTINUOUS ACTIVE GG INJECTOR COOLING.
 2. GG BED TEMPERATURE < 444 (430) DEG F WITHOUT ACTIVE GG INJECTOR COOLING IF HIGH TEMPERATURE IS DUE TO BED HEATER CYCLING.
 3. GG BED TEMPERATURE < 415 (401) DEG F WITHOUT ACTIVE GG INJECTOR COOLING IF HIGH TEMPERATURE IS DUE TO HEAT SOAKBACK FROM APU OPERATION.

Branch passage temperatures must be below 415 deg F for a safe restart. This temperature is not necessarily reflected by the GG injector instrumentation; therefore, the only reliable method to ensure a safe limit is to cool the injector for the 3.5-minute period or to verify the temperature, as measured by instrumentation at the injector, is below 415 deg F, which will ensure that the branch passages are also below the limit. Once cooling has been terminated the branch passage temperature will rise rapidly with the GG injector temperature, violating restart limits, and causing the APU to require additional cooling.

The A and B GG bed heaters are located on opposite sides of the bed and wrap 160 degrees around the bed. The GG bed temperature transducer is located near the B heater. If the supplied heat comes from either heater, Sundstrand thermal analysis has shown that the temperature of the branch passages will remain well below that indicated by the bed temperature transducer. However, if the supplied heat is from soakback due to APU operation, there are parts of the bed that will be much hotter than the transducer and the measured temperature will not be the maximum. See the SODB, vol. I, figure 4.4.3 for test data. If the GG bed temperature is above specified limits and a start attempt is made, the hydrazine fuel will begin decomposing before reaching the bed. The result will be extreme GG pressure spikes and possibly an uncontained APU GG explosion. The danger of explosion increases with GG temperature at the time of restart. On a test stand at Sundstrand, an APU was successfully restarted with sea-level pressure and a hot bed 19 times. It exploded during the 20th try. Later, with near space pressure in a chamber at JSC (TTA), an APU exploded during the first hot restart attempt without GG cooling (hot restart). Despite this test information, it is not possible to make a correlation between altitude and the probability of an explosion for a hot restart attempt (reference SODB, vol. I, 3.4.4.3).

Rules {A10-23B}, APU ENTRY START TIME, and {A10-33}, APU DEFINITIONS, reference this rule. @[072398-6685A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-22 APU START/RESTART LIMITS (CONTINUED)**

- B. AN APU CAN BE RESTARTED PROVIDED THE FUEL PUMP TEMPERATURE IS < 210 (204) DEG F, AND THE VALVE MODULE TEMPERATURE IS < 200 (194) DEG F. @[032802-5345A]

Large bubbles may form in the valve module or in the fuel pump due to decomposition. When the APU is started, the bubbles will collect in the filter downstream of the pump or in the valve, and the pump output pressure will increase as the pump comes up to speed when the APU is started. Adiabatic compression of the bubbles will increase their temperature and could cause the hydrazine to detonate. If allowed to cool, the bubbles that may have formed are much less likely to cause problems when the APU is started. During tests, an APU fuel system has detonated on a start attempt with fuel pump temperature above 240 deg F and GGVM temperature above 200 deg F. None have detonated during starts below 210 deg F on the pump and 200 deg on the valve, even if the temperature had been higher previous to the start attempt. While the high temperatures were not absolutely determined to have caused the APU detonations, they are still considered to be the most likely reason for the failures. Reference RI internal letter no. SSD-287-400-92-050, dated 1/6/92.

Rule {A10-23B}.4, APU ENTRY START TIME, references this rule.

- C. AN APU WILL NOT BE RESTARTED THAT HAS BEEN SHUT DOWN DUE TO CONFIRMED OVERSPEED.

An APU overspeed is an extremely hazardous situation as the turbine could disintegrate, producing shrapnel, and if uncontained, could damage other equipment in the aft fuselage. Once safed, either by manual or automatic shutdown, the affected APU should never be restarted.

- D. APU START WITH LOW FUEL TANK PRESSURE:

1. AUTO SHUTDOWN WILL BE INHIBITED FOR AN APU START WITH THE FUEL TANK PRESSURE < 90 (99) PSIA.

Normal APU starts at fuel tank pressures > 70 psia are not considered dangerous but may result in an APU underspeed shutdown. Low tank pressures will cause a slower than normal turbine spinup (violating the 10.5-second startup criteria); hence, auto shutdown inhibit mode is recommended.

Reference SODB, Vol. I, 3.4.4.3, and Rule{A10-1A.8}, APU LOSS DEFINITIONS.

2. RESTART WILL NOT BE PERFORMED ON AN APU WITH THE FUEL TANK PRESSURE < 100 (109) PSIA. @[032802-5345A]

Restarts at low fuel pressures can result in uncontrolled hydrazine decomposition in the APU bed, causing a detonation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-22

APU START/RESTART LIMITS (CONTINUED)

E. AN APU WILL NOT BE STARTED WITH THE GAS GENERATOR BED TEMPERATURE < 70 (84) DEG F, UNLESS REQUIRED. ©[072398-6685A] ©[032802-5345A]

Should both GG bed heaters fail on orbit, this rule allows the affected APU to be restarted as long as the bed temperature remains above 70 deg (84 deg) F. Testing at the component GG level showed that peak chamber pressures and catalyst ignition time delays were affected more by bed temperature than catalyst poisoning and both began increasing below a temperature of 100 deg F. Below 70 deg F, the peak chamber pressures and ignition time delays increased exponentially, indicating a potential for detonation at APU start.

Operationally, the risk of APU detonation as a result of low GG bed temperatures is judged to be less than the risks associated with entry on only one APU. An APU with both GG bed heaters failed off will not be considered lost for mission planning purposes since it may be used when absolutely necessary.

Documentation: SODB, Vol. I, sec. 3.4.4.3 and Figure 4.4.3-20, and ORBITER APU REVIEW, Sundstrand, June 28, 1990, p. 22-25.

Reference Rules {A10-30A}, LOSS OF APU HEATERS/INSTRUMENTATION [CIL], and {A10-33}, APU DEFINITIONS.

F. DURING ASCENT, IF AN APU LUBE OIL OUTLET TEMPERATURE EXCEEDS 375 (368) DEG F OR GEARBOX BEARING TEMPERATURE EXCEEDS 400 (389) DEG F, THE AFFECTED APU WILL NOT BE STARTED FOR ENTRY UNLESS REQUIRED.

Above these limits, lubrication is degraded, and gear/bearing/APU damage will eventually occur. Engineering tests have not been performed to determine APU life with temperatures above these limits. However, based on engineering judgment, the APU should be able to support entry, although seal and/or lube oil degradation and increased APU temperatures may result. In addition, consideration can be given to starting the APU at TAEM to provide three APU's if a real-time evaluation of the ascent temperature signature indicates that the oil/bearing heat up rate will be slow enough to prevent overheating from TAEM through wheel stop. Reference SODB, Vol. I, sec. 3.4.4.3. ©[032802-5345A]

Rule {A10-23B}, APU ENTRY START TIME references this rule. Reference Rule {A10-33}, APU DEFINITIONS. ©[072398-6685A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-22

APU START/RESTART LIMITS (CONTINUED)

- G. ON ORBIT, AN APU CAN ONLY BE STARTED IN OPS 8 OR OPS 3. ALL AEROSURFACE AMPLIFIERS MUST BE ON TO PRECLUDE DAMAGE TO THE AEROSURFACE ACTUATORS.

With the APU's and aerosurface amplifiers (ASA's) off (normal on-orbit conditions), the aerosurfaces, over a period of days, tend to "drift" from their original positions. This is due to a combination of gravity torques and circulation pump operations. If an APU is then started with the ASA's off and full hydraulic pressure applied, the actuator will try to drive the aerosurface to its hardstop, possibly causing damage. With the ASA's on and the software in OPS 3 or OPS 8, new commands are issued which cause little or no surface motion. Without OPS 3 or OPS 8, the surfaces will drive at high rate to the last commanded position. Once an APU has been started in OPS 3 or OPS 8, transition back to OPS 2 can be accomplished without fear of damage to an actuator.

Reference Rule {A8-112}, AEROSURFACE ACTUATOR PROTECTION.

- H. THE FUEL ISOLATION VALVES WILL NOT BE OPENED ON AN APU WITH A FUEL PUMP INLET PRESSURE < 15 (34) PSIA, UNLESS THE APU IS REQUIRED. THE FUEL ISOLATION VALVES MAY BE CYCLED OPEN ONCE TO REPRESSURIZE THE FUEL LINE PRIOR TO REACHING THE LOWER LIMIT. ©[021998-6491A] ©[072398-6685A]

Starting an APU with a low FPIP may result in high surge pressures and introduces the possibility of Adiabatic Bubble Compression Detonation (ABCD). Reference SODB, vol. I, 3.4.4.3, and Rules {A10-1}, APU LOSS DEFINITIONS, and {A10-33}, APU DEFINITIONS. ©[072398-6685A]

If a corresponding increase in drain line pressure is noted, , the fuel isolation valves may be opened to repressurize the fuel line to prevent reaching the loss limit. The pressure in the drain line and the fuel feed line should equalize to a value greater than 16.8 psia (the reseal pressure of the drain line overboard relief valve) if leakage continues. This should not be done more than once, since continued leakage below the limit indicates a possible external leak.

The 34 psia limit accounts for transducer inaccuracies. Actual transducer biases are given for each mission based on data from KSC and should be taken into account for each system. ©[021998-6491A]

FLIGHT RULES

A10-23

APU ENTRY START TIME

- A. AT LEAST ONE APU/HYDRAULIC SYSTEM MUST BE OPERATING PRIOR TO EXECUTING THE DEORBIT BURN.
1. PRIOR TO THE DEORBIT BURN, IF AN APU/HYDRAULIC SYSTEM FAILS OR ITS CAPABILITY TO SUPPORT TAEM THROUGH WHEELSTOP IS SUSPECT, ANOTHER APU WILL BE STARTED IF THE FOLLOWING WEATHER PLACARDS ARE MET FOR THE TARGETED LANDING SITE:
@[021199-6814]
 - a. CEILING ? 10K FEET
 - b. VISIBILITY ? 7 STATUTE MILES
 - c. CROSSWIND ? 10 KNOTS (PEAK)
 - d. NO GREATER THAN LIGHT TURBULENCE
 - e. ACCEPTABLE ROLLOUT MARGIN/BRAKE ENERGY ON HALF BRAKES WITHOUT NWS (DIFFERENTIAL BRAKING)

OTHERWISE, THE DEORBIT BURN WILL NOT BE EXECUTED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-23

APU ENTRY START TIME (CONTINUED)

2. IF AN APU/HYDRAULIC SYSTEM IS NOT OPERATING NOMINALLY PRIOR TO THE DEORBIT BURN, BUT IS NOT CONSIDERED FAILED, AND ITS CAPABILITY TO SUPPORT TAEM THROUGH WHEELSTOP IS NOT SUSPECT, THE DEORBIT BURN WILL BE EXECUTED. IF NECESSARY, ANOTHER APU WILL BE STARTED AND THE FIRST APU SHUT DOWN. ©[021199-6814]

Starting an APU prior to the deorbit burn gives a measure of confidence that at least one APU will support entry. Nominally, more than one APU is not started prior to the deorbit burn in order to preserve consumables for dynamic flight where operating APU/hydraulic systems are required. The loss of a second APU can be sustained as long as the weather placards are observed. Actual runway priority depends on weight and C.G. (reference Rule {A2-207}, LANDING SITE SELECTION). Once the deorbit burn begins, no action will be taken to terminate above safe Hp for APU/hydraulic system failures.

An APU that is not operating nominally, yet not considered failed (e.g., shift to high speed), can still be operated during the critical portions of entry, though it may be preferable to shut it down until it is needed. If there is a situation where it is prudent to shut down the off-nominal APU, the plan is to start another APU prior to the deorbit burn and shut down the off-nominal APU/hydraulic system. If there is not time to start a second APU, the deorbit burn will proceed, and appropriate action will be taken during deorbit coast. In this situation, starting a second APU is acceptable even though, in some cases, if the APU had actually been failed, a second APU would not have been started. However, if the failure mode is not understood, then that APU capability to support TAEM through wheelstop will be considered suspect. ©[021199-6814]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-23

APU ENTRY START TIME (CONTINUED)

B. AN APU WILL HAVE ITS ENTRY START TIME DELAYED FOR THE FOLLOWING:

FAILURE/CONSTRAINT	START TIME
1. LOSS OF WSB COOLING CAPABILITY	TAEM
2. APU LUBE OIL OUTLET OR GEARBOX BEARING TEMPERATURES EXCEEDED LIMITS SPECIFIED IN RULE {A10-22F}, APU START/RESTART LIMITS, DURING ASCENT	NO EARLIER THAN TAEM (IF NEEDED TO MAINTAIN TWO SYSTEMS)
3. APU WILL ONLY OPERATE WITH THE AUTO SHUTDOWN FUNCTION INHIBITED	TAEM (UNLESS NEEDED EARLIER TO MAINTAIN TWO SYSTEMS)
4. APU DOES NOT HAVE GG INJECTOR COOLING (IF APPLICABLE TO SINGLE APU ONLY)	EI-13
5. GEARBOX OR GN ₂ REPRESS BOTTLE HAS KNOWN EXTERNAL LEAK WHICH WILL NOT SUPPORT ENTIRE ENTRY OR GN ₂ REPRESS VALVE IS FAILED CLOSED	NO LATER THAN MACH 1.0
6. HYDRAULIC SYSTEM LEAK	NO EARLIER THAN TAEM BASED ON LEAK RATE
7. FREON LEAK INTO A HYDRAULIC SYSTEM	TAEM
8. HYDRAULIC SYSTEM RESERVOIR PRESSURE LOST	AFTER OTHER APU'S RUNNING AT NORMAL PRESSURE
9. HYDRAULIC SYSTEM RESERVOIR TEMPERATURE > 162° (154°) F PRIOR TO DEORBIT APU START.	TAEM

@[051194-1619B] @[ED] @[ED]

1, 2. *The loss of lube oil cooling will limit APU run time to approximately 11 minutes, based on data from previous flights. The time period from TAEM through landing is more critical for APU/hydraulic system availability since the system will be needed for heavy aerosurface activity, landing gear deployment, and braking during that period.*

If WSB cooling was lost for the hydraulic fluid (due to a failure of the bypass valve), the impact to the system is not so much overheating of the hydraulic system, but rather possible premature depletion of the water supply for the water boiler, resulting in the loss of APU cooling. Bypass valve failures during entry on STS-7 and STS 61-C caused significant depletion in the water supply. The hydraulic fluid temperature sensors demanded spraying, but the bypass valve failure did not allow the fluid to receive any cooling and spraying continued. The APU start time should be delayed to move the time at which the hydraulic fluid temperatures will demand spraying to as close to TAEM as possible.

Reference Rule {A10-22F}, APU START/RESTART LIMITS.

3. *Since inhibiting the auto shutdown logic does remove one layer of protection, starting the APU at TAEM will reduce the amount of time this protection is not present. However, if another APU/ hydraulic system is failed or failing, this APU may be started earlier than TAEM to maintain two systems. In this case, it would not be necessary to start the APU any earlier than EI minus 13 minutes.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-23

APU ENTRY START TIME (CONTINUED)

4. *If an APU is started at TIG minus 5 minutes and then a one-orbit waveoff is declared, the APU will have to be shut down. Without injector cooling, this APU could not be restarted to support entry as it would not have had time to cool (reference Rule {A10-22A}, APU START/RESTART LIMITS). For this case, the APU should be started after the deorbit burn as a waveoff is no longer a possibility.*
5. *If gearbox GN₂ leakage occurs, the GN₂ repressurization bottle will repressurize the gearbox at APU start. GN₂ will leak, requiring further represses and eventually depleting the bottle. By delaying the start of the APU until Mach 1.0, atmospheric pressure would prevent further leakage from the gearbox while the APU is running and actually would tend to back pressurize the gearbox. It is not possible to distinguish between an oil leak and a GN₂ leak when the APU is not running. If the drop in pressure is due to oil leakage, low oil pressure will be seen at startup, bearing temperatures will rise rapidly, and the APU will have to be shut down.*

If the GN₂ bottle develops a leak or the repress valve fails closed, typical GN₂ leakage from the gearbox may not support the entire entry. In this case, delay the start of the APU until it will support through wheelstop or Mach 1.0, where atmospheric pressure will prevent GN₂ leakage from the gearbox. With an evacuated repress bottle, if a gearbox repress is required, the valve will come open and the oil/GN₂ from the gearbox will flow into the bottle. The pressure would equalize at a lower value, the valve will remain open, and the oil/GN₂ will continue to leak. Below Mach 1, the repress valve most likely will not be activated. If it is, there will be some atmospheric pressure in the bottle that will reduce the amount of flow from the gearbox. ©[021199-6814]

Reference Rules {A10-1A}.5, APU LOSS DEFINITIONS, and {A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE.

6. *See Rule {A10-72}, HYDRAULIC LEAKS, for rationale.*
7. *Analysis by RI/Downey has determined that when Freon and hydraulic fluid are mixed, the bulk modulus of the hydraulic fluid is maintained within an acceptable range as long as fluid temperatures are limited to below 150 deg F. To prevent excessive temperature buildup in a hydraulic system with a Freon leak into it, the associated APU start should be delayed until no earlier than TAEM. The temperature rise from TAEM to wheelstop is not expected to exceed 100 deg F. ©[021199-6814]*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-23****APU ENTRY START TIME (CONTINUED)**

8. *Loss of bootstrap pressure may result in cavitation of the hydraulic pump when a start attempt is made. Rockwell/Downey studies have shown that start capability is questionable when reservoir pressure is below 15 psi. If bootstrap pressure is lost and cannot be maintained by the circulation pump, the start attempt should be delayed until the most favorable conditions exist. Intersystem leakage from two other hydraulic systems operating at full pressure will provide some head pressure. Additional head pressure may be obtained by starting the APU at a lower altitude, when atmospheric pressure and gravity will be acting on the hydraulic system. Once the APU has started, the main pump should be run in NORM pressure. Reference Rule {A10-51A}.5, HYDRAULIC LOSS DEFINITIONS; RIC IL 288-503-81-055, November 10, 1981; and STS-7 SPAN/MER Action Request 041, June 21, 1983.*
9. *Hydraulic system temperatures greater than 162 deg F at APU start will lead to early water spray boiler spraying. The early spraying coupled with cool lube oil temperatures could lead to a water spray boiler freeze up and loss of the associated APU lube oil cooling. Loss of lube oil cooling would require an APU shutdown. The APU could not be restarted until Mach 1 to support through wheelstop (reference Rule {A10-24B}, APU OIL/GEARBOX TEMPERATURE/PRESSURE). To avoid this situation, starting an APU/hydraulic system with reservoir temperature greater than 162 (154) deg F should be delayed until TAEM. At reservoir temperatures below 162 (154) deg F the APU lube oil will require cooling prior to hydraulic spraying. The heat load from the APU will prevent a water spray boiler freezeup. ©[021199-6814]*

Rules {A10-24C}, APU OIL/GEARBOX TEMPERATURE/PRESSURE; {A10-122B}, LOSS OF WSB(s) ACTIONS; and {A10-73E}, HYDRAULIC SYSTEM PRESSURE/TEMPERATURE, reference this rule. ©[051194-1619B]

FLIGHT RULES**A10-24****APU OIL/GEARBOX TEMPERATURE/PRESSURE**

- A. POST-MECO, AN APU WILL BE SHUT DOWN IF THE LUBE OIL OUTLET TEMPERATURE EXCEEDS 325 (318) DEG F OR IF THE GEARBOX BEARING TEMPERATURE EXCEEDS 350 (339) DEG F (MCC CALL). ©[032802-5345A]

The APU should be shut down after MECO is obtained, since the consequences are no longer severe. This is done to protect the APU for use during entry and landing. At or below these temperatures, APU reuse is guaranteed.

Reference Rule {A10-1A}.6, APU LOSS DEFINITIONS, and SODB, vol. I, 3.4.4.3.

- B. DURING ENTRY/ABORTS, FOR CONFIRMED LOSS OF APU LUBE OIL COOLING CAPABILITY, IF POST-MECO AND MACH > 1.0, THE AFFECTED APU WILL BE SHUT DOWN ASAP IF AT LEAST ONE OTHER GOOD APU/HYDRAULIC SYSTEM REMAINS. A RESTART WILL BE PERFORMED NO EARLIER THAN MACH 1.0, IF THE APU IS REQUIRED. FOR MACH < 1.0, AN APU WILL NOT BE SHUT DOWN FOR LOSS OF LUBE OIL COOLING UNTIL POST-WHEELSTOP. ©[072398-6685A] ©[ED]

If all lube oil cooling capability has been lost due to water spray boiler failure(s), the affected APU will have only a limited operational lifetime. APU lube oil and bearing temperature rise rates without sufficient cooling may be higher than during previous operation. This is due to a continuous breakdown of lube oil viscosity at elevated temperatures as well as the high workload of the APU in the latter portions of approach and landing.

If cooling capability is lost after the normal cooling control point is reached (250 deg F), the available APU run time is estimated to be no more than a few minutes before gearbox seals are lost and/or bearing seizure occurs. For this reason, the APU should be shut down and the remaining run time saved if needed to provide a second system operating during final approach and landing.

Once a velocity of Mach 1 (approximately 4 minutes to touchdown) is reached, an APU that loses its lube oil cooling capability should be left running through wheelstop. This is because below Mach 1, there may not be sufficient time to perform shutdown, cooldown, and restart before touchdown. Though continued operation through wheelstop may be questionable, it is preferable to have the APU operating as long as possible. ©[021199-6814] ©[ED]

Rules {A10-23B}.9, APU ENTRY START TIME, and {A10-33}, APU DEFINITIONS, reference this rule. ©[051194-1619B] ©[072398-6685A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-24 APU OIL/GEARBOX TEMPERATURE/PRESSURE (CONTINUED)**

C. AN APU WITH GEARBOX PRESSURE < 2.0 (3.1) PSIA WILL ONLY BE USED FOR ENTRY. FOLLOWING APU START, IF THE OIL OUTLET PRESSURE IS NOT > 20 (27) PSIA AFTER 30 SECONDS AND OIL OUTLET TEMPERATURE IS NOT INCREASING, THE APU WILL BE SHUT DOWN AND NOT RESTARTED. @[032802-5345A]

If the APU gearbox pressure is < 2 psia, a leak is present in the gearbox or associated plumbing and some amount of lube oil/GN₂ has been lost. Starting the APU will repressurize the gearbox from the GN₂ bottle, but it may only be able to do this once (GN₂ bottle may be dumped into the gearbox) and this will also begin to leak from the gearbox. Because of this one-shot potential, the APU should only be started to support entry. Once the APU is started, if the oil pressure is greater than 20 psia, then the gearbox has been successfully repressurized and sufficient lube oil is still present to allow the APU to operate.

D. DURING ENTRY/ABORTS, AN APU WILL BE SHUT DOWN POST-MECO IF THE OIL OUTLET PRESSURE IS > 150 (143) PSIA.

Structural damage could result if the APU is run with an oil pressure > 150 psia. Reference SODB, Vol. I, 3.4.4.3. @[072398-6685A]

Rules {A10-1A}.4, 5, and 8, APU LOSS DEFINITIONS, and {A10-23B}.5, APU ENTRY START TIME, reference this rule.

E. POST-MECO AND MACH > 1.0, AN APU THAT IS RUNNING WITH A GEARBOX PRESSURE OF < 2.0 (3.1) PSIA WILL BE SHUT DOWN ASAP IF AT LEAST ONE OTHER GOOD APU/HYDRAULIC SYSTEM REMAINS. A RESTART WILL BE PERFORMED, NO EARLIER THAN MACH = 1.0, IF THE APU IS REQUIRED. FOR MACH < 1.0, AN APU WILL NOT BE SHUT DOWN FOR LOSS OF GEARBOX PRESSURE UNTIL POST-WHEELSTOP.
@[ED] @[032802-5345A]

If an APU is running with its gearbox pressure < 2 psia, a leak is present in the gearbox or associated plumbing that can no longer be supported by repressurizations from the GN₂ bottle. It is not possible to distinguish between a lube oil or GN₂ leak. However, if the leak is mostly GN₂, shutting down the APU at this point will prevent it from seizing due to loss of lubrication. The APU can then be restarted, if required, at Mach 1.0 since the atmospheric pressure would prevent further leakage from the gearbox while the APU is running and actually would tend to back pressurize the gearbox. If a significant amount of oil is also being lost, the bearing temperatures will eventually begin to rise, indicating the loss of lubrication and imminent bearing seizure. In this case, the APU would be shut down based on temperature rise and would be nonrecoverable.

Rule {A10-33}, APU DEFINITIONS, references this rule. @[072398-6685A]

FLIGHT RULES

A10-25

APU HIGH SPEED SELECTION/SHIFT

- A. THE REMAINING APU(S) WILL BE RUN AT HIGH SPEED IF ONE OR MORE APU/HYDRAULIC SYSTEMS ARE LOST DURING ASCENT OR RTLS.

In order to minimize the performance degradation resulting from APU/hydraulic system loss(es), the remaining APU(s) are taken to high speed as soon as a system is declared lost.

- B. DURING ENTRY/ABORTS (EXCEPT RTLS), HIGH SPEED WILL BE SELECTED:
1. AT MM 304 IF ONLY A SINGLE GOOD APU/HYDRAULIC SYSTEM IS OPERATING.

If two APU's have been lost, then there is degradation in aerosurface movement rate capability. The remaining APU must be in high speed in order to obtain maximum horsepower to minimize this degradation. Also, it is absolutely essential that the APU be operating at maximum rpm when the vehicle first enters the Earth's atmosphere (MM 304-EI) to provide the best chance of landing the orbiter on one APU.

2. AT TAEM, IF ONLY TWO GOOD APU/HYDRAULIC SYSTEMS ARE OPERATING.

If one APU is lost, the two remaining APU's can still meet all aerosurface rate demands with no loss of performance even if they are running at normal speed. They are taken to high speed at TAEM as a precautionary measure in the event one of the remaining APU's fails during the critical final landing maneuvers.

Rule {A10-72}, HYDRAULIC LEAKS, references this rule.

- C. AN APU WILL NOT BE SHUT DOWN PRIOR TO MECO, EXCEPT FOR CONFIRMED OVERSPEED > 129 (129) PERCENT.

Shutting down an APU in powered flight will result in the associated main engine going into hydraulic lockup. Test data on SSME valve drift is very limited while in the hydraulic lockup condition. Excessive SSME valve drift can severely impact ascent performance to the point of risking loss of orbit capability. For this reason, it is highly desirable to avoid hydraulic lockup even at the expense of possible loss of an APU.

In addition to valve drift concerns, the failure of an SSME bypass valve prior to STS-26 has also contributed to the desire to avoid the SSME hydraulic lockup condition. Failure of the bypass valve in combination with hydraulic lockup (i.e., APU shutdown) can result in loss of hydraulic and pneumatic engine shutdown capability. A catastrophic engine shutdown will result. Because the bypass valve failure is not detectable (transparent to crew and MCC), manual shutdown of an APU in response to any failure except a confirmed overspeed during powered flight is not allowed. Reference Ascent/Entry Flight Techniques #50, October 20, 1988.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-25 APU HIGH SPEED SELECTION/SHIFT (CONTINUED)

- D. DURING ASCENT, AN APU WHICH SHIFTS TO HIGH SPEED WITH NORMAL SPEED SELECTED WILL BE SHUT DOWN ASAP POST-MECO.

An APU that shifts to high speed (due to a failure of the pulse control valve to regulate speed) is a single failure (failed open secondary valve) from a possible uncontained overspeed. The risk of a second failure in that APU is accepted in powered flight in order to retain SSME throttling capability and SSME hydraulic valve control. (Shutting down one APU results in hydraulic lockup of one main engine.) Risk of operating the APU after MECO is not warranted, and the APU will be shut down.

Though it has experienced a shift to high speed, the APU will not be considered lost for planning purposes since it may be used when absolutely necessary.

- E. DURING ENTRY/ABORTS, IF AN APU SHIFTS TO HIGH SPEED WITH NORMAL SPEED SELECTED AND TWO GOOD APU/HYDRAULIC SYSTEMS REMAINING, THE APU WILL BE SHUT DOWN ASAP POST-MECO. A RESTART WILL BE PERFORMED IF THE APU IS REQUIRED (SHUTDOWN WILL NOT BE PERFORMED FOR THESE CASES IF INSUFFICIENT TIME IS AVAILABLE TO RESTART THE AFFECTED APU). ©[072398-6685A]

If the other APU's are functioning properly, the affected APU will be shut down to protect against a possible uncontained overspeed. That APU may be considered available for restart after completion of injector cooling should a second APU be required.

If only one other APU is functioning properly, the affected APU will be left operating in order to provide dual APU flight control authority throughout entry.

APU operations after an uncommanded shift to high speed shall be performed with the APU SPEED SELECT switch in high in order to prevent nuisance alarms. This will also enable the 115 percent comparator, which will provide backup speed control in the case that the initial failure was in the 103 percent comparator. In addition, auto shutdown shall remain enabled as long as one other good APU remains.

Reference Rules {A2-254C}, ENTRY STRING REASSIGNMENT; {A10-26}, APU AUTO SHUTDOWN INHIBIT MANAGEMENT; and {A10-33}, APU DEFINITIONS. ©[072398-6685A]

FLIGHT RULES

A10-26

APU AUTO SHUTDOWN INHIBIT MANAGEMENT

- A. AN APU WILL HAVE ITS AUTO SHUTDOWN FUNCTION INHIBITED IF:
1. ONE OTHER APU/HYDRAULIC SYSTEM IS LOST OR FAILING SUCH THAT SUPPORT OF NOMINAL ASCENT THROUGH MECO IS SUSPECT (SEE PARAGRAPH B FOR EXCEPTIONS).
 2. THE OTHER TWO APU/HYDRAULIC SYSTEMS ARE LOST OR FAILING SUCH THAT SUPPORT OF ABORT/ENTRY THROUGH WHEELSTOP IS SUSPECT. @[021199-6814]
 3. THE APU IS NEEDED TO PROVIDE A LAST METHOD OF GEAR DEPLOY OR DIRECTIONAL CONTROL. @[072398-6685A]

The purpose of the auto shutdown function is to quickly secure the APU in the event of a potentially hazardous situation (such as an overspeed condition). The auto shutdown logic secures the APU by disabling the shutoff valve commands and removing power from the fuel tank isolation valves (causing the valves to close). The auto shutdown function can be inhibited to protect against an erroneous shutdown of an APU, but this also removes all overspeed/underspeed protection.

With the redundancy inherent in the digital controller, an erroneous APU shutdown is highly unlikely. At least two controller component/magnetic pickup unit (MPU) failures are necessary to cause an inadvertent shutdown after the first 10.5 seconds of run time. Due to their design, location, and failure history, the probability of two MPU failures is considered much greater than that of two controller failures. And in INHIBIT, the loss of two MPU's would result in an uncontained overspeed. Therefore, inhibiting the auto shutdown function is not likely to prevent a spurious shutdown, and it does increase the risk of an uncontained overspeed.

However, there are some specific mechanical failure scenarios where the APU would only continue to run if the auto shutdown was inhibited. These single mechanical failures are more likely than the dual controller/MPU failures, but the ability of the affected APU/hydraulic system to provide useful support is highly questionable.

Even though the increased risk associated with running an APU in INHIBIT is relatively small, the potential consequences do not warrant accepting the risk except for the cases listed. In these cases, even the small gains associated with inhibiting auto shutdown are considered necessary to maintain critical functions. This applies to the loss of a single APU during power flight due to controllability concerns associated with the loss of a second APU.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-26 APU AUTO SHUTDOWN INHIBIT MANAGEMENT (CONTINUED)**

4. INHIBIT IS NECESSARY TO ALLOW THE APU TO OPERATE (SEE PARAGRAPHS B AND C FOR EXCEPTION).

There are several component failure scenarios in the digital controller (e.g., false overspeed), as well as several mechanical scenarios (e.g., low fuel tank pressure, valve contamination), that would result in an erroneous shutdown during APU startup. These situations would require inhibiting the auto shutdown function to get the APU running. For the controller failures, the auto shutdown must remain inhibited since the erroneous signal(s) in the controller would shut the APU down if the function were reenabled.

In these cases, the risk of running an APU with its auto shutdown inhibited is considered less dangerous than the risk of losing entry-critical APU/hydraulic systems. Therefore, the auto shutdown logic is inhibited to maintain a fail-safe configuration for entry even if two other good APU's remain.

- B. THE AUTO SHUTDOWN FUNCTION WILL BE (RE)ENABLED FOR AN APU WHICH HAS ONE OF THE FOLLOWING CONDITIONS WHEN AT LEAST ONE GOOD APU/HYDRAULIC SYSTEM REMAINS:
1. THE APU TURBINE SPEED HAS SHIFTED TO THE HIGH SPEED BAND, IS ERRATIC WITH HIGH SPEED SELECTED, OR IS LOST DUE TO A SUSPECTED MPU FAILURE.
 2. THE APU IS RUNNING WITH AN ISOLATABLE FUEL LEAK.

IF (RE)ENABLING THE AUTO SHUTDOWN FUNCTION WILL CAUSE THE APU TO SHUT DOWN, THE AUTO SHUTDOWN MAY REMAIN INHIBITED TO MAINTAIN TWO APU'S THROUGH MECO OR WHEELSTOP. @[021199-6814]

Auto shutdown should be enabled in situations where there is a high potential for an uncontrolled shutdown which could cause damage to other equipment in the aft compartment. If the turbine speed is erratic and selecting high speed did not clear the problem or if turbine speed has shifted to the high speed band, the APU is one failure away from an overspeed condition. Similarly, the loss of a MPU (i.e., loss of turbine speed not explainable by an MDM/DSC or other failure), with the auto shutdown function inhibited, places the APU one failure away from an uncontained overspeed condition. In these cases, the risk of an uncontrolled shutdown is considered greater than an erroneous shutdown causing single APU operations. If the APU is in INHIBIT to allow it to operate, taking it back to ENABLE will cause the APU to shut down. Therefore, this should only be done if two good APU/hydraulic systems remain.

A fuel leak can lead to a fire and an explosive shutdown such as occurred on STS-9. The auto shutdown logic is beneficial in this case because it automatically closes the fuel tank isolation valves upon shutting down the APU. This may isolate the leak, thus minimizing the risk due to hydrazine in the aft compartment.

FLIGHT RULES

A10-26

APU AUTO SHUTDOWN INHIBIT MANAGEMENT (CONTINUED)

- C. DURING ENTRY/ABORTS, FOR AN APU THAT HAS SHUTDOWN DUE TO AN UNEXPLAINED UNDERSPEED WITH AUTO SHUTDOWN ENABLED: @[062797-4889]
1. THE APU WILL BE RESTARTED WITH AUTO SHUTDOWN ENABLED AND NORM SPEED SELECTED ONLY IF TIME IS AVAILABLE TO PERFORM TWO APU RESTARTS (T/D > APPROX 10 MIN) AND ANY OF THE FOLLOWING ARE TRUE:
 - a. ANOTHER APU/HYD SYSTEM IS FAILED OR SUSPECT.
 - b. THE APU IS REQUIRED. @[072398-6685A]
 - c. SINGLE APU WX PLACARDS ARE EXCEEDED.
 2. IF A RESTART IS ATTEMPTED AND THE APU:
 - a. STARTS AND RUNS, THE APU WILL CONTINUE TO OPERATE WITH AUTO SHUTDOWN ENABLED. THE APU WILL BE CONSIDERED SUSPECT.
 - b. DOES NOT START OR SUSTAINS AN UNDERSPEED SHUTDOWN WITHIN THE FIRST 10.5 SECONDS OF OPERATION, THE APU WILL BE RESTARTED AND OPERATED WITH AUTO SHUTDOWN INHIBITED IF REQUIRED. @[072398-6685A]
 - c. SUSTAINS AN UNDERSPEED SHUTDOWN AFTER 10.5 SECONDS, ANOTHER RESTART OF THE APU MAY BE ATTEMPTED IF TIME PERMITS. THE APU WILL BE OPERATED WITH AUTO SHUTDOWN ENABLED.
 - d. SUSTAINS AN OVERSPEED SHUTDOWN, THE APU WILL BE SHUT DOWN AND NO FURTHER TROUBLESHOOTING WILL BE ATTEMPTED. @[061297-4889]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-26

APU AUTO SHUTDOWN INHIBIT MANAGEMENT (CONTINUED)

3. IF TIME IS NOT AVAILABLE TO ATTEMPT TWO RESTARTS, AN APU COOLDOWN WILL BE PERFORMED AT MACH 7. THE APU WILL BE RESTARTED, WITH AUTO SHUTDOWN INHIBITED, ONLY TO PROVIDE A LAST APU/HYD SYSTEM, LANDING GEAR DEPLOY METHOD, OR BRAKING. ©[061297-4889]

An APU has sustained an “unexplained” underspeed shutdown if a dual magnetic pickup unit (MPU) failure cannot be ruled out as the cause of the shutdown (other than by attempting a restart of the APU; examples of explainable underspeed shutdowns include failures within the underspeed slow latch circuit, overspeed slow latch circuit, and timer failures). Analysis performed by JSC SR&QA indicates that the most probable APU electrical failure is an MPU. The APU has three MPU’s which provide APU turbine speed data to the APU controller - dual MPU failures result in APU shutdown. The signature for a dual MPU failure case is closure of the fuel tank isolation valves (FIV), illumination of the F7 APU underspeed light, and closure of the shutoff valve (SOV) while the APU is running in NORM or HIGH speed. This occurs because three of the four speed control channels indicate zero speed due to the failed MPU’s which results in the logic on these three channels voting for underspeed. The same signature can result with two intermittent MPU’s. Another signature is also possible for the case of two intermittent MPU’s. The signature for this scenario is the APU spinning down from NORM or HIGH speed, and at a turbine speed of 80 percent, the FIV’s close and the F7 APU underspeed light is illuminated. The signature for two intermittent MPU’s is dependent on which of the three MPU’s have failed. Therefore, there is not a specific shutdown signature for all MPU failure cases.

During APU start, the controller locks out the underspeed shutdown logic for 10.5 seconds to allow the APU adequate time to spin up. The overspeed shutdown logic is not affected during this 10.5 second period. Since the dual MPU failure is interpreted as a zero turbine speed by the APU controller on three of the four speed control channels, the controller does not sense the APU spinning up. As a result, the APU continues to increase in RPM until the remaining MPU senses that the speed has reached 129 percent, which triggers the overspeed shutdown logic and shuts down the APU if auto shutdown is enabled. If auto shutdown was inhibited, the APU would experience an uncontained overspeed - the turbine could disintegrate, producing shrapnel that could damage other equipment in the aft fuselage.

To determine if the underspeed was due to a dual MPU failure, the APU is restarted with auto shutdown enabled. If the APU overspeeds and automatically shuts down, then the dual MPU failure case is confirmed - the APU will be safed and should never be restarted. If the APU does not start or experiences an underspeed shutdown within the first 10.5 seconds of operation, a dual MPU failure is not the cause of the shutdown (dual failures may be in the APU or the controller). If the APU restarts and operates but subsequently fails after 10.5 seconds, the failure is transient (e.g., a single failed MPU coupled with an intermittent MPU) - the APU would experience an uncontained overspeed if the transient MPU recurred with auto shutdown inhibited, so the APU will only be restarted and run with auto shutdown enabled. ©[061297-4889]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-26****APU AUTO SHUTDOWN INHIBIT MANAGEMENT (CONTINUED)**

Touchdown minus 10 minutes is the minimum amount of time needed to accomplish two APU cooldowns in order to support APU operations no later than approach and landing. Since hardware damage to the affected APU may result if an overspeed condition occurs, troubleshooting for an unexplained underspeed should only be performed if critical redundancy is lost. If there is insufficient time to perform two cooldowns and the APU is needed to provide a critical landing capability, a start attempt will be made with auto shutdown inhibited to provide the best chance of regaining the APU.
 ©[061297-4889]

Braking redundancy is defined as fault tolerance for 50 percent braking. This rule is referenced by Rule {A10-25}, APU HIGH SPEED SELECTION/SHIFT. Reference rule {A10-33}, APU DEFINITIONS. ©[061297-4889] ©[072398-6685A]

A10-27**APU FUEL LEAKS [CIL]**

A. DURING ASCENT, IF AN APU DEVELOPS A FUEL LEAK, IT WILL BE SHUT DOWN ASAP POST-MECO.

If the leak is upstream of the tank valves, then the leak is not isolatable and fuel will continue to leak into the orbiter aft compartment even with the APU shut down. A significant amount of free hydrazine in the aft compartments presents a severe safety hazard during entry. To avoid this, the APU should be restarted and allowed to run until its fuel is depleted. This will ensure that most of the hydrazine is burned and exhausted overboard and will minimize the amount of hydrazine that leaks into the aft bay. The restart should only be performed if fuel tank pressure is > 100 (107) psi.

If the fuel leak is downstream of the tank valves, the leak will be isolated when the APU is shut down. The APU is still considered lost, however, and should not be started unless one of the two remaining APU's fails (not available for entry).

Reference Rule {A10-1A}.1.b, APU LOSS DEFINITIONS.

- B. ON ORBIT POST-MECO, AN APU WILL BE OPERATED FOR THE PURPOSE OF BURNING ITS FUEL IF THERE IS A SUSPECTED OR CONFIRMED NONISOLATABLE HYDRAZINE LEAK. [CIL]
1. WITH TWO OTHER GOOD APU/HYDRAULIC SYSTEMS, THIS TECHNIQUE WILL APPLY WITHOUT CONSIDERING LANDING OPPORTUNITIES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-27

APU FUEL LEAKS [CIL] (CONTINUED)

2. WITH ONLY ONE OTHER GOOD APU/HYDRAULIC SYSTEM REMAINING, THIS WILL APPLY IF THE LEAK RATE DOES NOT SUPPORT THE NEXT PLS ASSUMING THE AFFECTED APU IS STARTED AT TAEM.

If the leak is upstream of the fuel tank isolation valves, then the leak is not isolatable and fuel will continue to leak into the orbiter aft compartment even with the APU shut down. A significant amount of free hydrazine in the aft compartment presents a severe safety hazard during entry. If two fully operational APU's remain, the leaking APU will be started and its fuel burned off in order to minimize the amount of free hydrazine that is left to leak in the aft compartment. If one APU has already failed, however, the leak rate will be assessed to see if fuel will support a next PLS entry. If the leak rate is slow enough that the APU would be able to support a next PLS entry, then the APU will not be started to burn off its fuel. Performing a single APU entry is more hazardous than having free hydrazine in the aft bay. Start of the APU will be delayed until TAEM to reduce entry usage requirements and optimize the remaining capability to support the leak rate. If the leak rate will not support the next PLS, then the APU will be started and the fuel burned off since it would not be available for entry whether the APU was started or not.

- C. DURING ENTRY/ABORTS, FOR A FUEL LEAK, ACTION WILL BE TAKEN IN ORDER TO PROVIDE AT LEAST TWO APU/HYDRAULIC SYSTEMS FROM TAEM THROUGH WHEELSTOP. @[021199-6814]

1. IF ONLY ONE OTHER GOOD APU/HYDRAULIC SYSTEM REMAINS AND THE LEAK SUPPORTS CONTINUED OPERATION THROUGH WHEELSTOP, THE APU WILL BE ALLOWED TO RUN. IF THE LEAK WILL NOT SUPPORT CONTINUED OPERATION THROUGH WHEELSTOP OR IF TWO OTHER GOOD APU/HYDRAULIC SYSTEMS REMAIN, THE AFFECTED APU WILL BE SHUT DOWN IF IT IS DETERMINED THAT THE FUEL TANK PRESSURE WILL NOT FALL BELOW 100 (109) PSIA BEFORE AN APU RESTART COULD BE PERFORMED. [CIL] @[032802-5345A]

- a. IF THE LEAK IS ISOLATED, THE AFFECTED APU WILL BE RESTARTED IF NEEDED TO MAINTAIN TWO APU/HYDRAULIC SYSTEMS FROM TAEM THROUGH WHEELSTOP, A LAST METHOD OF GEAR DEPLOY, OR DIRECTIONAL CONTROL [CIL]. @[072398-6685A] @[021199-6814]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-27

APU FUEL LEAKS [CIL] (CONTINUED)

- b. IF THE LEAK IS NOT ISOLATED AND THE LEAK RATE WILL NOT SUPPORT APU OPERATIONS FROM TAEM THROUGH WHEELSTOP, THE AFFECTED APU WILL BE RESTARTED ASAP. OTHERWISE, THE AFFECTED APU WILL BE RESTARTED WHEN ABLE TO SUPPORT APU OPERATIONS THROUGH WHEELSTOP (NO LATER THAN TAEM). [CIL]
 ©[021199-6814]

There are two important goals to achieve when troubleshooting a leaking APU: maintaining two good APU's for flight control and minimizing fuel leakage into the aft compartment, which can lead to fire. This rule will minimize free hydrazine in the aft compartment and reduce the risk of a fire that could potentially cause the loss of a second APU. The risk of fire damaging remaining APU's is considered greater than APU detonation concerns as a result of APU shutdown and subsequent heat soakback. Restarting a leaking APU risks a large fuel leak and potential detonation of the GGVM, but this risk is considered acceptable when considering the inability of the vehicle to land on a single APU.
 ©[032802-5345A]

We are forced to accept the risk of an aft compartment fire in order to provide two APU's for flight control. If only two APU's are operating, we do not want to risk shutting one down to try and isolate the leak, since it may not restart when required at TAEM. If the leaking APU will not support through wheelstop in its present condition, it is acceptable to shut it down and try to isolate the leak. If the leak is isolatable, this may allow a restart at TAEM to provide two APU's for landing.

If the leak rate is large enough that the fuel tank pressure would fall below 100 psia before an APU restart could be performed (in the event shutting the APU down does not isolate the leak), it should be assumed that the leak is nonisolatable; thus, the APU should be allowed to run to continue burning off fuel. Simulation experience shows that it takes approximately 5 minutes for the crew to shut down and then immediately restart an APU; this 5 minute time should be used when determining if the tank pressure will fall below 100 psia.

Reference Rule {A10-22A}, APU START/RESTART LIMITS, and SODB, Vol. I, 3.4.4.3.

2. PRIOR TO TAEM, AN APU WITH A SUSTAINED OVERBOARD FUEL PUMP SEAL CAVITY DRAIN SYSTEM LEAK WILL BE SHUT DOWN ASAP IF TWO OTHER GOOD APU/HYDRAULIC SYSTEMS REMAIN AND THE LEAKING APU FUEL TANK PRESSURE IS > 100 (109) PSIA. THE APU WILL BE RESTARTED IF NEEDED TO MAINTAIN TWO APU/HYDRAULIC SYSTEMS FROM TAEM THROUGH WHEELSTOP, A LAST METHOD OF GEAR DEPLOY, OR DIRECTIONAL CONTROL.
 ©[072398-6685A] ©[040899-6824] ©[032802-5345A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-27 APU FUEL LEAKS [CIL] (CONTINUED)

This rule accepts the risk of aft compartment fire damage after TAEM caused by ingestion, through the aft vent doors, of the fuel leaking overboard. A fuel pump seal leak may be detected by repeated excursions in drain line pressure to the relief valve cracking pressure (28 to 42 psia) or sustained drain line pressure above the relief valve reseal pressure (16.8 to 25.2 psia). A fuel pump seal leak will, by nature, be small; combined with the low probability of ingestion, chances of catastrophic damage from such a leak are small. There is insufficient time post-TAEM for a cooldown and restart of the affected APU, if required. Therefore, it is better to allow the APU to continue running so it will be available to support operations through wheelstop in the event another APU is lost. If the fuel tank pressure has already fallen below 100 psia, the APU should not be restarted if it is shut down. @[021199-6814] @[040899-6824] @[032802-5345A]

Reference Rule {A10-22A}, APU START/RESTART LIMITS, and SODB, Vol. I, 3.4.4.3. @[032802-5345A]

A10-28 AOA APU/HYDRAULIC SYSTEM OPERATIONS

A. IF ORBIT CAPABILITY IS QUESTIONABLE, THE APU'S WILL REMAIN RUNNING UNTIL THE DECISION IS MADE TO CONTINUE TO ORBIT. THE HYDRAULIC MAIN PUMPS WILL BE TAKEN TO "LOW PRESS" FOLLOWING MPS DUMP COMPLETION.

If an AOA has been declared, or is even a strong possibility, the APU's should continue operating to preclude the need for a later restart of all three APU's in order to support the AOA. Performing a restart on an APU is not something to be done without good reason and should be avoided if at all possible. A single failure in the injector cool system could cause the loss of all restart capability. The hydraulic main pumps will be depressurized to minimize fuel usage as well as WSB H₂O usage.

Reference SODB, vol. I, 3.4.4.3.5a

Rule {A2-66}, APU SHUTDOWN DELAY CRITERIA, references this rule.

B. DURING AN AOA, THE APU'S WILL REMAIN RUNNING WITH HYDRAULIC PUMPS IN "LOW PRESS" UNTIL MM 304. AN APU WILL BE SHUT DOWN, IF REQUIRED, TO MAINTAIN THE APU FOR ENTRY REGARDLESS OF OTHER APU/HYDRAULIC SYSTEMS STATUS.

APU consumables are loaded to account for continuous APU operation throughout an AOA. However, the margins are very small. Any off-nominal APU or WSB operation could result in exceeding these margins. Failure modes, such as a MPS/TVC ISOL valve failing to fully close (STS 51-J), result in additional loads and increased fuel and water usage on the APU which are not accounted for in the consumable analyses. When required, an APU should be shut down if this will allow it to be available throughout entry and landing.

FLIGHT RULES

A10-29

FCS CHECKOUT APU OPERATIONS

- A. APU SELECTION FOR FCS CHECKOUT WILL BE DONE REAL TIME BASED ON APU/HYDRAULIC SYSTEMS STATUS. CONSIDERATION WILL NOT BE GIVEN TO LANDING GEAR REDUNDANCY OR SWITCHING VALVE CYCLING.

The overriding consideration for APU system management decisions during the orbit/FCS checkout flight phase is the upcoming entry. The APU's must be in the best possible condition for entry. Therefore, the APU selected for FCS checkout must have had no potentially serious anomalies during ascent, consumables must be adequate to meet redline criteria, and there must be no major loss in performance monitoring instrumentation.

If APU 1 is selected for FCS checkout and should fail as a result of being selected, landing gear deploy redundancy would be lost. However, if APU 1 ran only long enough for FCS checkout, then it probably would not have supported the entire entry anyway. Thus, landing gear redundancy will not be considered when selecting an APU.

Certain hydraulic switching valves will change state during FCS checkout depending on which APU is selected. Should they fail in that state, hydraulic redundancy would be lost. But some switching valves must change state no matter which APU is selected; so switching valve cycling is not good criteria for selecting an APU.

- B. FCS CHECKOUT WITH AN APU WILL BE PERFORMED ONLY IF IT IS DETERMINED THAT TWO OF THREE APU/HYDRAULIC SYSTEMS WILL HAVE AT LEAST 192 LB APU FUEL AND 63 LB WSB H₂O FOLLOWING FCS CHECKOUT. ©[012694-1596]

The fuel and H₂O quantities above are based on the following:

	<u>APU</u>
FCS CHECKOUT	14.7
DEORBIT COAST	27.1
ENTRY	98.0
RESIDUALS	5.4
LOADING UNCERTAINTY	8.0
RESERVES AND ALLOWANCES	<u>53.4</u>
TOTALS	206.6 LB
TOTAL WITHOUT FCS CHECKOUT	191.9 LB

FLIGHT RULES

A10-29

FCS CHECKOUT APU OPERATIONS (CONTINUED)

- C. IF THE STATUS OF AN APU/HYDRAULIC SYSTEM IS QUESTIONABLE TO SUPPORT ENTRY, ATTEMPTS MAY BE MADE TO START AND OPERATE THAT SYSTEM FOR FCS CHECKOUT IN ORDER TO VERIFY ENTRY CAPABILITY PROVIDED THAT THE SYSTEM CAN BE OPERATED SAFELY (MCC CALL).

If only one or two APU's are nominally operable, it is unwise to activate either, except to support entry. If the orbit FCS checkout part 1 (secondary actuator check) were to be performed, one of the two remaining nominal APU's (or the last operational APU for the single remaining APU case) would have to be activated twice, increasing the risk of loss. Under these conditions, if an APU/hydraulic system has experienced suspect operation such that its capability to support entry is questionable, its entry status can be verified, if determined safe to operate, by attempting to use the system for FCS checkout.

- D. IF CONDITIONS PRECLUDE OPERATION OF ANY ONE OF THE THREE APU/HYDRAULIC SYSTEMS, THE HYDRAULIC CIRCULATION PUMP ON A FAILED SYSTEM MAY BE ACTIVATED IN ORDER TO PERFORM AN ABBREVIATED SECONDARY ACTUATOR CHECK. IF CONDITIONS ALSO PRECLUDE USE OF A CIRCULATION PUMP ON A FAILED SYSTEM, A CIRCULATION PUMP ON A NOMINAL HYDRAULIC SYSTEM MAY BE USED TO PERFORM THE CHECK.

If only one or two APU's are nominally operable or if it could be determined that operating an APU would be unsafe (isolated fuel leak, etc.), an abbreviated actuator check could be performed utilizing the system circulation pump. If it would also be unwise to activate the hydraulic system utilizing the circulation pump, a circulation pump on a nominal system could then be used to perform the abbreviated actuator check.

Reference Rule 10-74E}, HYDRAULIC CIRCULATION PUMP OPERATION. ©[072398-6686B]

- E. IF MISSION CONSTRAINTS PRECLUDE ACCOMPLISHING EITHER THE FULL OR ABBREVIATED ACTUATOR CHECK ON ORBIT, THE NOMINAL APU/HYDRAULIC SYSTEM WHICH IS STARTED AT TIG MINUS 5 MINUTES MAY BE OPERATED WITH THE HYDRAULIC MAIN PUMP IN "NORM PRESS" IN ORDER TO SUPPORT AN ABBREVIATED ACTUATOR CHECK IN MM 303.

Self-explanatory.

FLIGHT RULES

A10-30

LOSS OF APU HEATERS/INSTRUMENTATION [CIL]

- A. AN APU WILL BE STARTED PERIODICALLY OR THE ORBITER ATTITUDE ADJUSTED, IF REQUIRED TO MAINTAIN ACCEPTABLE APU SYSTEM TEMPERATURES. [CIL]

If there is a dual heater failure in an APU subsystem, orbiter attitude adjustment will be considered to prevent component freeze-up. If this is not practical, this rule allows an APU to be started to generate heat in the system and, using the heat soakback, to warm the surrounding components.

Reference Rules {A10-1A}.8, APU LOSS DEFINITIONS, and {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT.

Rules {A8-104}, FCS CHECKOUT; {A8-112}, AEROSURFACE ACTUATOR PROTECTION; {A10-1A}.1, APU LOSS DEFINITIONS; {A10-21B}, LOSS OF APU/HYDRAULIC SYSTEMS(S) ACTIONS; and {A10-22}, APU START/RESTART LIMITS, reference this rule.

- B. THE FOLLOWING ACTIONS WILL BE TAKEN FOR AN APU WITH BOTH FUEL LINE TEMPERATURE TRANSDUCERS T1 AND T2 LOST:
1. SIDE/TOP SUN SOLAR INERTIAL ATTITUDE WILL BE ESTABLISHED ASAP AND MAINTAINED SUBJECT TO HIGH PRIORITY PAYLOAD REQUIREMENTS (? S90 ØS45 FOR APU 3; ? S90 ØS315 FOR APU 1, 2).
 2. WHEN NOT IN SIDE/TOP SUN ATTITUDE OR PRIOR TO THERMAL STABILIZATION AFTER SIDE/TOP SUN ATTITUDE HAS BEEN ESTABLISHED, MANUAL HEATER MANAGEMENT WILL BE PERFORMED BY CYCLING APU HEATERS TANK/FUEL/ LINE/H₂O SYSTEMS A AND B SIMULTANEOUSLY TO "AUTO" FOR 18 MINUTES THEN "OFF" FOR 42 MINUTES. THE HEATERS WILL BE TURNED "OFF" DURING ON-ORBIT OPERATIONS WHEN MANUAL HEATER MANAGEMENT IS NOT REQUIRED AND DURING ENTRY.
 - a. FOR SIDE/TOP SUN ATTITUDE ESTABLISHED BEFORE MET = 35 HOURS, MANUAL HEATER MANAGEMENT IS REQUIRED UNTIL MET = 40 HOURS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-30

LOSS OF APU HEATERS/INSTRUMENTATION [CIL]
(CONTINUED)

- b. FOR SIDE/TOP SUN ATTITUDE ESTABLISHED AFTER MET = 35 HOURS, MANUAL HEATER MANAGEMENT IS REQUIRED FOR 5 HOURS AFTER SIDE/TOP SUN HAS BEEN ESTABLISHED.

Because APU fuel line heater operation cannot be verified, steps must be taken to ensure that a failed-on heater does not detonate the fuel line, while also ensuring the fuel line does not freeze. Going to a side/top Sun attitude will eventually provide a warm enough environment for the fuel line that the heaters can be turned off. After an MET of 40 hours, going to side/top Sun will provide a stable environment within about 5 hours, but before 40 hours, the MPS cryogenic chilldown in the aft compartment hinders the warming process. For the period prior to the establishment of side/top Sun and thermal stabilization, manual heater cycling must be conducted to try to prevent the fuel from freezing. Both heaters are cycled on simultaneously to preclude a failed-off heater from allowing fuel line freezing, and a manual off cycle is required to prevent a failed-on heater from detonating the line. Once the affected APU is started, heater management is no longer required and the heaters can be powered off for entry.

Analysis by Rockwell-Downey has determined that as long as the manual heater cycling is done when the aft compartment is not warm enough to keep the heater off, the affected APU can be considered good and usable for entry. The APU will be started prior to the deorbit burn to preclude heater management postburn.

Reference Rockwell IL SETO TCS-87-134, Heater Duty Cycles for Low/Intermediate Angle Top LV & GG Attitudes, and SODB submittal R1-1371, December 11, 1987.

3. IF THE INSTRUMENTATION IS LOST BEFORE DEORBIT TIG - 5 MINUTES, THE AFFECTED APU WILL BE STARTED AT TIG - 5 MINUTES.

Because a failed fuel line heater has little or no impact upon an APU that is running, it is best to start this APU at the "single APU start" time in order to protect against subsequent heater failures and to have this APU for entry operations.

4. IF THE INSTRUMENTATION IS LOST AFTER DEORBIT TIG - 5 MINUTES, THE AFFECTED APU WILL BE STARTED ASAP.

As stated above, fuel line heater failures are not a concern when the APU is running. Because there are sufficient consumables margins in all APU's to run for the entire entry, the affected APU can be immediately started.

FLIGHT RULES

A10-31

APU FREEZE/THAW

- A. FOR AN APU THAT HAS SUSTAINED ONE OR MORE FUEL LINE FREEZES THE FOLLOWING ACTIONS WILL BE TAKEN (UNLESS THE FREEZE IS SUSPECTED TO BE THE RESULT OF THE APU LEAKING FUEL):
@[011295-1736C]
1. POWER BOTH 'A' AND 'B' FUEL LINE HEATERS SIMULTANEOUSLY.
@[011295-1736C]
 2. ESTABLISH A SIDE/TOP SUN SOLAR INERTIAL ATTITUDE AS LONG AS NECESSARY TO THAW THE FROZEN FUEL LINE SEGMENT (THETA S90 PHI S45 FOR APU 3; THETA S90 PHI S315 FOR APU 1,2).
- B. FOR AN APU THAT HAS SUSTAINED MULTIPLE FUEL LINE FREEZE/THAW CYCLES AND NO FUEL LEAKAGE IS SUSPECTED, THE APU WILL NOT BE STARTED UNLESS REQUIRED. @[072398-6685A]

APU data from STS-62, TTA , and McDonnell Douglas indicate that the APU fuel lines can sustain a single freeze/thaw cycle without rupture. The STS-62 fuel line freeze was a result of aft water intrusion that pooled between the fuel line insulation and the fuel line. The sublimation of the water provided enough heat transfer from the hydrazine to overcome the effect of the fuel line heater resulting in a line freeze during the post insertion time frame. The frozen fuel line segment was located near the fuel tank isolation valves downstream of where the test line attaches to the fuel line. This prevented pressure relief back into the APU fuel tank during soakback and resulted in fuel line pressures of around 800 psia. The location of the frozen segment was determined by the effect of the fuel line and test line heaters on the fuel pump inlet pressure trace.

Although difficult to determine, the time frame in which line freezing occurs may help to indicate what type of mechanism is causing the freeze. STS-62 data indicates that the water intrusion failure mode should occur relatively shortly after post insertion.

During STS-62 the engineering community (JSC engineering, RI/Downey, Sundstrand and SR&QA) concluded that there were no constraints with APU operation due to the single freeze/thaw cycle. The APU was started at TAEM due to the slight possibility the fuel line freeze may have been caused by an external fuel leak. Although inconclusive on the exact cause of the failure, post landing examination of the affected area did not reveal any fuel leaks or line bulges.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-31**APU FREEZE/THAW (CONTINUED)**

The published freezing point of N_2H_4 is 35 Deg F. As N_2H_4 freezes the density increases resulting in a decreased volume. Superpacking results when a line full of liquid transforms into a line full of solid. As N_2H_4 expands during the thaw process line yield may result if the pressures can not be relieved. For this to occur the thaw would have to occur in a trapped volume or from the middle outward in a frozen line segment.

TTA tests performed in 1988 (JSC-22912) used a 3/8 inch diameter APU fuel line to study the effects of frozen N_2H_4 in a superpacked state. The results indicate that line yield occurred in both tests, with a maximum line pressure of 6300 psia. ©[011295-1736C]

A separate theoretical analysis was performed by McDonnell Douglas and JSC which indicate that a fuel line may rupture if it sustains as few as 3 freeze/thaw cycles (McDonnell Douglas Report TM-950002-02, December 23, 1994). The analysis addressed a straight 1/2 inch diameter fuel line that has yielded as a result of the freeze/thaw cycle. The fuel line radius has permanently expanded due to the yield. The line freezes again, and during thaw the resulting pressures further yield the line. This process continues until the ultimate strain of the line has been exceeded which results in rupture. The engineering community feels that this analysis, due to the level of detail, is more representative of the freeze/thaw event as compared with analysis performed during STS-62. RI/Downey performed an analysis on fuel line bends that coupled TTA test data with a theoretical analysis. The engineering community decided, after a review of the analysis, that the fuel line bends could withstand two freeze/thaw cycles. A qualitative review of the fuel line welds and T's found them to be less critical for freeze/thaw than the tube bend section. The McDonnell Douglas analysis also concluded that a straight section of yielded fuel line has infinite fatigue life due to fuel pump pressure cycles and vibration.

Establishing a vehicle attitude will warm the affected APU fuel lines which will accelerate the sublimation of the frozen fluid that may be causing the line freeze.

FLIGHT RULES

A10-33

APU DEFINITIONS

- A. FOR ENTRY/ABORTS AND PLANNING PURPOSES, AN APU IS DEFINED AS "REQUIRED" IF IT IS NEEDED TO PROVIDE THE FOLLOWING: @[072398-6685A]
1. TWO APU/HYD SYSTEMS FOR AEROSURFACE ACTUATOR OPERATION,
 2. LANDING GEAR DEPLOY REDUNDANCY,
 3. NWS (IF REQUIRED), OR
 4. BRAKING REDUNDANCY FOR MAINTAINING HALF BRAKES CAPABILITY.

Single APU/HYD system landings are uncertified. The critical need for gear deploy necessitates having deploy redundancy when possible. NWS requirements are defined in Rule {A10-141A}, NOSE WHEEL STEERING (NWS). Braking redundancy is satisfied if the next failure (following recovery of the "required" APU) results in at least single string, 50 percent braking.

This rule is referenced by {A10-22E}, F, H, APU START/RESTART LIMITS; {A10-24B}, D, E, APU OIL/GEARBOX TEMPERATURE/PRESSURE; {A10-25E}, APU HIGH SPEED SELECTION/SHIFT; {A10-31B}, APU FREEZE/THAW; and {A10-72E}, HYDRAULIC LEAKS.

- B. AN APU "START" IS DEFINED AS INITIATING APU OPERATION WHILE BRANCH PASSAGE TEMPERATURE IS WITHIN ACCEPTABLE LIMITS WITHOUT REQUIRING ACTIVE GG INJECTOR COOLING.
- C. AN APU "RESTART" IS DEFINED AS INITIATING APU OPERATION WHEN ACTIVE GG INJECTOR COOLING WAS REQUIRED TO ENSURE ACCEPTABLE BRANCH PASSAGE TEMPERATURE.
- D. AN APU "HOT RESTART" IS DEFINED AS INITIATING APU OPERATION WHILE BRANCH PASSAGE TEMPERATURE IS ABOVE ACCEPTABLE LIMITS.

These are the definitions for "START," "RESTART," and "HOT RESTART" used by other flight rules.

Reference Rule {A10-22A}, APU START/RESTART LIMITS. @[072398-6685A]

A10-34 THROUGH A10-50 RULES ARE RESERVED

FLIGHT RULES**HYDRAULIC SYSTEMS LOSS/FAILURE DEFINITIONS** [ED]**A10-51 HYDRAULIC LOSS DEFINITIONS**

A. A HYDRAULIC SYSTEM IS CONSIDERED LOST IF:

1. IT IS UNABLE TO PROVIDE HYDRAULIC PUMP PRESSURE OF 2760-3500 (2860-3400) PSIA AT DEMANDED FLOW WITH THE APU RUNNING AND THE MAIN PUMP PRESSURIZED.

Operation of the hydraulic actuators requires a minimum pressure of 2700 psi. A 60 psi safety margin is given. Maximum hydraulic pressure is 3500 psia (reference SODB, vol. I, 3.4.3.1-12 and 4.2.4.8.1.).

2. THE SYSTEM HAS A CONFIRMED NONISOLATABLE HYDRAULIC LEAK :
[022201-3989]
 - a. DURING ASCENT/ORBIT, THE SYSTEM WILL BE CONSIDERED LOST FOR PLANNING PURPOSES.

For planning purposes, a system with a nonisolatable leak should be considered lost since its capability to support entry from EI through wheelstop in NORM PRESS is suspect. [ED]

- b. DURING ENTRY/ABORTS, THE SYSTEM WILL BE CONSIDERED FAILED IF THE ASSOCIATED RESERVOIR QUANTITY IS LESS THAN 20 (25) PERCENT FOR SYSTEM 1, OR 5 (10) PERCENT FOR SYSTEMS 2 AND 3.

A reservoir quantity of 20 percent is required for system 1 due to the drop in quantity typically seen at landing gear deploy. This quantity drop is 15 to 20 percent for OV-102, and 12 to 16 percent for all other vehicles (the difference in quantity drop between the vehicles is due to the larger diameter pistons in the strut actuators on OV-102). Failure to maintain 20 percent for landing gear deploy may lead to pump cavitation and the loss of that system. Since systems 2 and 3 are prime for elevon operation, a reservoir quantity of 5 percent is required to protect control system operations during approach and landing (reference SODB, vol. I, 3.4.2.4.4.). [022201-3989]

3. HYDRAULIC FLUID TEMPERATURES CANNOT BE MAINTAINED ABOVE - 40 DEGREES F.

At -40 deg F, the hydraulic fluid viscosity will have increased to a point where it is no longer possible for the hydraulic main pump to push the fluid through the system. Other hydraulic system components may be damaged if their temperatures are less than -65 deg F (reference SODB, vol. I, table 3.4.2.4-1.).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-51

HYDRAULIC LOSS DEFINITIONS (CONTINUED)

4. A SWITCHING VALVE WILL NOT SELECT A HYDRAULIC SYSTEM TO AN ACTUATOR (DUE TO A FAILURE IN THE SWITCHING VALVE). (FAILURE OF PRIMARY/STANDBY 1 VALVE TO STANDBY 1 POSITION IS LOSS OF ONE SYSTEM. FAILURE OF STANDBY 2 VALVE TO STANDBY 2 POSITION IS LOSS OF TWO SYSTEMS.)

Switching valves are two-position valves which compare pressure between two of the redundant hydraulic systems assigned to a control element to ensure that the actuator receives flow from a hydraulic system with adequate pressure. Redundant hydraulic systems are designated as primary, standby 1, and standby 2 systems.

An actuator having three redundant hydraulic systems assigned to it will have two switching valves, a primary/standby 1 valve and a standby 1/standby 2 valve. A switching valve failure to one position will only allow pressure from the hydraulic systems assigned to that position to operate the actuator. The hydraulic system assigned to the other position is essentially lost insofar as the actuator is concerned.

A failure in the primary/standby 1 valve to either position results in the loss of one of the hydraulic systems to the actuator. A failure in the standby 1/standby 2 valve to the standby 1 position results in the loss of one system, the standby 2 system. Both the primary and standby 1 systems may still operate the actuator through the standby 1 port.

A failure of the standby 1/standby 2 valve to the standby 2 position will allow only the standby 2 system to operate the control element, resulting in the loss of the primary and standby 1 systems.

5. UNABLE TO MAINTAIN RESERVOIR PRESSURE GREATER THAN 15 (28) PSIA WITH THE APU NOT RUNNING. ©[ED]

Hydraulic pumps may cavitate with insufficient head pressure at startup. Main pumps require a minimum 15 psia positive pressure to start. Reference SODB, vol. I, 3.4.2.4-7.

Rules {A10-23}, APU ENTRY START TIME; {A10-73E}, HYDRAULIC SYSTEM PRESSURE/TEMPERATURE [CIL]; and {A10-74A}.1, HYDRAULIC CIRCULATION PUMP OPERATION [CIL], reference this rule. ©[051194-1619B] ©[070899-6879A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-51 HYDRAULIC LOSS DEFINITIONS (CONTINUED)

- B. A HYDRAULIC CIRCULATION PUMP WILL BE CONSIDERED LOST IF THE CIRCULATION PUMP BODY TEMPERATURE IS > 230 (222) DEG F, OR RESERVOIR TEMPERATURE > 230 (222) DEG F WHILE THE CIRCULATION PUMP IS RUNNING. ©[091098-6554B]

Operating a circulation pump above 230 deg F exceeds the circulation pump electronics temperature limit. (ref SODB, vol. I, table 3.4.2.4-1). Testing has shown that operating a circulation pump above this limits significantly reduces the pump electronics lifetime. The loss of a circulation pump alone is not considered loss of a hydraulic system. If the circulation pump is running to maintain accumulator pressure fore a leaking accumulator, it is possible that the accumulator may lock up (as it did on STS-50). Therefore, the loss of a circulation pump does not require loss of a hydraulic system actions. ©[051194-1619B]

Rule {A10-73E}, HYDRAULIC SYSTEM PRESSURE/TEMPERATURE [CIL], references this rule. ©[051194-1619B] ©[091098-6554B]

A10-52 THROUGH A10-70 RULES ARE RESERVED

FLIGHT RULES

HYDRAULIC SYSTEMS MANAGEMENT [ED]

A10-71 HYDRAULIC SYSTEMS CONFIGURATION [ED]

- A. THE LANDING GEAR EXTEND ISOLATION VALVE WILL REMAIN CLOSED EXCEPT WHEN OPENED DURING ENTRY/ABORTS.

Landing gear extend isolation valve remains closed to safeguard the hydraulic system from attempting to deploy the landing gear at any time other than landing. The landing gear cannot be retracted during flight once it has been deployed. Landing gear extend isolation valve is opened when the vehicle reaches Vrel of 800 fps to set up gear deployment.

- B. THE BRAKE ISOLATION VALVES WILL REMAIN CLOSED UNTIL OPENED DURING ENTRY/ABORTS UNLESS REQUIRED FOR ON ORBIT THERMAL CONDITIONING.

Brake isolation valves 1, 2, and 3 remain closed when the landing gear systems are not in use to protect the hydraulic systems in the event of a leak downstream of one of the isolation valves. All brake isolation valves open automatically at main gear touchdown.

- C. DURING ENTRY/ABORTS, IF AUTOMATIC CAPABILITY TO OPEN A BRAKE ISOLATION VALVE AT WOW IS LOST, THE VALVE WILL BE OPENED MANUALLY AFTER M=8 TO PROVIDE NWS (IF REQUIRED) OR FULL BRAKING. BRAKE ISOLATION VALVE 2 WILL BE OPENED BETWEEN M=8 AND LANDING GEAR DEPLOY IF REQUIRED TO PROVIDE REDUNDANT NLG DEPLOY.

To protect against uncommanded brake pressure, brake isolation valves will only be opened manually for the cases listed. It is desirable to open the valves during wings-level flight periods to reduce the risk of vertigo in the PLT. Manual valve opening will be delayed until after M=8 to reduce the opportunity for silting of the brake system (can lead to uncommanded brake pressure). Brake silting is a function of the time the isolation valve is open with the hydraulic system in NORM PRESS. Reference Ascent/Entry Flight Techniques Panel #45 minutes, June 23, 1988.

The risk of uncommanded brake pressure is acceptable to gain redundant nose landing gear deploy capability.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-71

HYDRAULIC SYSTEMS CONFIGURATION (CONTINUED)

⑥[ED]

Opening brake isolation valves after WOW for braking and nosewheel steering retains protection against uncommanded brake pressure, which is no longer catastrophic after wheel spinup. However, manual valve opening prior to landing is acceptable, if automatic capability is lost, due to the high crew workload after touchdown and the risk of inducing vertigo. Allowing the isolation valves to open automatically is considered acceptable due to the inherent reliability of the redundant WOW cue. Brake energy and rollout margin calculations do not protect for the loss of half brakes (reference Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS). Half brakes are adequate for any directional control requirements between MGTD and NGTD. For uncommanded brake pressure actions, reference Rule {A10-145}, UNCOMMANDED BRAKE PRESSURE [CIL]. For nosewheel steering requirements, reference Rule {A10-141A}, NOSE WHEEL STEERING (NWS).

- D. THE MPS/TVC ISOLATION VALVES WILL BE CLOSED ON ORBIT AND WILL REMAIN CLOSED EXCEPT FOR SSME HYDRAULIC REPRESSURIZATION AND SSME REPOSITIONING.

The TVC isolation valves are pressure-actuated valves requiring a minimum of 100 psid positive pressure to close. This pressure may be supplied by the APU or the hydraulic circulation pump.

Closing the MPS/TVC isolation valve during powered flight will cause the hydraulically actuated main engine valves to lock up, so the MPS/TVC isolation valve is left open past MECO.

The MPS/TVC isolation valves are normally closed after SSME stowage on orbit is complete.

Two isolation valves are normally opened for 10 seconds each prior to EI to repressurize the hydraulic fluid in the TVC actuators (SSME HYD REPRESS). This is done to eliminate any voids which may be formed in the actuators due to hydraulic fluid contraction as a result of orbit cooling. Eliminating the voids ensures that the actuators will hold the engine bells in place when subjected to aerodynamic loads during entry.

The isolation valves will be cycled in order to reposition the main engines to preclude contact with the drag chute during deploy and post-rollout for rain drain.

- E. THE HYDRAULIC MAIN PUMP WILL BE RUN IN "NORM PRESS" AFTER APU START ON A HYDRAULIC SYSTEM WITH AN ACCUMULATOR LEAK.

Accumulator pressure is used to charge the hydraulic reservoir and maintain the required inlet pressure for the main pump to operate without cavitation. The main pump must provide its own inlet pressure through a bootstrap system when the accumulator has lost its charge. Operating the main pump at low pressure (800 psi) may not provide sufficient head pressure at the pump inlet (reference RIC IL 288-503-81-055, November 10, 1981). The main pump is nominally run in low pressure after APU start on an APU started prior to the deorbit burn.

FLIGHT RULES

A10-72

HYDRAULIC LEAKS

FOR A HYDRAULIC FLUID LEAK, THE FOLLOWING ACTIONS WILL BE TAKEN:

- A. DURING ASCENT, NO ACTION WILL BE TAKEN UNTIL POST-MECO. IF THE APU/HYDRAULIC SYSTEM IS STILL OPERATING POST-MECO, THE APPROPRIATE MPS/TVC ISOLATION VALVE WILL BE CLOSED. IF THE LEAK IS NOT SUBSEQUENTLY ISOLATED, THE SYSTEM(S) WILL BE TAKEN TO "LOW PRESS" AND/OR SHUT DOWN AS REQUIRED IN ORDER TO EVALUATE AND MAINTAIN REMAINING CAPABILITY. ©[072398-6686B]

The MPS/TVC isolation valve is closed in an attempt to isolate the leak if the leak is downstream of the isolation valve. Closing the MPS/TVC isolation valve before MECO would cause the main engine hydraulically actuated valves to lock up, resulting in a loss of throttle control and TVC redundancy.

If the leak is not isolated by closing the MPS/TVC valve, the leaking hydraulic system should be taken to low pressure to reduce the stress on the system while allowing continued evaluation of the leak. Efforts within system limitations will be made to verify that the location of leakage does not exist downstream of an actuator switching valve where it could potentially cause imminent loss of all three hydraulic systems. Additionally, the leak could be due to intersystem leakage. It may become necessary to depressurize additional hydraulic systems to try to pinpoint the source of the leak. If the leak is determined to be downstream of an actuator switching valve, a mission abort will be required.

After all pertinent troubleshooting has been completed, the APU should be shut down as soon as practical to further reduce the pressure on the system thereby reducing the leak.

Rule {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL], references this rule. ©[072398-6686B]

- B. ON ORBIT, IF A LEAK IS DETECTED AND THE ASSOCIATED HYDRAULIC SYSTEM BRAKE ISOLATION VALVE IS OPEN, THE VALVE WILL BE CLOSED ASAP.

Closing the brake isolation valve may isolate the leak. If the leak is isolated, then the valve will remain closed to protect the system and to limit the amount of hydraulic fluid leaked into the wheel well. This reduces the chance of a fire at wheelstop due to hydraulic fluid on hot brakes. ©[ED]

- C. DURING ENTRY/ABORTS, IF A LEAK IS DETECTED PRIOR TO TOUCHDOWN AND THE ASSOCIATED SYSTEM BRAKE ISOLATION VALVE IS OPEN AND THE LEAK WILL NOT SUPPORT OPERATIONS THROUGH WHEELSTOP, THE VALVE WILL BE CLOSED ASAP. THE VALVE MAY BE OPENED AT TOUCHDOWN TO PROVIDE BRAKING AND WILL BE CLOSED ASAP POST-WHEELSTOP. ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-72

HYDRAULIC LEAKS (CONTINUED)

The brake isolation valve will be allowed to open automatically at main gear touchdown to provide braking capability but must be closed ASAP post-wheelstop to reduce the amount of hydraulic fluid leaked into the fuselage or wheel well. This will reduce the chance of a tire fire due to hydraulic fluid on hot brakes if the leak is in the wheel well. ©[ED]

- D. DURING ENTRY/ABORTS, IF A LEAK IS DETECTED AND THE LANDING GEAR EXTEND ISOLATION VALVE IS OPEN AND THE LEAK WILL NOT SUPPORT OPERATIONS THROUGH WHEELSTOP, THE VALVE WILL BE CLOSED ASAP. THE VALVE WILL BE REOPENED ONLY TO GAIN NWS OR REDUNDANT LANDING GEAR DEPLOY. THE VALVE WILL BE CLOSED ASAP POST-WHEELSTOP. ©[ED]

Closing the landing gear extend isolation valve may isolate the leak, and hydraulics for NWS and two methods of gear deploy remain. If the leak is isolated, the valve will remain closed to preserve the system unless NWS or a redundant landing gear deploy method is required. In these cases, the valve will be opened near the ground and closed post-wheelstop to minimize the amount of hydraulic fluid leaked. This reduces the chance of a fire due to hydraulic fluid on hot brakes if the leak is in the wheel well. ©[ED]

- E. DURING ENTRY/ABORTS, A SYSTEM WITH A NONISOLATABLE HYDRAULIC LEAK WILL HAVE ITS MAIN PUMP TAKEN TO "LOW PRESS". IF THE LEAK RATE IS SUCH THAT, WITH "NORM PRESS" SELECTED AT HAC INTERCEPT, THE SYSTEM WILL: ©[072398-6686B]

Taking the main hydraulic pump to "low press" will likely slow the leak by reducing pressure in the system. Even if the leak rate as detected in "norm press" will support to wheelstop, there is a possibility that the leak will become larger, so the system should be depressurized to improve its chances of supporting the later phase of entry. To protect for a subsequent failure of one of the good systems, the leaking system should be allowed to operate in "low press" to be ready to provide two APU/Hydraulic systems during entry should another APU/Hydraulic system fail.

1. SUPPORT TO WHEELSTOP, THE SYSTEM, IF REQUIRED, WILL BE TAKEN BACK TO "NORM PRESS" AS SOON AS THE CAPABILITY TO SUPPORT TO WHEELSTOP IS ACHIEVED (NO EARLIER THAN TAEM).
2. NOT SUPPORT TO WHEELSTOP, THE APU WILL BE SHUTDOWN. THE APU WILL BE RESTARTED (TIME PERMITTING), IF REQUIRED, WHEN THE LEAKING SYSTEM WILL SUPPORT TO WHEELSTOP.

If the leaking hydraulic system will not support entry at its present leak rate, then the APU should be shut down to minimize fluid leakage. It will be restarted later to support the final phase of entry if there is enough time to perform a cooldown and restart. ©[072398-6686B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-72 HYDRAULIC LEAKS (CONTINUED)**

During STS-76, when a known hydraulic leak existed, the APU was started at TAEM with the hydraulic system kept in "low press" for the remainder of the entry. Remaining in "low press" affords support in a standby mode while minimizing fluid leakage. Additionally, remaining in "low press" allows the other two good hydraulic systems to be in control of all the aerosurface actuators. In the event that the leaking system fails at a critical time while close to the ground, the aerosurface switching valves will already be set up to use the good system(s) and will not enter into a "chattering" mode whereby control could be jeopardized. ©[072398-6686B]

Reference Rule {A10-33}, APU DEFINITIONS. ©[072398-6686B]

A10-73 HYDRAULIC SYSTEMS PRESSURE/TEMPERATURE [CIL] ©[ED]

- A. A HYDRAULIC SYSTEM THAT CANNOT MAINTAIN > 200 (300) PSIA WILL HAVE ITS APU SHUT DOWN. DURING ASCENT, THE APU WILL BE SHUT DOWN POST-MECO.

Running the main pump at less than 200 psi does not support actuator performance and may result in cavitation and/or overheating of the main pump due to insufficient hydraulic fluid flow.

- B. A HYDRAULIC SYSTEM WILL BE TAKEN TO "LOW PRESS" OR ITS APU SHUT DOWN (DURING ASCENT, THE APU WILL BE SHUTDOWN POST-MECO), IF PUMP PRESSURE FLUCTUATIONS OCCUR SUCH THAT PUMP OUTLET PRESSURE REPEATEDLY FALLS BELOW 1500 (1600) PSI. [CIL]

Pressure fluctuations below 1500 psi are indicative of a malfunction in the main pump compensator system. This type of failure will not allow the pump to maintain system pressure on demand.

The pump supply pressure will decrease in response to the demand from an actuator supplied by the pump. The actuator will not respond until the failed system pressure falls below the switching valve pressure (1500 psi). At that pressure, the standby hydraulic system cycles the switching valve and takes over control of the actuator. With the standby system controlling the actuator and the demand gone, the failed hydraulic pump pressure will recover and eventually the switching valve will cycle back to the failed system. The switching valve will cycle in this manner each time the actuator is commanded.

The switching valve cycling will cause the actuator response to be slower due to the time required for the switching valve to transfer. Additionally, continued operation of the actuator could cause switching valve cycling to occur at a rapid rate, which could cause damage to the valve or create undesirable vibration frequencies due to pressure fluctuations.

Depressurizing the failed pump will drop its output pressure to 800 to 1000 psi, which will allow the standby hydraulic systems to cycle the switching valves and take control of the actuators. If the main pump cannot be depressurized, the APU will have to be shut down.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-73

HYDRAULIC SYSTEMS PRESSURE/TEMPERATURE [CIL]
(CONTINUED) @[ED]

C. DURING ASCENT, NO ACTION WILL BE TAKEN FOR A HIGH HYDRAULIC RESERVOIR TEMPERATURE UNTIL AFTER MECO. DURING ENTRY/ABORTS, THE FOLLOWING ACTIONS WILL BE TAKEN:

1. THE HYDRAULIC MAIN PUMP WILL BE TAKEN TO "LOW PRESS" IF THE RESERVOIR TEMPERATURE EXCEEDS 250 DEG (TBD) F.
2. THE APU WILL BE SHUT DOWN IF THE RESERVOIR TEMPERATURE EXCEED 275 DEG (268 DEG) F.

The hydraulic reservoir temperature increases based on the amount of APU run time and the load on the system. Flight data has shown that ascent conditions typically cause the hydraulic reservoir temperatures to increase to 150 deg to 175 deg F at APU shutdown (approximately 4 to 8 minutes after MECO). For this reason, the reservoir temperature is very unlikely to demand action prior to MECO, except in the case of a pump compensator failure. This failure results in high output pressure and flow through the relief valve and is considered unlikely. The hydraulic system design is, therefore, considered to be protection against exceeding the SSME interface temperature requirements (reference SODB, vol. I, 3.4.2.4-12.).

Hydraulic fluid temperatures in excess of 275 deg F can cause degradation of the hydraulic seals which could ultimately lead to leakage (ref. SODB, vol. I, 3.4.2.4.1.d). Depressurizing the main pump reduces the heat input into the hydraulic system and should allow the APU to continue operating. If depressurizing the main pump fails to maintain the reservoir temperature below 275 deg F, the APU will have to be shut down.

D. DURING DEORBIT, HYDRAULIC THERMAL CONDITIONING WILL BE PERFORMED IF THE ACTIVE HYDRAULIC SYSTEM FLUID LINE TEMPERATURES ARE PREDICTED TO BE < 35 DEG F, OR THE FIRST STANDBY SYSTEM FLUID LINE TEMPERATURES ARE PREDICTED TO BE < 0 DEG F AT EI.

The active hydraulic system fluid line temperatures are required to be > 35 deg F since this is the minimum hydraulic fluid temperature where optimum system performance can be expected. Standby system temperatures need to be above 0 deg F (per Rockwell/Downey thermal analysis) by EI so they may be quickly warmed up to the full performance temperature if required. Preentry hydraulic thermal conditioning involves cycling the aerosurfaces with all three APU's running before EI (reference SODB, vol. I, table 3.4.2.4.1.).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-73

HYDRAULIC SYSTEMS PRESSURE/TEMPERATURE [CIL]
(CONTINUED) ©[ED]

- E. ON ORBIT, ATTEMPTS WILL BE MADE TO MAINTAIN HYDRAULIC RESERVOIR TEMPERATURE < 162 (154) DEG F PRIOR TO APU START. THE FOLLOWING ARE ACCEPTABLE METHODS TO ATTEMPT TO MAINTAIN RESERVOIR TEMPERATURES < 162 (154) DEG F.
1. MINIMIZE CIRC PUMP RUN TIME WHILE MAINTAINING RSVR p > 15 (28) PSIA. ©[ED]
 2. POWER DOWN ORBITER/SPACELAB EQUIPMENT OR RECONFIGURE THE ORBITER ACTIVE THERMAL COOLING SYSTEM (ATCS) TO LOWER FREON TEMPERATURES AT THE FREON/HYDRAULIC HEAT EXCHANGER TO < 95 DEG F AS INDICATED BY THE FREON COOLANT RAD IN TEMP (V63T1209A AND V63T1409A).

During STS-50, hydraulic system 2 circulation pump was run for extended periods due to an accumulator GN2 leak. The hydraulic system fluid temperature continued to increase during this time. Post flight data revealed the increase was due to high Freon temperatures (Freon temperatures greater than 95 deg F at the Freon/hydraulic heat exchanger). As the hydraulic fluid temperature increased, the Freon/hydraulic heat exchanger bypass valve cycled causing the hydraulic fluid to bypass the heat exchanger. Heat from the hydraulic circ pump caused the hydraulic fluid temperature to continue to increase until the circulation pump was taken off. Flight data indicates that maintaining Freon temperatures below 95 deg F allows the hydraulic fluid to reject heat to the Freon loops and prevents the bypass valve from bypassing the Freon/hydraulic heat exchanger (the bypass valve cycles when the hydraulic fluid reaches 115 deg F). Once the heat exchanger is bypassed, the hydraulic fluid will continue to heat up as long as the circulation pump continues to run.

Minimizing circulation pump run time will minimize the heat added to the hydraulic system. The reservoir pressure however should not be allowed to drop below 15 (24) psia (reference Rule {A10-51A}.5, HYDRAULIC LOSS DEFINITION).

Powering down orbiter and Spacelab equipment, deploying the radiators, or activating the FES can lower the Freon/hydraulic heat exchanger temperature. Radiator deployment will not affect the Freon/hydraulic heat exchanger temperature.

Excessively high hydraulic systems temperatures can lead to a delayed APU start for entry and loss of the hydraulic circulation pump (reference Rules {A10-23B}, APU ENTRY START TIME, and {A10-51B}, HYDRAULIC LOSS DEFINITIONS). ©[051194-1619B]

FLIGHT RULES

A10-74

HYDRAULIC CIRCULATION PUMP OPERATION [CIL]

A. HYDRAULIC CIRCULATION PUMPS WILL BE USED AS REQUIRED: [CIL]

1. TO MAINTAIN BOOTSTRAP ACCUMULATOR PRESSURE. [CIL]

The hydraulic main pump requires a minimum positive inlet pressure of 15 psia to avoid cavitation during on-orbit zero-gravity starts. This pressure is provided by the bootstrap accumulator acting on the hydraulic reservoir. ©[070899-6879A]

- a. THE CIRCULATION PUMP WILL BE RUN BEFORE THE ACCUMULATOR PRESSURE HAS DECAYED TO THE PREFLIGHT CHARGE PRESSURE (1700 (1820) PSIA FOR A PISTON ACCUMULATOR AND 1715 (1835) PSIA FOR A BELLOWS ACCUMULATOR). [CIL]

The preflight charge pressure is the GN₂ pressure with the piston/bellows bottomed out at the fluid end of the cylinder (equivalent to the maximum GN₂ volume and hence the minimum GN₂ pressure possible, assuming no GN₂ has leaked). If fluid pressure falls below this value (and no GN₂ has leaked), the GN₂ pressure is pushing against the cylinder wall rather than against the hydraulic fluid, and bootstrap pressure is lost. Repressurization with the circulation pump is required to prevent the piston/bellows from bottoming out in this manner (reference SODB, vol. I, 4.2.4.4.c).

- b. FOR A PISTON ACCUMULATOR, IF A GN₂ LEAK CAUSES THE ACCUMULATOR PRESSURE TO BE < 2500 (2380) PSIA WITH THE CIRCULATION PUMP RUNNING, THE ACCUMULATOR WILL BE RECHARGED BEFORE THE PUMP OFF PRESSURE DECAYS TO HALF THE PREVIOUS PUMP RUNNING PRESSURE PLUS 200 PSI. IF THE ACCUMULATOR PRESSURE DECAYS TO 615 (735) PSIA, THE CIRCULATION PUMP WILL BE OPERATED CONTINUOUSLY UNTIL APU START.

A GN₂ leak is detectable on a piston accumulator since the pressure sensor is on the GN₂ side of the piston. Once enough GN₂ has leaked, circulation pump pressure will push the piston all the way to the GN₂ end of the accumulator, and no further pressure from the circulation pump can be exerted on the remaining GN₂ (within the hollow piston). Therefore, accumulator pressure of less than 2500 psia with the circulation pump running is evidence that the piston has reached the GN₂ end, and GN₂ is leaking. Note that with slow leaks (such as have been experienced on flights), for the first two or three accumulator represses, there is sufficient GN₂ to prevent the piston from reaching the GN₂ end, so this signature will not be seen until subsequent represses occur. Accumulator GN₂ leaks occurred on flights STS-7 and STS-50. ©[070899-6879A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-74

HYDRAULIC CIRCULATION PUMP OPERATION [CIL]
(CONTINUED)

Once a GN₂ leak is confirmed, accumulator pressure can be allowed to drop below the preflight charge value of 1700 psia. If an internal hydraulic leak (e.g., past the unloader or priority valve) occurs concurrently, then, with the circulation pump off, the piston will begin traveling over to the fluid end of the cylinder. Without taking the GN₂ leak into account, when the piston reaches the fluid end of the cylinder, the pressure will decay to half the value when the piston was at the GN₂ end (i.e., when the circulation pump was running). Therefore, the circulation pump must be turned on before the pressure indicates the piston has reached the fluid end. An additional 200 psi is added to account for transducer error and the effect of the ongoing GN₂ leak. ©[070899-6879A]

The hydraulic main pump requires a minimum positive pressure of 15 psia from the hydraulic reservoir to avoid cavitation during startup. The reservoir is pressurized by the accumulator at a 41:1 ratio (accumulator to reservoir). Therefore, accumulator pressure below 615 psia (due to a GN₂ leak) will result in reservoir pressure below the loss limit (reference SODB, vol. I, 4.2.4.3.h). Reference Rule {A10-51A}.5, HYDRAULIC LOSS DEFINITIONS.

The bellows accumulator pressure transducer is on the fluid side. Since no GN₂ remains when the bellows extends all the way to the GN₂ end of the cylinder (unlike with the piston design), the GN₂ leak signature described above does not occur (i.e., represses will continue to reach the expected >2500 psia until all the GN₂ has leaked). Therefore, it is not possible to distinguish between a fluid and a GN₂ leak prior to possibly losing the system. Due to this, and because the design of the bellows accumulator makes a GN₂ leak much less likely than with the piston design, a leak is always assumed to be on the fluid side. ©[070899-6879A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-74

HYDRAULIC CIRCULATION PUMP OPERATION [CIL] (CONTINUED)

2. FOR SUPPLEMENTARY FREON LOOP COOLING FOR FES FAILURES.

The circulation pump can be used to circulate hydraulic fluid through the hydraulic heat exchanger to remove heat from the orbiter Freon loops.

3. TO PROVIDE WARMING FOR HYDRAULIC FLUID, IF REQUIRED, SHOULD APU START BE DELAYED PAST EI MINUS 13 MINUTES.

The hydraulic fluid is warmed before entry to the minimum fluid temperature for system full performance, which is 35 deg F. This is normally done by the APU at nominal startup time. If APU startup is delayed, the circulation pump may be used to warm the hydraulic fluid until APU start. This is done to assure that the hydraulic fluid will be warmed to 35 deg F in time for hydraulic system performance (reference SODB, vol. I, table 3.4.2.4-1.).

4. TO MAINTAIN HYDRAULIC SYSTEM COMPONENT AND LINE TEMPERATURES WITHIN THE FOLLOWING LIMITS: @[121296-4173B]

<u>COMPONENTS AND LINES</u>	<u>TEMPERATURE LIMIT</u>
DOWNSTREAM OF BRAKE ISOLATION VALVES	ABOVE -20 DEG F PRIOR TO LANDING
ELEVON, BODYFLAP, AND RUDDER/SPEEDBRAKE	- 40 DEG F
DOWNSTREAM OF LANDING GEAR EXTEND ISOLATION VALVE	NOT APPLICABLE
ALL OTHERS	ABOVE -4 DEG F

Hydraulic fluid viscosity increases at low temperatures. Maintaining the fluid above -4 degrees F where practical will keep fluid viscosity at a level where the hydraulic pumps will have no problem pumping the fluid. Reference: SODB, vol. I, 3.4.2.4-8. @[121296-4173B]

Starting the circulation pump at low fluid temperatures will result in a longer period of time for the pump to reach operating speed and may adversely affect the lifetime of a pump. @[091098-6554B]

The components and line temperatures downstream of all the brake isolation valves should be above -20 degrees F prior to landing due to brake system limitations. The -20 degrees F is the lower limit for the brakes for degraded performance and exceeding that may result in a delayed release from a brake lockup condition. Reference: SODB, vol. I, 3.4.2.4-8. @[121296-4173B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-74

HYDRAULIC CIRCULATION PUMP OPERATION [CIL]
(CONTINUED)

The elevon bodyflap and rudder/speedbrake components typically get very cold on orbit due to the shading effects of the vertical tail. These components experience highly localized temperature excursions and recover immediately as soon as fluid is circulated. There are no adverse effects to the circulation pump start-up due to these particular cold temperatures so these components have lower allowable temperatures. ©[121296-4173B]

Hydraulic system 1 landing gear extend isolation valve is closed during all flight phases (except entry) to protect against deploying the landing gear inadvertently. Therefore, system 1 hydraulic components downstream of the landing gear extend isolation valve cannot be warmed by the circulation pump on orbit and have lower allowable temperatures. ©[ED]

5. TO CYCLE MPS/TVC ISOLATION VALVES OR BRAKE ISOLATION VALVES WHILE THE APU IS NOT RUNNING.

The valves are pressure-actuated, requiring a minimum of 100 psid positive pressure to operate. Therefore, the circulation pump is required to supply adequate hydraulic pressure to operate the valves when the APU's are not running.

6. TO MAINTAIN CIRCULATION PUMP BODY AND INLET TEMPERATURE ABOVE 20 (20) DEG F (EXCEPT IN POWER-CRITICAL SITUATIONS). ©[091098-6554B] ©[062801-4522]

Hydraulic circulation pump starts with the pump body temperature between 240 and -20 deg F were performed during testing. Longer than nominal starts (>1 second to attain stable operating speed) occurred at 0 deg F, and nominal starts occurred at 20 deg F. No further testing was performed between these two temperatures, so the 20 deg F limit was conservatively chosen as the lower limit. Longer starts produce high stress on the circulation pump inverter/motor transistors and possibly limit the lifetime of the pump (reference SODB, vol I, 3.4.2.4.8b and table 3.4.2.4-1, JSC-14860 Internal. Note: Hydraulic Circulation Pump Test, July 1979). There was a concern that in certain attitudes the minimum 20 deg F temperature at the inlet could be violated while the thermal control temperatures remained above the pump 'on' limits. Due to this concern and the inability to predict temperatures in that region, circ pump inlet temperature measurements were added (reference CCB, 9/9/97). ©[062801-4522]

The value used in this rule does not take into account transducer error. The circ pump body temperature transducer has proven reliable in accuracy, and the hydraulic community has signed up to not protecting for transducer error. ©[091098-6554B]

7. TO GENERATE WATER FOR ACTIVE THERMAL CONTROL SYSTEM USE.

The circulation pumps may be used to generate water through consumption of fuel cell cryogenic fuel. This was done successfully during STS 61-C.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-74

HYDRAULIC CIRCULATION PUMP OPERATION [CIL]
(CONTINUED)

- B. CIRCULATION PUMPS WILL NOT BE ALLOWED TO CYCLE DURING PAYLOAD DEPLOYMENT WHEN THE DEPLOYMENT MECHANISM INVOLVES PYROTECHNICS WHICH ARE POWERED BY THE ORBITER. FOR CONDITION REQUIRING CONTINUOUS CIRCULATION PUMP OPERATION, THE PUMPS WILL BE PLACED IN THE "ON" POSITION VICE "GPC" (REFERENCE THE FLIGHT RULES ANNEX FOR OPERATING CONSTRAINTS DURING PAYLOAD ACTIVITIES).

The startup transient of a circulation pump has a high inrush current, a bus voltage drop of 4 to 5 volts, and considerable EMI. This transient is only present for less than 1 second, but the concern is that the bus voltage spikes or EMI could trigger any armed pyrotechnics in the vicinity. There is no concern with a circulation pump that is already running at the start of these types of payload operations - only the startup transient causes problems. Since in GPC mode the pump could be commanded on at an inopportune time caused by the failure of control transducers or their respective MDM's or DSC's, the GPC position will not be allowed during these operations.

- C. A CIRCULATION PUMP WILL NOT BE STARTED ON A MAIN BUS THAT POWERS THE PRIMARY PAYLOAD BUS WHILE A PAYLOAD IS ACTIVATED AND SENSITIVE TO CIRCULATION PUMP ACTIVATION, EXCEPT TO PREVENT LOSS OF AN APU/HYDRAULIC SYSTEM IF REACTION TIME DID NOT PERMIT FOR POWER SOURCE RECONFIGURATION.

The voltage ripple caused by the startup of a hydraulic circulation pump may be greater than the payload ICD requirements. Critical orbiter systems take precedence over payload systems if those orbiter systems are in jeopardy.

DOCUMENTATION: ICD2-19001, NSTS 07700, Volume XIV, Attachment 1.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-74 **HYDRAULIC CIRCULATION PUMP OPERATION [CIL]**
(CONTINUED)

D. HYDRAULIC THERMAL CONDITIONING SOFTWARE WILL NOT BE REQUIRED FOR CONTINUING ANY FLIGHT PHASE.

For loss of software control of the hydraulic circulation pumps, the ground controllers will be responsible for tracking the relevant temperatures. The crew will then control the circulation pumps per ground instruction. Since these actions can be performed manually, there will be no constraints to continuing any flight phase.

E. A CIRCULATION PUMP ON A HYDRAULIC SYSTEM WITH A NON-ISOLATABLE LEAK WILL ONLY BE USED FOR HYDRAULIC ACCUMULATOR/RESERVOIR PRESSURE MANAGEMENT AND TO MAINTAIN SYSTEM COMPONENTS AND LINES ABOVE THEIR MINIMUM OPERATING TEMPERATURES. THE CIRCULATION PUMP WILL NOT BE USED FOR FCS CHECKOUT. ©[072398-6686B]

Circulation pump cycles on a hydraulic system with a non-isolatable leak may potentially degrade that system or possibly decrease the available run time for entry. Therefore, the use of this circ pump should be minimized. It is acceptable to run circ pumps for accumulator/reservoir pressure management to preclude the loss of that hydraulic system. Additionally, thermally conditioning this particular system in order to protect for optimal hydraulic performance is not warranted. However, a better trade-off can be made by keeping the system only minimally conditioned so as to only protect for minimum performance.

(Reference SODB, vol. I, table 3.4.2.4-1)

Rule {A10-29}, FCS CHECKOUT APU OPERATIONS references this rule. ©[072398-6686B]

FLIGHT RULES

WATER SPRAY BOILER (WSB) LOSS/FAILURE DEFINITIONS

A10-101 WSB LOSS DEFINITIONS

A WSB IS CONSIDERED LOST IF:

- A. AN N₂ OR H₂O LEAK IS VIOLATING CONSUMABLES REDLINES OR N₂ REGULATOR PRESSURE < 19.0 (21.6) PSIG WITH THE N₂ SUPPLY VALVE OPEN.

If consumables (water or GN₂) are below the redline, there is insufficient water supply for the WSB to provide adequate cooling for the APU or hydraulic fluid. The water spray bar will not operate properly at pressures < 19 psig; thus, there will be inadequate cooling (reference SODB, vol. I, 3.4.2.4.11b.).

- B. UNABLE TO MAINTAIN APU LUBRICATION OIL RETURN TEMPERATURE < 325 DEG (310 DEG) F OR HYDRAULIC RESERVOIR TEMPERATURE < 230 DEG(222 DEG) F WITH CONTROLLER A OR B.

These temperatures are the SODB (vol. I, 3.4.2.4.1d and table 3.4.4.3-1) limits on these fluids. At 325 deg F, lubrication oil breakdown occurs and its viscosity becomes unacceptable. At 275 deg F, the seals in the hydraulic system become degraded which could result in leaks. Since the WSB primary purpose is to maintain these temperatures within limits, its failure to do so using both controllers constitute its loss.

- C. UNABLE TO MAINTAIN H₂O TANK TEMPERATURES < 125 DEG (118 DEG) F OR > 32 DEG (39 DEG) F.

The WSB controllers are mounted on the water tank which serves as the heat sink for the controllers. Temperatures > 125 deg F may cause excessive controller temperatures which could cause controller failure (reference SODB, vol. I, table 3.4.2.4-1). Temperatures below 32 deg F will allow the water to freeze.

- D. BOTH STEAM VENT HEATERS ARE LOST.

A steam vent heater is required prior to deorbit APU start to ensure that ice does not plug or restrict the steam vent orifice. A restricted steam vent orifice causes excessive boiler core pressure and may result in a steam vent duct rupture. The rupture (large orifice) may lead to a boiler spray bar freeze up and loss of lube oil cooling. This would require the APU to be shut down prior to Mach 1. A TAEM start of the associated APU ensures that cooling is not required and the system is available from TAEM to wheelstop. ©[021199-6814]

Reference Rules {A10-23}, APU ENTRY START TIME, and {A10-24}, APU OIL/GEARBOX TEMPERATURE/ PRESSURE.

NOTE: LOSS OF WSB RESULTS IN EVENTUAL LOSS OF ITS ASSOCIATED APU/HYDRAULIC SYSTEM.

FLIGHT RULES

A10-102 THROUGH A10-120 RULES ARE RESERVED

FLIGHT RULES

WSB SYSTEMS MANAGEMENT ©[ED]

A10-121 WSB CONFIGURATION

THE WSB N₂ SUPPLY VALVE WILL BE CLOSED EXCEPT IN PREPARATION FOR AND DURING APU OPERATIONS.

The valve provides isolation of the GN₂ tank. If a leak develops downstream of the valve, keeping it closed will preserve the GN₂ until needed for WSB operation.

A10-122 LOSS OF WSB(S) ACTIONS

A. FOR THE LOSS OF A SINGLE WSB, FLIGHT WILL CONTINUE TO NOMINAL EOM. ©[041097-4611B]

The WSB's are essentially quiescent while on orbit. Because a subsequent failure of another APU/hydraulic/WSB system will likely only occur when these systems are operated for entry, there are no significant risks to continuing the flight until nominal EOM.

The loss of a WSB system does not indicate the immediate loss of an APU/hydraulic system, though the APU can only run for about 11 minutes before reaching an overtemperature condition. The APU associated with the lost WSB will be started late during entry to support landing (reference Rule {A10-23}, APU ENTRY START TIME). Assuming the other two APU/hydraulic/WSB systems are good, three APU/hydraulic systems will be available to support the latter part of entry and landing. ©[041097-4611B]

B. FOR THE LOSS OF TWO WSB'S, A NEXT PLS ENTRY WILL BE PERFORMED. IF THE FAILURE OCCURS ON LAUNCH DAY:

1. FOR NONDEPLOYABLE PAYLOAD FLIGHTS, A FIRST DAY PLS ENTRY WILL BE PERFORMED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-122 LOSS OF WSB(S) ACTIONS (CONTINUED)

2. FOR DEPLOYABLE PAYLOAD FLIGHTS, PAYLOAD DEPLOY AND/OR JETTISON WILL BE SCHEDULED TO ALLOW FOR DEORBIT ON DAY 2.

The loss of a WSB system does not indicate the immediate loss of an APU/hydraulic system, though the APU can only run about 11 minutes before reaching temperature limits. The APU associated with the lost WSB will be started late during entry to support landing (reference Rule {A10-23}, APU ENTRY START TIME). Assuming the other APU/hydraulic/WSB systems are good, three APU/hydraulic systems will be available to support the latter part of entry and landing.

For the loss of two WSB's, entry should be made at the next PLS opportunity after deployable payloads have been deployed. It is desirable to deploy the payloads since this will improve the vehicle capability to maneuver and land safely if an APU or hydraulic system fails during entry. Jettison of deployable payloads that, for some reason, cannot be deployed should be considered as a means of last resort to improve the vehicle entry and landing capability.

If the APU/hydraulic system not associated with the lost WSB's fails or if the remaining WSB fails, one of the APU/hydraulic systems with limited run time must be started. Starts and restarts of both limited lifetime APU/hydraulic systems must be managed to allow for at least one system running at all times. Accomplishing this may be an impossible task if the good APU/hydraulic system fails at the worst possible time, i.e., prior to the deorbit burn. A next PLS entry should be performed for the loss of two WSB's in order to minimize the amount of time the vehicle is exposed to the next failure that would result in the orbiter being down an APU/hydraulic system and two water spray boilers.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

FLIGHT RULES

LANDING/DECEL SYSTEMS MANAGEMENT

A10-141

NOSE WHEEL STEERING (NWS)

- A. NWS IS DEFINED AS "REQUIRED" IF IT IS NEEDED TO MAINTAIN DIRECTIONAL CONTROL DURING ROLLOUT: @[102402-5804C]
1. FOR RTLS/TAL/AOA (KSC) LANDINGS.
 2. AT ANY LANDING SITE IF THERE ARE KNOWN DIRECTIONAL CONTROL PROBLEMS (MLG OR NLG TIRE PREDICTED TO BE BELOW THE MINIMUM ACCEPTABLE PRESSURE AT TOUCHDOWN, UNCOMMANDED BRAKE PRESSURE, OR PEAK CROSSWINDS ABOVE THE SURFACE WIND LIMITS).

EFFORTS WILL BE TAKEN TO REGAIN NWS AS SPECIFIED IN THE REFERENCED FLIGHT RULES.

NWS provides the most effective means of preventing runway departure at any site where lateral margins are very limited, especially if a subsequent directional control problem develops. Ames VMS testing (July/August 1988, May/June 1989) demonstrated that differential braking and rudder inputs may not always provide adequate directional control capability when directional control problems are known to exist, even for runways with wide lateral margins. The forward position of the nose wheel provides a long moment arm (relative to the vehicle CG) for very effective vehicle steering. Therefore, NWS can overcome high frictional forces that may develop between a flat tire and a runway surface and also overcome the high frictional forces caused by uncommanded brake pressure. Moreover, excessive energy dissipated through differential braking can lead to subsequent loss of tire pressure (overtemperature of fuse plugs, post wheelstop). In all cases, NWS is much more effective for directional control than differential braking. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-141 NOSE WHEEL STEERING (NWS) (CONTINUED)

- B. NWS WILL BE TURNED OFF FOR ENTRY IF, DURING THE OPS 8 CHECKOUT, TWO OF THREE STEERING POSITION TRANSDUCERS DO NOT INDICATE -0.42 ± 0.31 VOLTS (GROUND) OR 0.0 ± 0.75 DEGREES (ONBOARD). @[102402-5804C]

The NWS system requires at least two good steering position transducers for reliable nose wheel position SOP operation. If none of the steering position transducers have been comm faulted (all three inputs available), the nose wheel position SOP will midvalue select from the three position transducer values, regardless of their failure status. If one transducer is failed or biased, one of the two good transducers will always yield the midvalue of the three, and the SOP will always select a good value. If two transducers are failed or biased, one of these two may yield the midvalue, and the SOP would then select an erroneous value. However, Ames VMS data (July/August 1988) confirmed that, for this scenario, the selected value will exceed the nose wheel position comparison limits when compared against the DAP-commanded nose wheel position and rate. The nose wheel position SOP will then generate a nose wheel position error and downmode to castor. @[102402-5804C]

- C. NWS1 WILL BE USED AS THE PRIMARY MEANS OF DIRECTIONAL CONTROL. IF NWS1 HAS FAILED: @[102402-5804C]
1. BEFORE NGTD: NWS2 WILL BE SELECTED AND USED AS THE MEANS OF DIRECTIONAL CONTROL.
 2. POST-NGTD: NWS2 CAN BE SELECTED AND USED AS THE MEANS OF DIRECTIONAL CONTROL.

Although both NWS1 and NWS2 modes of nosewheel steering provide identical functions and capabilities, NWS1 provides more downlisted system status parameters; NWS1 is, therefore, preferred over NWS2. @[102402-5804C]

If NWS is determined to be failed during the OPS 8 checkout or anytime prior to nose gear touchdown (ground speed enable flag set true), selecting NWS2 will provide the best alternative for rollout directional control. Ames VMS testing (July/August 1988) demonstrated that switching NWS modes during rollout was an effective procedure, particularly for MDM hardover failure cases.

However, SAIL testing (April 1991) demonstrated that for certain scenarios where the NWS1 channel downmoded to free castor (post-NGTD), the NWS system did not recover after selecting NWS2. In these cases, the NWS2 channel was selected coincident with a large rudder pedal command (DR 100737 and 106206). The NWS system was never perceived to have recovered as it downmoded to castor unnoticeably 240 milliseconds after selection. Although the NWS software may not recover if the alternate NWS channel is selected on rollout, NWS2 can still be safely selected post-NGTD and is likely to regain control if a large rudder pedal input is not present at selection. @[102402-5804C]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-141 NOSE WHEEL STEERING (NWS) (CONTINUED)**

D. NWS WILL BE TURNED OFF FOR LOSS OF ANY OF THE FOLLOWING, UNLESS NWS IS REQUIRED: @[102402-5804C]

1. TWO LATERAL AA'S
2. TWO LEFT OR TWO RIGHT RPTA CHANNELS
3. RIGHT DDU (TWO POWER SUPPLIES - A, B, OR C)
4. TWO STEERING POSITION TRANSDUCERS @[102402-5804C]

Once two lateral AA's or RPTA's have failed, there are potential vehicle control risks if NWS is selected. A hardover or high bias of one of these remaining components could result in loss of vehicle control. For runways with wide lateral margins, where differential braking and rudder inputs can provide adequate vehicle control, the use of NWS is not warranted at the risk of a third AA or RPTA failure, provided there are no known directional control problems. However, for abort landing sites (without wide lateral margins), the risk of runway departure due to a subsequent directional control problem outweighs the potential for a third AA or RPTA failure during the small window of rollout, and NWS should be selected.

Results of a NWS test matrix performed using the NASA Ames VMS in May/June 1991 indicate that vehicle control can be difficult to nonrecoverable after a third AA or RPTA hardover failure has occurred (Cooper/Harper ratings from 5 to 10). The matrix also demonstrated that, although landing with a known directional control problem (failed tire) without NWS is unsatisfactory (Cooper/Harper ratings between 5 and 8), this condition is sometimes controllable. Again, the risk of runway departure due to a known directional control problem outweighs the potential for a third AA or RPTA failure during rollout, and NWS should be selected. @[102402-5804C]

FLIGHT RULES

A10-142

TIRE PRESSURE [CIL]

A. THERMAL EFFECTS:

THE ORBITER ATTITUDE WILL BE MANAGED TO THERMALLY CONDITION THE TIRES TO MAINTAIN ACCEPTABLE PRESSURES AND TEMPERATURES FOR LANDING. THE FOLLOWING CONSTRAINTS APPLY: @[041097-4009E]

1. FOR NEOM LANDING AND EXTENSION DAYS, MAIN LANDING GEAR TIRE PRESSURE WILL BE MAINTAINED ABOVE THE MINIMUM PRESSURE DERIVED FROM THE NEOM/EXTENSION DAY PLOTS (+2 PSI UNCERTAINTY).
2. DURING THE FLIGHT, WHEN PAYLOAD ACTIVITIES ALLOW, MAIN LANDING GEAR TIRE PRESSURE WILL BE MAINTAINED ABOVE THE MINIMUM TIRE PRESSURE DERIVED FROM THE NEOM/EXTENSION DAY PLOTS (+2 PSI UNCERTAINTY) (OR AS HIGH AS PRACTICAL IF THE LIMIT CANNOT BE MET).
3. AT ALL TIMES DURING THE FLIGHT, MAIN LANDING GEAR TIRE PRESSURE WILL BE MAINTAINED ABOVE THE MINIMUM PRESSURE DERIVED FROM THE ANYTIME DEORBIT CONCRETE (+2 PSI UNCERTAINTY) PLOTS. EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX.
4. FOR A DEORBIT PRIOR TO NEOM, ALL REASONABLE EFFORTS WILL BE MADE TO SATISFY THE EOM REQUIREMENT. IN THE EVENT THE NEOM MINIMUM TIRE PRESSURE CANNOT BE MET (I.E., EMERGENCY DEORBIT), THEN DRAG CHUTE DEPLOY MAY BE USED TO REDUCE TIRE LOADS. @[050495-1771B]
5. TIRE TEMPERATURE WILL BE MAINTAINED ABOVE THE MINIMUM OPERATIONAL TEMPERATURE OF -45 (-43) DEG F. @[111298-6764A]

Depending on the orbiter attitude, main gear tire temperatures are typically between 0 to 30 deg F while on orbit (some flights have seen temperatures as low as -25 deg F). Since the tires are very good insulators and require significant time to warm up, there is no significant change in tire pressure from TIG to landing. The nose gear tires have never required thermal conditioning. @[111298-6764A]

Michelin Aircraft Tire Corporation completed a Delta Certification for the Space Shuttle Orbiter Main Landing Gear Tire on August 20, 1998 (reference CR # 26-194-0007-0005B), verifying that the tire is capable of operating at a temperature of -45 deg F (previous certification limit was -35 deg F). The tire demonstrated the ability to maintain air retention after being subjected to four landing load tests at -45 deg F. @[111298-6764A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-142****TIRE PRESSURE [CIL] (CONTINUED)**

Protecting the -45 deg F thermal limit is required in order to ensure emergency deorbit capability, since there would be no time to thermally condition the tires in an emergency deorbit timeline. (Reference SODB, vol. I, table 3.4.2.1-1.) ©[050495-1771B] ©[041097-4009E] ©[111298-6764A]

Past flight experience and thermal analysis show that, after going to a bottom Sun attitude, it is typically 4 to 5 hours before any increase is seen in the wheel wells due to thermal inertia. Once this occurs, the temperature typically goes up 1 deg per hour which results in a pressure increase of approximately 0.77 psi per hour. (Reference AEFTP #91, July 17, 1992.) ©[041097-4009E]

In order to avoid significant payload impact, the limits for anytime deorbit which do not include the undispersed limit (nominal load for given mass properties without RSS'd performance dispersions added) will be used. This is acceptable due to the unlikely event of an anytime deorbit, the availability of drag chute deploy, and the additional capability of the tire/strut shown in off-nominal testing. In the event of deorbit earlier than NEOM, all reasonable attempts will be made to meet the dispersed limits (i.e., MDF or next PLS with deorbit the following day should allow sufficient time to condition the tires). ©[050495-1771B]

Tire load capability and thereby minimum tire pressure allowed depend greatly on the maximum load conditions that the tires may encounter. The maximum load is a function of several parameters primarily associated with the initiation of the derotation maneuver post-main gear touchdown. Orbiter mass properties (total weight and X center of gravity) are significant factors in the maximum tire loading. The other factors which significantly affect tire loading are controlled by crew procedures which affect the derotation maneuver, especially in the first second or two of the initiation of derotation. These procedures are documented in the Flight Procedures Handbook; Approach, Landing, and Rollout, JSC-23266, Section 5.3.6.7. Among these crew procedure controlled parameters are the indicated airspeed at which derotation is initiated. This is a significant factor in the maximum load that the tires will experience. Crew technique to initiate derotation is to wait for an indicated 185 KEAS and perform a beep trim derotation. Errors in display plus some allowance for human factors lead to a maximum dispersion on the high side of 195 KEAS actual for a dispersed initiation of derotation. Lower airspeeds lead to significantly lower main gear loads but increase the nose gear load at slapdown. Lakebed runways have significantly higher loads on the nose gear. The same 10-KEAS error applies to lakebed runway derotation as well as to concrete runway derotation. The second parameter affecting main gear maximum loads that is controlled by crew procedure is the derotation rate that is established by the crew in the initial part of the derotation for a manual derotation. This should not be confused with the overall or average derotation rate for the entire maneuver since quite high rates can be achieved after theta = 0 degree. Nor should this rate be confused with the actual rate the vehicle achieves in the initial few seconds of derotation. Ames VMS sims (and flight data) have consistently shown that the average rate achieved in the initial derotation is on the order of 0.7 to 0.8 deg/sec. For simplicity, the analysis assumes the derotation rate of 1.0 deg/sec and includes dispersions to 1.5 deg/sec. In some few very dispersed cases, an early rate of nearly 2.0 deg/sec was accomplished but this took significantly longer than the 1.0-second time (next parameter) to achieve. The third important parameter affected by crew procedural control is the speed with which the derotation rate is achieved. A rapid or jerky rate can lead to tire "bounce" with greatly increased (though oscillating) loads. Crew procedures specifically call for the rate to be put in smoothly over a 1- to 2-second interval. Ames VMS studies (and flight data) show that the average time for rate buildup is 1 second with the most dispersed times being 0.5 second. When initial studies

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-142

TIRE PRESSURE [CIL] (CONTINUED)

were done with the maximum dispersions (185 KEAS derotation, 2.0 deg/sec, 0.5 second ramp input time), the loads exceed the tire capability at nominal (launch) pressures. Further examination of the Ames VMS data (and flight data) shows that the combination of high rate (over 1 deg/sec) and short input time (less than 1 second) never occurs. The 1 deg/sec with 0.5 second input time represents a worst case combination from the load standpoint. Therefore, this was chosen as the dispersed case (the other option, 2 deg/sec with 1 second ramp time yielded significantly lower loads). This is why the table in this rule shows the command initiation time to be 1.0 second with -0.5 second dispersion. Other combinations of dispersions may be postulated, but all real-world possible combinations result in lower main gear loads. ©[050495-1771B]

Interpolation for different orbiter weights on the tire plots is allowed between 185,000 pounds and 248,000 pounds. Extrapolation below 185,000 pounds on the tire plots is not allowed. If vehicle landing weight is less than 185,000 pounds, either mission-specific analysis is required or use the 185,000 pound line at the proper CG. If vehicle mass properties are otherwise off the chart (landing weight above 248,000 pounds, CG forward of 1076 or aft of 1111.0 - which is a contingency case), specific analysis is required. The forward CG limit of 1075.2 inches is for Mach 3.5 and not touchdown. Gear deploy causes the CG to shift AFT and therefore the carpet plots were only derived to 1076 inches. ©[050495-1771B] ©[091098-6713]

All plots use the following nominal and dispersed pitchover command parameters for main gear rollout assessments shown below and are taken from the SODB (reference SODB, vol. V, sec. 4.3 and Rule {A2-206}, DEROTATION SPEED.) Current derotation is at 185 KEAS using beep trim. The minimum loads and tire pressures for 185 KEAS beep trim and 175 KEAS manual derotation are protected by the 185 manual derotation plots. The 185 KEAS beep trim and 175 KEAS manual derotation plots are not shown here but are in SODB, vol V., sec. 4.3.3. ©[050495-1771B]

Parameter	Value	
	Nominal	Dispersion
<i>Derotation speed</i>		
? Concrete	185 KEAS	+10 KEAS
? Lakebed	185 KEAS	+10 KEAS
<i>Command initiation time</i>	1.0 sec	-0.5 sec
<i>Pitch command rate *</i>	-1.0 deg/sec	-0.5 deg/sec
<i>Crosswind</i>	15 knots	+5 knots

©[050495-1771B]

- This is RHC commanded rate being fed into the system.
Since derotation rate increases during derotation, actual pitch rate at slapdown would be of a high magnitude.

FLIGHT RULES**A10-142 TIRE PRESSURE [CIL] (CONTINUED)****B. LEAKING/FLAT TIRE:**

1. A TIRE LEAK IS DEFINED AS A DECREASE IN A TIRE'S PRESSURE MEASUREMENTS THAT IS INCONSISTENT WITH CHANGES IN PRESSURE OF THE OTHER TIRES AND CANNOT BE EXPLAINED BY INSTRUMENTATION INACCURACY/FAILURE OR VARIATIONS IN TEMPERATURE. @[041097-4009E]
2. LOSS OF TIRE PRESSURE INSTRUMENTATION WILL NOT BE CAUSE FOR EARLY MISSION TERMINATION.
3. FOR A LEAKING TIRE, IF THE AFFECTED TIRE PRESSURE CAN BE MAINTAINED > 260 (262) PSIG/275 (277) PSIA AT THE LANDING TIME FOR THE NEXT PLS PLUS 2 EXTENSION DAYS, PLANNED ON-ORBIT ACTIVITIES MAY CONTINUE. OTHERWISE, DEORBIT WILL BE SCHEDULED AT THE NEXT PLS OPPORTUNITY. PAYLOADS MAY BE DEPLOYED/JETTISONED PRIOR TO ENTRY IN ORDER TO DECREASE TIRE LOADS. [CIL]
4. FOR A LEAKING MAIN GEAR TIRE, A LANDING WITH A CROSSWIND FROM THE SIDE OF THE AFFECTED TIRE IS HIGHLY DESIRABLE.

Since tire pressure is greatly dependent upon temperature, a leak cannot be confirmed unless there is a sustained unexpected decay in both the actual and temperature-corrected pressure measurements on a tire. The loss of both pressure measurements will not be cause to declare a leaking/flat tire. The 2 psi transducer error is based on the ability to compare the TPDMS system to KSC mechanical gauge readings (0.1 percent accuracy) prelaunch and to eliminate the measurement scatter. The remaining 2 psi error includes the KSC mechanical gauge error and scatter seen prelaunch in the TPDMS pressure readings due to variations in temperature.

If a leaking condition is confirmed in a main or nose gear tire, the load-carrying capability of that tire is reduced. The main gear and nose gear values were derived from Convair 990 low pressure testing which simulated a 248K vehicle landing at 225 knots in a 15 knot crosswind for the mains (20 knot crosswind for the nose tires) and showed a low pressure tire could sustain a heavy load. Neither main or nose gear tire failed at the lowest pressures tested on Convair. The flat tire limit was derived from this lowest pressure tested (235 psig/250 psia) with 10 percent added for safety. The good main gear tire, 355 psia, received 62 percent of the strut load (162.5K peak vert. load) while the flat tire, 250 psia, received 48 percent (123.5K) of the load (Convair flight tests 121/122). The 161.5K peak load tested exceeds the tire

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-142

TIRE PRESSURE [CIL] (CONTINUED)

certification of 142.5 klbs. The CV-990 test demonstrated additional vertical load capability by reducing the crosswind to 15 knots. The good nose gear tire, 325 psia, received 61 percent of the strut load (55.0K peak vert. load) while the flat nose tire, 250 psia, received 49 percent (46.3 percent of the load. (Convair flight tests 145/150). (Ref. Dryden Test Report, August 1995: Landing System Research Aircraft Low Pressure Stress Test Flights.) Reference SODB, vol. I, 3.4.2.1. ©[041097-4009E]

The intent of a nominal drag chute deploy is to achieve disreef just prior to NGTD (reference Ascent/Entry Flight Techniques Panel #104). In the event of a leaking/flat tire, by minimizing MLG loads there is a possibility that the good tire on that strut will not fail. Ames (6/93) data indicates that main landing gear loads are minimized (decreased by up to 17 percent) by obtaining disreef just before NGTD. Flight data and testing at Ames (1/96) show that to ensure disreef prior to NGTD, the chute should be deployed 10 knots prior to derotation. Deploy will be performed regardless of the status of SSME repositioning (reference Rule {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES). ©[041097-4009E]

Rule {A10-143}, DRAG CHUTE DEPLOY TECHNIQUES references this rule. ©[111094-1690B]

Requiring the tire pressure to support 2 additional days maintains tire capability should a deorbit waveoff or bad weather occur to prevent landing on the desired PLS opportunity (protects for one additional PLS landing opportunity). Because load-carrying capability of the tire is reduced if tire pressure is degraded, deploy or jettison of the payload is desired, if accomplishable, so that orbiter landing weight and tire loading may be reduced, increasing the possibility of tire survival. The one additional PLS landing opportunity should not be sacrificed in order to avoid an early payload deploy or jettison, if applicable.

Landing with a crosswind from the side of the affected main gear tire is highly desirable because landing loads on the adjacent tire and strut will be less than those encountered on the leeward side of the vehicle, thereby decreasing the possibility of a second failed tire on the same strut. If such a tradeoff is necessary, a higher priority should be placed on choosing a landing with the crosswind from the side of the affected main gear tire over considerations due to head winds or tail winds. Minimizing the tailwind component is a secondary priority. Vehicle ground speed increases with increasing tail winds. A higher ground speed decreases vehicle controllability, especially in the presence of directional control problems such as a tire failure. Though a lower ground speed is desirable, a beneficial crosswind component is the highest priority in order to reduce the possibility of a second tire failure. ©[041097-4009E]

Rule {A2-207}, LANDING SITE SELECTION, references this rule.

FLIGHT RULES

A10-143

DRAG CHUTE DEPLOY TECHNIQUES

A. NOMINAL DEPLOY: DRAG CHUTE DEPLOY WILL BE PERFORMED POST MGTD AT 195 KNOTS. THE FOLLOWING EXCEPTIONS APPLY:

The intent of a nominal drag chute deploy is to achieve disreef just prior to NGTD. Flight data and testing at Ames (1/96 and 7/96) show that, to ensure disreef prior to NGTD, the chute should be deployed 10 knots prior to derotation. Results from DTO 521 (Drag Chute System) show that a chute deploy after the derotation rate is established results in a disreef immediately after NGTD. Ames (2/93) data shows that the vehicle sensitivity to lateral excursions is a function of how long the orbiter's nose is in the air after chute disreef, due to the limited ability of the rudder to compensate for large yawing moments. STS-47 chute disreef occurred approximately 2 seconds prior to NGTD, which resulted in a 40 ft lateral excursion off the runway centerline and subsequent redesign of the drag chute (5 ribbons were removed to improve chute stability). Ames (1/96, 7/96, and 1/97) data shows that deploying the chute 10 knots prior to the initiation of derotation is a safe technique for all vehicle mass moment cases with regard to nose gear slapdown limits and lateral excursions. The delta between chute deploy speed and the speed at the initiation of derotation should be no greater than 10 knots to prevent lateral control position and rate saturation from occurring, particularly with crosswinds > 10 knots with a lightweight vehicle. A nominal deploy alleviates the concern of objectionable vehicle performance which may occur if disreef occurs significantly prior to NGTD (ref. Ascent/Entry Flight Techniques Panel #97, #104). Flight experience) supports these conclusions. ©[041097-4890A]

1. EARLY DEPLOY: DRAG CHUTE DEPLOY MAY BE PERFORMED BETWEEN MGTD AND THE NOMINAL DEPLOY TIME ONLY FOR INSUFFICIENT ROLLOUT MARGIN. ©[041097-4890A]

Maximum deceleration benefits from the drag chute are obtained when the drag chute is deployed as early as possible. A chute deploy at MGTD provides approximately an additional 1000 ft of rollout margin over a nominal deploy (ref. Ames Pilot Report dated 4/93).

Adequate braking capability is determined based on brake energy predictions, rollout margin, and landing conditions of the day (reference Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS). An analysis performed by Flight Design & Dynamics (10/92) indicated that for adequate control and stopping distance, ? 37.5 percent brakes are required without NWS, and that ? 25 percent brakes are required with NWS (for all landing sites). This analysis assumed 15 kt crosswinds and no drag chute, and looked at brake torque only. The rollout margin predictions made from real-time trajectory simulations must satisfy flight Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS, specified minimums to make a runway GO. These simulations do not include the effects of the drag chute. After committing to a landing site, if a braking/deceleration system partially or totally fails or TD energy is unexpectedly high, an early drag chute deploy is allowed to provide additional rollout margin protection.

Ames data from 2/94 indicated that early deploys with vehicle mass moments > 1.80×10^6 ft-lb may violate NLG slapdown limits (6 percent of the VMS runs). Ames testing performed in 1993, 1994, and 1997 has shown that strut loads and handling qualities are acceptable with all vehicle mass moments. ©[041097-4890A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-143

DRAG CHUTE DEPLOY TECHNIQUES (CONTINUED)

2. LATE DEPLOY: DRAG CHUTE DEPLOY WILL BE PERFORMED AFTER NGTD FOR A LOW ENERGY LANDING. @[111094-1690B]

Ames data shows a late deploy is required because, after drag chute deployment during a low energy landing, deceleration happens so quickly that trailing edge "up" saturation occurs, and it is difficult to control derotation precisely. These factors cause high pitchdown rates and excessive NLG strut loads. Late deployment of the chute still allows some of the benefits of the chute to be retained.

- B. EMERGENCY DEPLOY: DRAG CHUTE DEPLOY WITH SSME REPOSITIONING INCOMPLETE WILL ONLY BE PERFORMED FOR A TAL/ELS, LEAKING/FLAT TIRE, INSUFFICIENT ROLLOUT MARGIN, LOSS OF BRAKING CAPABILITY, OR A SINGLE APU LANDING. @[111094-1690B]

If SSME repositioning is not complete, the drag chute will not be deployed unless one or more of the above conditions are present. If none of the above conditions are present, the call to the crew should be "Go for emergency chute deploy only", indicating to the crew to not deploy the drag chute unless they feel that the drag chute could provide some additional benefit. If SSME repositioning did not occur and one or more of the above conditions are present, the call to the crew will be the type of deploy to be performed (e.g. Go for nominal deploy, early deploy, or late deploy).

Deploying the drag chute without SSME repositioning risks damage to engine bells. Rockwell analysis (1/91) shows that the most likely contact point would be between the top edge of the center main engine bell and the risers, when the risers are at full line stretch (twang). For certain cases, the benefits of the drag chute outweigh the risk of potential damage to the SSME bells.

The drag chute minimizes MLG loads if disreef occurs prior to NGTD. The additional loads margin of a nominal chute deploy and the margin the chute provides for the uncertainties of a short, narrow runway outweigh the risk of engine bell damage in the event of a TAL or ELS landing. During an RTLS, the engine bells are moved to the RTLS stow position which is the same as the drag chute stow position. Due to the length and width of the KSC runway, RTLS is not a sufficient reason to deploy if failures prevent the center main engine from reaching the stow position.

In the event of a leaking/flat tire, by minimizing MLG loads there is a possibility that the good tire on that strut will not fail. Main landing gear loads are minimized (decreased by up to 17 percent) by obtaining disreef just before NGTD (reference Rule {A10-142}, TIRE PRESSURE [CIL], and Ascent/Entry Flight Techniques Panel #104, September 17, 1993).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-143 DRAG CHUTE DEPLOY TECHNIQUES (CONTINUED)**

Adequate rollout margin is determined based on brake energy predictions and landing conditions of the day (reference Rule {A4-108}, TIRE SPEED, BRAKING, AND ROLLOUT REQUIREMENTS AND ROLLOUT REQUIREMENTS). An analysis performed by Flight Design & Dynamics (10/92) indicated that for adequate control and stopping distance, ? 37.5 percent brakes are required without NWS, and that? 25 percent brakes are required with NWS (for all landing sites). This analysis assumed 15 kt crosswinds and no drag chute, and looked at brake torque only.

For a single APU landing, the drag chute provides rollout margin in the event the last APU fails during rollout. Ames '91 testing shows no noticeable changes in drag chute handling qualities due to a single APU landing.

*Rule {A2-262}, LANDING DTO's, and {A10-142}, TIRE PRESSURE [CIL] reference this rule.
©[111094-1690B]*

A10-144 DRAG CHUTE DEPLOY CONSTRAINTS

THE DRAG CHUTE WILL BE DEPLOYED FOR ALL LANDINGS SUBJECT TO THE FOLLOWING: ©[111094-1690B]

The drag chute adds margin to the landing and rollout capabilities of the shuttle by reducing main gear strut loads (possibly preventing a second blown tire at NGTD in the event of a leaking/flat tire), increasing directional stability (especially with directional control problems), and reducing rollout distance. Ames (6/93) data indicates that main gear load savings are maximized (loads decreased up to 17 percent) by obtaining disreef just before NGTD (ref. Ascent/Entry Flight Techniques Panel #104, September 17, 1993).

- A. THE DRAG CHUTE WILL NOT BE DEPLOYED IF CROSSWIND > 15 KNOTS PEAK.

The crosswind limit is for peak winds, in accordance with Rule {A2-6}, LANDING SITE WEATHER CRITERIA [HC]. Ames 1991 data shows that deploying the chute in high crosswinds will increase the vertical loads on the downwind tires and may also cause reduced pilot handling qualities. Handling qualities ratings (HQR's) degrade as the crosswinds approach 15 kts, but are still typically within acceptable limits (level 1-2 Cooper Harper ratings). A few level 3 HQR's occurred during 6/93 VMS runs with crosswinds of 15 and 20 kts (ref Ascent/Entry Flight Techniques Panel #104, September 17, 1993).

- B. THE DRAG CHUTE WILL NOT BE DEPLOYED PRIOR TO MGTD.

Before MGTD, the crew may not have time to jettison the chute nor will there be sufficient force to cause the pivot pin (105k - 125k lb shear pin) to disengage and release the chute (Ames 1990).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-144 DRAG CHUTE DEPLOY CONSTRAINTS (CONTINUED)

- C. THE DRAG CHUTE WILL NOT BE DEPLOYED AT SPEEDS > 230 KEAS OR < 80 KGS. ©[111094-1690B]

The pivot pin in the attach/jettison mechanism is designed to disengage and release the chute for forces between 105k lbs and 125k lbs, preventing structural damage. Above 230 KEAS, the loads are expected to exceed the pivot pin disengage limits. If these limits are exceeded, the pivot pin will most likely release the chute during disreef, the period of maximum loading. If this occurs, the elevons may not have enough time to react to the sudden change in moment of the orbiter, and derotation could increase to a rate which would result in exceeding NLG slapdown loads. ©[111094-1690B]

If the drag chute is deployed at speeds < 80 KGS, only the pilot chute will deploy (ref. Rockwell Downey 1992 Computer Simulations). Analytical data shows there should be no contact between the risers and the center main engine bell at speeds as low as 75 KGS. Flight data shows that 75 KGS may be conservative, as the chute is riding higher than anticipated.

- D. THE DRAG CHUTE WILL BE ARMED AND DEPLOYED SIMULTANEOUSLY.

When the chute is armed, an inadvertent deploy can result from additional failures in a deploy switch and/or electrical components within the drag chute avionics. An inadvertent deploy of the chute can result in excessive sink rates, which can be catastrophic.

- E. FOLLOWING DEPLOY, THE CHUTE WILL BE JETTISONED AT A SPEED OF 60 ± 20 KGS. THE CHUTE WILL NOT BE JETTISONED BELOW 40 KGS.

Ames (1/93) data has shown that jettison of the chute prior to NGTD can result in poor handling qualities, and can increase the nose gear slapdown loads above allowable structural limits.

If the chute is jettisoned below 20 KEAS, there is an increased probability that the drag chute risers will contact and possibly damage the engine bells (Rockwell engineering analysis). All crew procedures after nose gear touchdown that are cued to velocity must use ground speed because the HUD display changes from airspeed to ground speed at WONG. The 40 KGS minimum jettison cue is 20 kt faster than the 20 KEAS constraint to account for wind and atmospheric effects, instrumentation error, and system lag.

Rules {A2-6}, LANDING SITE WEATHER CRITERIA [HC], and {A2-262}, LANDING DTO's, reference this rule. ©[111094-1690B]

FLIGHT RULES

A10-145

UNCOMMANDED BRAKE PRESSURE [CIL]

- A. BRAKE ISOLATION VALVE (S) WILL BE CLOSED IF NECESSARY TO PREVENT LANDING WITH UNCOMMANDED BRAKE PRESSURE > 180 (180) PSI IN ONE OR MORE BRAKE/SKID CONTROL VALVES. THE ASSOCIATED BRAKE ISOLATION VALVE (S) WILL BE OPENED AFTER NOSE GEAR TOUCHDOWN TO PROVIDE FULL BRAKING.

Brake application is possible at pressures ? 180 psi. If brake pressure increases above 180 psi at main gear touchdown, the tire(s) will "skid" until tire failure. The tire adjacent to the failed tire may fail at nose gear touchdown, resulting in severe lateral-directional control problems during rollout. The high friction forces of a locked wheel may also result in nose gear loads in excess of structural limits.

Closing the affected isolation valve(s) isolates the brakes from the high pressure flow, and the pressure should decrease to nominal levels through the return pressure lines. This covers the most credible failure modes (brake servovalve problems due to contamination and silting or an antiskid card failure).

- B. IF CLOSING THE BRAKE ISOLATION VALVE(S) FAILS TO RELIEVE THE BRAKE PRESSURE, AN APU WILL BE SHUT DOWN TO PREVENT LANDING WITH BRAKE PRESSURE > 180 (180) PSI IN A SINGLE BRAKE/SKID CONTROL VALVE IF TWO OTHER GOOD APU/HYDRAULIC SYSTEMS REMAIN. TWO APU'S WILL BE SHUT DOWN IF NECESSARY TO RELIEVE UNCOMMANDED BRAKE PRESSURE IN MULTIPLE BRAKE/SKID CONTROL VALVES. THE ASSOCIATED BRAKE ISOLATION VALVE(S) WILL BE OPENED PRIOR TO APU SHUTDOWN.

If uncommanded brake pressure is not relieved when the isolation valve(s) is closed, the selector valve is stuck such that it is blocking both the primary and secondary return lines. The primary system brake isolation valve(s) will be reopened to allow a return path for the hydraulic fluid, and the primary APU (1 or 2) will be shut down. If high brake pressure is detected in only one brake/skid control module, a second APU will NOT be shut down because of the possibility that the failure is a transducer failure.

The 180-psi value used in this rule does not take into account the ± 100 psi transducer error. If transducer error was considered, the value at which to take action would be well within the nominal system operating range. The transducers have proven to be reliable in their accuracy.

With OI-21 software and the major modification hydraulic changes, the brake isolation valves will remain closed until MGTD. Therefore, it would take at least two failures to implement this rule.

Rule {A10-71}, HYDRAULIC SYSTEMS CONFIGURATION, references this rule.

FLIGHT RULES

A10-146

BRAKING

A. DEFINITIONS:

1. NOMINAL BRAKING PROFILE - THE NOMINAL BRAKING PROFILE CONSISTS OF APPLYING THE BRAKES WHEN THE VEHICLE HAS REACHED A SPEED OF 140 KNOTS GROUND SPEED (GS). ONCE BRAKES ARE APPLIED, A DECELERATION RATE OF 8 FPS² SHOULD BE MAINTAINED UNTIL A SPEED OF 40 KNOTS GS IS REACHED, WHEN THE DECELERATION RATE SHOULD BE REDUCED TO LESS THAN 6 FPS².

The 140 knots GS was chosen as the nominal brake-on speed because it is the maximum speed that can be used with this deceleration rate and not exceed the reuse energy limit of the brakes. This was determined by landing and rollout analysis programs discussed at Flight Techniques meetings and verified in the SMS and Ames VMS. Applications of brakes before 140 knots will lead to brake energies above the allowable limits before wheelstop occurs. Applying brakes below this speed will lengthen rollout distances from the predicted values. An additional consideration with regards to brake-on speed is that the hydroplaning speed for the orbiter tire pressure is approximately 140 knots, and skidding could occur above this speed if brakes are applied. The deceleration rate was chosen to provide the most efficient stop versus total brake energy and takes into consideration the following design characteristic of the brakes: working best under moderately high torque values. (Because of heat buildup and transfer throughout the brake, it is desirable to stop quickly, before thermal damage can occur - yet not so quickly that total energy exceeds limits.) Finally, brake torque increases at lower speeds, and it is therefore desirable to let off on the deceleration rate below 40 knots GS to prevent brake structural failure and subsequent lockup of the wheel. ©[ED]

2. MAXIMUM BRAKING PROFILE - THE MAXIMUM BRAKING PROFILE CONSISTS OF APPLYING MAXIMUM BRAKE PRESSURE TO ACHIEVE THE HIGHEST POSSIBLE DECELERATION RATE. MAXIMUM DECELERATION RATE SHOULD BE ACHIEVED IN NOT < 2 SECONDS FROM BRAKE APPLICATION. WHEN THE VEHICLE REACHES 40 KNOTS GS, IF SUFFICIENT RUNWAY REMAINS, THE DECELERATION RATE SHOULD BE DECREASED TO < 6 FPS² UNTIL WHEELSTOP. ©[ED]

Since the maximum braking profile is to be used only when there is a danger of the vehicle running off the end of the runway, no regard is given to using up the brake hardware by exceeding energy limits; therefore, the maximum amount of torque available should be used. A smooth rather than sudden application is preferred to prevent possible high-speed failure of the brake stack. Also, if sufficient runway remains after the high-speed part of the stop, it is desirable to release the brakes below 40 knots GS to prevent low-speed lockup of the wheel, since brake torque increases at lower speeds.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-146 BRAKING (CONTINUED)

B. BRAKING PROFILE SELECTION - THE FOLLOWING CRITERIA DETERMINE THE SELECTION OF THE BRAKING PROFILE TO BE USED:

1. NO BRAKING BEFORE MIDFIELD.

All shuttle runways are at least 11,000 feet long to ensure that midfield will always provide a minimum distance (5,500 feet) to the end of the runway. Landing analysis shows that stopping distance requirements can always be met in this distance; therefore, there is no requirement to apply the brakes before midfield, thus preserving the brakes and reducing the risk of failures.

2. AFTER MIDFIELD, BUT BEFORE THE 5,000-FOOT REMAINING POINT, THE NOMINAL BRAKING PROFILE WILL BE USED WHEN A SPEED OF 140 KNOTS GS IS REACHED. (BRAKES WILL NOT BE APPLIED IN THIS REGION UNTIL THE 140 KNOTS GS SPEED IS REACHED.)

Landing and deceleration analysis has shown that the nominal braking profile can stop the vehicle with sufficient margin when used before the 5,000-foot remaining point when brakes are applied at 140 knots GS. There is no requirement to apply the brakes before the 140 knots GS speed in this region thus preventing damage from high-energy stops.

3. WHEN THE VEHICLE PASSES THE 5,000-FOOT REMAINING POINT AND IF THE GROUND SPEED IS < 140 KNOTS, THE NOMINAL BRAKING PROFILE WILL BE OBSERVED. IF THE GROUND SPEED IS > 140 KNOTS, THE MAXIMUM BRAKING PROFILE WILL BE OBSERVED.

If the vehicle is still going faster than 140 knots GS when it passes the 5,000-foot remaining point, maximum braking will be required to stop before the end of the runway with adequate margins. Maximum braking effort is reserved for this extreme case, since it will lead to extensive brake damage, possibly before wheelstop, and creates a potential for a post-stop brake fire. If the vehicle has already slowed to less than 140 knots GS at the 5,000-foot remaining point, the vehicle can be stopped using the nominal braking profile. ©[ED]

A10-147 THROUGH A10-160 RULES ARE RESERVED

FLIGHT RULES

MECHANICAL SYSTEMS LOSS/FAILURE DEFINITIONS

A10-161 DRIVE MECHANISMS LOSS DEFINITIONS

DRIVE MECHANISMS ASSOCIATED WITH VENT DOORS, PLBD'S, RADIATORS, ET UMBILICAL DOORS, PAYLOAD RETENTION LATCHES, ACTIVE KEEL LATCHES, KU-BAND, AND ROEU/ROFU ARE CONSIDERED FAILED IF: @[062801-4355A]

- A. THE DRIVE TIME EXCEEDS SINGLE MOTOR DRIVE TIME (EXCEPT IN THOSE CASES WHERE VISUAL INDICATIONS ARE AVAILABLE).

The drive mechanisms mentioned above each possess two motors for redundancy purposes. A single motor can drive the mechanism; however, dual motor drive will actuate the mechanism in half the time (dual motor drive is nominally used for the mechanisms above). Therefore, if the drive time (for open/close, latch/unlatch, etc.) associated with the mechanism exceeds that for single-motor drive (the maximum it would take if either motor drove), then it is assumed that the mechanism has failed to reach the desired position. If visual cues are available to ascertain the mechanism's position and it is determined that the desired position has been reached, the mechanism is not considered failed.

- B. THE DRIVE MECHANISM CAN BE OBSERVED AND IS NOT MOVING IN RESPONSE TO THE COMMAND.

Assuming the proper switch and circuit breaker configuration and that the mechanism has not already attained the commanded position, movement should be seen; otherwise, the mechanism has failed.

- C. THE DRIVE MECHANISM CANNOT BE OBSERVED AND THERE IS NEITHER OPEN NOR CLOSED POSITION INDICATIONS AND DRIVE TIME EXCEEDS SINGLE-MOTOR DRIVE TIME.

If sufficient time has elapsed for the mechanism to have reached the desired state for only one motor driving and no indications of it reaching the commanded position are seen, then the mechanism is considered to have failed in transit. This applies only to that mechanism's position. This is based on the low probability of transducer failures for the end-of-travel indications that would imply that the mechanism had failed coupled with the assumption that it is safer to consider the mechanism failed.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-161 DRIVE MECHANISMS LOSS DEFINITIONS (CONTINUED)

APPROXIMATE SINGLE MOTOR DRIVE TIMES ARE:

PLBD CENTERLINE LATCHES (*OPEN ONLY).....	40 SECONDS
PLBD BULKHEAD LATCHES*	60 SECONDS
PLBD DRIVE*	126 SECONDS
RADIATOR LATCHES	60 SECONDS
RADIATOR STOW/DEPLOY DRIVE*	100 SECONDS
ET DOOR CENTERLINE LATCHES	12 SECONDS
ET DOOR DRIVE	48 SECONDS
ET DOOR UPLOCK LATCHES	12 SECONDS
VENT DOOR DRIVE	10 SECONDS
PAYLOAD RETENTION LATCHES	60 SECONDS
KU-BAND DRIVE*	46 SECONDS
ROEU/ROFU DRIVE*	60 SECONDS
ROEU/ROFU LATCH	40 SECONDS
ROEU/ROFU RELAX	24 SECONDS

*VISUAL CUE AVAILABLE @[062801-4355A]

The table above gives the design specification time required for the indicated drive mechanism to reach the full open/close/etc. position. These times can vary somewhat and are usually less than that shown. The dual motor drive time can be determined by dividing the single-motor drive time by two.

Visual cues are provided by bulkhead camera views and/or by looking out the payload bay windows. For the centerline latches only, the open position can be observed. When partially or fully closed, the latch hook is hidden behind the extended guide roller and the latch hook roller brackets. It is not possible to visually determine if the latches are closed far enough.

A10-162 THROUGH A10-180 RULES ARE RESERVED

FLIGHT RULES

GENERAL MECHANISMS SYSTEMS MANAGEMENT

A10-181 DRIVE MECHANISMS

- A. IF VISUAL CUES ARE NOT AVAILABLE, A DRIVE MECHANISM WILL BE CONSIDERED TO HAVE ATTAINED ITS COMMANDED POSITION, OPEN/CLOSED/STOWED/DEPLOYED/LATCHED/RELEASED, IF AT LEAST ONE INDICATION OF THAT STATE OCCURS WITHIN SINGLE-MOTOR OPERATING TIME.

Redundant indications are provided for the drive mechanisms for the open/closed/stowed/deployed/latched/released positions. If, during a drive sequence for any of the above mechanisms that does not have means of visual verification, any of the end-of-travel indications are present within the single-motor drive envelope, the mechanism will be considered to be in the desired position. This is based on the low probability of a transducer failing within the time that the indication was expected thereby giving a false verification of position.

- B. DRIVE MECHANISM COMMANDS WILL BE TERMINATED IF THE MECHANISM CAN BE OBSERVED AND IS NOT MOVING IN RESPONSE TO THE COMMAND.

To prevent damage to motors (burnout), drive mechanism commands will be terminated if no mechanism movement is observed for those mechanisms which can be visually verified.

- C. DRIVE MECHANISMS WHICH CANNOT BE OBSERVED WILL BE ALLOWED TO DRIVE TO THE SINGLE-MOTOR DRIVE TIME. COMMANDS WILL BE TERMINATED AFTER SINGLE-MOTOR TIME OR AFTER RECEIPT OF ONE TERMINAL POSITION INDICATION IN THE DIRECTION OF TRAVEL.

If one motor fails, the time required for the mechanism to change state will be twice the normal dual motor time. If the mechanism cannot be observed, it is safe to send drive commands for the single-motor drive time which will be adequate even if one motor has failed. Commands should be terminated after single-motor time even if no terminal indication is received because (the mechanism may have a more serious failure, possible jam) continuing the command could possibly damage the motor(s) or clutch(es).

- D. DRIVE MECHANISMS WHICH CAN BE OBSERVED WILL BE ALLOWED TO DRIVE IN EXCESS OF SINGLE-MOTOR DRIVE TIME WHEN DRIVING IN THE CLOSED/LATCHED DIRECTION WITH DETECTABLE MOTION.

Allowing a mechanism to drive beyond single-motor drive time, as long as the mechanism can be observed, can possibly place that mechanism in a fail-safe configuration (closed/latch direction is fail-safe and desirable).

A10-182 THROUGH A10-200 RULES ARE RESERVED

FLIGHT RULES

PAYLOAD DOOR (PLBD) SYSTEMS MANAGEMENT

A10-201

PLBD GENERAL

A. LAUNCH DAY LANDING PLBD OPERATIONS:

1. IF A LANDING IS REQUIRED AND SUPPLY/WASTE WATER WILL SUPPORT FES OPERATIONS UNTIL ENTRY, NO ATTEMPT WILL BE MADE TO OPEN ONE OR BOTH THE PLBD'S. ©[020196-1804A]

For launch day landings at the first available PLS, the supply and waste water tanks are loaded such that there is sufficient water for FES operations; therefore, there is no requirement to incur the risks associated with opening the PLBD's, thus eliminating an increase in the crew workload during this timeframe.

2. IF A LANDING IS REQUIRED AFTER PREDICTED EXHAUSTION OF SUPPLY AND WASTE WATER FOR THE FES, THE PLBD'S MAY BE OPENED.

For launch day landings after the first PLS opportunity, insufficient supply/waste water may have been loaded to support FES operations to entry. If the first PLS opportunity is no-go or likely to be no-go, then PLBD opening will be required. This situation may result in having to open the PLBD without close redundancy. ©[020196-1804A]

3. FOR PROBLEMS PROHIBITING NECESSARY HEAT REJECTION, THE PLBD'S MAY BE OPENED (TIME PERMITTING) WITHOUT REGARD TO CLOSE-MOTOR REDUNDANCY, FES WATER SUPPLY AVAILABILITY, OR MET OF LANDING. ©[020196-1804A]

For cases where there are cooling problems and opening the PLBD's is required to alleviate heating of critical equipment needed for entry, the PLBD's should be opened to provide the increased cooling capability. This may be necessary even though redundant PLBD closure does not exist and the timeline/workload would be increased.

- B. IF A LATCH GANG FAILS TO FULLY OPEN BUT CAN BE VERIFIED TO CLEAR THE ROLLERS BY VISUAL OBSERVATION/TV, IT WILL NOT BE CYCLED CLOSED.

In order to provide a maximum chance to at least complete an MDF, a failed in-transit latch gang that can be observed to be open will not be cycled closed. Some risk is associated with cycling the latch gang closed. It may fail close or nearly closed prohibiting PLBD opening operations. There is no real advantage in cycling the latch gang closed when the problem is first discovered over closing it in preparation for entry.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-201 **PLBD GENERAL (CONTINUED)**

- C. PLBD LATCHES WILL NOT BE CYCLED CLOSED WHILE THE PLBD'S ARE OPEN.

To preclude system failures (mechanical, structural, software) that may occur while the latch gang is being closed or is closed, the most conservative thing to do is not close the latch gang while the PLBD's are opened. There is no EVA capability to open a failed closed latch gang. A failure where the latch gang remains closed would prohibit complete PLBD closure and latching for entry. Cycling of a latch gang while the PLBD's are open will not be done for troubleshooting purposes.

- D. THE STARBOARD PLBD WILL NOT BE CLOSED WITH THE PORT PLBD OPEN.

Structural interference between the centerline latch hangers (port PLBD) and the bell- crank/hook bracket assembly (starboard PLBD) prevents complete PLBD closure and latching. Also, if the starboard PLBD drive mechanism fails (PLBD jams closed) while the port PLBD is open, the orbiter is in an unflyable system configuration.

- E. PLBD WILL NOT BE REOPENED ONCE IT HAS BEEN CLOSED DURING AN EVA.

If an EVA had to be performed in order to put the vehicle in a fail-critical configuration, reopening a failed latch and/or PLBD in any case is not a prudent thing to do. Entry should be made at the next PLS opportunity after the EVA is completed.

FLIGHT RULES

A10-202

PLBD VISUAL CUES

THE PLBD'S AND PLBD LATCHES ARE CONSIDERED OPEN OR CLOSED IF THEY CAN BE VISUALLY VERIFIED VIA THE FOLLOWING CRITERIA:

- A. PLBD'S OPEN - THE SIX PUSH RODS SHOULD HAVE 10 STRIPES IN THE FIELD OF VIEW ABOVE THE LONGERON SILL.

Opening and closing of the PLBD's is accomplished by actuators acting through pushrods and bell cranks and thus on the PLBD's themselves. The actuators are hidden beneath the payload bay liner. Each pushrod has 10 stripes; the first, eighth, and ninth (counting from the top) are gold with the other seven being silver. When the PLBD's are closed, the pushrods retract behind the liner and only the uppermost stripe may be visible on any of the six pushrods for that door. For the fully open position, the pushrods must extend far enough that all 10 stripes can be seen. The other stripes indicate intermediate door positions.

- B. CENTERLINE LATCHES CLEAR OF ROLLERS (DESIGN OVERLAP CASE) - THE TIP OF THE LATCH SHOULD BE POINTING ABOUT 30 DEGREES DOWN FROM THE Y-AXIS WITH THE TIP APPROXIMATELY 1 INCH FROM THE ROLLER.

When the centerline latches are in the open position, the tip of the latch is pointing about 30 degrees down from the horizontal (see SSSH drawing 14.1,2). If this can be visually confirmed, then the latches are clear of the rollers. Due to the position of the latches when partially to fully closed, it is not possible to determine if the latches are closed far enough. Binoculars are available, but no markings are provided.

FLIGHT RULES

A10-203

PLBD CRITICAL LATCHES

- A. FOR FAILURE OF ANY TWO PLBD LATCH GANGS TO FULLY ENGAGE (CENTERLINE OR BULKHEAD), AN EVA WILL BE PERFORMED TO INSTALL MANUAL LATCH TOOLS ON AT LEAST ONE OF THE FAILED LATCH GANGS.
- B. FOR FAILURE OF ANY SINGLE OR MULTIPLE PLBD LATCH GANGS TO FULLY ENGAGE (CENTERLINE OR BULKHEAD), ENTRY LOADS WILL BE MINIMIZED PER THE FOLLOWING:
1. ENTRY TEST MANEUVERS WILL NOT BE PERFORMED, AND ANY PROGRAMMED TEST INPUTS (PTI'S) WILL BE INHIBITED.
 2. CONSIDERATION WILL BE GIVEN TO TARGETING A RUNWAY/HAC APPROACH AT THE PLS OR SLS TO MINIMIZE TAILWIND AT HAC INITIATION AND TURBULENCE/SURFACE WINDS.

There is no analysis which indicates that entry with multiple latch gang failures is an acceptable condition. Although the latch tools have not been proven to provide the same structural integrity as a nominal latch gang, performing an EVA to install these latch tools provides a workaround to recover at least some load-carrying capability. Two latch tools are required to secure a single failed latch gang; however, only two centerline and two bulkhead latch tools are flown. When two of the same type gangs have failed, only one gang can be secured, as both available tools are required to secure one of these latch gangs.

A 1991 Rockwell assessment (which refined analyses performed in 1981 and 1987/1988) for a PLBD single latch-out (centerline or bulkhead) certified a nominal entry trajectory in AUTO flight control by exhibiting structural, thermal, and aerodynamic margins above the required 1.4 safety factor. This analysis shows that steps and gaps may occur as a result of the payload bay-to-ambient delta pressure and latch disengagement. Temperature exceedances may occur at these steps and gaps, but the resulting thermal damage poses no flight safety concerns. The extent of the postflight repairs can be limited by minimizing side slip and steady pitch-up maneuvers, according to the 1991 analysis. (Reference Structural Assessment of Shuttle Payload Bay Doors for Entry with a Latch Gang Out, SSD91D0276, May 1991, and A/E FTP #96, 12/18/92.)

Although entry test maneuvers and PTI's should not expose the vehicle to conditions outside of its certification limits, flying a nominal entry trajectory minimizes adverse mechanical, thermal, and aerodynamic loads. Vehicle accelerations, heating, and compartment-to-ambient pressure differentials can be limited by avoiding these maneuvers. Selecting a runway/HAC that minimizes HAC winds (most importantly, tailwind at HAC initiation) will help to minimize normal loads, and selecting a landing site with benign turbulence and surface wind conditions reduces the need for any abrupt directional control maneuvers.

Rules {A2-260}, ENTRY LOAD MINIMIZATION, and {A10-209}, PLBD RULE REFERENCE MATRIX, reference this rule.

FLIGHT RULES

A10-204 FAILED PLBD GPC SEQUENCE

IF THE GPC CONTROLLING THE PLBD SEQUENCE FAILS DURING PLBD OPERATIONS, THE PAYLOAD MDM'S WILL BE CYCLED OFF, THEN ON, TO TERMINATE EXISTING PLBD COMMANDS UNTIL THE SOFTWARE FUNCTION CAN BE REESTABLISHED.

Cycling the MDM's will clear the commands.

A10-205 PLBD CLEARANCE CONSTRAINTS

- A. THE KU-BAND ANTENNA CAN BE DEPLOYED ONLY IF THE STARBOARD PAYLOAD BAY DOOR IS FULLY OPEN.

The starboard PLBD must be fully open (reference Rule {A10-202A}.1, PLBD VISUAL CUES) in order to allow the antenna to rotate freely without any interference with orbiter hardware. If the starboard PLBD is open to 160 degrees, interference will occur between the PLBD bellcrank/pushrod assembly and the Ku-band antenna deployed electronics assembly (DEA). Each pushrod has 10 stripes; nine visible stripes indicate that the door is only 140 degrees open and 10 visible stripes confirm a full-open position of 175 degrees. Intermediate PLBD positions (e.g., 160 degrees) between 140 degrees and 175 degrees cannot be accurately determined. Therefore, the open microswitch indications and/or the tenth pushrod stripe must be visible prior to performing any Ku-band deploy/stow operation. (Reference SODB, vol. I, 3.4.5.2-25.)

- B. THE MANIPULATOR POSITIONING MECHANISMS (MPM) CAN BE DEPLOYED ONLY IF THE PORT PLBD PUSHRODS HAVE AT LEAST SIX STRIPES VISIBLE. IF THE RMS IS INSTALLED, NINE STRIPES MUST BE VISIBLE.

The port PLBD must be open greater than 69 degrees in order to allow the MPM's to be deployed without any interference with the PLBD structure. If the port PLBD is open less than 69 degrees, the bottom of the RMS shoulder pedestal will interfere or drive against the bottom of the PLBD. Each PLBD pushrod has 10 stripes; six stripes indicate that the door is at a minimum angle of 84 degrees. A PLBD position of 69 degrees is indicated on the fifth silver stripe. Intermediate positions prior to the sixth stripe cannot be accurately measured for adequate clearance margins. Therefore, in order to provide acceptable clearance capability prior to performing any MPM deploy operations, six PLBD pushrod stripes must be visible.

The port PLBD must be open greater than 130 degrees in order to allow MPM's to deploy a cradled RMS. If the port PLBD is open less than 130 degrees, interference will occur between the RMS wrist yaw joint and the EVA slidewire mount. Each PLBD pushrod has 10 stripes; nine visible stripes indicate that the door is at a minimum angle of 137 degrees. Eight pushrod stripes correspond to a maximum PLBD angle of 125 degrees. Intermediate PLBD positions (e.g., 130) cannot be accurately determined; therefore, the ninth pushrod stripe must be visible prior to performing any MPM deploy operations.

FLIGHT RULES**A10-206****PLBD CLOSE GO/NO-GO****A. THERMAL CONSTRAINTS:**

1. ON ORBIT, PLBD CLOSURES WILL NOT BE PERFORMED FOR THE FOLLOWING THERMAL CONDITIONS:
 - a. PORT DOOR - IF V34T1126A IS ? -100 DEG (-87 DEG) F. FOR FAILURE OF V34T1126A, V34T1128A IS AN ALTERNATE.
 - b. STARBOARD - IF V34T1130A IS ? -100 DEG (-87 DEG) F. FOR FAILURE OF V34T1130A, V34T1132A IS AN ALTERNATE.

The PORT RDY-TO-LATCH switch module failed on STS-3. The failure of this module to switch state after PLBD opening (during cold case testing) determined these low temperature operational limits (ref. paragraph B).

2. FOR NOMINAL END OF MISSION PLBD CLOSURE, THE BENDING EFFECT TEMPERATURE MUST BE LESS THAN 160 DEG F. THE BENDING EFFECT TEMPERATURE IS DEFINED AS THE DIFFERENCE BETWEEN AVERAGE LOWER BONDLINE AND AVERAGE SILL LONGERON TEMPERATURES ADDED TO THE DIFFERENCE BETWEEN 70 DEG F AND THE AVERAGE SILL LONGERON TEMPERATURES. (LOWER BONDLINE TEMPERATURES - V09T1016A, V34T1110A, V34T1112A; PORT LONGERON TEMPERATURES - V34T1114A, V34T1116A, V34T1118A; AND STBD LONGERON TEMPERATURES - V34T1120A, V34T1122A, V34T1124A USE THE AVERAGE OF THE COLDER SIDE LONGERON TEMPERATURES.)

Bending effect temperature (BET) = (lower bondline avg. T - sill longeron avg. T) + (70 deg F - sill longeron avg. T). This equation uses both the delta between top and bottom on the orbiter and a comparison between a standard ground temperature of 70 deg F and average sill longeron temperatures to predict door closure constraints caused by thermal defections. The worst case thermal conditions for PLBD closure were seen on STS-3. During the first attempt to close the doors, door closure was prevented by structural interference between the port PLBD and the aft bulkhead. This occurred because of the extremely cold overall temperatures and the high thermal delta between the top and bottom, resulting in a "banana effect" which expanded the bottom and shrunk the top to make the gap between the door and the aft bulkhead too small to allow proper door closure. After thermal conditioning, the doors closed properly with a delta between lower bondline and sill longerons of approximately 52 deg F and an average sill longeron temperature of -41 deg F. For this case: $BET = 52 \text{ deg F} + (70 \text{ deg F} - 41 \text{ deg F}) = 163 \text{ deg F}$. From this, 160 deg F was selected as the limit. This constraint is for all planned PLBD operations.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-206

PLBD CLOSE GO/NO-GO (CONTINUED)

3. THERMAL ATTITUDE WILL BE MANAGED TO MAINTAIN THE BET BELOW 200 DEG F TO FACILITATE CONTINGENCY PLBD CLOSURE. THERMAL CONDITIONING WILL BE PERFORMED FOR AS LONG AS PRACTICAL TO ATTEMPT TO GET WITHIN THE CONSTRAINTS DEFINED IN PARAGRAPH B. FLIGHT SPECIFIC EXCEPTIONS FOR HIGH PRIORITY FLIGHT OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT RULES ANNEX. FOR ANY MISSION NOMINALLY EXCEEDING THE CONTINGENCY LIMITS, THE EXCEPTION WILL BE TAKEN TO THE PRCB FOR INFORMATION.

After STS-3, the hardware was modified by shaving 0.39 inch off the aft lug to allow for additional door gap clearance between the doors and aft bulkhead. This additional clearance would have allowed the doors to close, even for the worst-case thermal conditions seen during the unsuccessful door closing attempt on STS-3. (BET = 74 deg F + (+7 deg minus -64 deg F) = 208 deg F. A limit of 200 deg F was selected to allow for uncertainties in the analysis. This constraint is for contingency deorbit/PLBD closure anytime during the mission.

Reference Rockwell Document, Effect of On-Orbit Temperature on Shuttle Payload Bay Door Closure, STS90D0172, March 1990, for temperature effect and bulkhead modification descriptions.

Rules {A2-106}, PBD OPERATIONS [CIL], and {A2-129}, ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS, reference this rule.

B. PLBD CENTERLINE LATCH EXTENDED GUIDE ROLLER TRAJECTORY:

THE GO/NO-GO CRITERIA FOR PLBD CLOSE IS PER RULE {A10-205}, PLBD CLEARANCE CONSTRAINTS. THE PORT PLBD WILL BE CLOSED AND LATCHED, AND THE STARBOARD PLBD WILL BE CLOSED TO THE POINT THAT THE CLOSEST EXTENDED GUIDE ROLLER (STARBOARD DOOR) IS AS NEAR AS FEASIBLE TO ITS STRIKER PLATE (PORT PLBD) WITHOUT IMPACTING IT. THE VISUAL PROJECTION OF THE EXTENDED GUIDE ROLLER TRAJECTORY MUST NOT EXCEED THE BOUNDARIES IDENTIFIED IN THE PLBD CENTERLINE LATCH EXTENDED GUIDE ROLLER TRAJECTORY DIAGRAM BELOW.

The crew will utilize the PLBD CENTERLINE LATCH EXTENDED GUIDE ROLLER TRAJECTORY (diagram) as GO/NO-GO criteria to latch the centerline latches on entry day. In addition, this diagram is used to satisfy the "PLBD FIT TEST" DTO requirement to continue the mission on launch day for the first flight of a new vehicle.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-206

PLBD CLOSE GO/NO-GO (CONTINUED)

PLBD CENTERLINE LATCH EXTENDED GUIDE ROLLER TRAJECTORY (DIAGRAM):

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-206

PLBD CLOSE GO/NO-GO (CONTINUED)

C. PORT AFT BULKHEAD LATCH GO/NO-GO CRITERIA:

PLBD'S CLOSED SUFFICIENT FOR BULKHEAD LATCHING - THE PORT PLBD SCALLOP MUST BE ON OR BELOW THE TOP OF TARGET STRIPE (AFT BULKHEAD) OR THE PORT AFT PLBD CLOSE INDICATION MUST BE PRESENT AS SHOWN IN THE PORT AFT BULKHEAD LATCH GO/NO-GO DIAGRAM ON THE FOLLOWING PAGE.

The PORT AFT BULKHEAD LATCH GO/NO-GO CRITERIA was developed to aid in bulkhead latching subsequent to the jamming of the port PLBD edge of the aft bulkhead seal bracket on STS-4. If the port PLBD close indications are present, then the PLBD is sufficiently closed to permit bulkhead latching. Without these indications, visual verification can be made by observing if the port PLBD scallop (the leading edge of the PLBD/latch mechanism at the extreme aft portion of the PLBD) is on or below the top of the black stripe (1 inch wide) painted on the aft bulkhead. If so, the PLBD is closed far enough for the latches to engage.

PLBD CLOSE GO/NO-GO (CONTINUED)

PORT AFT BULKHEAD LATCH GO/NO-GO (DIAGRAM)

PORT AFT LATCH
GO/NO-GO CRITERIA

- GO - IF SCALLOP IS ON OR BELOW TOP OF TARGET PLANE OR IF PORT AFT PLBD CLOSE INDICATION IS PRESENT.
- NO-GO - IF SCALLOP IS ABOVE TOP OF TARGET PLANE AND PORT AFT PLBD CLOSE INDICATION IS NOT PRESENT.

FLIGHT RULES

A10-207

PLBD OVERLAP

IF A PLBD OVERLAP CONDITION EXISTS AT EOM DOOR CLOSURE SUCH THAT THE PLBD'S CANNOT BE CLOSED, ENTRY WILL BE DELAYED 24 HOURS ALLOWING PLBD THERMAL CONDITIONING TO REGAIN NORMAL CLOSING CONDITIONS. IF ENTRY-CRITICAL SYSTEMS ARE NOT SINGLE-FAULT TOLERANT OR A 1-DAY WAVE-OFF CAPABILITY IS NOT AVAILABLE, THEN TOP SUN PLBD CONDITIONING WILL BE DONE FOR AS LONG AS PRACTICAL. IF ADVERSE OVERLAP CONDITIONS STILL EXIST AFTER TOP SUN, THE SIMULTANEOUS PLBD CLOSING PROCEDURE WILL BE USED.

Steps will be undertaken to thermal condition the PLBD's for entry when nominal preentry conditioning does not adequately allow for PLBD centerline latching. The simultaneous PLBD closing procedure is the last means by which the centerline can be latched and is used as a contingency means to latch the PLBD's.

Rule {A2-301}, CONTINGENCY ACTION SUMMARY, references this rule.

FLIGHT RULES

A10-208

CONTINGENCY PLBD CLOSURE

FOR PLBD JAM CASES, WHICH RESULT IN THE INABILITY TO NOMINALLY LATCH THE AFT BULKHEAD LATCHES, THE FOLLOWING CONTINGENCY PLBD CLOSE PROCEDURES WILL BE IMPLEMENTED IN LISTED ORDER UNTIL ONE METHOD IS SUCCESSFUL.

A. NOMINAL EOM PLBD CLOSE PROBLEMS:

1. CYCLE PLBD.
2. ONE ORBIT TOP SUN THERMAL CONDITIONING - REPEAT PLBD CYCLE.
3. DRIVE AFT LATCHES AND PLBD PART WAY.
4. WAVE OFF (THERMAL CONDITION IN TOP SUN - CHECK CLOSE BEFORE SLEEP).
5. PERFORM EVA.

B. EMERGENCY DEORBIT PLBD CLOSE PROBLEMS:

1. CYCLE PLBD.
2. TOP SUN THERMAL CONDITIONING (IF TIME PERMITS) - REPEAT PLBD CYCLE.
3. DRIVE AFT LATCHES AND PLBD PART WAY.
4. DRIVE AFT LATCHES AND PLBD TO STALL.
5. CLOSE BOTH PLBD'S AND FORWARD BULKHEAD LATCHES, THEN CLOSE CENTERLINE LATCHES IN FORWARD TO AFT ORDER, THEN CLOSE AFT BULKHEAD LATCHES.

PLBD contingency PLBD closure procedures were developed as a result of the PLBD closure problems experienced on STS-3 and STS-4 during thermal testing of the orbiter. Postmission investigations resulted in the conclusion that midfuselage structure thermal distortion caused by the extreme thermal attitudes had closed the gap between the PLBD and the X=1307 bulkhead. These attitudes were (1) at the end of tail Sun, top to space, orbital late roll attitude and (2) at the end of bottom solar inertial attitude. In response to these problems, PLBD and latch modifications were made to the orbiters. The solution basically allowed the PLBD lug to be moved forward to increase the gap. Flight verification of this fix has not been done; however, analysis has indicated that a positive gap will exist at more severe temperature gradients than was experienced on STS-3 and STS-4; i.e., PLBD closure should not be a problem after experiencing the same attitude profiles.

The procedures listed above start with the most benign steps and progress to the more severe action to be taken for each case.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-209

PLBD RULE REFERENCE MATRIX (CONTINUED)**A. LATCH GANG DOES NOT HAVE TWO MOTORS FOR CLOSE.**

The vehicle is in a fail-safe condition where the redundant motor remains to close the latch gang. Loss of the redundant motor will still allow safe entry. Rockwell's 1991 latch-out analysis has shown that an entry can be performed with a single bulkhead or centerline latch gang out. Adequate structural, thermal, and stability margins exist above the required 1.4 factor of safety for all tested flight conditions. (Ref. Structural Assessment of Shuttle Orbiter Payload Bay Door for Entry with a Latch Gang Out, SSD91D0276, May 1991; and SODB, vol. I, 3.4.2.3.)

B. ONE MOTOR IN EACH OF TWO SEPARATE LATCH GANGS FAILED DUE TO A MECHANICAL, ELECTRICAL, OR PL MDM FAILURE, AND NEXT FAILURE WILL RESULT IN MULTIPLE LATCH GANGS OUT, WHERE MOTOR FUNCTION IS: [022201-3996]**1. NOT RECOVERABLE BY IFM.**

Entry should be made at the next PLS opportunity in order to minimize exposure time to the next failure which could result in multiple latch gangs out. There is no analysis to indicate that entry with multiple latch gangs out is an acceptable condition or that the manual latch tools provide the same structural integrity as a latch gang. (Reference Rule {A10-203}, PLBD CRITICAL LATCHES, and Structural Assessment of Shuttle Orbiter Payload Bay Door for Entry with a Latch Gang Out, SSD91D0276, May 1991.) [121296-3194B]

Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule. [121296-3194B] [ED]

2. RECOVERABLE BY IFM.

PLBD IFM procedures exist that allow for closing a PLBD latch group(s) and/or the PLBD's if one or both payload MDM's (or associated cards) is lost or if control busses AB1, AB2, BC1, BC2, CA1, or CA2 are failed. These IFM procedures are considered a level of redundancy for PLBD and latch gang closure. Therefore, after the loss of one PL MDM or one of the aforementioned control busses, single-fault tolerance to close the PLBD's and latch gangs exists. Since single-fault tolerance exists and since the probability of requiring the IFM is extremely low, NEOM is acceptable after the loss of one PL MDM or applicable control bus. (Reference AEFTP #131 and #164 minutes, and 6/96 MDF splinter AEFTP.) [ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-209

PLBD RULE REFERENCE MATRIX (CONTINUED)

- C. CENTERLINE (C/L) LATCH GANG FAILS CLOSED OR IN TRANSIT AND CANNOT BE VISUALLY VERIFIED TO BE CLEAR OF THE ROLLERS.

If the C/L latch gang fails closed or in transit without visual verification that it is clear of the rollers, the PLBD's should remain closed and entry should be done at the next PLS opportunity. For the C/L latch gang failed in transit where the latches cannot be verified clear of the rollers, opening the PLBD's with no positive cues that the C/L latch gangs are completely open could lead to structural damage to the PLBD and/or latches (reference Rule {A10-202A}.2, PLBD VISUAL CUES). Additionally, full PLBD closure and/or C/L latching may be inhibited. ©[022201-3996]

Entry should be performed as early as possible, and entry loads should be minimized (reference Rule {A10-203B}, PLBD CRITICAL LATCHES).

- D. STARBOARD BULKHEAD LATCH GANG FAILS CLOSED OR IN TRANSIT AND CANNOT BE VISUALLY VERIFIED CLEAR OF THE ROLLERS.

If a starboard bulkhead latch gang fails closed or in transit and cannot be visually verified to be clear of the rollers, the PLBD's cannot be opened and entry should be done at the next PLS opportunity. For a starboard bulkhead latch failed in transit where it cannot be visually verified clear of the rollers, opening the starboard PLBD without positive cues that the latches are clear of the rollers could also lead to structural damage of the PLBD and/or bulkhead latches. PLBD closing could be inhibited. Entry loads should be minimized (reference Rule {A10-203B}, PLBD CRITICAL LATCHES).

- E. PORT BULKHEAD LATCH GANG FAILS CLOSED OR IN TRANSIT AND CANNOT BE VISUALLY VERIFIED TO BE CLEAR OF THE ROLLERS.

For a port bulkhead latch failed closed or in transit with no visual verification that it is clear of the rollers, the starboard door should remain open to provide cooling. The port door cannot be opened, and a MDF should be invoked. If a port bulkhead latch gang is partially open, but not clear of the rollers, any attempt to open the door could cause structural damage to the door and/or latches, and PLBD closure could be inhibited. An MDF should be considered, if adequate cooling allows, otherwise, entry must be done next PLS. Entry loads should be minimized (reference Rule {A10-203B}, PLBD CRITICAL LATCHES).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-209

PLBD RULE REFERENCE MATRIX (CONTINUED)

F./G. CENTERLINE/BULKHEAD LATCH GANG FAILS OPEN OR IN TRANSIT AND CAN BE VERIFIED CLEAR OF THE ROLLERS.

If a centerline or bulkhead latch gang fails open or in transit and can be verified clear of the rollers the flight can continue as planned since entry with a single bulkhead latch gang out has been deemed acceptable (SODB, vol. 1, 3.4.2.3 and Rockwell Latch Out Analysis, 1991). Auto PLBD software will terminate PLBD operations if single motor drive time is exceeded and manual mode will have to be used. The only single-point failure that will result in multiple latch gang failure is a mechanical jam during PLBD closure. Since the doors are already open, the risk associated with another mechanical jam is incurred only when the doors are closed. Terminating the mission early does not reduce the risk of the next failure. Consequently, the mission can continue as planned. EVA is not required for a single latch gang out, but entry loads should be minimized if a gang is unlatched (reference Rule {A10-203}, PLBD CRITICAL LATCHES).

H. PLBD DOES NOT HAVE CLOSE REDUNDANCY DUE TO MECHANICAL, ELECTRICAL, OR PL MDM FAILURE, WHERE MOTOR FUNCTION IS: ©[022201-3996]

1. NOT RECOVERABLE BY IFM.

For loss of door closure redundancy due to an electrical or mechanical failure, an MDF must be declared to minimize exposure to the next failure that would prevent the payload bay doors from closing without an EVA.

2. RECOVERABLE BY IFM. ©[022201-3996]

Reference B2 rationale. ©[121296-3194B] ©[ED]

Reference Rules {A2-104A}.1.b, SYSTEMS REDUNDANCY REQUIREMENTS, and {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA. ©[ED]

I. STARBOARD DOOR FAILED CLOSED.

For the starboard door failed closed, entry must be done at the next PLS opportunity. The failed starboard door prevents either door from opening, and results in lack of radiator cooling.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-209

PLBD RULE REFERENCE MATRIX (CONTINUED)

J. STARBOARD PLBD FAILED OPEN OR IN TRANSIT.

If the ready-to-latch indications are present, the starboard door is within 4 degrees of being fully closed. The bulkhead latches can be used to help “pull” the PLBD closed, since this position is within the bulkhead latch reach capability. Entry should be made at the next PLS since the PLBD’s cannot be opened and limited vehicle cooling exists.

If the ready-to-latch indications are not present, the starboard door is partially or fully opened. The starboard door is opened greater than two stripes on the pushrods, there is sufficient clearance for the port door to open without interference. The port door should be opened and remain open to allow some radiator cooling since an EVA will have to be performed to close the starboard door. An MDF will be done, if adequate cooling allows, to limit exposure to the next failure that might affect EVA capability or cooling. If the door is jammed while opening, a 5-second drive test can be done to troubleshoot the problem as long as closing the door will not threaten cooling margins, port door closure, or the payload deploy envelope.

If the failure occurs on entry day, a 24-hour waveoff will be required to prepare for and complete the EVA. A next PLS entry will be required after the EVA is complete. If the starboard door is not open far enough (two pushrod stripes) to allow the port door to open, an entry must be done at the next PLS opportunity, since neither door can be opened for radiator cooling. If the door will drive closed, close it; if jammed in the open direction, perform an EVA to close the door.

K. PORT PLBD FAILED CLOSED.

If the port door fails closed, the starboard door should remain open to provide radiator cooling. An MDF should be considered if adequate cooling is available, otherwise enter next PLS.

L. PORT PLBD FAILED OPEN OR IN TRANSIT.

For a port door failed open or in transit, an MDF can be considered, but whether it can be accomplished depends on how far the failed PLBD is open for radiator cooling. Even if there is no cooling constraint, an MDF must be invoked to limit exposure to the next failure that will affect EVA capability. The starboard door should remain open. An EVA should be planned. If the door jammed while opening, a 5-second drive test may be performed to troubleshoot the problem as long as closing the door will not threaten cooling margins or the payload deploy envelope.

For a failure on entry day, a 24-hour waveoff should be done to prepare for and complete the EVA. Landing at the next PLS will be required upon completion of the EVA.

Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule. ©[ED]

A10-210 THROUGH A10-220 RULES ARE RESERVED

FLIGHT RULES

RADIATOR SYSTEMS MANAGEMENT

A10-221

RADIATOR MECHANICAL

- A. PORT OR STARBOARD RADIATOR PANELS WILL BE STOWED AND LATCHED WHEN ONLY SINGLE-MOTOR CAPABILITY REMAINS TO STOW OR LATCH THAT SIDE.

Failure of one radiator stow or latch motor places the vehicle one failure away from loss of stow/latch capability. Losing the stow function on a deployed radiator will require an EVA to stow that radiator prior to payload bay door closure. An unlatched radiator may cause the loss of the associated Freon loop due to entry loads and vibrations which would place the vehicle one failure away from possible loss of crew/vehicle (loss of remaining Freon loop). It is not known if the stowed, unlatched radiator could come into contact with items in the payload bay during entry. While EVA backup exists for stowing the radiators, it does not exist for latching them.

- B. THE FLIGHT WILL CONTINUE, WATER CONSUMABLES PERMITTING, WITH THE FOLLOWING FAILURES:

1. RADIATOR LATCHES FAILED CLOSED OR OPEN.
2. RADIATOR PANELS FAILED STOWED OR DEPLOYED.

The radiators were designed to operate in either the deployed or stowed position. This rule was written to document to the community that, regardless of the radiator position or latch status, the mission may continue.

- C. AN EVA WILL BE REQUIRED TO STOW A FAILED DEPLOYED RADIATOR PANEL.

The PLBD's cannot be closed with a failed, deployed radiator due to possible interference with the opposite door, radiator, or payload. EVA is the only means available if the deploy/stow mechanism has failed. No EVA capability is available for a failed radiator latch.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-221 RADIATOR MECHANICAL (CONTINUED)****D. OPERATIONS WHILE THE RMS IS UNCRADLED:****1. RADIATOR DEPLOY OPERATIONS:**

IF PRACTICAL, RADIATOR DEPLOY OPERATIONS WILL BE DELAYED UNTIL AFTER RMS OPERATIONS ARE COMPLETE OR THE RMS WILL BE CRADLED DURING DEPLOY OPERATIONS. IF IT IS NOT PRACTICAL TO CRADLE THE RMS, RADIATOR DEPLOY OPERATIONS WILL BE PERFORMED WITH THE CIRCUIT BREAKERS OPEN FOR MPM SYSTEM SAFING (SOME ACTUATORS WILL OPERATE SINGLE MOTOR).

2. RADIATOR STOW OPERATIONS MAY BE PERFORMED WHILE THE RMS IS UNCRADLED (SOME ACTUATORS WILL OPERATE SINGLE MOTOR).

In order to prevent the uncradled RMS from being one failure away from inadvertent MPM stow (possible loss of crew/vehicle), the following cb's are opened to remove power to the MPM system:

MA73C: C cb MCA PWR AC 2 3Ø MID 2

D cb MCA PWR AC 3 3Ø MID 4

These also affect radiator motors, but allow at least single-motor operations in all actuators. Stow operations may occur anytime since it is not necessary to verify dual-motor operations. During deploy operations, dual-motor operations must be verified so that the radiators and latches will not be one failure away from loss of latch/stow capability due to an undetected failure (i.e., it is not known if the powered-off motor is functional). Losing the latch or stow function on a radiator may cause the loss of the associated Freon loop due to entry loads and vibrations which would put the vehicle one failure away from the possible loss of crew/vehicle. It is not known if the unsecured radiator could come into contact with a returned payload; this should be considered, if applicable. Therefore, to ensure dual-motor radiator operations, deploy should wait until after RMS nominal operations are completed and the RMS can be safely cradled (payload berthed or released, etc.). If radiator deploy is time critical, the RMS will be cradled if present operations permit; otherwise, the radiators will be deployed single motor. It is highly desirable that dual-motor operations be verified ASAP after the RMS is cradled. This is especially critical for latching, because there is no known EVA backup to provide this function as there is for stowing.

Rule {A12-74}, INADVERTENT MPM CYCLING PROTECTION [CIL], references this rule.

FLIGHT RULES

A10-222 RADIATOR VISUAL CUES

- A. RADIATOR DEPLOYED - A SUSPECT RADIATOR IS CONSIDERED DEPLOYED IF IT APPEARS TO BE IN THE SAME RELATIVE POSITION AS THE OTHER RADIATOR WHEN IT IS DEPLOYED.

- B. RADIATOR STOWED - A SUSPECT RADIATOR CANNOT BE EVALUATED FOR THE STOWED POSITION (IF CLOSE TO IT) UNTIL THE PLBD IS PARTIALLY CLOSED (90 DEGREES). FOR SAFE LATCHING THE POSITIONS OF THE FIXED AND DEPLOYED PANELS ON THE SAME SIDE SHOULD BE ALIGNED WITH EACH OTHER.

If the radiator is thought to have not deployed fully (e.g., failure to receive the deploy indications), then the only visual means of determining if it reached the commanded position is to compare it to the other (fully deployed) radiator.

If a radiator is suspected to have not reached the stowed position (e.g., failure to receive the stow indications), then it can be checked in the following manner. The PLBD to which it is attached must be closed 90 degrees (about halfway) so that the radiator can be easily seen. On each PLBD, there are four radiator panels, two deployable (forward) and two fixed (aft). When the deployable panels are stowed, the seam between them and the fixed set should match up. If so, the radiator can be safely latched.

A10-223 THROUGH A10-240 RULES ARE RESERVED

FLIGHT RULES

ET UMBILICAL DOORS SYSTEMS MANAGEMENT

A10-241 ET UMBILICAL DOOR KEYBOARD ENTRY

THE ET DOOR CLOSE KEYBOARD ITEM ENTRY WILL ONLY BE USED IF MANUAL ET UMBILICAL DOOR CLOSE OPERATIONS ARE UNSUCCESSFUL AND:
@[022802-5110]

- A. THE CENTERLINE LATCHES ARE STOWED AND BOTH ET DOORS ARE CONFIRMED READY-TO-LATCH, OR
- B. AN AOA IS BEING PERFORMED.

With the exception of an RTL or a TAL, the software sequence is not nominally used, and the ET umbilical doors are closed manually. After ET separation, but while still in OPS 1 (MM 104, 105, 106), the software sequence may be initiated by an item entry on SPEC 51. This software issues commands based on single motor drive times and does not check (or stop) for anomalous operation. The potential exists to drive the doors against the centerline latches (if they do not stow nominally), damaging the drive mechanism and preventing proper door closure.

Crew initiation of the software sequence is possible only in OPS 1 via the SPEC 51 item entry. Therefore, for an AOA, the ET umbilical doors will be closed prior to transitioning out of OPS 1 in order to maintain redundancy in the event of an ET umbilical door switch failure. Following nominal ascent or an ATO, door closure can be delayed until OPS 2 since real-time commands (RTC's) can be used to close and latch the doors in the event of a switch failure. In cases where there is no potential for driving the doors against the centerline latches or latching the uplock latches before the doors are closed, the OPS 1 SPEC 51 item entry may be used instead of sending ground commands. Closure during an RTL/TAL is automatic, using the software sequence. In all other situations, the MCC will be contacted to determine the method of door closure. @[022802-5110]

A10-242 ET UMBILICAL DOORS ON ORBIT

THE ET DOORS WILL NORMALLY BE CLOSED AFTER THE H₂ PRESSURIZATION LINE VENTING IS COMPLETED. BOTH ET DOORS MUST BE CLOSED AND LATCHED BEFORE DEORBIT.

H₂ pressurization line venting should be completed before ET door closure to ensure that any residual H₂ in the line can dissipate into space. If the doors are closed, H₂ can be trapped in the ET door cavity and will take a much longer time to vent through the aft compartment. The doors should be closed and latched before entry to avoid structural damage because of protruding surfaces during reentry heating and to provide a smooth undersurface for stable aerodynamic control.

FLIGHT RULES**A10-243****ET UMBILICAL DOOR CLOSURE DELAY FOR DISCONNECT VALVE FAILURE [CIL]**

FOR FAILURE OF THE LO₂ AND/OR LH₂ 17-INCH DISCONNECT VALVE(S) TO CLOSE, ET UMBILICAL DOOR CLOSURE: @[022802-5110]

- A. FOLLOWING NOMINAL ASCENT OR AN ATO, WILL BE DELAYED IN ORDER TO OBTAIN A MINIMUM OF 40 CONTINUOUS MINUTES OF BOTTOM-SUN EXPOSURE IMMEDIATELY PRIOR TO ATTEMPTING CLOSURE.
- B. DURING AN AOA, WILL BE DELAYED AS LONG AS POSSIBLE, WITH BOTTOM-SUN EXPOSURE IF FEASIBLE, BUT WILL BE PERFORMED PRIOR TO TRANSITIONING FROM OPS 1.
- C. DURING A TAL OR RTLS, WILL NOT BE DELAYED.

When possible, ET umbilical door closure will be delayed following failure of the LO₂ or LH₂ disconnect valves to close in order to allow for venting of residual cryogenic propellants and thermal conditioning of the ET door pressure seal and thermal barrier. This will allow proper door closure/sealing, prevent pressurization of the ET umbilical compartment, and prevent residuals from entering the aft compartment. A bottom-sun attitude speeds this conditioning/venting. For most orbits (160 nm, 28.5-degree inclination), a maximum of 55 minutes of sun exposure can be obtained. For ATO orbits (106 nm altitude), only 40 minutes of sun exposure can be obtained. Higher inclination orbits provide longer sun exposure. A minimum of 40 continuous minutes with the orbiter in a bottom-sun attitude will ensure adequate conditioning/venting. Reference SODB submittal P1-1577 for thermal analysis.

Crew initiation of the software sequence is possible in OPS 1 only (MM 104, 105, 106), via the SPEC 51 item entry. Therefore, for an AOA, the ET umbilical doors will be closed prior to transitioning out of OPS 1 in order to maintain redundancy in the event of an ET umbilical door switch failure. For nominal ascent/ATO, door close redundancy exists in OPS 2 via ground-issued RTC's. Closure during an RTLS/TAL is automatic; also, the time criticality of door closure precludes additional venting or conditioning. @[022802-5110]

A10-244 THROUGH A10-260 RULES ARE RESERVED

FLIGHT RULES

VENT DOOR SYSTEMS MANAGEMENT [ED]

A10-261

VENT DOOR MANAGEMENT

A. ORBIT - ALL VENT DOORS WILL NOMINALLY BE OPEN DURING ORBIT OPS EXCEPT FOR THE FOLLOWING:

1. IF REDUNDANT CLOSE CAPABILITY IS LOST FOR VENT DOORS 1 AND 2, THE AFFECTED DOOR WILL BE CLOSED PROVIDED OPEN REDUNDANCY EXISTS ON THE OPPOSITE DOOR. FOR THE REMAINING DOORS, NO ACTION WILL BE TAKEN FOR THE LOSS OF REDUNDANT CLOSE CAPABILITY.

For loss of close redundancy, the affected door is closed to limit the exposure to the next failure that would leave the door failed open. It is predicted that the 1/2 vent box will melt if exposed, resulting in structural damage that, although not a flight-safety concern, is a significant impact to vehicle turnaround (upper and lower fuselage must be demated for repair - estimated > 1 year).

If open redundancy does not exist on the opposite door, the affected door will not be closed in order to protect against a subsequent failure that could fail the door in the closed position. With the loss of open redundancy, the flight rule is biased towards ensuring 1/2 compartment venting is guaranteed (i.e., door open) rather than closing the door to protect against the thermal impact during entry should subsequent failures occur.

The thermal impact with a door failed open is the most severe in the forward compartment. The midbody doors will experience 600 deg to 700 deg F heating while the aft compartment doors will experience less than 550 deg F heating. The structural impact associated with these temperatures is minimal. Consequently, no protective measures are implemented.

2. FOR A VENT DOOR FAILED OPEN, NO ACTION WILL BE TAKEN UNLESS CLOSE REDUNDANCY IS LOST ON THE OPPOSITE DOOR. LOSS OF CLOSE REDUNDANCY ON THE OPPOSITE DOOR WILL BE CAUSE TO CLOSE THE DOOR.

Discussions at the Entry Flight Techniques Panel (FTP) #43 determined that sufficient entry venting can be maintained with one side of a vent group closed. (Assumes nominal entry. If entry is dispersed and vent door fails closed, the factor of safety will be less than 1.4). Furthermore, entry with both sides open will result in structural damage due to hot plasma and possible flow-through of hazardous gas. Therefore, if a vent door fails open and close redundancy is lost on the opposite door, the opposite door will be closed to protect against the next failure that would leave the door failed open.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-261

VENT DOOR MANAGEMENT (CONTINUED)

3. VENT DOORS MAY BE CLOSED IN ORDER TO MINIMIZE THE POTENTIAL FOR CONTAMINATION OF SPACECRAFT OR EVA OPERATIONS WHEN A KNOWN CONTAMINANT EXISTS IN AN ACTIVELY VENTED COMPARTMENT. @[072398-6686B]

On-orbit, the vent doors are nominally left open to permit molecular venting of the thermal insulation. The risk of closing the forward and/or aft compartments to preclude any potential off-gassing of a known contaminant from these compartments outweighs the risk of compartment overpressurization should a large OMS or RCS tank leak occur. @[072398-6686B]

B. ENTRY

1. IF OPEN CAPABILITY IS LOST ON ANY VENT DOOR DUE TO A MULTIPHASE AC LOSS (NO SHORT), DEORBIT WILL BE DELAYED TO INSTALL THE AC BUS TRANSFER CABLE AND REGAIN OPEN CAPABILITY.

Deorbit will be delayed if the ac bus transfer cable can be installed to regain open capability on any vent door. This will allow entering with the maximum available venting.

2. IF VENT DOORS 1 AND 2 OR 8 AND 9 ARE FAILED CLOSED ON ONE SIDE AND OPEN REDUNDANCY IS LOST ON THE OPPOSITE SIDE, DEORBIT WILL BE DELAYED IF INSTALLATION OF THE AC BUS TRANSFER CABLE WILL REGAIN OPEN REDUNDANCY.

Deorbit will be delayed if the ac bus transfer cable can be installed to regain open redundancy after the opposite door has failed closed in the forward or aft compartment. This will allow entering with the doors closed, precluding entry heating structural damage.

3. ALL VENT DOORS WILL NOMINALLY BE CLOSED FOR ENTRY EXCEPT AS FOLLOWS:
 - a. FORWARD/AFT VENT DOORS:
 - (1) IF OPEN REDUNDANCY IS LOST ON BOTH SIDES OF THE AFFECTED COMPARTMENT (1 AND 2 OR 8 AND 9) AND ONE FAILURE (AVIONICS/POWER) WILL RESULT IN LOSS OF OPEN CAPABILITY OF DOORS ON BOTH SIDES, ONE DOOR WILL REMAIN OPEN THROUGHOUT THE MISSION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-261

VENT DOOR MANAGEMENT (CONTINUED)

During nominal entry, it is required to maintain the capability to open at least one side of each vent door group in the forward and aft compartments for sufficient compartment venting. After the loss of redundancy on both sides of either the forward or aft compartments and one failure of avionics or power resulting in loss of open capability of doors on both sides, one door will remain open throughout the mission. This action will cause structural damage to the orbiter due to the hot plasma (1200 deg F for 1 and 2 and less than 550 deg F for 8 and 9), but will protect against the next failure preventing any venting to a compartment. Loss of venting in the forward or aft compartments is catastrophic.

- (2) IF VENT DOORS 1 AND 2 OR 8 AND 9 ARE FAILED CLOSED ON ONE SIDE AND OPEN REDUNDANCY IS LOST ON THE OPPOSITE SIDE, THE OPPOSITE VENT DOORS WILL REMAIN OPEN FOR ENTRY. IF THE AFFECTED DOOR IS MECHANICALLY FAILED CLOSED, THE OPPOSITE DOOR WILL REMAIN OPEN FOR ENTRY INDEPENDENT OF OPEN REDUNDANCY.

Entry FTP #43 determined that it is expected that sufficient venting can be maintained during nominal entry with one side of a vent door group in the forward or aft compartment closed. Entry with both sides of a vent group failed closed in the forward or aft compartment will result in structural failure and possible loss of crew/vehicle. If a vent door fails closed in the forward or aft compartment, as long as open redundancy exists on the opposite door, no action will be taken. The orbiter is still two failures away from a catastrophic condition (i.e., no compartment venting), assuming a structural failure, gearbox jam, or torque limiter slip does not occur.

Single-point structural failures exist but are not protected because of the extreme low probability of occurrence (no failures experienced in testing or flight). However, if a vent door fails closed during flight and is unexplained, a mechanical failure will be assumed. The opposite vent door will remain open, protecting against a subsequent mechanical failure that would be catastrophic.

SODB and CIL's assume that failure to open a single vent door below 70,000 feet will result in loss of the crew/vehicle.

- (3) LEFT VENT DOORS 1/2 AND 8/9 WILL REMAIN OPEN FOR ENTRY IN THE EVENT OF AN OMS OXIDIZER, RCS OXIDIZER, OR OMS HE LEAK. IF THE LEAK IS SUBSEQUENTLY ISOLATED, THESE DOORS WILL BE CLOSED. FOR AN OMS FUEL, RCS FUEL, RCS HE, OR APU FUEL LEAK DURING ENTRY, NO ACTION WILL BE TAKEN.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-261 VENT DOOR MANAGEMENT (CONTINUED)

It has been determined that gas leaks which exceed structural limits occur so rapidly that the crew cannot respond. For example, assuming an initial tank pressure of 2000 psia and a hole diameter of 0.11 inch, transient leak analysis for the OMS pod large helium tank indicated that the peak differential pressure would occur 20.7 seconds after the leak started. In addition, if the OMS pod to ambient differential pressure exceeds 0.65 psid, the aft vent doors may not open when commanded (see JSC memorandum ES42-110M-85). As a result, a GPC item entry is used during MM 301 to command left doors 1/2 and 8/9 open independent of the other vent doors. This capability protects the orbiter from possible compartment overpressurization in the event of a massive OMS oxidizer, RCS oxidizer, or OMS He leak during MM 301, 302, and 303.

Nominally, the doors are closed at MM 304 transition to avoid structural damage and hazardous gas ingestion due to the plasma phase of entry. However, if a leak cannot be isolated, left vent doors 1/2 and 8/9 will remain open throughout entry in order to remain within structural limits.

If there is a question between an RCS helium or RCS oxidizer leak, an oxidizer leak will be assumed (ref. A/E FTP #13).

b. MIDBODY VENT DOORS:

- (1) NO ACTION WILL BE TAKEN FOR MIDBODY VENT DOORS FAILED CLOSED AND/OR LOSS OF REDUNDANCY.

Discussions at the Entry FTP #43 determined that with a nominal entry, sufficient venting can be maintained in the midbody after two opposite doors have failed closed.

- (2) FOR ENTRY WITH A MIDBODY H₂ LEAK > 1.0 LB/HR, MAXIMIZE VENTING BY LEAVING VENT DOORS OPEN UNTIL AUTO CLOSURE MM 304 TRANSITION (EI-5).

Leaks of H₂ greater than 1 lb/hr can lead to H₂ concentrations in the midfuselage that exceed the H₂ flammability limit during entry (ref. informal note, DF7/84-126, dated 6/20/84). Delaying the closure of the vent doors until the MM 304 transition will reduce the amount of time that is available for H₂ to build up within the midfuselage while providing the maximum amount of time prior to the high heating phase of entry that H₂ has the opportunity to escape.

The current vent door software will automatically close any vent doors at the MM 304 transition that might have been left open prior to that time. Additionally, the capability does not exist in the current software to open any midbody vent door prior to the MM 305 transition which occurs well below the 100,000 foot altitude. Therefore, the latest the midbody vent doors can be left open for H₂ venting is MM 304, and the earliest the doors can be opened is MM 305 (Mach 2.4).

A10-262 THROUGH A10-280 RULES ARE RESERVED

FLIGHT RULES

PAYLOAD RETENTION LATCHES (PRLA) SYSTEMS MANAGEMENT

A10-281

PRLA'S/AKA'S

A. PRLA/AKA MANAGEMENT:

1. FOR A DEPLOYABLE PAYLOAD (WITH RETURN CAPABILITY), THE ASSOCIATED PRLA'S/AKA'S WILL NOT BE CLOSED UNTIL PAYLOAD RETURN CAPABILITY IS NO LONGER AN OPTION. @[ED]
2. FOR A PAYLOAD RETRIEVAL MISSION, THE ASSOCIATED PRLA'S/AKA'S WILL NOT BE CLOSED ON ORBIT UNTIL THE PAYLOAD IS BERTHED.

Because of inherent single-point failures in the payload retention system, the PRLA's and AKA's will remain open to avoid a failure that could preclude returning a payload.

3. AN EVA WILL BE CONSIDERED TO OPEN OR CLOSE ANY TYPE PRLA THAT HAS FAILED TO RELEASE OR LATCH. AKA'S ARE EXCLUDED FROM CONSIDERATION. @[011801-3849]

The standard weight longeron latch, super middleweight longeron latch (SMWLL), middleweight longeron latch (MWLL), modified middleweight longeron latch (MMWLL), and lightweight longeron latch (LWLL) types have EVA release/latch drive mechanisms incorporated into their designs. EVA should be considered in lieu of discontinuing payload operations or payload jettison in order to preserve mission success. The standard weight and lightweight AKA types have neither EVA drive capability nor physical access. @[011801-3849]

B. PRLA/AKA REQUIREMENTS FOR NOMINAL PAYLOAD BERTHING OPERATIONS:

1. CONFIRMING VISUAL CUES AND/OR AT LEAST ONE OF TWO RELEASE INDICATIONS ON ALL PRLA'S/AKA'S MUST BE PRESENT BEFORE MANEUVERING THE PAYLOAD INTO THE PRLA V-GUIDES.

During berthing operations, PRLA's/AKA's must be verified released in order to preclude possible structural damage to the payload and orbiter.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-281

PRLA'S/AKA'S (CONTINUED)

2. CONFIRMING VISUAL CUES AND/OR AT LEAST ONE OF TWO READY-FOR-LATCH MICROSWITCH INDICATIONS MUST BE PRESENT ON ALL PRLA'S BEFORE CONTINUING NOMINAL PRLA/AKA CLOSE PROCEDURES.

The absence of both PRLA R-F-L indications represents a condition where a payload trunnion may be outside the 2-inch PRLA latch envelope. Continuation of PRLA ops without further evaluation could allow the payload operator to drive this latch against the trunnion, causing the PRLA motors to stall.

For contingency IUS reberthing operations, R-F-L indications are not required, since the IUS keel kick-off spring will nominally prevent the IUS trunnions from contacting the R-F-L microswitch lever arms. The AFTA, however, will maintain the trunnions within the PRLA latch envelope once the IUS is returned to the PRLA release position.

When latching an AKA, the R-F-L indication is not expected until the latch is almost completely closed. The indication actually serves as a trunnion-in-place indication instead of a R-F-L cue.

3. WHEN NOMINALLY BERTHING A PAYLOAD WITH MULTIPLE PRLA'S AND ONE OR MORE AKA'S, THE AKA(S) MUST BE LATCHED FIRST BEFORE CLOSING THE PRLA'S. (REFER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX FOR EXCEPTIONS.)

During berthing operations, the AKA(s) provides the necessary force required to center the payload within the payload bay. The AKA has a limited capability in the Y-direction (2,500 lb with less than a 0.25-inch payload offset, 1,000 lb with a greater than 0.25-inch offset), which may be insufficient to overcome the longeron latch resistance once the PRLA's are latched. Therefore, the AKA(s) must be closed prior to the PRLA's to preclude an AKA from stalling. Reference RI STS84-0190A, Payload Retention System Latches Safety Assessment Report, July 1984; and Shuttle Flight Operations Manual (SFOM), Volume 16, Payload Deployment and Retrieval System, Final, June 1, 1981.

C. PRLA/AKA REQUIREMENTS FOR PAYLOAD DEPLOY

CONFIRMING VISUAL CUES AND/OR AT LEAST ONE OF TWO RELEASE INDICATIONS ON ALL PRLA'S/AKA'S MUST BE PRESENT BEFORE CONTINUING NOMINAL PAYLOAD DEPLOY OPERATIONS.

During deploy operations, PRLA's/AKA's must be verified released in order to preclude possible structural damage to the payload and orbiter.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-281 **PRLA'S/AKA'S (CONTINUED)**

D. PRLA/AKA LATCHED DEFINITION

FOR PAYLOAD RETURN OR ON-ORBIT MANEUVERS AND TRANSLATIONS, A PRLA/AKA WILL NOT BE CONSIDERED LATCHED WITHOUT THE COMBINATION OF AT LEAST ONE OF TWO LATCH MICROSWITCH INDICATIONS, AND AT LEAST ONE OF TWO RFL MICROSWITCH INDICATIONS (VISUAL CUES ACCEPTABLE FOR R-F-L INDICATIONS).

PRLA's/AKA's must be verified latched in order to preclude possible structural damage to the payload and orbiter. Failure of any PRLA/AKA to indicate a latched configuration will be evaluated on a flight-specific basis regarding subsequent on-orbit maneuvers, orbiter attitude control, and return to Earth capabilities.

E. PAYLOAD RETENTION PAYLOAD SELECT ROTARY SWITCH OPERATIONS:

1. FOR MISSIONS WHERE NOMINALLY ONLY A SINGLE PAYLOAD SELECT POSITION WILL BE UTILIZED, THE PAYLOAD RETENTION PAYLOAD SELECT ROTARY SWITCH WILL BE CONFIGURED TO THAT POSITION FOR LAUNCH AND WILL REMAIN IN THAT POSITION FOR THE DURATION OF THE FLIGHT.
2. FOR ALL OTHER MISSIONS, THE ROTARY SWITCH WILL BE LAUNCHED IN THE MONITOR POSITION AND WILL BE OPERATED AS REQUIRED TO BEST SUPPORT THE MISSION.

Operation of the rotary switch for single payload select missions is not necessary; and because of inherent single-point failures within the payload select rotary switch, use of this switch for this type mission is avoided to preclude the potential of mission failure. The payload retention system maintains fail op/fail safe redundancy against inadvertent operation when launched and flown in any position.

For missions using multiple payload select positions, use of the rotary switch is usually required. The monitor position allows a complete systems status verification for launch commit criteria purposes and for orbit operations.

F. PRLA/AKA CONFIGURATION FOR ASCENT/ENTRY @[072398-6687] @[011801-3849]

1. WITH NO PAYLOAD
 - a. PRLA'S: LATCHED
 - b. FLOATING AKA'S: RELEASED @[011801-3849]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-281

PRLA'S/AKA'S (CONTINUED)

- c. FIXED AKA'S: LATCHED OR RELEASED (REFER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX FOR EXCEPTIONS.) ©[011801-3849]

All PRLA certification testing for dynamic flight was done using hardware in the latched configuration. Because of the inherent latch mechanism free-play when not latched overcenter, the loads and vibration levels associated with dynamic flight may cause internal PRLA damage and accelerate mechanism wear. Without a payload trunnion present, a floating AKA in its latched position is free to move along its bridge fitting approximately 9 inches in the x-axis. Therefore, the AKA can impact its end stops, resulting in AKA and/or orbiter payload bay hardware damage. In addition, extensive ground turnaround testing/repair would be required. When released, however, a floating AKA opens up to completely fill the gap between its end stops, and movement along its bridge fitting cannot occur. A fixed AKA is installed with a center stop which prevents the AKA from sliding when fully latched. The bridge fitting end stops prevent movement when the AKA is released.

Reference SODB, vol. I, 3.4.2.5-14 and table 3.4.2.5-5 (Active Keel Latch Ascent and Entry Constraints). ©[072398-6687]

2. WITH PAYLOAD (REFER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES ANNEX FOR EXCEPTIONS)
- a. PRLA'S: LATCHED
- b. FLOATING AKA'S: LATCHED
- c. FIXED AKA'S: LATCHED

The payload must be constrained during ascent/entry to prevent movement that could lead to damage of the orbiter or payload, or loss of crew/vehicle. This constraint may be relaxed for entry based on loads analysis for the specific payload; the annex documents any such analysis. ©[011801-3849]

A10-282 THROUGH A10-300 RULES ARE RESERVED

FLIGHT RULES

KU-BAND ANTENNA DEPLOY MECHANISM SYSTEMS MANAGEMENT

A10-301 ANTENNA STOW REQUIREMENT [CIL]

A. FOR LOSS OF REDUNDANT KU-BAND ANTENNA STOW CAPABILITY, THE DEPLOYED ASSEMBLY WILL BE STOWED AS SOON AS PRACTICAL UNLESS REQUIRED TO SUPPORT RENDEZVOUS, DOCKING, PLANNED EVA, OR OTHER OPERATIONS STATED IN THE FLIGHT SPECIFIC ANNEX. FOR THESE CASES: [CIL] ©[090999-6930]

1. THE DEPLOYED ASSEMBLY WILL BE DEPLOYED AND REMAIN DEPLOYED TO SUPPORT THE OPERATION.
2. THE DEPLOYED ASSEMBLY WILL BE STOWED AS SOON AS PRACTICAL AFTER COMPLETION OF THE OPERATION(S) BUT NO LATER THAN THE BEGINNING OF THE DAY PRIOR TO ENTRY.

IF THE LAST OPERATION IS A PLANNED EVA, THE DEPLOYED ASSEMBLY WILL BE STOWED PRIOR TO THE END OF THE EVA.

Without redundant stow capability, the antenna could not be stowed normally if a single additional failure occurred. If stow capability could not be regained by one of the methods given in Rule {A10-303}, ANTENNA CONTINGENCY PROCEDURES, the antenna would be costly in terms of mission success (cases stated above or in the annex), the antenna will be stowed when redundancy is lost. For the loss of redundancy case, the antenna should be stowed prior to the end of the last planned EVA in the event that EVA assistance is needed to complete the stow operation.

Rule {A2-103C}, EXTENSION DAY REQUIREMENTS, references this rule. ©[090894-1670B]

B. FOR LOSS OF TEMPERATURE CONTROL OR TEMPERATURE MONITORING CAPABILITY, THE KU-BAND ANTENNA WILL BE STOWED AS SOON AS PRACTICAL EXCEPT FOR THOSE CASES STATED IN THE FLIGHT SPECIFIC ANNEX. [CIL]

Precise antenna positioning capability is required to lock the gimbals and properly stow the Ku-band antenna. When the temperature of the antenna gyro mechanism, signal feed, or the alpha or beta gimbal angle cannot be maintained within SODB limits, the capability to obtain correct stow angles may be lost. The Ku-band antenna deployed assembly (gimbals must be locked for entry, or jettison is inevitable. Therefore, when the Ku-band antenna temperature control or monitoring capability is lost, the Ku-band systems should be deactivated and the antenna stowed as a precaution. The Ku-band will be jettisoned if the gimbals cannot be locked for entry. ©[090999-6930]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-301 ANTENNA STOW REQUIREMENT [CIL]

Reference Rules {A10-303C}, ANTENNA CONTINGENCY PROCEDURES; {A11-56}, LOSS OF KU-BAND TEMPERATURE CONTROL [CIL]; {A11-57}, LOSS OF KU-BAND TEMPERATURE MONITORING CAPABILITY [CIL]; and {A11-77}, LOSS OF ANY OI DSC;. ©[090999-6930]

Rule {A2-103}, EXTENSION DAY REQUIREMENTS, references this rule.

C. THE KU-BAND ANTENNA WILL NOT BE REDEPLOYED FOR MISSION EXTENSION DAYS.

Reference Rule {A2-103C}, EXTENSION DAY REQUIREMENTS.

D. FOLLOWING UNSUCCESSFUL ATTEMPTS TO FULLY DEPLOY THE KU-BAND ANTENNA, THE ANTENNA WILL BE DRIVEN BACK TO THE STOWED POSITION.

If the antenna cannot be successfully deployed, there is a good possibility of a mechanism problem that could also affect the stow capability. It is important to stow the antenna early in the flight so IFM or EVA contingency procedures can be planned per Rule {A10-303}, ANTENNA CONTINGENCY PROCEDURES, if required. Also, the antenna is no use if not fully deployed and there is a potential for an additional failure to make antenna stowage impossible as the flight progresses. ©[090999-6930]

A10-302 DAP CONFIGURATION FOR ANTENNA STOW

THE DAP WILL BE CONFIGURED TO "VERN" OR "FREE DRIFT" DURING KU-BAND DEPLOY ASSEMBLY STOWING.

Reference SODB, vol. I, 3.4.5.2.10. In order to ensure proper gimbal locking during the antenna automatic stow sequence, the primary RCS jets cannot be selected. Damage to the gimbal locking mechanism may be caused by orbiter accelerations greater than 0.5 deg/sec² and orbiter rates greater than 5 deg/sec during the stow sequence. Either "vern" or "free drift" is acceptable.

FLIGHT RULES

A10-303

ANTENNA CONTINGENCY PROCEDURES

- A. IF THE KU-BAND ANTENNA GIMBALS CANNOT BE LOCKED FOR KU-BAND STOW, CONSIDERATION WILL BE GIVEN TO PERFORMING AN EVA TO LOCK THE GIMBALS IF A DEORBIT DAY PLUS 1-DAY WAVEOFF IS AVAILABLE AFTER EVA DAY.

For this case, an EVA is considered an option if it can be performed and consumables will support a deorbit day plus 1 day waveoff after EVA day.

- B. IF THE KU-BAND ANTENNA CANNOT BE STOWED OR THE GIMBALS CANNOT BE LOCKED BUT THE FAILURE OCCURS SUCH THAT AN EVA CANNOT BE PERFORMED, CONSIDERATION WILL BE GIVEN TO A 1-ORBIT WAVEOFF OR A 1-DAY EXTENSION IN ORDER TO PERFORM ANY OF THE FOLLOWING CONTINGENCY PROCEDURES IF A DEORBIT DAY PLUS 1-DAY WAVEOFF DAY IS MAINTAINED:
1. KU-BAND ANTENNA - FAILED DEPLOY/STOW SWITCH (IFM).
 2. KU-BAND ANTENNA - GIMBALS CAN BE LOCKED (IFM).
 3. USE OF THE KU-BAND ANTENNA DIRECT STOW SWITCH.
 4. KU-BAND ANTENNA JETTISON (IF FAILURE PREVENTS PLBD CLOSURE).

The rule assumes that, for whatever reason, performing an EVA has not been an option. It also assumes that on entry day we are unable to stow the antenna or lock the gimbals.

There are a few contingency procedures that do not involve an EVA, but might require a one-orbit waveoff or a 1-day extension to perform. Depending on the failure, they could result in saving the antenna and still enter with at least a 1-day backup.

The contingency procedure required to be used is dependent on the actual failure condition; however, if the failure can be corrected via IFM, the IFM procedure should have priority over the others. The IFM procedures allow for normal antenna stow procedures to be used once the gimbals are locked.

Rule {A10-301B and C}, ANTENNA STOW REQUIREMENT [CIL], references this rule.

- C. THE KU-BAND WILL BE JETTISONED IF THE GIMBALS CANNOT BE LOCKED FOR ENTRY.

With the Ku-band mechanism stowed and the antenna gimbals unlocked, the antenna disk is free to move about its gimbal axes and cause radiator damage when subjected to entry and landing loads. Loss of the ability to lock the antenna gimbals and secure the disk for entry is considered a criticality 1 failure.

Reference JSC VNS-87-26, Ku-Band Comm/Radar FMEA/CIL, Level III CCB minutes (12/10/86).

A10-304 THROUGH A10-320 RULES ARE RESERVED

FLIGHT RULES

REMOTELY OPERATED ELECTRICAL/FLUID UMBILICAL (ROEU/ROFU) SYSTEMS MANAGEMENT ©[062801-4355A]

A10-321 ROEU/ROFU OPERATIONS

- A. THE ROEU/ROFU WILL BE DEMATED FROM THE PAYLOAD PRIOR TO UNLATCHING THE PRLA(S) OR AKA(S).

The ROEU/ROFU was not designed to withstand the loads that may be caused by a payload that is not fully constrained in the payload bay. This will preclude possible damage to the ROEU/ROFU, which may lead to binding during unberthing of the payload.

- B. THE ROEU/ROFU WILL NOT BE MATED TO THE PAYLOAD UNTIL AND UNLESS THE PRLA(S) AND AKA(S) REQUIRED FOR ENTRY ARE CONFIRMED LATCHED.

The ROEU/ROFU was not designed to withstand the loads that may be caused by a payload that is not fully constrained in the payload bay. This will preclude possible damage to the ROEU/ROFU which may lead to binding should a contingency unberthing of the payload be required.

- C. THE PAYLOAD WILL NOT BE UNBERTHED UNTIL CONFIRMATION THAT THE ROEU/ROFU IS DEMATED AND OVERCENTER LOCKED OR VISUAL VERIFICATION OF CLEARANCE IS OBTAINED.

The separation distance between the payload and the orbiter disconnect assembly (ODA) is critical during berth and unberth. If the distance is less than the specified 3.2 inches, contact may occur between the ODA and the payload. If not overcenter locked, the orbiter arm drive mechanism (ODM) may be free to backdrive such that the clearance is less than 3.2 inches and potentially cause contact during berth or unberth. During unberthing, without confirmation of overcenter lock, the crew will have to visually verify the clearances to avoid ODA-to-payload contact. ©[062801-4355A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-321 ROEU/ROFU OPERATIONS (CONTINUED)

- D. IF A POSITIVE LATCH INDICATION IS NOT RECEIVED AFTER ROEU/ROFU LATCH HAS BEEN ATTEMPTED, THE ROEU/ROFU WILL BE UNLATCHED AND DEMATED PRIOR TO ENTRY. @[062801-4355A]

Without at least one microswitch confirming that the ODA hooks are overcenter locked, possible damage to the ROEU/ROFU may occur during entry due to separation of the ODA and the payload disconnect assembly (PDA). The overcenter demated position is safe for entry.

- E. IF THE ROEU/ROFU FAILS TO DEMATE, AN UNSCHEDULED EVA WILL BE CONSIDERED TO DEMATE THE ROEU/ROFU.

The ROEU/ROFU ODA Hooks and ODM Arm have EVA drive capability. Demating the ROEU/ROFU via EVA should be considered in lieu of discontinuing payload operations in order to preserve mission success.

- F. IF THE ROEU/ROFU CANNOT BE REMATED WITH THE PAYLOAD, AN UNSCHEDULED EVA WILL BE CONSIDERED TO REMATE THE ROEU/ROFU.

The ROEU/ROFU ODA Hooks and ODM Arm have EVA drive capability. Remating the ROEU/ROFU via EVA should be considered to avoid damage to the payload resulting from loss of functions provided by the ROEU/ROFU. @[062801-4355A]

A10-322 THROUGH A10-340 RULES ARE RESERVED

FLIGHT RULES

ANDROGYNOUS PERIPHERAL DOCKING SYSTEM (APDS) SYSTEMS MANAGEMENT

A10-341 APDS CONFIGURATION

- A. THE DOCKING RING MUST BE AT THE INITIAL POSITION AND THE RING ALIGNED BEFORE ATTEMPTING TO DOCK. @[021199-6816]

With the ring aligned at the initial position, each ballscrew/nut assembly has its maximum stroke available to react to and attenuate the docking loads. If the ring is not aligned, or if it is extended beyond or below the initial position, the available stroke decreases, thus decreasing attenuation capability. This would also increase the probability of bottoming out the mechanism, which could result in excessive loads and damage to the mechanism or the vehicles. In addition, if the ring is not aligned, the probability of achieving capture is reduced, since the mechanism must then overcome misalignments in the ring as well as piloting misalignments in order to engage all three capture latches.

- B. THE INNER HATCH WILL BE CLOSED AND LATCHED PRIOR TO ANY ATTEMPT TO DOCK WITH ISS. IF AN IFM IS REQUIRED TO COMPLETE DOCKING, THE IFM WILL BE SET UP PRIOR TO THE DOCKING ATTEMPT. THE INNER HATCH WILL BE OPENED AFTER CAPTURE IS OBTAINED TO DRIVE THE APPROPRIATE APDS MOTOR TO COMPLETE THE SEQUENCE.

Closing the inner hatch isolates the crew cabin from the ODS volume should the APDS hatch or ODS structure be breached during a docking attempt.

- C. THE DOCKING RING WILL NOMINALLY BE RETRACTED TO ITS FINAL POSITION PRIOR TO CLOSING THE PLBD'S. IF THE RING CANNOT BE RETRACTED, THE SYSTEM IS STILL IN A SAFE CONFIGURATION FOR ENTRY.

The active docking ring will nominally be retracted during the docking sequence and will not be re-extended. If the docking sequence is not completed, the ring should be retracted before attempting to close the payload bay doors. Analysis has not been done to show that damage to the ring or ballscrew mechanism will not occur if the ring is extended during entry. However, the ring does not interfere with the payload bay door envelope even at its fully extended position. If the capability does not exist to retract the ring, there are no safety concerns with the ring being extended during entry. Reference Rockwell-Downey Internal Letter ODS-36.11-94-142. @[021199-6816]

FLIGHT RULES

A10-342

APDS PRESSURE/TEMPERATURE

- A. THE DMCU, DSCU, LACU, PACU, AND PSU AVIONICS BOXES WILL NOT BE OPERATED IF THE EXTERNAL AIRLOCK PRESSURE IS LESS THAN 8.0 PSIA. @[021199-6816]

To ensure adequate heat dissipation, the atmospheric pressure within the DMCU, DSCU, LACU, and PACU avionics boxes (which is represented by the external airlock pressure) must be greater than 8.0 psia. If the airlock pressure falls below 8.0 psia and is subsequently repressurized to > 8.0 psia, operation of these boxes is acceptable (assuming paragraph D of this rule has not been violated). Reference APDS Multi-Mir Critical Design Review, February 1995.

- B. THE PFCU IS DESIGNED AS A ONE-TIME USE BOX AND MAY BE OPERATED IN A VACUUM IF REQUIRED.

There are no relays within the PFCU that are continuously energized as in the other boxes. Since it takes less than a second to activate the necessary relays to fire the hook 6, there is no issue with overheating and premature failure of the components due to lack of atmosphere in the box. In addition, the PFCU is designed to be used only once. This is due to the degradation of the fusistors as they are heated by the current flow and the probability of the KQ relay contacts welding closed. Reference APDS Multi-Mir Critical Design Review Protocol, February 23, 1995.

- C. THE DCU'S ARE SEALED BOXES AND MAY BE OPERATED AS REQUIRED IN A VACUUM.

There are no heat rejection concerns with the DCU's because the DCU's do not use the same heat-generation relays that the other boxes have. Since these boxes are also hermetically sealed, there is no constraint to operation in a vacuum.

- D. THE DMCU, DSCU, LACU, PACU, AND PFCU AVIONICS BOXES HAVE A MAXIMUM CUMULATIVE NON-OPERATING VACUUM EXPOSURE LIMIT OF 200 HOURS.

The DMCU, DSCU, LACU, PACU and PFCU avionics boxes are not sealed; therefore, exposing these boxes to a vacuum will expose the internal electronics to a vacuum. Due to concerns about the effect of vacuum exposure on the electronics, these boxes have a maximum cumulative nonoperation vacuum exposure limit of 200 hours. Reference: Procurement Specification for the Androgynous Peripheral Docking System for the ISS Missions (JSC-26938, Rev C). @[021199-6816]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-342

APDS PRESSURE/TEMPERATURE (CONTINUED)

E. DOCKING SYSTEM TEMPERATURES, AS INDICATED BY THE DOCKING BASE, CAPTURE LATCH, BALL DRIVE, RING DRIVE, AND HOOK DRIVE TEMPERATURES, MUST BE MAINTAINED WITHIN THE LIMITS LISTED BELOW. ORBITER ATTITUDE WILL BE MANAGED, OR THE DOCKING RING EXTENDED OR RETRACTED, TO MAINTAIN THESE LIMITS. @[021199-6816]

MISSION PHASE	LIMITS
DOCKING	-22°F/-30°C (-13°F/-25°C) ? T ? 122°F/50°C (113°F/45°C)
RING EXTENSION RING RETRACTION UNDOCKING	-58°F/-50°C (-49°F/-45°C) ? T ? 122°F/50°C (113°F/45°C)
NON-OPERATING	-85°F/-65°C (-76°F/-60°C) ? T ? 185°F/85°C (176°F/80°C)

A 9-degree F margin was used to protect worst case component temperatures. Reference: Procurement Specification for the Androgynous Peripheral Docking System for the ISS Missions (JSC-26938, Rev C).

F. THE DMCU, DSCU, LACU, PACU, AND PSU AVIONICS BOXES WILL NOT REMAIN POWERED ON FOR LONGER THAN 2 HOURS. THE AVIONICS MUST THEN BE POWERED OFF FOR A MINIMUM OF 30 MINUTES PRIOR TO THE NEXT POWERUP.

To avoid excessive heat buildup, the docking system avionics boxes have a maximum power on time constraint of 2 hours. Following powerup, the boxes must be powered down for a minimum of 30 minutes to allow for adequate heat dissipation.

G. THE DCU BOXES DO NOT HAVE A POWERON TIME CONSTRAINT.

The electronics within the data collection units have negligible heat buildup characteristics even though the box is sealed. Therefore, the DCU's are capable of remaining powered indefinitely. Reference APDS Multi-Mir Critical Design Review, February 23, 1995.

H. THE DAMPERS WILL NOT REMAIN POWERED ON FOR MORE THAN 5 MINUTES OF CONTINUOUS OPERATION.

RSC-Energia has constrained damper operation to a maximum of 5 minutes in order to preclude excessive heat buildup and potential hardware degradation. Note that once the dampers are powered off, they cannot be re-enabled during the same docking attempt. Reference Technical Interface Meeting, June 1998. @[021199-6816]

FLIGHT RULES

A10-343

APDS MECHANISM END OF TRAVEL INDICATIONS

- A. THE ACTIVE DOCKING RING WILL BE CONSIDERED TO HAVE ATTAINED ITS COMMANDED POSITION, FINAL/INITIAL/FORWARD, IF AT LEAST ONE OF THE FOLLOWING INDICATIONS OCCURS WITHIN SINGLE-MOTOR DRIVE TIME: @[021199-6816]
1. THE ASSOCIATED APDS CONTROL PANEL STATUS LIGHT OR THE ASSOCIATED DISCRETE TELEMETRY DATA INDICATES FINAL/INITIAL/FORWARD.
 2. THE ASSOCIATED ANALOG POTENTIOMETER MEASUREMENT IS AT 5 PERCENT (± 3 PERCENT) FOR FINAL POSITION, 76 PERCENT (± 3 PERCENT) FOR INITIAL POSITION, OR 98 PERCENT (± 2 PERCENT) FOR FORWARD POSITION.

Redundant indications are provided for the ring drive mechanisms for the final/initial/forward and analog position indications. During ring operations, if any of the proper end-of-travel indications are obtained within the single-motor drive envelope, the ring will be considered to be in the desired position. This is based on the low probability of a sensor failing within the time that the indication was expected, thereby giving a false verification of position. Reference January 1998, APDS ISS Brassboard Functional Testing.

- B. THE ACTIVE DOCKING RING WILL BE CONSIDERED PROPERLY ALIGNED IF AT LEAST ONE OF THE FOLLOWING INDICATIONS IS OBTAINED:
1. THE ASSOCIATED APDS CONTROL PANEL STATUS LIGHT OR DISCRETE TELEMETRY DATA INDICATES RING ALIGNED.
 2. THE ASSOCIATED ANALOG POTENTIOMETER MEASUREMENTS ON THE RING ARE AT 50 PERCENT (± 1 PERCENT) AND THOSE ON THE BASE ARE WITHIN 1 PERCENT OF EACH OTHER.

The docking ring is aligned when all six ballscrews are extended the same length. For the ring to be aligned in pitch, roll, and z, the base potentiometer measurements should be within 1 percent of each other. Alignment in the yaw, x, and y axes is confirmed by the ring potentiometer measurements being centered at 50 percent ± 1 percent.

- C. THE CAPTURE LATCHES WILL BE CONSIDERED OPEN IF AT LEAST ONE OF THE FOLLOWING INDICATIONS CAN BE VERIFIED:
1. THE ASSOCIATED APDS CONTROL PANEL STATUS LIGHT OR THE ASSOCIATED DISCRETE TELEMETRY DATA INDICATES OPEN WITHIN THE MOTOR DRIVE TIME. @[021199-6816]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-343

APDS MECHANISM END OF TRAVEL INDICATIONS (CONTINUED)

2. THE LATCHES CAN BE VERIFIED OPEN AS INDICATED BY A FULLY RETRACTED RING POST-HARD-DOCK. @[021199-6816]

The capture latches indicate open when all three latches are open (i.e., the redundant contacts of each sensor are wired in series). During latch operations, if the open indications are obtained within the expected drive time of 3-4 seconds, the latches will be considered to be in the desired position. This is based on the low probability of a sensor failing within the time that the indication was expected, thereby giving a false verification of position. Also, if the ring can be retracted to the final position as indicated by ring position or verified visually, all three latches are known to be open.

- D. THE CAPTURE LATCHES WILL BE CONSIDERED CLOSED IF THE ASSOCIATED APDS CONTROL PANEL STATUS LIGHT OR THE ASSOCIATED DISCRETE TELEMETRY DATA INDICATES CLOSED WITHIN THE MOTOR DRIVE TIME.

The capture latches indicate closed when all three latches are closed (i.e., the redundant contacts of each sensor are wired in series). During latch operations, if the closed indications are obtained within the expected drive time of 3-4 seconds, the latches will be considered to be in the desired position. This is based on the low probability of a sensor failing within the time that the indication was expected, thereby giving a false verification of position. Also, if the ring cannot be retracted to the final position post-hard-dock, at least one capture latch should be considered closed.

- E. EACH GANG OF APDS HOOKS WILL BE CONSIDERED OPEN/CLOSED IF AT LEAST ONE OF THE FOLLOWING INDICATIONS OCCURS WITHIN SINGLE-MOTOR DRIVE TIME:
 1. THE ASSOCIATED APDS CONTROL PANEL STATUS LIGHT OR THE ASSOCIATED DISCRETE TELEMETRY DATA INDICATES OPEN/CLOSED.
 2. THE ASSOCIATED ANALOG POTENTIOMETER MEASUREMENT IS AT 5 PERCENT (± 3 PERCENT) FOR HOOKS OPEN OR 92 PERCENT (± 3 PERCENT) FOR HOOKS CLOSED.

Redundant indications are provided for the hook drive mechanisms for the open/close and analog position indications. During hook operations, if any of the end-of-travel indications are obtained within the single-motor drive envelope, the hooks will be considered to be in the desired position. This is based on the low probability of a sensor failing within the time that the indication was expected, thereby giving a false verification of position. In addition to the indications above, the APDS hooks have close microswitches on each of the individual hooks (except for hooks 6 and 7, which are driven directly by the hook power drive units). These sensors indicate the individual hooks are closed when the hook potentiometer indicates approximately 80 percent. The PMA 2/3 hooks have close microswitches similar to the PMA-1 hooks; however, the PMA 2/3 sensors are wired in series, in groups of three. @[021199-6816]

FLIGHT RULES

A10-344

APDS DOCKING SEQUENCE OPERATIONS

- A. IF ANY APDS CONTROL PANEL STATUS LIGHT INADVERTENTLY ACTIVATES OR FAILS TO ACTIVATE: ©[021199-6816]
1. PRIOR TO DOCKING, IF THE FAILURE IS DETERMINED TO BE IN A SINGLE SENSOR CONTACT, DOCKING MAY PROCEED AS PLANNED. IF MULTIPLE FAILURES EXIST, DOCKING WILL BE DELAYED AS REQUIRED TO ALLOW TROUBLESHOOTING.
 2. DURING DOCKING, THE APDS DOCKING SEQUENCE WILL BE STOPPED VIA A POWER CYCLE. IF THE FAILURE IS DETERMINED TO BE IN A SINGLE SENSOR CONTACT, DOCKING MAY BE COMPLETED. IF MULTIPLE FAILURES EXIST, COMPLETION OF THE DOCKING SEQUENCE WILL BE DELAYED AS REQUIRED TO ALLOW TROUBLESHOOTING.

The design philosophy within the APDS avionics utilizes three separate electrical paths; two of the three are required to activate any particular function. For feedback from sensors external to the avionics boxes, the three paths are typically combined into two paths to the sensors, with the APDS A logic bus feeding both paths (i.e., A and B paths completed through one sensor contact, A and C through the other). In this way, with any two busses powered, the system can complete its function. Conversely, however, if any one contact or associated wiring shorts to ground or fails closed, two of the three paths associated with that sensor will be activated, possibly disrupting the system operation. This is the basis for all of the avionics single-point failures.

Due to the avionics design, workarounds are available to bypass any single contact failure (e.g., by removing one source of power to the contact). Removing one power source also provides a means of determining if a single-point failure exists, or if multiple failures have caused the erroneous indication. Since the single failure scenarios are already accounted for in the docking sequence cue cards, if there is a contact short, the docking may proceed using the appropriate workarounds. If multiple failures exist, further troubleshooting must be done to determine the source of the failures and any possible workarounds.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-344

APDS DOCKING SEQUENCE OPERATIONS (CONTINUED)

- B. POST-CONTACT, ALL RELATIVE MOTION BETWEEN THE ORBITER AND ISS MATED STACK WILL BE ALLOWED TO DAMP OUT PRIOR TO DRIVING THE ACTIVE DOCKING RING. WHEN THE RELATIVE MOTION HAS STOPPED, THE DOCKING SEQUENCE WILL BE RESTARTED. @[021199-6816]
1. IF THE RING IS NOT ALIGNED AFTER ALL RELATIVE MOTION HAS STOPPED, THE APDS SEQUENCE WILL BE RESTARTED BY EXTENDING THE RING TO THE FORWARD POSITION IN ORDER TO FORCE ALIGNMENT.
 2. IF THE RING IS ALIGNED, THE APDS SEQUENCE CAN BE RESTARTED BY EITHER EXTENDING THE RING TO THE FORWARD POSITION OR BY RETRACTING THE RING.

The APDS high and low energy dampers are automatically energized 5 seconds after contact. Preflight analysis has shown that the docking system dynamics will be over-damped, and therefore, the ring will likely not align itself after all relative motion has stopped. Consequently, before the ring can be retracted with fixers engaged, it must first be driven to the Forward position (against its hard stops) to force alignment. The dampers remain energized during this extension operation, in order to prevent excessive motion of the ring (caused by perturbations of the system induced during the ring extension). However, if the ring is aligned at the Initial position after motion is damped, the docking sequence can be restarted with a Ring In command. The ring can also be extended to Forward, and then retracted, in order to keep crew procedures consistent with nominal operations. However, ring extension is not required if ring alignment is achieved at the ring Initial position. MCC-H is usually prime for determining when relative motion has damped completely, and when the ring has been aligned sufficiently to allow ring extension/retraction. However, in a loss of communications scenario, the crew has sufficient indications/verifications in order to continue the docking sequence without ground concurrence.

- C. THE DOCKING SEQUENCE CAN BE PAUSED OR STOPPED AT ANY TIME AFTER CAPTURE, IN ORDER TO TROUBLESHOOT ERRONEOUS APDS OPERATION OR TO PERFORM A BACKAWAY.

Five seconds after capture, the high energy and low energy electromagnetic dampers are activated to null the relative motion between the vehicles. These dampers remain active until the crew performs a PWR ON reset or a power cycle of the avionics. If a backaway needs to be performed, the successful completion of damping becomes irrelevant, and the sequence may be stopped as required. @[021199-6816]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-344

APDS DOCKING SEQUENCE OPERATIONS (CONTINUED)

- D. IF RING EXTENSION TO THE FORWARD POSITION IS REQUIRED IN ORDER TO FORCE ALIGNMENT AND THE DAMPERS ARE DE-ENERGIZED, THE RING WILL BE PAUSED JUST PRIOR TO REACHING THE FORWARD POSITION. WHEN THE RELATIVE MOTION HAS STOPPED, THE RING DRIVE TO FORWARD WILL BE RESTARTED. ©[021199-6816]

Nominally, the dampers remain energized during ring extension to the Forward position in order to prevent excessive motion of the ring (caused by perturbations of the system induced during the ring extension). By stopping the ring drive just prior to the Forward position and allowing all relative motion to damp out, excessive loads against the mechanism hard stops can be avoided. Loads against the hard stops will be minimized when the ring drive is restarted.

- E. FOLLOWING CONTACT, IF CAPTURE CANNOT BE CONFIRMED, BUT SEPARATION DOES NOT OCCUR, THE DOCKING SEQUENCE SHALL CONTINUE AFTER PASSIVE DAMPING IS COMPLETED PROVIDED:
©[052302-5111A]
1. NO VISIBLE GAPPING BETWEEN THE ACTIVE AND PASSIVE RINGS EXISTS, AND
 2. THE HOOKS DRIVE AUTOMATICALLY UPON RING RETRACTION.

CAPTURE CAN BE CONFIRMED BY EITHER ILLUMINATION OF THE CAPTURE LIGHT OR INITIATION OF ACTIVE DAMPING. ©[052302-5111A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A10-344****APDS DOCKING SEQUENCE OPERATIONS (CONTINUED)**

If the interfaces do not separate post-contact, physical capture has most likely occurred. A single failed capture sensor could cause the capture latching logic to remain unlatched. This would result in no CAPTURE light and no active damping. Continuing the docking sequence is safe in this case provided any relative motion is allowed to damp passively. The "manual" steps in the docking sequence must be performed since the auto-sequence will not have initiated. ©[052302-5111A]

Analysis indicates that if one capture latch failed to engage the passive latch, separation would not likely occur. (Ref Mir FTP #12, November 18, 1994.) Prior to retracting the ring to the Ready-to-Hook position during the docking sequence, this case would not be distinguishable from the loss of a capture sensor unless visible gapping is noted between the active and passive rings at one or more petals. If the docking sequence were to continue, it may be possible to determine if all three latches are engaged when retracting the active ring to the Ready-to-Hook position. At the Ready-to-Hook position, four spring pushers (two on each mechanism) positioned around the structural ring will exert a separating force on the interface, which may result in the inability to compress one or more of the four Ready-to-Hook sensors. If two such sensors are not depressed far enough to make contact, the Ready-to-Hook light will not be illuminated and automatic hooks closure will not occur. Attempting to close the hooks manually in this case may result in binding and damage to the structural hook mechanisms. Under these circumstances the ring should be driven out to the Initial Position and the Failed Capture procedure executed to undock.

The likelihood of a failed capture sensor is considered much higher than the likelihood of a structural or mechanical failure of a capture latch. The three capture latches are configured to the closed (ready to dock) position at KSC before launch and are not driven open until structural mate is complete during the docking sequence. The LATCHES CLOSED light and accompanying telemetry can be used to confirm that all three capture latches are closed. ©[052302-5111A]

FLIGHT RULES

A10-345 **APDS RECONFIGURATION AFTER FAILED DOCKING**

- A. IN THE EVENT OF A FAILED CAPTURE, THE DOCKING RING WILL BE EXTENDED TO THE FORWARD POSITION (IF REQUIRED TO REALIGN THE RING), FULLY RETRACTED, AND THEN RE-EXTENDED TO THE INITIAL POSITION PRIOR TO A SECOND DOCKING ATTEMPT. THE AVIONICS WILL ALSO BE REINITIALIZED BY MEANS OF A POWER CYCLE.

To ensure the APDS mechanism did not experience excessive loads during a failed capture that could damage mechanism components and to ensure all active dampers have disengaged, the ring will be extended with the fixers off to the forward position (in order to force alignment), then retracted and re-extended. This allows a review of the drive system characteristics (drive time, currents) as an indicator of system health. The ring also needs to be realigned to be in the proper position for the next docking attempt. The avionics will also be reinitialized to ensure that its logic is in the proper state for another docking attempt.

- B. AFTER AN UNSUCCESSFUL DOCKING ATTEMPT DURING WHICH THE APDS ACTIVE DAMPING WAS COMMANDED ON, A SECOND DOCKING ATTEMPT WILL NOT BE ATTEMPTED UNTIL THE DAMPING MECHANISM IS CONFIRMED TO BE DISENGAGED.

During 6 degree-of-freedom docking loads testing in Moscow, an instance occurred during which the damping mechanism did not disengage after the damping commands were removed. During the next test, loads in excess of the acceptable docking loads were noted. Upon investigation of the high loads, it was determined that the damping mechanisms clutch had not disengaged. Therefore, to ensure that a similar problem does not occur during the Shuttle/ISS docking missions, a second docking attempt, following an attempt that failed after the dampers were commanded ON, should not be performed until the dampers can positively be verified disengaged. ©[021199-6816]

A10-346 **APDS REDUNDANCY REQUIREMENTS**

IN SUPPORT OF ALL FLIGHTS RULE {A2-104}, SYSTEMS REDUNDANCY REQUIREMENTS, EXTRAVEHICULAR ACTIVITY (EVA) WILL BE CONSIDERED AS A LEVEL OF REDUNDANCY IN ORDER TO ACCOMPLISH SHUTTLE/ISS UNDOCKING. EVA WILL BE USED AS THE THIRD METHOD TO ACHIEVE SEPARATION. ©[021199-6816]

The shuttle docking system has two sets of six hooks; each set is opened and closed by dual-motor electro-mechanical actuators and a pulley/cable drive system. Additionally, there are independent pyro systems that can remotely release the active and/or passive hooks. The active hooks pyro system releases all 12 shuttle hooks, and the passive hooks system releases all 12 passive hooks. In the event that either hooks drive system fails, and discharging either or both pyro systems is unsuccessful, the 96-Bolt EVA will be executed in order to separate the shuttle. ©[021199-6816]

A10-347 THROUGH A10-360 RULES ARE RESERVED

FLIGHT RULES

VIEWPORT SYSTEMS MANAGEMENT

A10-361 VIEWPORT (VP)

- A. WHEN THE VP IS NOT IN USE, THE OUTER COVER WILL REMAIN CLOSED. @[051194-1637]

Limiting VP use to experiment operations and earth/space observations minimizes the risk of mechanism damage (from landing loads) should the outer cover fail in the OPEN position. The outer cover provides mechanical and thermal protection when it is closed; however, it does not provide a redundant pressure seal.

- B. THE VP OUTER COVER MUST BE CLOSED WITHIN 35 MINUTES OF VP WINDOW EXPOSURE TO THE SUN IN FIELD OF VIEW (FOV) OR 2 HOURS OF VP WINDOW EXPOSURE TO DEEP SPACE (VP HEATER ACTIVATED AND FUNCTIONAL).

The sun exposure constraint precludes the VP internal surfaces from exceeding the maximum allowable touch temperature of 45 deg C (113 deg F). The deep space constraint precludes the formation of condensation on the actuator mechanism and VP glass (a free fluid, ice formation, and hardware degradation concern), and ensures VP seal integrity. The VP lower thermal qualification limit is -10 deg C (14 deg F). @[111501-4966A]

The sun is in FOV of the VP whenever it is within a 60 deg half-cone angle about the VP normal vector. The VP is exposed to deep space whenever the sun and the entire earth are outside an 80 deg half-cone angle about the VP normal vector. (The VP normal vector is in the orbiter -Z body axis.)

Reference: JSC-16744, Spacelab Operational Data Book (SLODB) 3.5.1, Constraints/Contingency Operations; TR-OK-0008, Thermal Vacuum Test Results: Viewport; TN-ER-36-061-77, VP/Viewport Adapter Assembly (VAA) Thermal Analysis, 5/30/78; and MDC-93-W-5652, 5/93. @[051194-1637]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-361

VIEWPORT (VP) (CONTINUED)

- C. THE INNER SAFETY COVER SHOULD REMAIN INSTALLED ON THE VP AT ALL TIMES, UNLESS ITS REMOVAL IS REQUIRED FOR PAYLOAD ACCOMMODATIONS OR PHOTOGRAPHY. THE INNER SAFETY COVER MUST BE INSTALLED PRIOR TO MODULE EGRESS. (INSTALLATION IS REQUIRED WHEN EGRESSING FOR MODULE DEACTIVATION, ENTRY PREP, OR EVA PREPARATIONS; INSTALLATION IS NOT REQUIRED WHEN EGRESSING FOR EMERGENCY DEACTIVATION.) AN INNER SCREEN OTHER THAN THE INNER SAFETY COVER WILL NOT BE INSTALLED ON THE VP.
 ©[051194-1637] ©[111501-4966A]

The VP glass assembly contains three laminated panes of Triplex "10-20" glass (26mm total thickness). Because these panes are laminated, the assembly cannot be considered fail-safe. However, the inner safety cover (a safety pane of polycarbonate plastic) provides a structural seal over the VP aperture that allows sufficient time to complete a contingency Spacehab deactivation/evacuation of the module in the event of a total glass failure. (A small port in the inner safety cover allows for venting/air circulation/pressure equalization between both sides of the cover.) The inner safety cover also protects the VP glass against impact from inside the module. However, safe return of the crew is not compromised if the inner safety cover is not installed for a Spacehab emergency deactivation. To preclude the scenario where an EVA is required during the mission, and subsequent module ingress is not possible, the inner safety cover must be installed to properly restrain it for entry. An installed inner screen (other than the inner safety cover) can cause a potential "greenhouse" effect from solar radiation whenever the outer cover is open, or from a failed on VP heater whenever the outer cover is closed. Either case can cause VP glass degradation. The inner safety cover provides similar optical qualities (transmissivity) as the VP glass assembly.

Reference: TN-ER-36-061-77, VP/Viewport Adapter Assembly (VAA) Thermal Analysis, 5/30/78.

- D. THE VP HEATER MUST BE ACTIVATED WHENEVER THE VP WINDOW IS EXPOSED TO DEEP SPACE, OR AT ANY TIME CONDENSATION FORMS ON THE VP GLASS OR ACTUATOR MECHANISM. THE VP HEATER MAY REMAIN POWERED FOR NO LONGER THAN 20 MINUTES WHEN THE SUN IS IN FOV OF THE VP GLASS.

The VP heater is only required when the VP window is exposed to deep space to prevent condensation from forming on the VP glass and/or to extend the time until condensation forms on the VP actuator. The seals will remain above the lower thermal qualification limit of -10 deg C (14 deg F) if the deep space exposure time limits are not exceeded, and/or the heater is active. The VP inner surface may exceed the maximum allowable touch temperature of 45 deg C (113 deg F) if the heater is activated with the outer cover closed, if the VP glass is not exposed to deep space, or if the VP heater is powered for more than 20 minutes with the sun in FOV of the VP glass.

Reference: TR-OK-0008, Thermal Vacuum Test Results: Viewport; and MDC-93-W-5652, 5/93.
 ©[051194-1637]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-361 VIEWPORT (VP) (CONTINUED)

- E. ORBITER ATTITUDE ADJUSTMENTS MAY BE MADE TO MAINTAIN THE VP TEMPERATURE WITHIN OPERATIONAL LIMITS IF HIGH PRIORITY MISSION OBJECTIVES ARE NOT JEOPARDIZED. @[051194-1637]

If required to work around an outer cover and/or heater failure, adjusting the attitude timeline is an acceptable option for maintaining the VP temperature within operational limits as long as high priority mission objectives are not significantly affected. The VP lower thermal qualification limit is -10 deg C (14 deg F); the upper limit is 60 deg C (140 deg F).

- F. ON-ORBIT VP ATTITUDE TIMELINE MANAGEMENT TO ENSURE COMPLIANCE WITH VP OPERATIONAL FLIGHT RULES/TEMPERATURE LIMITS IS THE RESPONSIBILITY OF MISSION CONTROL CENTER-HOUSTON (MCC-H).

Due to the dynamic nature of orbiter flight attitude timeline changes, MCC-H management of on-orbit VP operations will be required to ensure VP FOV constraints and operational temperature limits are not exceeded.

A10-362 CRACKED VIEWPORT

FOR A CRACKED VP WINDOW, THE INNER SAFETY COVER WILL BE INSTALLED, AND THE OUTER COVER WILL BE CLOSED AND REMAIN CLOSED. SPACEHAB OPS WILL BE ALLOWED TO CONTINUE IF THE VP WINDOW CAN MAINTAIN PRESSURE INTEGRITY.

The VP glass assembly contains three laminated panes of Triplex "10-20" glass (26 mm total thickness), each of which is capable of maintaining pressure. However, the VP inner safety cover (a safety pane of polycarbonate plastic) provides a structural seal over the VP aperture that allows sufficient time to complete a contingency Spacehab deactivation/evacuation of the module in the event of a total glass failure (A small port in the inner safety cover allows for venting/air circulation/pressure equalization between both sides of the cover.) VP operations should be terminated in order to minimize thermal stresses on a cracked VP window. Installing the inner safety cover and closing the outer cover ensures containment of any loose glass debris. Installing the VP inner safety cover also ensures safe continuation of Spacehab operations by providing cabin pressure redundancy (as long as the VP window is maintaining pressure). @[051194-1637]

FLIGHT RULES

A10-363 **VIEWPORT CONFIGURATION FOR CLOSED SPACEHAB HATCH**

FOR SPACEHAB OPERATIONS WITH THE SPACEHAB HATCH CLOSED, THE VP OUTER COVER WILL BE CLOSED AND THE INNER SAFETY COVER WILL BE INSTALLED. ©[051194-1637] ©[021600-7101]

Failure conditions exist which would prevent re-entry into the module (e.g., after an EVA) to secure the viewport. If orbiter entry is performed with the external cover open, damage to the cover/viewport is likely to occur.

A10-364 **LOSS OF VP PRESSURE INTEGRITY**

FOR LOSS OF VP PRESSURE INTEGRITY, THE INNER SAFETY COVER WILL BE INSTALLED, AND THE OUTER COVER WILL BE CLOSED AND REMAIN CLOSED. SPACEHAB OPERATIONS WILL BE TERMINATED.

The VP inner safety cover provides a structural seal over the VP aperture that allows sufficient time to complete a contingency Spacehab deactivation/evacuation of the module when VP pressure integrity has been lost. (A small port in the inner safety cover allows for venting/air circulation/pressure equalization between both sides of the cover.)

A10-365 **EVA REQUIREMENTS FOR FAILED VP OUTER COVER**

AN EVA IS NOT REQUIRED TO STOW OR SECURE A FAILED OPEN VP OUTER COVER.

When open, the VP outer cover does not infringe upon the PLBD dynamic envelope. Although there is a potential for VP mechanism damage from landing loads, the risk of an EVA to stow the outer cover is not warranted. ©[051194-1637]

©[021998-6492] ©[121400-3850]

A10-366 THROUGH A10-380 RULES ARE RESERVED

FLIGHT RULES

STRUCTURAL MANAGEMENT

A10-381 THERMAL WINDOWPANE FAILURE [CIL]

A THERMAL WINDOWPANE IS CONSIDERED FAILED IF PIECES OF THE PANE ARE MISSING. A CRACKED THERMAL WINDOWPANE IS NOT CONSIDERED FAILED WHILE THE PANE REMAINS INTACT.

NOTE: THE PROBABILITY OF A CRACKED PANE FAILING IS HIGHEST DURING THE MAXIMUM DYNAMIC PRESSURE PHASE (MAX Q) (T=40 TO T=60).

FOR A FAILED FORWARD WINDSHIELD OR SIDE HATCH THERMAL WINDOWPANE PRIOR TO THE RTLS BOUNDARY, ABORT RTLS, OTHERWISE CONTINUE EOM. FOR A FAILED OVERHEAD THERMAL WINDOWPANE, CONTINUE EOM.

A thermal windowpane could fail due to flaws caused by ice or other debris impacting it during ascent. A cracked thermal windowpane is more likely to fail during MAX Q phase. An RTLS abort should be performed if possible to minimize thermal effects on the remaining windowpanes and structure, as the RTLS abort has the most benign reentry thermal environment of all entry modes. The nominal and the thermally similar AOA impose the most heating on the panes.

TAL aborts have a slightly more benign thermal environment with respect to the windowpanes and surrounding structure than the nominal EOM. However, the risk of a TAL abort outweighs the benefit of slightly less heating on the windows. Therefore, post-RTLS, no other abort should be initiated. The overhead windows are not considered for an RTLS abort since the thermal environment for these windows during a nominal EOM entry is relatively benign (ref. A/E FTP #68, June 29, 1990).

A side hatch thermal pane failure may be undetectable during ascent because of crew visibility. For a failed side hatch thermal pane or forward windshield past the RTLS boundary, thermal conditioning of the affected window may be required prior to deorbit, based on real-time thermal analysis.

Rule {A2-54A}.2, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL], references this rule. ©[021998-6493]

FLIGHT RULES

A10-382

PRESSURE/REDUNDANT WINDOWPANE FAILURE

FOR A FAILURE OF EITHER A PRESSURE PANE (I.E., UNIFORM SHATTERING OF AN INNER PANEL INTO SMALL PIECES) OR A REDUNDANT PANE (I.E., CRACKED OR SHATTERED PANE WITH FRAGMENTS AROUND RETAINER FRAME), CABIN PRESSURE WILL BE REDUCED TO 10.2 PSI. CABIN DEPRESSURIZATION WILL NOT BE ATTEMPTED PRIOR TO THE POST INSERTION TIMEFRAME OR AFTER SEAT INGRESS FOR ENTRY:

- A. ON ASCENT, AN ORBIT 3 ENTRY WILL BE PERFORMED.
- B. ON ORBIT, ENTER NEXT PLS.

A severe impact may break the pressure pane. Neither the pressure pane (other than severe impact) nor the redundant panel should fail. If a failure of one of these panes has occurred for an unknown reason, the remaining windows may be threatened. Pressure redundancy is required in the orbiter window system (the thermal panel does not provide cabin pressure redundancy). The pressure redundancy requirement is violated with a failure of any one of the pressure panes or redundant panes (windshields, overhead windows, rear viewing windows, or side hatch window). Loss of both the pressure pane and the redundant pane in a window would result in loss of crew and orbiter.

Flight techniques discussions have resulted in the choice of an orbit 3 deorbit as the best choice to minimize exposure time to a single string windowpane situation without the risks entailed in more rapid abort situations. A reduced cabin pressure is desired due to the time-at-stress nature of windowpane failures.

Flight Techniques have indicated that wearing the LES helmet for the 4.6 hours of orbit 3 is acceptable. The reason for wearing the LES helmet after a pressure pane failure is to reduce the possibility of crewmember exposure to shattered pane particles. The LES helmet must be worn for all entries; therefore, using anticontamination goggles and masks until donning the LES helmet is not desired for the orbit 3 case due to the possibility of contamination during the donning process.

Reference Ascent Flight Techniques Panel Meetings #33 and #36, August 28 and October 15, 1987.

FLIGHT RULES

A10-383

BAILOUT/POSTLANDING EMERGENCY EGRESS PYROTECHNICS MANAGEMENT

- A. THE SAFING PIN FOR THE T-HANDLE BOX COVER WILL BE REMOVED AND STOWED PRELAUNCH, REINSTALLED DURING POST INSERTION, REMOVED AND STOWED DURING DEORBIT PREP, AND REINSTALLED POSTLANDING.

This procedure improves access to the pyro vent valve and side hatch jettison T-handles during an ascent, entry, or postlanding emergency, and ensures that the handles are less accessible at other times.

- B. THE SAFING PINS FOR THE PYRO VENT VALVE AND SIDE HATCH JETTISON T-HANDLES WILL NOT BE REMOVED UNLESS REQUIRED FOR ORBITER BAILOUT OF EMERGENCY GROUND EGRESS.

The purpose of this rule is to prevent accidental activation of the handles. Removal of the safing pins requires less than 1 second for each handle; therefore, an insignificant time delay is imposed during an emergency.

- C. THE PYRO VENT VALVE WILL ONLY BE ACTIVATED:
1. DURING AN IN-FLIGHT BAILOUT, PRIOR TO JETTISONING THE SIDE HATCH.
 2. DURING A POSTLANDING EMERGENCY EGRESS, IF NECESSARY.

The purpose of the pyro vent valve is to equalize the difference in pressure between the crew compartment and the outside atmosphere. If the side hatch is jettisoned during an in-flight bailout before the pressure is equalized, the large delta P will probably cause the floor of the middeck to buckle, leading to extensive damage within the vehicle. The postlanding delta P is much smaller and will not buckle the middeck floor. Because the pyro vent valve is an ignition source in the payload bay, it should not be activated postlanding unless a side hatch emergency egress is impossible and the overhead escape panel (W8) will not open due to the delta P.

- D. THE SIDE HATCH WILL ONLY BE JETTISONED:
1. DURING AN IN-FLIGHT BAILOUT.
 2. DURING A POSTLANDING EMERGENCY WHERE THE SIDE HATCH CANNOT BE OPENED NORMALLY AND RAPID EGRESS OF THE CREW IS NECESSARY IN ORDER TO PREVENT LOSS OF LIFE. IN THIS CASE, THE CREW SHALL MAKE EVERY EFFORT TO VERIFY THAT ALL FIRE/RESCUE PERSONNEL ARE CLEAR OF THE SIDE HATCH BEFORE IT IS JETTISONED.

This rule prevents unnecessary damage to the orbiter and minimizes the risk that side hatch jettison poses to fire/rescue personnel.

FLIGHT RULES

A10-384 **MAXIMUM NUMBER OF FILLED CWC'S**

THE NUMBER OF FILLED CONTINGENCY WATER CONTAINERS (CWC'S) WILL NOT EXCEED THE NUMBER OF AVAILABLE CERTIFIED STOWAGE LOCATIONS, AS DETAILED IN THE FLIGHT SPECIFIC RULES ANNEX. @[100997-6345A]

This assures that, in the event of an unplanned deorbit (PLS), all CWC's can be stowed in locations that will not cause structural damage or endanger the crew in the event of a hard landing. Determination of the number and placement of CWC's is performed by DF54/Crew Systems. Reference OFTP #161, February 14, 1997. @[072398-6621]

A10-385 **FILLED CWC STOWAGE MANAGEMENT**

A. FILLED CONTINGENCY WATER CONTAINERS (CWC'S) THAT MUST BE RETURNED IN THE ORBITER WILL BE DISPOSED OF WITH THE FOLLOWING PRIORITY, TIME AND AVAILABILITY PERMITTING:
@[100997-6345A] @[032802-5305]

1. OVERBOARD NOZZLE DUMP @[032802-5305]

A filled CWC represents a considerable mass that must be properly restrained to insure structural loads will not be violated in an emergency landing. CWC's can be used to transfer water from the orbiter to ISS. Stowage of filled CWC's will be required if water transfer cannot be accomplished. For ISS water transfer, CWC's are normally filled to approximately 100 lbs. This weight is assumed below, unless otherwise stated. Reference SODB, vol. I, 3.4.1. To avoid the stowage and structural limits concern, it is most desirable to dump the water from the CWC's overboard and then stow the empty CWC's. Filled CWC's can also represent considerable mass stowed far forward of the orbiter CG. An overboard CWC dump prior to deorbit may relax propellant margins if ballasting would otherwise be increased. However, there must be adequate time to dump water from filled CWC's overboard prior to deorbit prep. Flight data from STS-60 shows that it takes approximately 1 hour to dump a single CWC (the rate is 1.56 lbm/min). Certain stowage locations can accept loads imposed by a filled CWC during landing and will be utilized if dump capability is not available. In cases where propellant margins are tight, stowage locations minimizing ballast requirements are preferred. @[100997-6345A] @[092701-4840]

FLIGHT RULES

A10-385

FILLED CWC STOWAGE MANAGEMENT (CONTINUED)

- [1] ANY VOIDS SURROUNDING A CWC MUST BE FILLED WITH SOFT GOODS SUCH AS CLOTHING TO ENSURE THAT THE CWC IS SUPPORTED ON ALL SIX SIDES. @[032802-5305]
 - [2] 206 LBS IS MAX WEIGHT OF EXTERNAL AIRLOCK BAG. EXT A/L IS LIMITED TO 990 LBS MINUS THE WEIGHT OF EMU'S (TWO @ 330 LBS EACH). 649 IN. IS X-CG FOR BAY 2 EXTERNAL AIRLOCK LOCATION. 731 IS X-CG FOR BAY 3 EXTERNAL AIRLOCK LOCATION (FORWARD TUNNEL ADAPTER).
 - [3] THE LIMITS ARE VALID FOR THE SMALL AND LARGE VERSIONS OF THE MIDDECK BAG. @[072398-6621]
 - [4] 95 LBS EACH.
 - [5] RESERVED @[092701-4840]
 - [6] CWC'S STANDING ON END, SIDE-BY-SIDE
 - [7] AVAILABLE ONLY ON OV-102 WITH RCRS
 - [8] LOCKER REMOVAL REQUIRED TO ALLOW ACCESS TO VOLUME G. @[100997-6345A]
 - [9] ONLY AVAILABLE ON OV-102 @[022201-3987]
 - [10] VOLUME NOT AVAILABLE ON OV-103
3. DUMP INTO WCS. @[032802-5305]

This option would only apply if the nozzle dump were unavailable, no certified stowage was available, and adequate time existed. There is only limited ullage in the waste tank, and it is time consuming for the crew to do this. @[100997-6345A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A10-385 FILLED CWC STOWAGE MANAGEMENT (CONTINUED)

4. STOWED AND RESTRAINED IN THE FOLLOWING UNCERTIFIED LOCATIONS: @[032802-5305]

LOCATION	MAXIMUM WEIGHT (LBS.)	ORBITER COORDINATES			MAX. # CWC'S
		X _o	Y _o	Z _o	
EXTERNAL AIRLOCK FLOOR	300 (MINUS WEIGHT OF OTHER FLOOR STOWAGE)	649 (BAY 2) 731 (BAY 3)	0	333	2
FORWARD TUNNEL ADAPTER FLOOR	TBD	582	0	333	2
INTERNAL AIRLOCK FLOOR	225 WITH 4 EMU'S INSTALLED	545	0	333	2

@[100997-6345A]

These locations have not been certified, due to possible inability to fully restrain CWC's. These locations should only be used when necessitated by lack of certified stowage and the time criticality of entry. The priority reflects the desire to remove the CWC's as far as possible from the cabin, due to the possibility of hatch penetration by the CWC as a projectile during hard landing. Leakage or failure of a CWC carries the risk of damaging electronic equipment stowed in these locations. All stowage in these locations should be restrained on the floor in such a manner that it does not interfere with, or damage existing, certified equipment stowed nearby during landing settling. Gray tape and bungies are suggested (although uncertified) methods of restraint. @[100997-6345A]

B. THE NUMBER OF FILLED CWC'S IN THE ORBITER WILL NOT EXCEED THE NUMBER OF CERTIFIED STOWAGE LOCATIONS AVAILABLE FOR LANDING. THE MAXIMUM NUMBER OF FILLED CWC'S THAT MAY BE RETURNED IN THE ORBITER IS FOUR. EXCEPTIONS/ADDITIONS TO THIS LIMIT WILL BE ADDRESSED IN THE FLIGHT-SPECIFIC ANNEX.

Preflight planned stowage has been reviewed and the number of certified stowage locations is limited to this amount. The available CWC stowage locations are Vol H (1), Vol G (1), and Vol F (2). Changes to this limit based on planned stowage will be addressed on a flight-by-flight basis in the Flight-Specific Annex.

Analysis of the number of CWC's is performed by DX33/Crew Systems (OFTP #161, February 14, 1997). The structurally certified stowage locations are listed in Rule {A10-385B}, FILLED CWC STOWAGE MANAGEMENT. @[032802-5305]

FLIGHT RULES**A10-1001 MMACS GO/NO-GO CRITERIA (CONTINUED)**

The table above gives the action taken for specific MMACS hardware losses. The decision to invoke MDF or to enter next PLS is based on redundancy and safety requirements. Refer to the MMACS systems loss/failure definitions for what constitutes a "down" system.

NOTES:

- [1] LOSS OF A WSB COULD RESULT IN EVENTUAL LOSS OF ITS ASSOCIATED APU AND HYDRAULIC SYSTEM.
- [2] IF TWO APU'S ARE SHUT DOWN DURING ASCENT, AND THE THIRD APU/HYDRAULIC/WSB SYSTEM PERFORMANCE IS NOMINAL, THE THIRD ONE WILL BE SHUT DOWN AND LATER RESTARTED TO SUPPORT A DAY 1 PLS. THE THIRD APU/HYDRAULIC/WSB WILL NOT BE SHUT DOWN FOR AN AOA, TAL, OR RTLS ABORT. IF THE THIRD APU/HYDRAULIC/WSB SYSTEMS ARE NOT NOMINAL, IT WILL BE SHUT DOWN AND RESTARTED AS REQUIRED TO SUPPORT ANY ABORT OR ENTRY.
- [3] HYDRAULIC SYSTEM 1 PLUS 2 PYROS.
- [4] MUST BE CLOSED PRIOR TO ENTRY.
- [5] FAILURE TO DEPLOY ONE RADIATOR PANEL WILL RESULT IN A 20 TO 30 PERCENT LOSS OF HEAT REJECTION IN THAT FCL/RAD. ORBIT LIFETIME WILL BE DEPENDENT ON ORBITER THERMAL HEAT REJECTION REQUIREMENTS.
- [6] NEXT PLS IF IN SEPARATE LATCH GANGS AND NEXT FAILURE RESULTS IN MULTIPLE LATCH GANG FAILURES, OR IN SAME LATCH GANG AND CANNOT BE VISUALLY VERIFIED CLEAR OF ROLLERS. NOMINAL EOM IF IN SAME LATCH GANG AND CAN BE VISUALLY VERIFIED CLEAR OF ROLLERS.
- [7] RESERVED.
- [8] SAME DOOR. IF DOOR OPEN AND OPEN CAPABILITY LOST, INVOKE MDF. ENTRY IS REQUIRED AT NEXT PLS AFTER EVA TO CLOSE DOORS IS COMPLETED.
- [9] KU-BAND ANTENNA WILL BE STOWED FOR LOSS OF REDUNDANT STOW CAPABILITY.
- [10] ENTER NEXT PLS IF ONE APU/HYD/WSB FAILED AND THE NEXT FAILURE RESULTS IN A SINGLE APU ENTRY.
- [11] ENTER NEXT PLS AFTER EXPEDITED PAYLOAD DEPLOY, IF APPLICABLE.
- [12] IF PIECES ARE NOTED MISSING PRIOR TO THE RTLS BOUNDARY, AN RTLS ABORT WILL BE PERFORMED. OTHERWISE, CONTINUE NEOM.
- [13] ENTER NEXT PLS IF TIRE PRESSURE WILL BE \leq 260 PSIG (275 PSIA) AT NEXT PLS LANDING OPPORTUNITY PLUS 2 DAYS.
- [14] IF CAPABILITY TO CLOSE ET DOORS IS LOST PRIOR TO RTLS BOUNDARY, PERFORM AN RTLS. @[041097-4611B]

FLIGHT RULES

THIS PAGE INTENTIONALLY BLANK

FLIGHT RULES

SECTION 11 - COMMUNICATIONS

SYSTEM MANAGEMENT RULES

A11-1 COMMUNICATIONS DURING ASCENT

THERE ARE NO COMMUNICATIONS FAILURES FOR WHICH THE ASCENT PHASE WILL BE TERMINATED.

Termination of the ascent phase implies an immediate return; i.e., an RTLS, AOA, or TAL/TPL. Continuing to orbit is the most benign environment for the orbiter and crew. In addition, there is a high probability of restoring at least one communications link once on orbit; and, if communication is not restored, the orbiter is capable of a safe day 1 return without any further contact with the MCC.

A11-2 S-BAND/UHF LAUNCH REQUIREMENT

S-BAND PM VOICE WILL BE PRIME FOR LAUNCH. THE UHF SYSTEM WILL BE CONFIGURED IN TRANSMIT/RECEIVE MODE AS BACKUP TO THE S-BAND PM SYSTEM.

The S-band PM system is the only system available for launch that can provide redundant real-time telemetry, command, ranging, and duplex voice required for ascent phase support. SSME engine interface unit (EIU) data uses the S-band FM system and is redundantly recorded on Ops recorder 1. C-band skin tracking provides a redundant tracking source, and the UHF system provides an additional simplex voice source.

FLIGHT RULES

A11-3

UPLINK HANDOVER DURING ASCENT FROM KSC

UPLINK HANDOVER FROM MIL TO PDL WILL OCCUR BEFORE THE LINE-OF-SIGHT FROM THE ORBITER TO MIL INTERSECTS THE SRB PLUME. THE CARRIER WILL REMAIN ON PDL UNTIL POST-SRB STAGING. AT THAT TIME IT WILL BE HANDED BACK TO MIL TO REGAIN S-BAND TRACKING.

During ascent it is highly desirable to provide S-band ranging data to the MCC as an additional tracking source for trajectory evaluation. S-band ranging is available from MIL/MILX but not PDL. Ascents from KSC necessarily result in the line-of-site from the orbiter to MIL/MILX intersecting the SRB plume. The SRB plume characteristics are such that severe S-band attenuation (approaching 60 dB) and erratic phase shifts will adversely affect the S-band PM link, resulting in poor uplink lock conditions and intermittent downlink data. To avoid the plume, the orbiter antennas are optimized for PDL from lift-off and the uplink is handed to PDL just before plume intersection until after SRB staging. This loss of S-band ranging and somewhat weaker signal margin during this time period is considered preferable to intermittent S-band uplink and downlink lock conditions, since downlink vectors and C-band tracking are still available for trajectory monitoring. ©[092602-5734]

A11-4

ORBITER DATA PRIORITY DURING ASCENT/ENTRY

ORBITER DATA WILL TAKE PRIORITY OVER PAYLOAD DATA DURING ASCENT/ENTRY. PCMMU SWITCHES FOR THE PURPOSE OF RECOVERING ORBITER DATA WILL BE PERFORMED AT THE EXPENSE OF PDI PAYLOAD DATA.

OI MDM port failures and internal PCMMU failures affecting downlink or crew display of orbiter data can be recovered by power cycling the active PCMMU or by switching to the alternate PCMMU. During ascent/entry phases, when the SM major function for PCMMU reloading is unavailable, the PDI data downlinked to the MCC would be lost as the PCMMU defaults to Format 129 upon powerup and this format allocates no bandwidth to PDI data. The intent of this rule is to document that monitoring of orbiter data during ascent/entry takes precedence over remoting payload data to remote POCC's. PDI data displayed to the crew will not be affected.

FLIGHT RULES

A11-5 **POSTLANDING S-BAND ANTENNA SELECTION**

MCC WILL INSURE THAT THE UPPER ANTENNAS ARE SELECTED FOR POSTLANDING COMMUNICATIONS SUPPORT.

- A. MCC WILL NOMINALLY INHIBIT BFS ANTENNA POINTING AND SELECT UPPER ANTENNAS VIA COMMAND POST WHEELSTOP.
- B. FOR LOSS OF MCC COMMAND THE CREW WILL BE INSTRUCTED TO MANUALLY SELECT THE PROPER UPPER ANTENNAS AFTER WHEELSTOP.

Upper antennas are required to protect the convoy personnel from RF radiation. BFS automatic antenna pointing is required to be inhibited due to nominal postlanding nav state "drift". This drift in orbiter position could cause an inadvertent antenna selection which could result in a loss of comm or a hazard to the convoy personnel. If command is not available the crew will be instructed to manually select the proper upper antennas which overrides the BFS automatic pointing capability. This task will be performed for both GSTDN and TDRS landings.

A11-6 **MINIMUM COMMUNICATIONS REQUIREMENTS FOR SCHEDULED EVA**

IN ORDER TO COMMIT TO OR CONTINUE A SCHEDULED EVA, EACH EVA CREWMEMBER MUST HAVE TWO-WAY COMMUNICATIONS WITH THE ORBITER, EITHER DIRECTLY OR VIA THE OTHER EVA CREWMEMBER.

All scheduled EVA's are planned for two crewmembers who are trained to coordinate their activities and accomplish their task within a limited time. EVA activities often result in encountering unforeseen problems which must be solved by the EVA crewmember on the scene as the orbiter and MCC are in a poor position for offering assistance. Additionally, the EVA crewmembers must always be prepared to assist each other in case of emergency. As long as the EVA is scheduled and not required for contingency reasons (e.g., failure of the payload bay doors to close), it is not prudent to attempt an EVA without adequate means of crew coordination, even if some mission objectives cannot be accomplished.

Rule {A15-7}, MINIMUM RF COMMUNICATIONS DEFINITION, references this rule.

FLIGHT RULES

A11-7

KU-BAND OPERATIONS DURING EVA

- A. FOR EVA ACTIVITIES CONDUCTED WITHIN THE AREAS PROTECTED BY THE KU-BAND BETA MASK OR ORBITER STRUCTURAL BLOCKAGE, THE KU-BAND MAY BE OPERATED WITHOUT POINTING CONSTRAINTS DURING AOS AND WILL BE PLACED IN STANDBY DURING LOS.

When EVA activities are conducted within the areas protected by the microprocessor mask (including the Beta function in the communication mode) or orbiter structural blockage, the Ku-band transmitter is automatically turned off protecting the crew. The radiation exposure levels will remain below 20 volts/meter which is the limit exposed by the EMU specification. Although a single-point failure which could allow the transmitter to radiate into the normally protected region exists, the risk is considered acceptable because the MCC will monitor the automatic cutoff function during AOS and because a redundant cutoff function (standby mode) will be commanded by MCC to be effective during LOS periods. No permanent damage is expected at levels exceeding 20 volts/meter although this has not been confirmed by tests. Human exposure limits have been defined as 137 volts/meter. ©[ED]

1. A BETA MASK OF 0 DEGREES BETA ONLY WILL BE USED TO PROTECT EVA CREWMEMBERS OPERATING WITHIN THE GENERIC PAYLOAD BAY ENVELOPE. REFERENCE RULE {A15-24}, EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE. ©[ED]
2. A BETA MASK OF 21 DEGREES BETA + MASK WILL BE USED TO PROTECT EVA CREWMEMBERS OPERATING ENTIRELY WITHIN THE CONFINES OF THE PAYLOAD BAY MOLDLINE.

Analysis presented at EVA Flight Techniques #16 in January 1992 revealed that a Beta Mask of 0 degrees Beta Only will protect any EVA crewmember confined to operating within the limits of the generic payload bay envelope as defined in Rule {A15-24}, EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE. The SM default value of 21 degrees Beta + Mask is known to protect the Orbiter payload bay moldline boundary. ©[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A11-7

KU-BAND OPERATIONS DURING EVA (CONTINUED)

- B. FOR EVA ACTIVITIES WHICH MAY BE CONDUCTED EXTERNAL TO THE KU-BAND PROTECTIVE BETA MASK OR ORBITER STRUCTURAL BLOCKAGE, THE KU-BAND SYSTEM/ORBITER ATTITUDE WILL BE MANAGED TO PRECLUDE RADIATING THE EVA CREWMEMBER WITH AN EXPOSURE OF > 20 VOLT/METER OR EXPOSURE IN THE MAIN BEAM AT A RANGE < 125 METERS FROM THE ANTENNA FACE. DURING AOS PERIODS, THE CREW AND THE MCC WILL BOTH BE PREPARED TO TAKE THE KU-BAND SYSTEM TO STANDBY IN THE EVENT THAT THE LINE OF SIGHT CROSSES INTO THE PROTECTED HEMISPHERE. DURING PREDICTED LOS PERIODS, THE MCC WILL COMMAND THE KU-BAND SYSTEM TO STANDBY. @[021998-6515A]

When EVA activities are conducted outside the areas protected by the microprocessor mask or orbiter structural blockage, the Ku-band transmitter is not automatically turned off to protect the crew. In this case it is acceptable to manage the orbiter attitude so that Ku-band pointing will be restricted to the + Z hemisphere (below the X-Y plane) while EVA activities will be conducted in the opposite hemisphere. The crew and the MCC will both be prepared to take the Ku-band to STANDBY in the event that the line of sight crosses into the protected hemisphere. This will be based upon predicted times and will be backed up with real-time monitoring of antenna position. During predicted LOS periods, the MCC will command the Ku-band to STANDBY to positively preclude any possibility of radiation. The maximum exposure levels are defined in the rule for reference. @[021998-6515A]

- C. IF THE MMU IS FLOWN OUTSIDE THE PAYLOAD BAY AND SIMULTANEOUS KU-BAND TRANSMISSION IS REQUIRED, THEN MMU FLIGHT WILL BE RESTRICTED TO THE ORBITER - Z HEMISPHERE AND THE KU-BAND ANTENNA POINTING WILL BE RESTRICTED TO THE + Z HEMISPHERE.

The rationale for this rule applying to MMU operations is same as rationale for paragraph B.

- D. USE OF THE KU-BAND IN THE LOW POWER RADAR MODE DURING EVA OPERATIONS IS UNRESTRICTED.

When the Ku-band system is in the radar mode with low power selected, analysis has shown that the crewmember radiation limits will not be exceeded at any range or look angle. Therefore, EVA operations may be freely conducted without any special monitoring or procedure for the purposes of avoiding excessive radiation levels of exposure.

Rule {A15-24}, EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE, references this rule.

FLIGHT RULES

A11-8

ORBITER S-BAND OPERATIONS DURING EVA

- A. ALL ORBITER S-BAND SYSTEMS MAY BE OPERATED WITHOUT RESTRICTION DURING EVA OPERATIONS CONDUCTED WITHIN THE GENERIC PAYLOAD BAY ENVELOPE.

The generic payload bay EVA envelope was developed assuming the use of simple avoidance to control S-band radiation to less than 120 V/M (ref. Rule {A15-24}, EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE).

- B. ALL ORBITER S-BAND SYSTEMS MAY BE OPERATED WITHOUT RESTRICTION DURING EVA OPERATIONS OUTSIDE THE GENERIC PAYLOAD BAY ENVELOPE AS LONG AS THE EVA CREWMEMBER REMAINS AT LEAST 1 METER AWAY FROM ANY RADIATING OR POTENTIALLY RADIATING ANTENNA.

An S-band dipole antenna "near field" is generally considered to extend approximately 1 meter from the antenna in all directions. Within this near field region, exact field intensities cannot be computed, and as such, could exceed the acceptable level for the EMU (120 V/M). If an antenna is totally inhibited (e.g., PI turned OFF or S-band FM forced to the lower antenna by crew switch) then the EVA crewmember is not at risk in approaching these antennas. Since an S-band PM antenna under GPC control could begin radiating without warning, the crewmember must stay 1 meter away to ensure his/her safety.

- C. FOR EVA OPERATIONS WHICH MUST BE CONDUCTED LESS THAN 1 METER AWAY FROM AN ORBITER S-BAND ANTENNA, STEPS MUST BE TAKEN TO ENSURE THAT THE ANTENNA WILL NOT RADIATE WHILE THE CREWMEMBER IS WITHIN 1 METER.

An S-band dipole antenna's "near field" is generally considered to extend approximately 1 meter from the antenna in all directions. Within this near field region, exact field intensities cannot be computed, and as such, could exceed the certification level for the EMU (120 V/M). If an antenna is totally inhibited (e.g., PI turned OFF or S-band FM forced to the lower antenna by crew switch) then the EVA crewmember is not at risk in approaching these antennas. Since an S-band PM antenna under GPC control could begin radiating without warning, the crewmember must stay 1 meter away to ensure his/her safety.

Reference Documentation: United Technology/Hamilton Standard Engineering Memorandum EMUM-604, April 30, 1992.

Rule {A15-24}, EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE, references this rule.

FLIGHT RULES

A11-9

RECORDER USAGE

- A. THE OPS OR SOLID STATE RECORDERS WILL BE MANAGED FROM THE GROUND SUCH THAT ONE RECORDER WILL BE RECORDING DURING EACH LOS PERIOD. ©[092701-4847]

In order to maximize mission data recovery and retrieve data for analysis concerning events or anomalies that occur during LOS periods, the recorders will be managed accordingly. Since this is a continuous and repetitive function and since data playback involves coordination with ground stations or TDRS, it is best accomplished by the MCC rather than the crew. ©[092701-4847]

- B. OPS DATA AND VOICE (192 KBPS) WILL BE RECORDED DURING HIGH ACTIVITY PERIODS OR WHEN REQUIRED FOR CREW VOICE LOGS. DURING OTHER PERIODS, ONLY DATA (128 KBPS) WILL BE RECORDED. FOR DOD ENCRYPTED FLIGHTS, THE OPTION OF RECORDING 128 KBPS IS NOT AVAILABLE.

Crew voice will be recorded only during high activity mission phases (ascent, entry, EVA's, etc.) and upon crew request. At other times data will be recorded without voice. This technique allows quicker data retrieval as the recorders can be operated at a slower speed and dumped at an 8:1 vs. 5:1 rate with voice disabled.

- C. IF THE REQUIREMENT TO RECORD DATA AND VOICE CAUSES RECORDER CAPACITY TO BE EXCEEDED, THEN ONLY DATA WILL BE RECORDED.

If the recorders are expected to overflow for whatever reason (recorder failure, site or Ku-band problems, etc.) and data and voice recording is expected to be lost, only data will be recorded (no voice). This is the quickest and easiest way to avoid the overflow as the dump/ record ratio is then 8:1 as opposed to 5:1. The loss of crew recorded voice during high activity periods when recorded voice is scheduled can be compensated for by crew logs, more detailed real-time voice reports, or other hand-held recorders. The loss of recorded data is irretrievable, however, and should be avoided if possible.

FLIGHT RULES

A11-10

UHF USAGE

- A. THE UHF TRANSCEIVER WILL BE NOMINALLY CONFIGURED IN SIMPLEX 259.7 MHZ.

The UHF system provides a completely independent source of air/ground voice to the S-band system. The UHF system is simplex for air/ground use (one direction at a time) and can be configured to any one of three frequencies: 296.8, 259.7 and 243.0 MHz. The 243.0 MHz frequency is reserved as a guard channel (for contingency communications with air traffic control facilities only) and is not normally used on orbit. Either 296.8 MHz or 259.7 MHz can be used on orbit (not TDRS). The 259.7 MHz channel is preferred as it has the better circuit margins. Should ground interference disturb the crew, the UHF system is often turned off. It is generally turned off during DOD flights on orbit as UHF voice is not encrypted.

- B. IN THE EVENT OF A ONE-PERSON EVA, THE ORBITER WILL BE CONFIGURED FOR EVA DUPLEX, TRANSMIT ON 296.8, AND THE EVA CREWMEMBER WILL BE CONFIGURED FOR MODE "B". THERE WILL BE NO UHF COMMUNICATIONS WITH THE GSTDN. FOR A TWO-PERSON EVA, THE OTHER EVA CREWMEMBER WILL BE CONFIGURED FOR MODE "A".

During a two-person EVA it is desirable for each crewmember to transmit on his own frequency thus enabling full conferencing capability between the IVA crewmember in the orbiter and both EVA crewmembers. All three parties can have simultaneous communication, but only when the orbiter is configured for 296.8 MHz transmit; one crewmember is in EVA mode A and the other in mode B. Any other configuration results in less than full conferencing capability. In the case where there is only one EVA crewmember, it is arbitrary, from an onboard standpoint, whether or not the EMU is configured for mode A or B as either mode permits duplex communications. Mode B is preferred, however, since it uses a transmit frequency of 279.0 MHz which is not used at the GSDTN sites, thus allowing the ground an interference-free interrupt capability if required on the GSDTN prime frequency. When Mode A is used, the transmit frequency is 259.7 MHz, which coincides with the prime GSTDN UHF requiring the ground to interrupt on the GSTDN alternate frequency, 296.8 MHz. The orbiter UHF mode (the simplex power amp is bypassed) circuit margins do not permit UHF communications with the GSTDN during EVA's, but the ground will be configured to monitor the prime frequency (259.7 MHz) should the crew need to call.

FLIGHT RULES

A11-11

S-BAND FM USAGE

- A. THE S-BAND SYSTEM SHALL BE REQUIRED TO TRANSMIT MAIN ENGINE DATA DURING ASCENT PHASE.

The S-band FM system provides the only real-time source of main engine interface unit (EIU) high rate data. It is sufficiently important enough to require downlinking in real time as well as being redundantly recorded onboard.

- B. FOR THE REMAINDER OF THE FLIGHT, THE S-BAND FM SYSTEM WILL BE USED FOR TV, OPS RECORDER DUMPS, SOLID STATE RECORDERS DUMPS (SSR), REAL-TIME PAYLOAD DATA, AND PAYLOAD RECORDER DUMPS.
@[102402-5735]

The S-band FM system provides a wideband downlink to GSDTN sites (not for TDRS) which can be configured for any one of several inputs (e.g., Ops or Payload recorder dumps, SSR's, TV, and real-time analog, or digital payload data). Individual mission requirements will dictate when these inputs will be required to use the FM system for a particular flight and what the time-sharing plan will be.
@[102402-5735]

FLIGHT RULES

A11-12

S-BAND PM USAGE

- A. THE S-BAND PM SYSTEM 2 LRU'S WILL NOMINALLY BE SELECTED VIA COMMAND FOR THE ENTIRE FLIGHT. ONBOARD SWITCHES WILL BE IN THE SYSTEM 1 LRU CONFIGURATION.

Since the S-band system is the prime orbiter communications system, it is desirable that switchover capability to the redundant system be reachable from the CDR or PLT seats during ascent/entry and other high activity phases. The design of panel and command hybrid driver logic within the GCIL allows the entire S-band PM system (NSP, XPNDR, antenna electronics, Power Amp, Pre Amp) to be switched to the redundant string with a single switch on panel C3. The redundant string is selectable via the panel C3 switch (nominally string 1). The choice of system 1 or 2 is arbitrary; however, the Flight Data File has long been written assuming this configuration.

- B. THE GROUND WILL BE PRIME FOR OPERATION OF THE S-BAND PM SYSTEM.

The orbiter S-band PM system must be configured differently for TDRS, GSTDN or SGLS modes continuously as required during the flight. This is a routine, repetitive task necessary during both crew awake and crew sleep periods in order to maximize data retrieval and is best done by MCC to free the flightcrew for more mission-unique tasks. Additionally, through telemetry indications from the orbiter and using voice reports and other indications from TDRS, GSTDN, and SGLS sites, the MCC has better overall visibility into the total air/ground communications network and is better suited for operating the total system, especially during non-nominal conditions.

- C. S-BAND PM ANTENNA MANAGEMENT WILL BE VIA GPC AUTOMATIC ANTENNA SELECTION.

S-band PM antenna management can be done either manually by the crew or ground or via GPC automatic selection. As long as the GPC's knowledge of attitude and position is accurate, it is less error prone to enable automatic selection. This has the added benefit of greatly reducing crew or ground workload for what is largely a routine function.

FLIGHT RULES

A11-13

S-BAND PAYLOAD USAGE

- A. THE S-BAND PAYLOAD SYSTEM 1 LRU'S WILL NORMALLY BE USED TO SUPPORT PAYLOAD OPERATIONS. ONBOARD SWITCHES WILL MATCH THE DESIRED CONFIGURATION.

The S-band payload system consists of redundant PI/PSP strings. Although there are exceptions on some flights, the flightcrew is typically much more involved with the usage of this system than in the S-band PM system, the management of which is primarily a ground function. The switch setup for S-band PM is unmatched from that commanded so that the crew need throw a minimum number of switches to restore communications in the event of onboard failure. In the case of the S-band payload system, it is preferable to have the switches match the commanded configuration so that the crew can easily track the current status since they are the prime system operators.

- B. THE S-BAND PAYLOAD INTERROGATOR (PI) CHANNEL SELECT THUMBWHEELS WILL BE CONFIGURED SO THAT INADVERTENT PI ACTIVATION WILL NOT INTERFERE WITH THE S-BAND PM SYSTEM. THE STANDARD SETTING FOR ASCENT/ENTRY SHALL BE CHANNEL 910.
@[102402-5737]

Although the PI may be unpowered, a single-point failure exists that can inadvertently result in PI activation. Should this occur when the selected channel is one that interferes with the S-band PM uplink or downlink, a loss of uplink or downlink PM lock may occur disrupting the prime mode of communications. The cause of this unexpected disruption would be difficult to detect, result in confusion, and the workaround would not be obvious even if the alternate UHF link were available. Therefore, it should be avoided. Channel 910 is safe for ascent/entry since it cannot cause any interference. @[102402-5737]

FLIGHT RULES

A11-14 CREW ALERT SPC'S

DURING TIME PERIODS WHEN ALL CREWMEMBERS SLEEP SIMULTANEOUSLY, A CREW ALERT SPC WILL BE ROUTINELY USED TO ALERT THE CREW TO COMMUNICATIONS SYSTEMS PROBLEMS. THE SPC WILL TIME OUT APPROXIMATELY HALFWAY THROUGH THE SLEEP PERIOD IN THE EVENT OF A LOSS OF UPLINK COMMAND.

The crew alert commands result in an onboard class 3 alarm. When loaded into the SM SPC buffer during time periods when all crewmembers are sleeping, it can be used to alert the crew that uplink S-band command and probably voice capability has been lost. The crew alert commands are uplinked at the beginning of a sleep period and timetagged to execute midway through the sleep period. Should no loss of command occur, these commands are cleared from the SPC buffer before execution. If uplink command is lost, it is possible that uplink voice or even downlink voice and telemetry may be lost as well since common components are used. Single-point failures in the S-band PM system exist making this possible. UHF provides a redundant voice source but is often deactivated during crew sleep periods due to ground interference. Therefore, the crew alert commands are used to warn the crew of a possible loss of all monitoring capability and all communications capability. This is considered serious enough to wake the crew.

A11-15 ELBOW CAMERA/PAYLOAD INTERFERENCE [CIL]

FOR THOSE MISSIONS WHERE AN ELBOW CAMERA/PAYLOAD INTERFERENCE PROBLEM EXISTS, THE ELBOW CAMERA WILL NOT BE ACTIVATED UNLESS THE INTERFERENCE PROBLEM IS ELIMINATED. THIS APPLIES EVEN IF THE RMS IS DEPLOYED.

FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT RULES ANNEX.

Due to the geometry of the elbow camera 25-degree mounting wedge when the MPM is stowed, the maneuvering envelope of the camera intrudes upon the maximum payload envelope. A potential interference problem exists with a payload manifested at the same X location as the elbow camera. The interference could prevent stowing the MPM's and require an RMS jettison or EVA to close PLBD's.

FLIGHT RULES

A11-16

KU-BAND MANAGEMENT

THE ORBITER KU-BAND SYSTEM WILL BE OPERATED IN THE "BETA PLUS MASK" MODE WITH A LIMIT OF 21 DEGREES UNLESS A PAYLOAD EXTENDS BEYOND THE PAYLOAD BAY DOOR ENVELOPE. IN THIS CASE, FLIGHT-SPECIFIC KU MASKING IS DEFINED IN RULE {A2-325}, IFM PROCEDURES ON EXPERIMENTS WITH TOXIC HAZARDS. ©[ED] ©[102402-5742]

The Ku-band masking is used to protect a payload in the payload bay from the Ku main beam RF radiation. A limit of 21 degrees in the "Beta Plus Mask" mode will protect the entire bay up to the payload bay door moldline and prevent any part of the bay being exposed to a level greater than 10 volts per meter (the ICD limit). This masking mode also provides the maximum comm coverage while still providing the required protection. ©[102402-5742]

If a payload instrument is present which extends beyond the payload bay door moldline, then this masking may not protect the payload from levels higher than the ICD level. The required mode and beta limit is then dependent on the location of the payload in the bay and on the dimensions of the payload. Thus, the limit must be calculated for the specific mission case. ©[102402-5742]

Note that the beta mask function does not apply to Ku radar operation. The radar mode uses the old microprocessor mask which is equivalent to beta plus mask with a limit of -90 degrees. This is more restrictive (i.e., more protection) than 21 degrees. ©[ED]

Rule {A2-118}, RNDZ/PROX OPS COMMUNICATION SYSTEMS MANAGEMENT, references this rule. ©[061396-1961]

FLIGHT RULES

A11-17

PI CHANNELS AND S-BD FREQUENCIES COMPATIBILITIES

IN ORDER TO PREVENT MUTUAL INTERFERENCE BETWEEN THE PAYLOAD INTERROGATOR (PI) AND THE S-BAND PM SYSTEM, THE FOLLOWING PI CHANNELS AND S-BAND PM FREQUENCIES COMPATIBILITY TABLE WILL BE FOLLOWED FOR ALL PI OPERATIONS: @[090894-1648B]

COMPATIBLE PI CHANNELS AND S-BAND PM FREQUENCIES	
WHEN USING PI CHANNEL	USE S-BAND PM FREQUENCY
001-407	HIGH
408-433	NOT COMPATIBLE WITH LOW OR HIGH *
434-883	LOW
899-909	HIGH
910-920	LOW

* PI INTERFERENCE WITH SSA FORWARD LINK TEST SHOWS THAT THERE IS A POTENTIAL FOR DEGRADED SSA FORWARD LINK ACQUISITION AND; THEREFORE, THIS PI/S-BD PM COMBINATION (408-420/421-433) WILL NOT BE USED. EXCEPTIONS MAY BE MADE ON A FLIGHT SPECIFIC BASIS BY DETAILED ANALYSIS.

The S-Band PM system and Payload Interrogator selectable frequencies overlap and if not properly selected could interfere with each other. The consequence of selecting channels other than those noted in the table above are unknown and potentially compromise S-Band PM communications and/or communications with a detached payload. Reference ESTL report EE7-93-214. @[090894-1648B]

A11-18

COMSEC USAGE

IN ORDER TO PROTECT THE ORBITER FROM UNAUTHORIZED COMMANDS, THE S-BAND SYSTEM UPLINK WILL NORMALLY BE ENCRYPTED FOR ALL FLIGHTS.

Configuring the S-band uplink for encryption protects against unauthorized commands being received via both the S-band and Ku-band systems as the COMSEC equipment interfaces with the NSP which is common to both systems. Uplinks bypassing the NSP can still be received via the alternate (216 kbps) Ku-band channel, but this channel (intended for OCA and high rate payload data) does not interface with the GPC's or other critical orbiter systems. @[111298-6778] @[012402-5068]

FLIGHT RULES

A11-19

UPLINK BLOCK

- A. WHEN SM IS UNAVAILABLE AND THE UPLINK IS NOT ENCRYPTED, COMMANDS WILL BE BLOCKED VIA "UPLINK" SWITCH WHEN COMMAND ACTIVITY IS NOT REQUIRED. LOSS OF THE BLOCK FUNCTION, HOWEVER, IS NOT A CONSTRAINT TO CONTINUING TO NOMINAL EOM.

National Security Decision Directive 145 (NSDD 145) and NASA policy dictates that the uplink command path be blocked or encrypted to prohibit unauthorized command sources from reaching the orbiter. This is necessary to preclude any possibility of unwanted GMEM's, DEU equivalents, etc., from disrupting or endangering flight operations. When SM and encryption are both unavailable, the crew is required to manually enable or block the uplink using the UPLINK switch in panel C3 since no automatic function exists.

- B. WHEN SM IS AVAILABLE, UPLINK COMMANDS WILL BE AUTOMATICALLY BLOCKED BY THE SM SOFTWARE WHENEVER THE SITE-IN-VIEW FLAG IS NOT PRESENT AND THE UPLINK WILL NORMALLY BE ENCRYPTED. REFERENCE RULE {A11-64}, LOSS OF COMMUNICATION SECURITY (COMSEC).

SM software and the use of encryption provide uplink protection during on-orbit periods. Rule {A11-64}, LOSS OF COMMUNICATION SECURITY (COMSEC), addresses cases when COMSEC is failed.

A11-20

UPLINK COMMANDING DURING OPS TRANSITIONS

NORMALLY, UPLINK COMMANDING TO THE ORBITER WILL BE PROHIBITED DURING OPS MODE TRANSITIONS.

Because of software cleanup operations during an OPS transition, there is a short (1 second) window of vulnerability where a redundant set split, fail-to-sync, or erroneous command may occur if an uplink command is received. This could be hazardous during time-critical operations or could cause serious delays to mission completion operations.

FLIGHT RULES

A11-21 CRITICAL UPLINK COMMAND POLICY

CRITICAL COMMANDS SHALL NOT BE UPLINKED WITHIN 10 MINUTES OF LOS OR DURING PERIODS OF PREDICTED POOR COMMUNICATIONS UNLESS THOSE COMMANDS ARE TIME CRITICAL TO OPERATIONS.

During periods of marginal communications, error rates increase and uplinks have a higher probability of dropouts. Commands which are critical, such as GMEM's, state vectors, etc., but not time critical, should only be uplinked when sufficient time remains to assess the success of those commands on the onboard systems.

A11-22 TWO-STAGE COMMAND BUFFER TLM REJECT

NO TWO-STAGE COMMANDS SHALL BE EXECUTED WHEN THE TWO-STAGE COMMAND BUFFER IS NOT AVAILABLE VIA TELEMETRY TO VERIFY SUCCESSFUL UPLINK, WITHOUT THE APPROVAL OF THE FLIGHT DIRECTOR.

Without telemetry, the ground cannot verify that the uplinked command has correctly been received onboard. However, for cases where not executing a command may have worse consequences than the possible consequences of an erroneous command, the Flight Director may elect to approve execution of the command. @[060800-7213]

A11-23 KU BAND TRANSMITTER INHIBITED DURING ACQUISITION OF TDRS INSIDE THE RF PROTECT BOX

THE KU BAND SYSTEM SHALL BE INHIBITED FROM RADIATING, DURING ACQUISITION OF THE TDRS SATELLITE, WHEN IT IS PREDICTED TO BE POINTING INSIDE THE KU BAND RF PROTECT BOX. @[110900-7263]

A race condition was discovered in the antenna management flight software that allows radiation to occur while the Ku Band system is slewing to the designated pointing angles inside the RF protect box. To prevent inadvertent radiation of protected regions, the ground will inhibit the Ku Band from radiating prior to the acquisition of TDRS inside the RF protect box. This condition only occurs when the Ku Band is performing a fast slew to angles which are inside the RF protect box but outside the beta masking. @[110900-7263]

A11-24 THROUGH A11-50 RULES ARE RESERVED

FLIGHT RULES

SYSTEM FAILURE RULES

A11-51 LOSS OF TWO-WAY VOICE

IF ONLY A SINGLE SOURCE OF ENTRY TWO-WAY VOICE COMMUNICATIONS REMAINS (COMMAND OK), THE FLIGHT WILL BE TERMINATED AT THE NEXT PLS. IF THIS OCCURS ON FD 1 HOWEVER, DELAY ENTRY UNTIL FD 2. THIS COULD RESULT FROM THE FOLLOWING FAILURES:

- A. TWO NSP'S (UPLINK OR DOWNLINK).
- B. TWO XPNDRS (UPLINK OR DOWNLINK WITH UNSUCCESSFUL IFM).
- C. UHF AND ONE NSP OR XPNDR.

Voice communications is the most valuable communications mode of all due to its flexibility. In contingency cases when command or telemetry is lost, voice can be used as a substitute although it is a slower means of conveying this type of information. It is the only satisfactory means of crew/MCC coordination during high activity phases. The only available voice sources during entry are the two S-band channels (A/G 1 and 2) and UHF. A/G 1 and 2 are redundant and UHF is partially redundant. Should a combination of failures result in being a single failure away from loss of all entry two-way voice, it is best to be prudent and terminate the mission while overall systems and landing site status are known and understood. This is more prudent than risking future occurrences which could result in a crew or vehicle safety hazard due to the absence of a satisfactory means of crew/MCC coordination. In the event these multiple voice failures occur on FD 1, it is better to stay on orbit until the next day and deliberately plan on the possibility of a no-voice entry rather than rush through deorbit activities while adapting to the zero g environment.

Rules {A11-63A}, C, and D, LOSS OF NSP's; {A11-58B}, LOSS OF TRANSPONDERS; and {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A11-52

LOSS OF BOTH VOICE AND COMMAND

A. DURING ASCENT - CONTINUE TO ORBIT: @[092701-4816]

1. IF GPS IS NOT VERIFIED TO BE FUNCTIONING PROPERLY, DEORBIT ON ORBIT 2.
2. IF GPS IS VERIFIED TO BE FUNCTIONING PROPERLY, DEORBIT ON PREFERRED FIRST DAY PLS OPPORTUNITY.

Continuing to orbit is the most benign action. If GPS is not verified to be functioning properly (hardware problems or commfaults, extended periods of high FOM, extended periods of less than 4 satellite tracking), deorbit on orbit 2 is recommended since this allows sufficient time to perform the loss of command and voice procedures while minimizing the degradation of the onboard state vector. Deorbit on orbit 3 would probably not be useful from a systems recovery standpoint and only causes further degradation of the state vector.

GPS will provide an adequate source for orbit navigation and the deorbit state vector as long as it is verified to be functioning properly (no hardware problems or commfaults, no extended periods of high FOM, no extended periods of less than 4 satellite tracking). Caution should be taken when using GPS state vectors with FOM's > 5 (650 feet position error one sigma), since the estimated position error increases rapidly with higher FOM values. A later first day PLS deorbit may be preferred over an orbit 2 deorbit after a loss of both voice and command. Deorbit capability, weather forecasts, and lighting conditions will be considered for the landing site selection.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A11-52

LOSS OF BOTH VOICE AND COMMAND (CONTINUED)

- B. ON-ORBIT - DEORBIT TO THE PLS AT THE TIG OF THE SLEEP VECTOR TARGET SET. IF THIS TIG IS IN THE PAST OR A SLEEP VECTOR IS NOT ONBOARD, THEN:
1. IF GPS IS NOT VERIFIED TO BE FUNCTIONING PROPERLY AND NO ALTERNATE VOICE OR FILE TRANSFER PATH EXISTS TO UPDATE THE ONBOARD STATE VECTOR, DEORBIT WITHIN THE NEXT 13 HOURS IF PERIGEE IS GREATER THAN OR EQUAL TO 120 NM; OR THE NEXT 9 HOURS IF PERIGEE IS GREATER THAN 105 NM, BUT LESS THAN 120 NM; OR FROM LOSS OF VOICE AND COMMAND ACCORDING TO THE FOLLOWING PRIORITIES:
 - a. THE NEXT LIGHTED CONUS OPPORTUNITY.
 - b. THE NEXT CONUS OPPORTUNITY.
 - c. THE NEXT LIGHTED ELS OPPORTUNITY. @[092701-4816]
 2. IF GPS IS VERIFIED TO BE FUNCTIONING PROPERLY OR AN ALTERNATE VOICE OR FILE TRANSFER PATH EXISTS, DEORBIT NEXT PLS, PREFERABLY TO A LIGHTED OPPORTUNITY. @[092701-4816]

A study was presented to Orbit Flight Techniques Panel #86 (6/10/88) which shows, for a general case, an onboard state vector will remain within tolerances per Rule {A4-154}, DOWNTRACK ERROR, for 13 hours if perigee is greater than 120 nm. A subsequent study showed that the vector will remain within tolerances for 9 hours if perigee is greater than 105 nm. This assumes a 1-sigma case with a semi-major axis error of 1000 feet and a downtrack error of 20,000 feet at loss of communication (the crew will be informed if the ground is unable to maintain the vector to this accuracy.) This was approximately the average quality of the onboard state vector before a new one was uplinked based on previous flight data. This was selected to reduce the chance of committing to an ELS landing. It is therefore best to deorbit within the specified time limits unless the state vector is confirmed for a future landing opportunity or GPS is verified to be functioning properly (no hardware problems or commfaults, no extended periods of high FOM, no extended periods of less than 4 satellite tracking) to maintain state vector accuracy. State Vector confirmation can come as a sleep vector (zero delta-V command load with the TIG of the deorbit burn to the PLS) or by voice at the time the state vector was uplinked.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A11-52

LOSS OF BOTH VOICE AND COMMAND (CONTINUED)

If the onboard state vector has been confirmed for a deorbit to the next PLS, it is best to plan for that.

The case where the confirmation has not been received and GPS is not verified to be functioning properly (hardware problems or comm faults, extended periods of high FOM, extended periods of less than 4 satellite tracking) is more difficult. It is clearly more desirable to land at a CONUS landing site containing a full complement of landing aids. It is also more desirable to land during the day. Therefore, the next two priorities are a lighted CONUS landing, then a dark one.

If no CONUS opportunity exists within the specified times, it is best to deorbit as soon as possible to the next lighted ELS. There will always be a lighted ELS opportunity within the next 9 hours at any time during the mission, so a dark ELS landing is not addressed.

GPS will provide an adequate source for orbit navigation and the deorbit state vector as long as it is verified to be functioning properly. Caution should be taken when using GPS state vectors with FOM's > 5 (650 feet position error one sigma), since the estimated position error increases rapidly with higher FOM values. Orbit stay periods of up to 24 hours or longer may be performed to avoid ELS landings if GPS is used to maintain the onboard state vector. Deorbit capability, weather forecasts, and lighting conditions will be considered for the landing site selection.

If the Ku-band and Orbital Communications Adapter (OCA) systems are operational or a comm link via ISS is available, a delta state update can be performed. The orbiter state vector can be downlinked to the MCC via OCA file transfer or read down by the crew via OCA videoconference or ISS assets if GNC downlist telemetry is not available. Once the ground has computed the delta state, it can be uplinked to the orbiter via OCA file transfer or read up via OCA videoconference or ISS assets. The crew can then manually enter the delta state into the GPC in GNC OPS 3. The generation of the orbit delta state by the ground is no longer trained and will require a thorough procedure review prior to implementation. Orbit stay periods can be extended to next PLS to avoid an ELS landing if GPS or delta states are available to keep the state vector within limits. @[021998-6516] @[092701-4816]

FLIGHT RULES

A11-53 LOSS OF COMMAND

IF ALL COMMAND CAPABILITY IS LOST BUT AT LEAST TWO SOURCES OF ENTRY VOICE ARE STILL AVAILABLE, AN MDF WILL BE PERFORMED.

Loss of all command capability implies redundant failures and would impose a significant increase in workload to the crew as state vectors, gyro biases, target loads, etc., would have to be relayed to the crew by voice or OCA and entered into the computers manually, in many cases, by GMEM Read/Write. Recorder dumps and communications configurations would also have to be done manually and, for some flights, payload operations would be adversely affected as control is only from the POCC. Therefore, the potential for introducing errors into computer updates is increased. ©[021998-6516] ©[012402-5068]

Rules {A11-58B}, LOSS OF TRANSPONDERS; {A11-63A}, LOSS OF NSP's; and {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, reference this rule.

A11-54 LOSS OF TELEMETRY

IF ALL SOURCES OF TELEMETRY TO MCC ARE LOST THE FLIGHT WILL TERMINATE AT THE NEXT PLS. THIS COULD RESULT FROM:

- A. LOSS OF DOWNLINK FROM BOTH NSP'S.
- B. LOSS OF BOTH PCMMU'S.
- C. LOSS OF BOTH TRANSPONDERS FOLLOWED BY AN UNSUCCESSFUL IFM. (REF. RULE {A11-58C}, LOSS OF TRANSPONDERS.)

The MCC has a much greater systems monitoring capability than available onboard and most crew procedures and training are based on the availability of having telemetry data in the MCC or POCC monitored by systems experts. Without telemetry, computer loads could not be verified before execution. Some future system failures could remain undetected (such as those requiring trend monitoring) or the extent of the failure unappreciated (e.g., bus transients). Also, for many missions, payload data is only retrievable via telemetry. If telemetry during the entry phase is known to be unavailable (even though onboard data may be unaffected), then it is safest to terminate the mission while overall systems status is known and understood by all rather than risk adverse future occurrences which could result in a crew or vehicle safety hazard due to the loss of insight normally provided by the MCC.

Rules {A11-63}, LOSS OF NSP's; and {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A11-55 **LOSS OF KU-BAND**

LOSS OF KU-BAND WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM. IF THE MISSION-SPECIFIC CAPABILITY JUSTIFIES THE REQUIREMENT FOR THE KU-BAND, PERFORM AN MDF.

Refer also to mission-specific rules that may be documented in Flight Rules Annexes.

Ku-band communication is provided primarily to support payloads. It is used to provide supplemental capabilities unavailable via the prime S-band communications system such as TDRS television, TDRS recorder dumps, OCA, and high rate payload data. Generally speaking, other useful mission objectives can be accomplished even with the loss of these capabilities and, therefore, early mission termination is not justified. The Ku-band system also provides the only source of rendezvous radar capability, but alternate onboard and ground capabilities allow rendezvous to continue in the event of radar failure. Specific mission objectives that cannot be accomplished with a loss of Ku-band are identified in the Flight Rules Annex. ©[021998-6516] ©[012402-5068]

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-56 **LOSS OF KU-BAND TEMPERATURE CONTROL [CIL]**

INABILITY TO MAINTAIN KU-BAND TEMPERATURES WITHIN THEIR SODB LIMITS (DEFINED AS ABOVE MINIMUM TURN-ON AND BELOW MAXIMUM SURVIVAL) WILL RESULT IN KU-BAND DEACTIVATION AND STOWAGE.

If temperature control of the Ku-band gyro or either alpha or beta gimbal cannot be maintained within SODB limits, the subsequent potential of degradation could result in inability to properly stow the deployed assembly since fairly precise positioning is required for the antenna to lock. Stowing the deployed assembly with an unlocked antenna could result in damage to the antenna or the adjacent radiator panel during entry. Temperature control of the antenna feed, the transmitter, and the receiver is also required to prohibit damage to these components. For any of these cases the system should be deactivated and stowed as a precaution.

Rule {A10-301B}; ANTENNA STOW REQUIREMENT [CIL], and {A11-57}, LOSS OF KU-BAND TEMPERATURE MONITORING CAPABILITY [CIL], reference this rule.

FLIGHT RULES

A11-57

LOSS OF KU-BAND TEMPERATURE MONITORING CAPABILITY
[CIL]

LOSS OF THE CAPABILITY TO MONITOR THE KU-BAND GYRO, ALPHA GIMBAL, OR BETA GIMBAL TEMPERATURES WILL RESULT IN DEACTIVATION AND STOWAGE EXCEPT FOR THOSE CASES DOCUMENTED IN THE FLIGHT RULES ANNEX.

FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT RULE ANNEX.

Ku-band temperature control is necessary to ensure that component damage will not occur and to ensure that the antenna can be properly locked and stowed for entry (ref. Rule {A11-56}, LOSS OF KU-BAND TEMPERATURE CONTROL [CIL]). A failed transducer would result in the inability to detect a heater that is failed ON or failed OFF. Since heater monitoring locations are relatively insulated, attempting to extrapolate remaining measurements to determine an out-of-limits condition for the gyro or either gimbal is unreliable.

FLIGHT RULES

A11-58 LOSS OF TRANSPONDERS

- A. LOSS OF ONE TRANSPONDER (UPLINK OR DOWNLINK) WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of one transponder is still one failure away from any condition resulting in either a minimum duration flight or a next PLS landing.

- B. LOSS OF UPLINK CAPABILITY FROM BOTH TRANSPONDERS WILL RESULT IN A NEXT PLS LANDING.

Refer to Rule {A11-51}, LOSS OF TWO-WAY VOICE; and Rule {A11-53}, LOSS OF COMMAND. This failure results in the loss of all S-band voice and command.

- C. IF ALL S-BAND PM DOWNLINK TO MCC IS LOST RESULTING FROM A FAILURE OF BOTH TRANSPONDERS AND THE IFM TO USE THE S-BAND FM IS SUCCESSFUL, AN MDF WILL BE COMPLETED. IF THE IFM IS UNSUCCESSFUL THEN THE FLIGHT WILL TERMINATE AT THE NEXT PLS.

Loss of telemetry and downlink voice from two transponders leaves only Ku-band as a telemetry source and UHF and Ku-band for voice. An IFM is available to restore real-time S-band telemetry and downlink S-band voice in the event of a dual transponder failure using the S-band FM transmitters. This coverage is unavailable via TDRS and would result in limited ground coverage from DOD and NASA stations which would have to be called up for support. However, it still would provide a source for entry telemetry. This failure leaves recorded telemetry still available. Therefore, sufficient systems insight remains to complete a minimum duration flight. An unsuccessful IFM would result in no telemetry and only UHF voice following Ku-band stowage. To avoid the possibility of a no-telemetry entry with an orbiter degraded by a subsequent systems failure, a next PLS landing is justified as being the conservative approach.

Rules {A11-54}, LOSS OF TELEMETRY; and {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A11-59

FM SYSTEM IFM GROUND RULE

FOLLOWING A CONFIRMED LOSS OF DOWNLINK IN ONE S-BAND TRANSPONDER, CONSIDERATION WILL BE GIVEN TO IMPLEMENTING AN IFM PROCEDURE TO ALLOW THE USE OF THE FM SYSTEM AS A REDUNDANT TELEMETRY SOURCE FOR ENTRY.

Following a transponder loss, no redundancy remains for downlink telemetry. The IFM regains this redundancy using the FM system, and implementation of the IFM should be considered prior to entry. The IFM procedure to allow the use of the S-band FM system for downlink voice and telemetry results in disconnecting flight cables and terminating the use of one of the Ops recorders. The NSP's must be switched when real-time and dump data share the FM downlink. This is compatible only with ground stations, not TDRS. For these reasons it is desirable to troubleshoot the transponders to determine alternate capabilities before considering the IFM which nominally requires about 2-1/2 hours of crew time. As transponder troubleshooting necessarily requires a ground station or TDRS to confirm status, the ground should direct the procedure rather than the crew if the remaining capability makes this feasible. The ground is required because compatible configurations are necessary onboard and at the STDN to ensure valid checks.

A11-60

LOSS OF TDRS TRACKING CAPABILITY

LOSS OF TDRS TRACKING CAPABILITY WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of TDRS tracking would require call up of contingency use S-band tracking stations that are obligated to provide support in the event of such an orbiter or ground system failure. These stations, supplemented as required by C-band radars, can provide satisfactory support to continue nominal orbital operations and entry preparations.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-61

LOSS OF S-BAND PREAMPS AND POWER AMPS

LOSS OF BOTH S-BAND PREAMPLIFIERS AND/OR BOTH POWER AMPLIFIERS WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of either both preamps or both power amps results in loss of all TDRS S-band capability. Ku-band still remains but does not provide a tracking source and is unavailable following antenna stowage during deorbit prep. A total loss of TDRS S-band would require call up of the contingency ground stations that are obligated to provide support in the event of such an orbiter failure. These stations would be a combination of the NASA Spacecraft Tracking and Data Network (STDN), DOD remote tracking stations (RTS), and C-band radars. These stations can provide satisfactory support to continue nominal orbital operations and nominal entry preparations. ©[102402-5741]

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-62

LOSS OF ANTENNA ELECTRONICS

THE FLIGHT WILL BE CONTINUED FOR LOSS OF THE S-BAND ANTENNA ELECTRONICS.

Loss of both S-band antenna electronics results in the inability to select S-band antennas (i.e., only one antenna could be used). All communications functions would remain, but severe attitude constraints would have to be imposed to maintain TDRS S-band. TDRS Ku-band would be unaffected, and ground station (GSTDN) S-band would be slightly degraded due to reduced (but still acceptable) circuit margins. Since the attitude timeline would be affected, it is reasonable to assume that mission activities would be impacted. As long as productive mission objectives can still be accomplished, the mission need not be shortened. Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-63

LOSS OF NSP'S

- A. LOSS OF UPLINK CAPABILITY FROM ONE NSP WILL RESULT IN CONTINUING TO NOMINAL EOM.

Loss of uplink from one NSP is still one failure away from any condition resulting in either a minimum duration flight or a next PLS landing. Refer to Rules {A11-51}, LOSS OF TWO-WAY VOICE; and {A11-53}, LOSS OF COMMAND.

- B. LOSS OF ALL DOWNLINK REAL TIME AND ALL RECORDED DATA OUTPUTS FROM ONE NSP WILL RESULT IN AN MDF.

The NSP's are required to provide all telemetry, recorded telemetry and voice, all command and all S-band voice. UHF voice may still remain, but the limited ground coverage (essentially Continental U.S.) is insufficient to satisfy orbital requirements. Ku-band OCA and downlink TV capabilities may also remain during the period that the Ku-band is deployed. Although two-way voice and video capability with OCA may be available, flight experience has demonstrated that this capability is not robust. Considering the impact of losing all NSP capability in the event of a second failure versus the small gain in mission achievement that may be possible, redundant NSP's should be required to extend the flight beyond minimum duration. [021998-6516] [012402-5068]

- C. LOSS OF UPLINK CAPABILITY FROM BOTH NSP'S WILL RESULT IN A NEXT PLS LANDING.

Refer to the rationale for Rule {A11-51}, LOSS OF TWO-WAY VOICE. Loss of both NSP uplinks would result in only UHF availability for two-way voice.

- D. LOSS OF ALL DOWNLINK REAL TIME AND ALL RECORDED DATA OUTPUTS FROM BOTH NSP'S WILL RESULT IN A NEXT PLS LANDING.

Refer to the rationale for Rules {A11-51}, LOSS OF TWO-WAY VOICE; and {A11-54}, LOSS OF TELEMETRY. Loss of all downlink capability from both NSP's would result in only UHF availability for two-way voice and no telemetry to MCC.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-64

LOSS OF COMMUNICATIONS SECURITY (COMSEC)

- A. LOSS OF COMSEC WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

Refer also to mission-specific rules that may be documented in Flight Rules Annexes.

Current agency policy with a fully operational TDRSS is to encrypt command/control uplinks or data as appropriate to protect sensitive government data and provide protection from unauthorized commands. When all data is unclassified, as it is for NASA flights, this policy would be waived (as it has been in the past) in order to complete the mission. In the event of total COMSEC failure, uplink protection will be provided by use of the uplink block protection. When data is classified, as for DOD flights, COMSEC rules will be defined in the Flight Rules Annex.

- B. FOR LOSS OF A SINGLE COMSEC (UPLINK AND/OR DOWNLINK), ORBIT OPERATIONS WILL CONTINUE TO BE ENCRYPTED. FOR ASCENT AND ENTRY, REDUNDANCY WILL BE PROVIDED BY GOING TO CLEAR. IF UPLINK ENCRYPTION IS DESELECTED, THE UPLINK BLOCK SWITCH WILL BE USED BY THE CREW TO PROTECT COMMAND UPLINK WHEN COMMAND ACTIVITY IS NOT REQUIRED.

ENCRYPTION LOST	CONFIGURATION FOR ASCENT/ENTRY
BOTH UPLINK AND DOWNLINK	CLEAR UPLINK AND DOWNLINK (CREW USES BLOCK SWITCH)
UPLINK ONLY	CLEAR UPLINK AND DOWNLINK (CREW USES BLOCK SWITCH)
DOWNLINK ONLY	ENCRYPTED UPLINK, CLEAR DOWNLINK

Loss of a single COMSEC (uplink and/or downlink) does not prevent protection of that link with the remaining COMSEC system. Subsequent COMSEC failures can be resolved by deselecting encryption. For ascent and entry, the encryption will be deselected (uplink and/or downlink) to recover redundancy for command and S-band voice (the encryption switches are not accessible from the crew seats). When data are classified, as for DOD flights, COMSEC rules will be defined in the Flight Rules Annex.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-65

AUDIO CENTRAL CONTROL UNIT (ACCU)

THE ACCU IS CONSIDERED LOST IF TWO-WAY VOICE ON THE FOLLOWING LOOPS IS INOPERABLE:

- A. AIR/GROUND 1.
- B. AIR/GROUND 2.
- C. AIR/AIR.

These are the only loops that interface with the communications equipment (both air/ground and EVA). Only Intercom and Page loops remain. Therefore, a subsequent failure in the alternate ACCU would result in the loss of all orbiter communications. One-half of the ACCU BYPASS IFM (J4) should be performed as described in Rule {A11-66}, LOSS OF ACCU's.

Rule {A11-66}, LOSS OF ACCU's, references this rule.

FLIGHT RULES

A11-66

LOSS OF ACCU'S

- A. FOR THE LOSS OF ONE ACCU, ONE-HALF OF THE ACCU BYPASS IFM (J4) WILL BE PERFORMED AS SOON AS PRACTICAL AND THE NOMINAL FLIGHT COMPLETED. IF UNSUCCESSFUL A NEXT PLS LANDING WILL BE PERFORMED.

Refer to Rule {A11-65}, AUDIO CENTRAL CONTROL UNIT (ACCU).

- B. FOR THE LOSS OF BOTH ACCU'S, THE IFM WILL BE COMPLETED AND AN MDF WILL BE PERFORMED.

The primary difference between A and B above is that loss of an ACCU is only loss of one source of redundancy while loss of total IFM is loss of two sources.

Loss of one ACCU is one failure away from loss of all air/ground voice. The IFM, when installed, provides two sources of air/ground voice. Implementing the J4 half of the IFM allows normal use of the remaining ACCU but with the following lost capabilities:

1. PS, OS, and AIRLOCK ATU's.
2. TACAN 3 tones.
3. C&W B tones via ACCU (Middeck Speaker Unit). ®[102402-5743]
4. NSP 2 voice record channel 1.
5. NSP 1 voice record channel 2.
6. NSP 1 Air/Ground 2 loop.
7. PLT ATU is limited to only the Air/Ground 1 loop in NSP 2 and only in hot mike mode.

The extent of these lost capabilities is of minor mission impact and does not constitute grounds for shortening the mission. For vehicles 103 and 104 only one crewmember in the airlock will have hardline communications which has a minor procedural impact. Should the remaining ACCU fail after the J4 IFM, the CDR and PLT ATU's (only) will still retain an S-band communications capability although it will be nonredundant. The IFM should then be completed restoring dual S-band communications redundancy. Since redundancy is available, an immediate (next PLS) landing is not necessary, but the dwindling communication capabilities justify that the flight be continued only until MDF.

Rule {A11-65}, AUDIO CENTRAL CONTROL UNIT (ACCU), references this rule.

FLIGHT RULES

A11-67

LOSS OF THE PLT AND MS ATU'S

LOSS OF BOTH THE PLT AND MS ATU'S WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

These two ATU's are necessary to process audio system configuration data for external interfaces such as the NSP's, recorders, UHF, etc. In the event of a subsequent ACCU switch failure, these external configurations would come up in a random state. However, testing and analysis have shown that the probability of regaining a working Air/Ground loop on each switch attempt (A/G 1, 2, or UHF) exceeds 90 percent. Therefore, shortening the mission for these failures is not justified. ©[092701-4872]

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-68

LOSS OF INTERCOM

THE FLIGHT WILL BE CONTINUED FOR THE LOSS OF ALL INTERCOM.

Intercom is desirable but not mandatory for crew coordination. When seated for entry, the CDR and PLT can easily communicate without the intercom. Communications with MS1 and MS2 can be done using the Air/Ground or Air/Air loops if necessary, although simultaneous transmissions to the STDN in these cases would occur. It would also be necessary to use the Air/Ground or Air/Air loops to record voice on the Ops recorders. These conditions may be undesirable but not considered serious enough to shorten the mission

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-69 **LOSS OF UHF**

LOSS OF UHF WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

UHF voice is used as the sole source of EVA communications, as the source of communication on the universal guard channel (243.0 MHz), and as an alternate source of communication during ascents and entries. Failures of UHF affecting air/ground communications should not result in an early mission termination as long as S-band redundancy exists for entry.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-70 **LOSS OF GCIL**

LOSS OF GCIL WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

Loss of GCIL capability implies loss of command capability to most of the communications systems, loss of a quick way to switch S-band strings (the "Panel/Command" capability) and loss of some unique functions that require a GCIL; e.g., frequency selection. Workarounds exist in all cases although the crew would have to assume some additional workload. The resulting loss of efficiency does not justify shortening the mission.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-71

LOSS OF RECORDERS

- A. THE FLIGHT WILL BE CONTINUED FOR A LOSS OF ALL OPS, SOLID STATE, MADS/OEX AND PAYLOAD RECORDERS. @[092701-4848A]

In order to justify a mission termination, either an actual or potential crew safety hazard must exist, all planned mission objectives must have been achieved, or no further useful mission objectives can be achieved on this flight for whatever reason. It is extremely unlikely that failure of any or all of these recorders would result in one of these three conditions. Recorders are generally used to document a complete mission history and to backup or supplement analog or digital data that is acquired by other means, e.g., real time. When this is not the case, the data is rarely critical to total mission success as a backup was apparently not justifiable. The MADS/OEX recorder is a sole source of orbiter supplemental data; but, since this data is usually for entry performance evaluation, a MADS/OEX recorder failure does not justify an early reentry as the data is lost regardless. Recorder criticality, if any, would be defined in the Flight Rules Annex.

- B. IN THE EVENT BOTH OPS RECORDERS FAIL, THE OPS 2 RECORDER WILL BE REPLACED WITH THE PAYLOAD RECORDER.

The payload recorder is not used for recording orbiter systems data and, therefore, its loss can only impact the degree of mission success. Since real-time orbiter systems data is not continuous, but is limited by station coverage or entry blackout, it is probable that the Ops recorders could prove the sole source of orbiter data and recorded voice at the time a systems anomaly occurs. Since this data is much more extensive than that available to the crew, it is potentially critical for allowing complete systems anomaly troubleshooting. It is also the only source of crew intercom voice. Therefore, giving up the payload recorder for these dual failure conditions is prudent. Ops 2 is preferred as it is much more accessible than Ops 1. No third unit will be available to back up solid state recorders. Likewise, if the payload recorder is not flown on a particular mission, it is not available to back OPS recorders.
@[092701-4848A]

- C. NO RECORDER CHANGEOUTS WILL BE ACCOMPLISHED FOR LOSS OF A SINGLE OPS RECORDER.

The availability of TDRS and the reduction of the need for voice recording to only high activity mission phases results in only one Ops recorder for a given flight being required to satisfy requirements. The other Ops recorder is considered a backup. Since the payload recorder is used on some flights to acquire data unavailable elsewhere and since approximately 2 hours of crew time is necessary to change out recorders, the replacement of the backup Ops recorder with the payload recorder is not justified.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A11-71 LOSS OF RECORDERS (CONTINUED)

D. IF THE OPS 2 RECORDER FAILS DURING ASCENT, THE OPS 1 RECORDER WILL BE RECONFIGURED TO RECORD BOTH MAIN ENGINE DATA AND OI DATA. THE SPEED WILL BE THE OPTIMUM (24 IPS) FOR OI DATA RATE. A RECORDER IS CONSIDERED FAILED WHEN ANY OF THE FOLLOWING OCCUR:

1. RECORDER BITE INDICATION PRESENT.
2. RECORDER TEMPERATURE > 120 DEG F.
3. UNABLE TO DETECT TAPE MOTION.

The Ops 1 recorder can be configured to record orbiter OI telemetry and voice, but provides the only means of recording SSME EIU data during ascent. The Ops 2 recorder can only be used to record OI data and voice which is its nominal ascent configuration. Should the Ops 2 recorder fail during ascent, both EIU and orbiter data can be recorded on Ops 1 during powered flight in a slightly degraded but recoverable mode. After powered flight, Ops 1 can be reconfigured to record only OI data and voice.

Recent test data shows both EIU and OI data and voice may be recorded and recovered, on the same recorder, with minimum degradation.

This reconfiguration is not necessary if flying solid state recorder (SSR), since solid state recorder 2 (SSR 2) records Main Engine and OPS data simultaneously. @[092701-4848A]

E. IF SSR 2 FAILS DURING ASCENT ON A MISSION IN WHICH SSR 1 IS RECORDING PAYLOAD DATA INSTEAD OF OPS DATA, SSR 1 WILL BE RECONFIGURED TO RECORD OI DATA. @[092701-4848A]

F. AN SSR IS CONSIDERED FAILED WHEN ANY OF THE FOLLOWING OCCUR:

1. RECORDER BITE INDICATION PRESENT.
2. RECORD POSITION DOES NOT INCREASE.

SSR 2 normally records Main Engine and OPS data during ascent; SSR 1 normally records OPS data also, but is available for use as a payload recorder if required. Should SSR 2 fail during ascent, SSR 1 is required to record OPS data. @[092701-4848A]

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A11-72 LOSS OF TV

THE FLIGHT WILL BE CONTINUED FOR LOSS OF ALL OR PART OF THE TV SYSTEM.

The TV system has never been identified as being essential for crew safety purposes. It is usually used for real-time or near real-time public information purposes and for mission documentation of payload bay activities. It has also proven useful as a close-in ranging aid, as an RMS grapple aid, for monitoring PAM PKM burns, and miscellaneous, often unforeseen, mission activities such as water dump nozzle survey. None of these uses are considered a realistic justification for an early flight termination. It is conceivable however, that some mission objectives may not be satisfied for a total TV system loss. These will be identified in the Flight Rule Annex.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-73 LOSS OF OCA @[012402-5068]

LOSS OF OCA WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

OCA is a major convenience for passing information to the crew. If OCA capability were lost, the same information would be passed via voice. @[021998-6516] @[012402-5068]

A11-74 PCM MASTER UNIT (PCMMU)

THE PCMMU IS CONSIDERED LOST IF ANY ONE OR MORE OF THE FOLLOWING IS TRUE:

- A. IT CANNOT SUPPLY DATA TO AT LEAST ONE GPC.
- B. IT CANNOT SUPPLY HIGH DATA RATE AND LOW DATA RATE TELEMETRY TO THE GROUND.
- C. IT CANNOT SUPPLY DOWNLIST DATA FROM AT LEAST ONE GPC TO THE GROUND.

The PCMMU is required for three major purposes. It supplies all orbiter real-time and recorded telemetry (OI MDM and PDI data). It supplies OI and PDI data to the SM and BFS GPC's for onboard display and fault detection (class 3 alarms). It supplies all GPC downlist data to real-time and recorded telemetry. The loss of either of these three functions is a serious impact upon systems monitoring visibility for either the crew or MCC. The extent of the visibility loss is significant enough to consider the PCMMU as unusable and essentially failed.

FLIGHT RULES

A11-75 **LOSS OF PCMMU'S**

A. LOSS OF ONE PCMMU WILL RESULT IN AN MDF.

The PCMMU's are required to provide all real-time and recorded telemetry to MCC and much onboard systems data to the SM or BFS GPC's for crew display and class 3 alerts. There are no available workarounds for a PCMMU failure. Considering the impact of losing such extensive insight into the onboard systems in the event of a second failure versus the small gain in mission achievement that may be possible, redundant PCMMU's should be required to extend the flight beyond minimum duration.

B. LOSS OF TWO PCMMU'S WILL RESULT IN A NEXT PLS LANDING.

This failure results in a significant loss of telemetry or onboard monitoring capability.

Rule {A11-1001}, COMMUNICATIONS GO/NO-GO CRITERIA, references this rule.

A11-76 **LOSS OF OI MDM**

LOSS OF ANY OI MDM WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

The impacts of losing any single OI multiplexer/demultiplexer have been analyzed with the results documented in JSC-16983, OI MDM/DSC Failure Impacts. The analysis reveals that adequate instrumentation remains for making mission-critical decisions using other sources. Flight Data File procedures exist that reference any configurations that are necessary following the loss of the LRU.

A11-77 **LOSS OF ANY OI DSC**

LOSS OF ANY OI DSC WILL RESULT IN THE FLIGHT CONTINUING TO NOMINAL EOM.

The impacts of losing any single OI Dedicated Signal Conditioner have been analyzed with the results documented in JSC-16983, OI MDM/DSC Failure Impacts. The analysis reveals that adequate instrumentation remains for making mission critical decisions using other sources. Flight Data File procedures exist that reference any reconfigurations that are necessary following the loss of the LRU.

FLIGHT RULES

SECTION 12 - ROBOTICS

GENERAL

A12-1 **EVA FOR RMS OPERATIONS**

- A. FOR RMS FAILURES THAT ARE KNOWN PRIOR TO THE START OF RMS OPERATIONS:

AN UNSCHEDULED EVA TO CONFIGURE THE RMS FOR OPERATIONS (E.G., SHOULDER BRACE RELEASE, MPM DEPLOY) MAY BE CONSIDERED ONLY IF A SECOND EVA WILL NOT BE REQUIRED TO MAKE THE ORBITER SAFE FOR ENTRY.

FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

EVA techniques are available to release the shoulder brace and to deploy the arm which will place the RMS into an operational configuration. Subsequent to MPM deploy, there could be occasions where the EVA crewmember would wait for the accomplishment of the mission objective and stow the MPM within the same EVA. But it is not safe to require another EVA to stow the MPM because the orbiter must retain the capability to perform a contingency payload bay door EVA.

The shoulder brace is only required for ascent loads; so, once it is released, an additional EVA will not be required to reattach it. However, if the arm is deployed EVA, it is very likely a second EVA would be required to stow it. If a second EVA is not available, the arm would have to be jettisoned to make the payload bay safe for entry.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-1

EVA FOR RMS OPERATIONS (CONTINUED)

B. FOR RMS FAILURES THAT OCCUR OR ARE DISCOVERED AFTER RMS OPERATIONS HAVE COMMENCED:

IF CONDITIONS PERMIT, AND AFTER ALL OTHER METHODS HAVE FAILED, AN UNSCHEDULED EVA MAY BE CONSIDERED FOR THE FOLLOWING TASKS TO PRECLUDE HAVING TO JETTISON THE RMS, PAYLOAD, AND/OR MPM:

1. END EFFECTOR (EE) RELEASE.
2. RMS JOINT ALIGN.
3. RMS TIEDOWN.
4. MPM STOW.
5. PAYLOAD BERTHING.

Once RMS operations have commenced, there are additional EVA techniques available for various failures in the end effector, joint motors, MRL, and MPM which will make the RMS safe for entry and preclude jettison of the arm, payload, and/or MPM. For certain payloads, the crew may also be trained to berth the payload manually using EVA techniques.

Rule {A2-112A}, PDRS, references this rule. ©[ED 1

FLIGHT RULES

A12-2

UNATTENDED RMS CONSTRAINTS

- A. DURING CREW AWAKE PERIODS, THE UNCRADLED RMS (LOADED OR UNLOADED) MAY BE LEFT UNATTENDED IF ALL OF THE FOLLOWING CONDITIONS ARE MET:
1. THE ARM IS SELECTED.
 2. THE BRAKES ARE ON.
 3. THE MODE SWITCH IS NOT IN DIRECT.
 4. THE JOINT SWITCH IS IN THE CRITICAL TEMPERATURE POSITION.
 5. THE MCIU MAINTAINS I/O WITH THE GPC.
 6. THE FLIGHT-SPECIFIC ANNEX RULES ARE MET.
 7. RMS/PAYLOAD CLEARANCE OF AT LEAST 1.5 METERS (5 FEET) FROM STRUCTURE IS MAINTAINED.

With the arm selected, I/O established with the MCIU, and the brakes on, the RMS software is in the idle mode with all six joints held by the mechanical brakes. Idle mode is required to determine the health of the arm. The RMS mode switch should be left in any position except DIRECT so that the joint slip algorithm will operate. The joint switch should be in the CRIT TEMP position so that a failure of the SINGLE/DIRECT DR switch will not lead to a single-joint runaway. Meeting the flight-specific annex rules is required to ensure that specific DAP configuration and RMS position/clearance constraints are met to prevent orbiter/RMS/payload contact (PDRS Working Panel 16-4 baselined this criteria).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-2 UNATTENDED RMS CONSTRAINTS (CONTINUED)

- B. NOMINALLY, DURING CREW SLEEP PERIODS AND DURING EXTENDED PERIODS OF NON-RMS OPERATIONS, THE RMS SHALL BE CRADLED, LATCHED, AND THE SYSTEM LEFT IN THE TEMPERATURE MONITOR MODE. HOWEVER, PREFLIGHT PLANNED OVERNIGHT PARKING IS ACCEPTABLE IF THE RMS IS UNGRAPPLED AND THE CONDITIONS IN PARAGRAPH A ARE SATISFIED. FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY PAYLOADS ARE IDENTIFIED IN THE FLIGHT RULES ANNEX. THE RMS CONFIGURATION FOR THE EXCEPTIONS IS DEFINED IN PARAGRAPH A.

The cradled and latched configuration of the RMS protects against RMS and MRL failures causing a delay should an emergency deorbit be required. Preflight planned parking of the ungrappled RMS is acceptable to accommodate specific customer requirements such as witness plates and other data gathering that cannot be accomplished in 1 crew day. No flight-specific analysis needs be done for the ungrappled RMS.

- C. FOR A CONTINGENCY REQUIRING OVERNIGHT PARK, THE UNCRADLED RMS (LOADED OR UNLOADED) MAY BE LEFT UNATTENDED PROVIDED ALL CONDITIONS IN PARAGRAPH A ARE SATISFIED.

The crew response time to an RMS alert is longer when the crew is asleep. The additional risk imposed by a longer response time is considered small and preferable to RMS/payload jettison. The arm shall be left configured per paragraph A for the same reasons as above. On-Orbit Flight Techniques Panel #130 baselined acceptability of this RMS configuration for contingency overnight parking.

- D. FOR RMS/ORBITER CONTINGENCIES WHERE THE CONDITIONS OF PARAGRAPH A CANNOT BE MET, UNLOADED, UNATTENDED OVERNIGHT PARK IS ACCEPTABLE WITH THE ARM UNPOWERED.

FLIGHT-SPECIFIC EXCEPTIONS FOR LOADED CASES WILL BE IDENTIFIED IN THE FLIGHT RULES ANNEX.

Certain RMS anomalies (e.g., loss of health monitoring insight or loss of one electrical inhibit) combined with mission situations may require the RMS to be deselected and/or power removed. An unpowered arm prevents subsequent electrical failures from causing a possible unannounced or unprotected hazard. Deselecting the arm is the preferred method of removing power to allow temperature, MCIU, and D&C health monitoring. RMS power may also be removed via the RMS power switch. RMS temperature control and/or monitoring should be considered prior to removing RMS power. Real-time insight and annunciation as to the status of the RMS will be affected when removing RMS power.

FLIGHT RULES

A12-3

TEMPERATURE CONSTRAINTS [CIL]

- A. BOTH RMS HEATERS SHALL BE ACTIVATED AT LEAST 1 HOUR PRIOR TO RMS OPERATIONS. IF EVENTS REQUIRE THE RMS TO BE USED BEFORE THE 1 HOUR REQUIREMENT HAS BEEN MET, BOTH HEATER SYSTEMS SHOULD BE ACTIVATED AND THE LIGHT EMITTING DIODE (LED) AND THE ARM BASED ELECTRONICS (ABE) TEMPERATURES MUST BE AT LEAST 10 DEG (21 DEG) F.

SPAR Aerospace recommended, during the FMEA/CIL activities, that both RMS heater buses be turned on at least 1 hour before arm operations to guarantee that thermal gradients across the joints do not cause joint problems in the event of a heater failure. SPAR also confirmed that RMS operations may proceed immediately without any risk of uncommanded motion if the temperatures as reported by the thermistors are within the nominal range (at least 21 deg F). (SPAR Aerospace Response to NASA-VP-87-020.)

- B. RMS OPERATIONS WILL BE TERMINATED AND THE ARM CRADLED AND LATCHED WITHIN 25 MINUTES IF THE LOW TEMPERATURE ALARM LIMIT (LED -20 DEG (0 DEG) F, ABE -20 DEG (0 DEG) F) IS REACHED, AND TROUBLE-SHOOTING DOES NOT ALLEVIATE THE PROBLEM. IF THE LOW TEMPERATURE QUALIFICATION LIMIT (LED -42 DEG (-10 DEG) F, ABE -33 DEG (-10 DEG) F) IS REACHED, FURTHER RMS OPERATIONS WILL NOT BE PERFORMED UNTIL THE TEMPERATURES RETURN WITHIN THE ALARM LIMITS. A JOINT DRIVE TEST IN DIRECT WILL BE PERFORMED TO VERIFY HEALTH PRIOR TO ANY FURTHER OPERATIONS.

There is an SODB requirement that heater power must be restored within 25 minutes of receipt of the low temperature alarm. If troubleshooting does not alleviate the low temperature problem, the arm must be placed in a safe configuration (meaning cradled and latched) within 25 minutes to prevent any degraded performance due to the low temperature. If the low temperature qualification limits are reached, arm performance may be unreliable; so, further RMS operations will not be performed until temperatures return within the alarm limits. Once within limits, a joint drive test in direct will be performed to ascertain joint health. Numbers in parentheses assume a 1-3/4 count potential error in the thermistor readings.

FLIGHT RULES

A12-3

TEMPERATURE CONSTRAINTS [CIL] (CONTINUED)

- C. RMS OPERATIONS WILL BE TERMINATED AND THE ARM CRADLED AND LATCHED WITHIN 15 MINUTES IF THE HIGH TEMPERATURE ALARM LIMIT (LED 176 DEG (172 DEG) F, ABE (EE) 147 DEG (144 DEG) F, ABE (SPA) 110 DEG (106 DEG) F) IS REACHED, AND TROUBLESHOOTING DOES NOT ALLEVIATE THE PROBLEM. THE ARM MUST BE CRADLED AND LATCHED BEFORE THE TEMPERATURE REACHES THE ACCEPTANCE TEMPERATURE LIMIT (LED 186 DEG (181 DEG) F, ABE (EE) 157 DEG (154 DEG) F, ABE (SPA) 120 DEG (117 DEG) F). IF THE ARM REACHES THE ACCEPTANCE TEMPERATURE LIMIT, POWER WILL BE REMOVED. IF THE HIGH TEMPERATURE QUALIFICATION LIMIT (LED 205 DEG (202 DEG) F, ABE (EE) 178 DEG (176 DEG) F, ABE (SPA) 140 DEG (136 DEG) F) IS REACHED, FURTHER RMS OPERATIONS WILL NOT BE PERFORMED UNTIL THE TEMPERATURES RETURN WITHIN THE ALARM LIMITS. A JOINT DRIVE TEST IN DIRECT WILL BE PERFORMED TO VERIFY HEALTH PRIOR TO ANY FURTHER OPERATIONS. ©[ED]
 ©[111298-6744]

There is an SODB requirement that continued operation of the RMS is limited to 15 minutes if the high temperature alarm limit has been reached. In addition, all power will be removed from the arm if the high temperature acceptance test limits are reached. If troubleshooting does not alleviate the problem, the arm must be placed in a safe configuration (meaning cradled and latched) as soon as possible to prevent any degraded performance due to the high temperature. If the high temperature qualification limits are reached, arm performance may be unreliable so the arm should not be uncradled again until temperatures return within the alarm limits. Once within limits, a joint drive test in direct will be performed to ascertain joint health prior to any further arm operations. Numbers in parentheses assume a 1-3/4 count potential error in the thermistor readings. Spar Aerospace Memo PMO/97-017, dated June 25, 1997, updated the upper limit ABE numbers based on the redesigned SPA lower acceptance and qualification limits. ©[111298-6744]

Rules {A18-451}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL], and {A12-1001V}, RMS GO/NO-GO CRITERIA, reference this rule. ©[ED]

FLIGHT RULES

A12-4 RMS ACTIVITY TERMINATION

- A. FOR MPM AND MRL EOM CONSTRAINTS, REFERENCE RULE {A2-103C} AND D, EXTENSION DAY REQUIREMENTS. @[090894-1670B] @[113095-1809A]
- B. DECLARATION OF A NEXT PLS DEORBIT IS CAUSE TO TERMINATE RMS ACTIVITIES IMMEDIATELY. FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH-PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

In the event of a next PLS situation, the orbiter must be in a safe configuration as soon as possible. This requires that the RMS be cradled, latched, and stowed prior to payload bay door closure. If important arm operations are being performed, such as berthing a payload, the situation may allow for those operations to be completed depending on the time left before deorbit.

A12-5 ORBITER AVOIDANCE MANEUVERS CONSTRAINT [CIL]

A PILOT SHALL ALWAYS BE AVAILABLE TO PERFORM A COLLISION AVOIDANCE MANEUVER DURING ALL LOADED RMS OPERATIONS IN THE EVENT OF A PAYLOAD UNCOMMANDED RELEASE.

Since there are failure modes that result in an uncommanded release of a payload that is attached to the arm, it may be necessary to maneuver the orbiter in a short period of time to avoid collision with the free-flying payload.

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS

A. VRCS @[113095-1809A]

1. VRCS CONTROL IS NOT PERMITTED WHEN THE RMS IS:
 - a. IN TEST MODE AND GRAPPLED TO A NON-CONSTRAINED PAYLOAD.
 - b. PERFORMING FREE-FLYING PAYLOAD END EFFECTOR OPERATIONS.
 - c. IN MOTION WITH A PAYLOAD OVER 3640 KG (8000 LBS).
(NOTE: THIS CONSTRAINT APPLIES TO DAP AUTO CONTROL ONLY; DAP MANUAL MODE IS ALLOWED.)
2. FOR OTHER VRCS CONSTRAINTS DURING LOADED RMS OPERATIONS (DUE TO DAP STABILITY PROBLEMS, PAYLOAD CLEARANCE CONCERNS, PAYLOAD LOADS SENSITIVITY CONCERNS, OR OTHER PAYLOAD CONSTRAINTS), REFERENCE THE FLIGHT RULES ANNEX.

When in test mode, unexpected arm motion due to payload inertia may result from VRCS firings since all joints are at maximum current attenuation and are essentially free to rotate when external forces are applied (except for internal gearbox friction). No free-flying EE operations should be performed with VRCS because jet firings may cause unexpected motion of the EE when the arm is limped for capture or rigidize sequences or tipoff rates may occur at release. Volume XIV, Appendix 8 states that prior to the grapple sequence, the orbiter RCS will be configured to free drift. It also specifies an orbiter DAP free drift period prior to release between 15 and 120 seconds to allow RMS oscillation damping.

Both SPAR and MPAD have performed analyses which show there is no chance of exceeding RMS or longeron loads for any combination of VRCS firings with a loaded RMS. However, there can be stability problems associated with manipulation of high mass payloads due to the change in the composite cg of the orbiter/payload. Volume XIV, Appendix 8 states that for payloads weighing over 8000 pounds, DAP free drift is required while the RMS is maneuvering the payload. @[113095-1809A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS (CONTINUED)

B. PRCS ATTITUDE CONTROL @[113095-1809A]

1. PRCS PRI DAP ATTITUDE CONTROL IS NOT PERMITTED WHEN THE RMS IS:
 - a. IN A SINGULARITY.
 - b. AT A REACH LIMIT.
 - c. IN TEST MODE UNLESS GRAPPLED TO A CONSTRAINED PAYLOAD.
 - d. PERFORMING END EFFECTOR OPERATIONS.
 - e. MANEUVERING A PAYLOAD OVER APPROXIMATELY 450 KG (1000 LBS).
 - f. CLOSER THAN APPROXIMATELY 1.5M (5 FT) FROM ORBITER STRUCTURE, OTHER PAYLOADS, OR EVA CREWMEMBER.
2. FOR ADDITIONAL LOADED RMS PRCS CONSTRAINTS, REFERENCE THE FLIGHT RULES ANNEX.

Both SPAR and MPAD have performed analyses that show there is no constraint to an unloaded arm for PRCS firing as long as the arm is not positioned near a reach limit or singularity. At these positions, a degree of freedom is lost and the arm cannot relieve loads through backdriving. When in test mode, unexpected arm motion may result from PRCS firings since all joints are at maximum current attenuation and are essentially free to rotate when external forces are applied (except for internal gearbox friction). No EE operations should be performed with PRCS because jet firings may cause unexpected motion of the EE when the arm is limped for capture or rigidize sequences or tipoff rates may occur at release. Volume XIV, Appendix 8 states that prior to the grapple sequence, the orbiter RCS will be configured to free drift. It also specifies an orbiter DAP free drift period prior to release between 15 and 120 seconds to allow RMS oscillation damping.

The ICD specifically prohibits RMS from maneuvering a payload greater than 450 kg (1000 lbs) unless PRCS is inhibited.

Level B Groundrules and Constraints defines minimum clearance of 1.5 M (5 ft) to protect for induced motion resulting from PRCS auto hold and PRCS auto maneuver. @[113095-1809A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS (CONTINUED)

C. PRCS TRANSLATIONS @[113095-1809A]

1. PRCS TRANSLATIONS ARE NOT PERMITTED EXCEPT WHEN THE RMS IS:
 - a. UNLOADED PROVIDED CLEARANCE OF APPROXIMATELY 1.5M (5 FT) OR GREATER IS MAINTAINED BETWEEN THE RMS AND OTHER ORBITER STRUCTURE.
 - b. GRAPPLED TO A SIX-DOF CONSTRAINED PAYLOAD IN CONTINGENCY SITUATIONS THAT REQUIRE TRANSLATIONS.
2. REFERENCE THE FLIGHT RULES ANNEX FOR EXCEPTIONS FOR PAYLOADS REQUIRING TRANSLATIONS.

The loaded RMS has not been certified to withstand the motion or loads associated with PRCS translations, and a flight-specific analysis will need to be done for each specific case.

D. OMS USAGE: @[113095-1809A]

1. OMS BURNS WILL NOT BE PERFORMED WITH AN UNCONSTRAINED LOADED RMS.
2. PLANNED OMS BURNS (DUAL OR SINGLE ENGINE) ARE PERMITTED PROVIDED THE RMS IS CRADLED WITH AT LEAST TWO OF THREE MRL'S LATCHED OR THE UNLOADED RMS IS IN THE PRECRADLE POSITION (SY = 0, SP = 25, EP = -25, WP = 5, WY = 0, WR = 0).
3. IN CONTINGENCY SITUATIONS THAT REQUIRE OMS BURNS (I.E., OMS LEAK), OMS USAGE IS PERMITTED WITH THE UNLOADED RMS UNCRADLED AND NOT IN THE PRECRADLE POSITION (ASSUMES BEST EFFORT TO POSITION THE RMS AS CLOSE TO THE PRECRADLE POSITION AS POSSIBLE). OMS BURNS ARE ALSO PERMITTED IF THE RMS IS GRAPPLED TO A SIX-DOF CONSTRAINED PAYLOAD.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS (CONTINUED)

Rockwell Space Operations Company (RSOC) analysis has determined that loads from OMS burns are well below the flight planning load limits, and no joint slippage occurs when the RMS is in the precradle position during an OMS burn. The analysis investigated single, double, and worst case failure conditions as well and determined all loads and motion were acceptable. Other positions analyzed showed several inches to several feet of motion for worst case OMS failures. OMS burns with a loaded RMS showed unacceptable motion and loads and could result in payload-to-orbiter contact. If a contingency OMS burn is required and the RMS cannot be maneuvered to the precradle position, a best effort to maneuver to the precradle is required to minimize the potential motion. Refer to STSOC transmittal Form, RSOC-635/250-91-066, October 4, 1991.

- E. EXCEPT FOR TRANSITORY MOTION, NO PART OF THE RMS SHALL BE MANEUVERED OR PARKED WITHIN THE FOLLOWING DISTANCES OF AN RCS JET CONTINUOUS FIRING RATE STAY-OUT ZONE, AS DEFINED BELOW, UNLESS THE JET IS DESELECTED. @[113095-1809A]

- F. FLIGHT-SPECIFIC EXCEPTIONS FOR THE LOWER RATE STAYOUT ZONES MAY BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX. @[113095-1809A]

- 1. PRCS:

FIRING RATE	STAY-OUT ZONES*							
CONTINUOUS	X=0	R=200	X=425	R=150	X=500	R=100	X=600	R=0
6 SECONDS	X=0	R=200	X=200	R=100	X=340	R=0		
80 MSEC	X=0	R=40	X=130	R=40	X=160	R=30	X=180	R=0

- 2. VRCS:

FIRING RATE	STAY-OUT ZONES*							
CONTINUOUS	X=0	R=18	X=50	R=18	X=70	R=10	X=80	R=0
80 MSEC	X=0	R=5	X=30	R=0				

*X = DISTANCE IN INCHES FROM THRUSTER IN DIRECTION OF THRUSTER PLUME

R = LATERAL DISTANCE IN INCHES FROM CENTER OF THRUSTER

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS (CONTINUED)

Based on data presented by SPAR at the STS-2 Orbit Flight Techniques Meeting #19 on August 28, 1981, the above clearances are required to prevent damage to the RMS thermal protection system. This is the minimum required separation in direct line with the center axis of the thruster. Based on Orbit Flight Techniques Meeting #149 on December 16, 1994, the decision was made to deselect the affected jets for long-term parking of the RMS in a jet stay-out zone to preclude the inadvertent pluming of the RMS. Additionally, PDRS Ops Checklist Unloaded Survey procedures have been updated to deselect jets for those surveys that violate RCS stay-out zones. @[113095-1809A]

- G. IN UNPLANNED CONTINGENCY SITUATIONS, WHEN THE STATIONARY RMS IS LOADED, CLOSED-LOOP VRCS ATTITUDE CONTROL (I.E., DAP AUTO, INRTL-DISC, LVLH-DISC) IS PERMITTED FOR ARM CONFIGURATIONS THAT HAVE NOT BEEN ANALYZED FOR DAP STABILITY PREFLIGHT IF THE FOLLOWING CRITERIA ARE MET: @[113095-1809A]
1. THE PAYLOAD WEIGHT IS LESS THAN 35K LB.
 2. THE RMS IS NOT IN A REACH LIMIT OR SINGULARITY.
 3. CLEARANCE BETWEEN THE PAYLOAD AND ORBITER IS AT LEAST 10 FEET.
 4. THE PAYLOAD IS NOT LOAD SENSITIVE.
 5. THE CREW MONITORS THE RMS AND ORBITER FOR SIGNS OF DAP INSTABILITY.
 6. THE FLIGHT CONTROL TEAM MONITORS FOR SIGNS OF DAP INSTABILITY.
 7. TIGHT RATE AND ATTITUDE DEADBANDS, SUCH AS THOSE USED FOR PAYLOAD RELEASE, ARE NOT USED.
 8. CLOSED-LOOP ATTITUDE HOLD WILL NOT BE INITIATED DURING LOS.
 9. CLOSED-LOOP ATTITUDE MANEUVERS WILL NOT BE INITIATED OR TERMINATED DURING LOS.
 10. THE BEST AVAILABLE DAP I-LOAD SET (CNTL ACCEL) FOR THE RMS/PL CONFIGURATION IS USED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-6

OMS/RCS CONSTRAINTS (CONTINUED)

IF AN INSTABILITY IS DETECTED, THE ORBITER DAP SHOULD BE DOWNMODED TO FREE DRIFT AND MANUAL CONTROL USED FOR ATTITUDE HOLD AND MANEUVERS.

IN ORDER TO REGAIN CLOSED-LOOP DAP CAPABILITY AFTER AN INSTABILITY HAS OCCURRED, THE RMS AND/OR DAP SHOULD BE RECONFIGURED BEFORE REINITIATING AUTO CONTROL.

A limited analysis of the effects of an unstable VRCS DAP on the loaded RMS (22k PL) has shown loads to be below the flight planning load limit and motion of the payload at a rate less than 2 in/min with the RMS brakes on and insignificant when the RMS was in position hold (Orbit Flight Techniques Panel Meeting #101). Discussion at Orbit Flight Techniques Panel meeting #105 concluded that the magnitude of the uncommanded motion of the RMS/PL is more than an order of magnitude below any unacceptable limit and that the RMS joints will backdrive to relieve loads as long as the RMS is not in a singularity or reach limit. Additionally, flight controllers can monitor phase plane activity and jet firing patterns to determine whether or not the DAP is unstable if the crew cannot detect the instability (ref. Draper memo SSV-88-49, Identification of RMS/FCS Instability During Payload Extended Operations, 10/21/88). Tight deadbands should not be used at nonanalyzed configurations because they have a high probability of causing an instability. Draper Lab recommends widening the deadbands to a rate limit of 0.1 deg/sec and an attitude deadband of 2.0 degrees. Instability during attitude maneuvers is less likely to occur by using a maneuver rate less than or equal to the rate limit. The most likely time for an instability to occur is when closed-loop control is first initiated or when an auto maneuver is started or terminated. Because the crew cannot easily detect an instability, it is preferable to initiate closed-loop control during a period of AOS to allow the flight control team to assess the DAP's performance. Auto maneuvers should be scheduled to begin and end during an AOS period, also. Before initiating closed-loop attitude control, the DAP I-load set (CNTL ACCEL on SPEC 20) that best matches the RMS/PL configuration should be selected. In determining the best CNTL ACCEL, the payload Z position is the most important parameter. An improper CNTL ACCEL can lead to inefficient jet selection and possible loss of attitude control.

If an instability occurs, the crew should downmode to free drift and use manual control. Reconfiguring the RMS and/or DAP before reinitiating auto control may result in a stable DAP.

FLIGHT RULES

A12-7

RMS IFM D&C KIT

- A. FOR RMS A8 D&C PANEL FAILURES, IF THE MISSION TIMELINE CAN ACCOMMODATE THE INSTALLATION AND REMOVAL TIME OF THE RMS D&C KIT, FOR GO/NO-GO DECISIONS, ITS PRESENCE CAN BE ASSUMED WHETHER IT IS CURRENTLY INSTALLED OR NOT. CONVERSELY, WHEN THE KIT IS INSTALLED, PANEL A8 CONTROLLED FUNCTIONS WHICH ARE DISABLED BY KIT INSTALLATION (AUTO/MAN EE DRIVE AND DIRECT DRIVE) WILL NOT BE CONSIDERED PERMANENTLY LOST FOR GO/NO-GO DECISIONS.

Approximately 1 hour is required to install the RMS D&C kit and an additional hour is required for removal. If sufficient time exists for installation and removal, the system configuration (and capabilities) will be modified by the kit; hence, its functions should be used in the decision-making process.

Since the kit will only be installed if sufficient time exists for its removal, the system configuration will be returned to nominal, and those functions disabled by kit presence should not be considered permanently lost in the decision-making process.

- B. WHEN THE RMS D&C KIT IS INSTALLED, THE APPLICABLE AC/DC SWITCH POWERING THE KIT WILL REMAIN OFF UNTIL IMMEDIATELY PRIOR TO THE REQUIRED OPERATION AND WILL BE RETURNED TO OFF IMMEDIATELY AFTER THE OPERATION IS COMPLETED. THE KIT WILL BE REMOVED AS SOON AS PRACTICAL AFTER THE REQUIRED FUNCTION IS COMPLETED.

The RMS D&C kit utilizes separate cabling for ac and dc controlled functions. Since the kit design does not include an enable switch for the joint drive or end effector functions, failures of these switches with the kit installed will potentially produce CRIT 1 situations. For this reason, the switch powering the kit will be used as an enable/inhibit switch, and power will only be applied during the actual operation which caused installation of the kit. @[111298-6744]

- C. USE OF ANY APPROVED DC POWER KIT FUNCTIONS EXCEPT EE OPERATIONS IN SUPPORT OF PAYLOAD RELEASE MUST BE PRECEDED BY A KIT VERIFICATION. PRIOR TO APPLICATION OF DC POWER TO THE KIT, THE FOLLOWING CONDITIONS MUST BE MET:
1. THE RMS/PL MUST BE POSITIONED WELL CLEAR OF (> APPROXIMATELY 5 FEET) STRUCTURE.
 2. THE KIT JOINT SELECT SWITCH MUST BE POSITIONED TO A JOINT WHICH WILL PRODUCE BENIGN MOTION IF UNCOMMANDED DIRECT DRIVE OCCURS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-7

RMS IFM D&C KIT (CONTINUED)

3. IF LOADED, THE RMS MUST BE POSITIONED SUCH THAT PAYLOAD ROTATIONS DUE TO UNCOMMANDED DERIGID WILL NOT CAUSE CONTACT, AN ORBITER PILOT MUST BE AVAILABLE TO PERFORM AN IMMEDIATE SEPARATION SHOULD AN UNCOMMANDED RELEASE OCCUR, AND DOWNLINK MUST BE AVAILABLE TO CONFIRM LACK OF EE STALL CURRENTS.

When dc power is applied to the kit, the direct drive, and EE drive, switches are all enabled and failures within these switches could command those functions. Failures within the kit direct drive switch will override all commands (even if brakes on and RMS stationary) and result in uncommanded drive of the joint selected on the kit. The best method to halt this motion is to remove primary power from the RMS (application of brakes will be ineffective). Also, when dc power is applied to the kit, EE functions are enabled, and subsequent failure of those switches could result in uncommanded payload derigid, release, or EE burnout. ©[111298-6744]

It should be determined that the selected joint does not drive in the presence of no command and that multiple joints do not drive when a command is issued. The kit joint select switch should be prepositioned to the joint which would produce the most benign motion should uncommanded joint drive occur when power is applied to the kit. Application of dc power to support EE functions is short term and hence an acceptable risk.

- D. USE OF THE RMS D&C KIT IS APPROVED FOR THE FOLLOWING FUNCTIONS:
 1. RMS SHOULDER BRACE RELEASE
 2. EE OPERATIONS

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-7

RMS IFM D&C KIT (CONTINUED)

3. DIRECT DRIVE (LOADED OR UNLOADED) ©[111298-6744]

RMS shoulder brace release utilizes ac power. There are no other ac kit functions hence no risk associated with use of this function.

When dc power is applied to the kit, the direct drive, and EE drive switches are all enabled and failures within these switches could command those functions. However, health status of the kit is verified prior to its operational use (except for PL release) and; hence, the period of vulnerability to subsequent failure is limited to the timeframe that dc power is actually applied to the kit. Other flight rules constrain power application times to the minimum required to perform the desired function with the kit. ©[111298-6744]

EE operations utilize dc power. EE drive times are procedurally limited to under 30 seconds; hence, this is deemed to be an acceptable risk (to failures within the direct drive switch).

Direct drive operations utilize dc power. Direct drive may require extensive time periods for maneuvering; however, the potential benefits to loaded RMS mission success outweigh the risk of uncommanded EE operations if a successful kit verification has been completed as required.

The redesign of the Servo Power Amplifiers has obviated the need for a safing inhibit function.
©[111298-6744]

FLIGHT RULES

A12-8

RMS OPCODE UPLINKS

- A. RMS OPCODE UPLINKS ARE NOT PERFORMED ON A NOMINAL BASIS. UPLINKS MAY BE PERFORMED FOR THE FOLLOWING CASES.

RMS level C data is nominally defined during the flight cycle of the flight software (FSW) build.

1. IDENTIFICATION OF LEVEL C REQUIREMENTS LATE IN THE PROGRAM FLOW.

FLIGHT-SPECIFIC REQUIREMENTS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

Previously, payload or program requirements identified after the nominal flight cycle deadlines could only be accommodated by a costly software patch. The uplink capability provides a cost-efficient alternative to meeting these requirements.

2. PAYLOAD OR PROGRAM REQUIRES MORE LEVEL C DATA THAN FSW LIMITATIONS CAN SUPPORT.

FLIGHT-SPECIFIC REQUIREMENTS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

Current manifest projections and increased payload complexities may require more EEID's, PLID's, or autosequences than FSW can support. The opcode uplink enables RMS to have the capability to support these situations without requiring a GMEM read/write.

3. CONTINGENCY RMS OPCODE UPLINKS DESIGNED AND SUBMITTED DURING A MISSION.

Situations unanticipated preflight could arise where the opcode unlink capability is useful to successfully meet mission objectives.

- B. CONTINGENCY OPCODE UPLINK DATA WILL BE DEVELOPED AND TESTED WITH THE RMS PLANNING SYSTEM (RPS) TOOL AND VALIDATION WILL CONSIST OF THE FOLLOWING:

RPS is a configuration controlled (MOD Software Management Plan for Workstation Applications) RMS tool used to design, develop, and test nominal level C data and RMS procedures. An application exists on RPS to build and test data files for uplink applications.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-8 RMS OPCODE UPLINKS (CONTINUED)

1. RPS TESTING FOR LEVEL C GENERATION, RANGE LIMIT CHECKING, AND RMS FUNCTIONAL TESTS. ANY RANGE LIMIT EXCEEDANCES WILL BE DOCUMENTED IN A MER CHIT, RESOLVED WITH THE MER, AND BROUGHT TO THE FD'S ATTENTION PRIOR TO UPLINK.

Data range limits defined in STS-97-0017 (RMS Level C Functional Subsystem Software Requirements document) are based on formulas developed to ensure RMS integrity given payload-specific mass property data. Level C data must be within these specified ranges else it will be rejected by the SM preprocessor and the opcode program. Situations arise where these limits can safely be exceeded. Range limit exceedances announced to the RPS or workstation user will be evaluated on a case-by-case basis to determine if the uplink should be performed.

RPS and the opcode uplink program software are designed to perform testing and procedure verification comparable to the Shuttle Avionics Integration Laboratory (SAIL), RSOC Level 8, IBM Software Development Facility (SDF), and SM preprocessor. Therefore, no additional testing is required.

2. MER CONCURRENCE ON THE UPLINK AND RPS VALIDATION VIA MER CHIT.

The MER chit ensures the RMS community concurs the data is valid and will not compromise the RMS.

- C. THE RMS MUST HAVE THE BRAKES ON WHEN THE OPCODE UPLINK IS PERFORMED.

This ensures a runaway due to the uplinked data will not occur. Additionally, the FSW will reject the uplink if the RMS is not in the suspend, idle, or temperature monitor mode.

A12-9 RMS MCIU BITE OVERRIDES [CIL]

MCIU OVERRIDES (SM 95, ITEMS 36, 37, OR 38) WILL NOT BE PERFORMED WITHOUT MCC CONCURRENCE. ©[071494-1644]

With BITE overrides enabled, the failed joint is one failure away from a crit 1 situation for which the autobrakes are designed to catch. With a joint BITE failure overridden, autobrakes and fault annunciation are disabled for a subsequent failure of that same joint. Requiring the MCC to concur with performing BITE overrides ensures that the risks are assessed and precautions taken to mitigate the effects of subsequent failures. ©[071494-1644]

A12-10 THROUGH A12-50 RULES ARE RESERVED

FLIGHT RULES

MPM/MRL LOSS/FAILURE DEFINITIONS

A12-51 MPM/MRL POSITIONING

AN MPM OR MRL MECHANISM SHALL BE CONSIDERED TO HAVE ATTAINED ITS COMMANDED POSITION IF AT LEAST ONE INDICATION OF THAT STATE OCCURS WITHIN THE SINGLE MOTOR DRIVE TIME.

If a microswitch changes to reflect what is believed to be the true state of the hardware at the exact time the hardware is supposed to achieve that state, it is extremely probable that the hardware is indeed at the indicated state even if the redundant microswitch does not verify the condition.

While operating the MPM or MRL, flight experience has demonstrated that there are normal drive times associated with failure free conditions. Anything other than those times achieved during operation would be grounds to suspect an anomalous condition. However, if the drive time is within the single motor specification time and other cues (visual and/or duration of current signatures) corroborate the single microswitch indication, it is assumed that the mechanism is actually at the indicated state.

A12-52 MPM FAILED IN TRANSIT

WHEN COMMANDING THE MPM, IF NEITHER THE SHOULDER DEPLOYED (ONE OF TWO) NOR STOWED (ONE OF TWO) POSITIONS ARE INDICATED AFTER THE SINGLE MOTOR DRIVE TIME HAS ELAPSED, IT SHALL BE ASSUMED THAT THE MPM HAS FAILED IN TRANSIT.

Without a deploy or stow indication of the MPM, the system is considered in transit and unlocked. The rule is only applicable when the MPM is being driven. Once the MPM has reached the stowed or deployed position, it is assumed that it remains there, even if the microswitches change state, unless there is a drive command present.

In fact, this has occurred during flight on several occasions. While the arm was being driven, the MPM deploy microswitches cycled to the "not deploy" state. The community has concluded that this phenomenon is associated with arm operational stresses applied to the base of the MPM and the relatively sensitive nature of the microswitch rigging calibration.

FLIGHT RULES

A12-53

MRL FAILED IN TRANSIT

WHEN COMMANDING THE MRL'S, IF AN MRL DOES NOT INDICATE THE LATCHED (ONE OF TWO) OR RELEASED (ONE OF TWO) POSITION AFTER THE SINGLE MOTOR DRIVE TIME HAS ELAPSED, IT SHALL BE ASSUMED THAT THE MRL HAS FAILED IN TRANSIT.

Without the proper latched or released indications, the latch position is indeterminate.

A12-54 THROUGH A12-70 RULES ARE RESERVED

FLIGHT RULES

MPM/MRL SYSTEMS MANAGEMENT

A12-71

MPM/MRL CYCLING

CYCLING OF THE MPM OR MRL SHALL ONLY BE PERFORMED WHILE THE ARM IS CRADLED.

There are two intentions for this rule. The first is to prevent MPM motion with the arm uncradled since the system was not designed for that capability. The other is to prevent the latches from failing closed when the RMS is uncradled. If this occurred, the RMS could not be cradled. Therefore, adequate clearance would not exist between the arm and radiators with the doors shut, and the arm would have to be jettisoned.

FLIGHT RULES

A12-72

MPM DEPLOY/STOW CONSTRAINTS

- A. THE MPM'S SHALL BE STOWED AS SOON AS PRACTICAL IF ONLY SINGLE MOTOR DRIVE IS AVAILABLE.

The MPM's are all driven by a single torque tube from two separate motors. The MPM shall be stowed if a single motor is lost since a subsequent failure of the other motor would require an EVA or jettison of the arm and MPM's. During normal operations of the arm, it is unacceptable to continue if the system is one failure from having to jettison or perform an EVA. EVA tools and procedures are available to deploy or stow the MPM that has stopped because of an electrical failure but not for a mechanical jam.

@[110900-7257]

Rule {A2-103E}, EXTENSION DAY REQUIREMENTS, references this rule. @[090894-1670B]

- B. FOR LOSS OF MPM STOW REDUNDANCY DURING HIGH PRIORITY OPERATIONS, THE MPM'S WILL REMAIN DEPLOYED UNTIL OPERATIONS ARE COMPLETE. IF FAILURE OF THE REMAINING MPM STOW SYSTEM OCCURS WHILE DEPLOYED, OPERATIONS WILL CONTINUE UNTIL AN EVA CAN BE PERFORMED OR JETTISON IS REQUIRED.

The MPM must be deployed to achieve mission success for high priority RMS operations. Termination of loaded activities due to loss of stow capability during loaded operations will be of no benefit. A subsequent failure of the second MPM drive system would require an EVA to roll in the MPM or jettison of the RMS/MPM. EVA may be viable for electrical failures only (mechanical jam may result in jettison). Due to the priority of the mission objectives, the risk is acceptable.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule. @[110900-7257]

- C. FOR THE COMPLETE LOSS OF MPM MOTOR DRIVE CAPABILITY, AN EVA TO DEPLOY AND/OR STOW THE MPM'S WILL BE PERFORMED TO PERMIT HIGH PRIORITY LOADED RMS OPERATIONS. @[110900-7257]

The MPM must be deployed to achieve mission success for high priority RMS operations. Electrical failures which prevent driving the MPM can be worked around via IFM or EVA; mechanical failures cannot. Due to the priority of the mission objectives, EVA support for these contingencies has been preflight planned.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A12-72** **MPM DEPLOY/STOW CONSTRAINTS (CONTINUED)** ©[ED]

D. THE MPM MUST BE POSITIONED AS FOLLOWS DURING RMS OPS:

1. UNLOADED RMS - THE MPM MUST BE EITHER FULLY DEPLOYED OR FULLY STOWED. IF STOWED, DAP FREE DRIFT, VRCS, OR ALT MODE ATTITUDE CONTROL IS REQUIRED. IF ALT MODE IS USED, TWO JET CONTROL WITH JET ON TIME OF 0.08 SECONDS MUST BE USED. DELAY TIMES OF 5 SECONDS OR LESS ARE ACCEPTABLE.
©[071494-1662A]
2. LOADED RMS - THE MPM MUST BE FULLY DEPLOYED. FLIGHT-SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

Without deployed or stowed indications, the MPM's are considered in transit and unlocked with only the stiffness of the torque tube present to maintain a firm shoulder position. This is not a sufficient load path to support any arm operations without possible structural failure. In the fully deployed or stowed positions, loads are distributed to the sill longeron by overcenter locked structural links plus, if fully deployed, a load-bearing J-hook. Supplemental Rockwell-Downey analyses (280-STSD-106-89-027) have shown that for an unloaded RMS, positive MPM structural margins exist during nominal RMS maneuvering or RMS runaway failures at various worst case (bounding) RMS orientations with the shoulder MPM in the stowed position. Previous analyses have concluded that runaway loads bound VRCS induced loads but do not always bound Pri DAP induced loads. RSOC Analysis (RSOC-635/250-94-009) also shows that longeron loads induced by reasonable worst case PRCS alt mode jet firings are bounded by the previous runaway loads, hence, the free drift, VRCS, or alt mode constraint.

©[071494-1662A] ©[113095-1809A]

E. ONCE THE MPM'S ARE DEPLOYED, THEY MAY REMAIN DEPLOYED UNTIL RMS MISSION OPERATIONS ARE COMPLETED. REFERENCE PARAGRAPHS A, B, AND C FOR THE LOSS OF DUAL-MOTOR STOW CAPABILITY.

With two-motor stow capability, there is no problem with leaving the MPM's deployed. Paragraphs A, B, and C of this rule address the loss of dual-motor stow capability. The intent of this rule is to not require stowing the MPM's at the end of each day if RMS operations are planned on subsequent days.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule. ©[110900-7257]

FLIGHT RULES

A12-73

MRL CONSTRAINTS

- A. THE RMS SHALL BE CRADLED AND LATCHED AS SOON AS PRACTICAL IF THE MRL'S ARE ONE FAILURE AWAY FROM BEING UNABLE TO LATCH AT LEAST TWO OF THREE PEDESTALS.

There are failures that result in the loss of two or three MRL latch motors. If the configuration of the MRL is such that the next failure can result in the inability to latch at least two MRL's, the arm shall be cradled ASAP since there is no analysis that indicates that it is safe to return the orbiter with the RMS unlatched (ref. paragraph C). ©[110900-7257]

Rule {A2-103E}, EXTENSION DAY REQUIREMENTS, references this rule. ©[090894-1670B]

- B. FOR HIGH PRIORITY MISSION OBJECTIVES, IF FAILURES CAUSE THE MRL'S TO BE ONE FAILURE AWAY FROM THE LOSS OF ABILITY TO LATCH TWO PEDESTALS, RMS OPERATIONS WILL BE ALLOWED TO CONTINUE. THE RMS SHALL BE CRADLED AND LATCHED AS SOON AS PRACTICAL AFTER ALL RMS SUPPORTED HIGH PRIORITY MISSION OBJECTIVES ARE COMPLETED.

At least two of three MRL's are required to be latched to allow the orbiter to enter with the RMS. Due to the importance of the mission objectives, operations will be permitted to continue if the MRL's are one failure away from the loss of ability to latch two or three MRL's. Either EVA tiedown or RMS jettison is available as an alternative means to safe the RMS or orbiter for entry.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule.

- C. THE RMS MUST HAVE TWO OF THREE MRL'S SECURED FOR ENTRY.

Each of the three MRL's have two independent drive motors, and either a mechanical jam would have to occur or both drive systems would have to fail to cause loss of latch capability for an MRL pedestal. Flight Techniques analysis has indicated that two of three MRL's must be secured for entry (via MRL latch or EVA technique) to prevent RMS/radiator contact. This capability is protected by staying at least two failures away from not being able to latch two of three MRL's.

Rules {A12-1001}, RMS GO/NO-GO CRITERIA, and {A2-103E}, EXTENSION DAY REQUIREMENTS, reference this rule. ©[090894-1670B] ©[110900-7257]

FLIGHT RULES

A12-74

INADVERTENT MPM CYCLING PROTECTION [CIL]

WHILE THE RMS IS UNCRADLED, THE FOLLOWING CIRCUIT BREAKERS WILL BE OPENED TO PREVENT INADVERTENT CYCLING OF THE MPM SYSTEM:

MA73C:C cb MCA PWR AC2 3Ø MID 2

MA73C:D cb MCA PWR AC3 3Ø MID 4

FMEA'S exist for MPM DPLY/STOW switch or hybrid relay failures that result in uncommanded motion of the MPM. The orbiter/RMS/payload may be damaged if the MPM stows during RMS operations. Opening these circuit breakers removes ac power from both MPM motors. This provides protection while the payload bay mechanical power switches are on. These cb's must be closed for vent and payload bay door operations; neither of which are normally done during RMS operations. For radiator stow/deploy, see Rule {A10-221D}, RADIATOR MECHANICAL.

A12-75 THROUGH A12-90 RULES ARE RESERVED

FLIGHT RULES

RMS PREOPERATION SYSTEM MANAGEMENT

A12-91

SHOULDER BRACE OPERATION

THE SHOULDER BRACE SHOULD BE RELEASED AS EARLY AS PRACTICAL AFTER PLBD OPENING.

There are failure modes which may prohibit the operation of the shoulder brace release mechanism. Orbit thermal effects could also prevent release. Therefore, it is prudent to release the brace as soon as practical since its only function is to support ascent loads.

Rule {A12-1001A}, RMS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A12-92

RMS CHECKOUT

- A. THE RMS FLIGHT DATA FILE CHECKOUT PROCEDURES SHALL BE PERFORMED ONCE PER MISSION, AS EARLY AS PRACTICAL, PRIOR TO ANY NOMINAL RMS OPERATIONS.

There are several failure modes that can be detected during the RMS checkout. Early detection of a failure may provide adequate time to troubleshoot the problem and develop workaround procedures.

- B. FOR OFF-NOMINAL SITUATIONS WHERE A RAPID RMS RESPONSE IS DESIRED, COMPLETION OF THE CHECKOUT PROCEDURES FOR BACKUP AND DIRECT DRIVE MODE SHALL BE ACCOMPLISHED AS A MINIMUM.

This will ensure that the arm is not a single failure away from having to be jettisoned or stowed EVA. One of these modes is required to cradle the arm. Approximately 5 to 10 minutes are required to complete these tests. A test of direct drive gives valuable insight into any possible joint degradation while testing single may not indicate the problem. The PDRS checklist has been modified to give the crew a success criteria for direct drive.

- C. THE EE CHECKOUT WILL BE PERFORMED ONCE PER MISSION PRIOR TO ANY EE OPERATIONS.

It is important to understand if there are any failures resident in the EE prior to operations to prohibit unsafe use of the system. This rule also implies that the EE does not have to be checked if there are no EE operations for the flight.

- D. RESERVED

- E. THE DIRECT DRIVE TEST SHALL BE PERFORMED ON EACH JOINT WITH A MINIMUM CONTINUOUS DRIVE IN EACH DIRECTION FOR 12 SECONDS.

RMS checkout operations on orbit are the only tests of the RMS in which the results are not affected by gravity and the inadequacies of the test equipment. Parametric studies by SPAR Aerospace Limited have concluded that the direct drive mode tests, if properly run, will supply the necessary data for trend analysis of the individual RMS joints. To make this data meaningful, each joint must be driven continually in each direction for 12 seconds to guarantee that the motor has stabilized at the maximum rate.

A12-93 THROUGH A12-110 RULES ARE RESERVED

FLIGHT RULES

RMS DRIVE SYSTEM MANAGEMENT

A12-111 MODE AVAILABILITY DRIVE CONSTRAINT

- A. RMS OPERATIONS SHALL CEASE AND THE RMS SHALL BE CRADLED AND LATCHED IF BACKUP PLUS ONE OTHER PRIMARY SINGLE JOINT MODE IS NOT AVAILABLE TO DRIVE EACH JOINT. ©[110900-7257]

Backup mode is electrically independent from all other modes; therefore, requiring this mode in addition to one other single joint mode to begin or continue normal RMS operations ensures that, after a single point failure, the arm can still be cradled. It has not been demonstrated that the arm can be cradled in any mode other than one utilizing a single joint drive method. In addition, the only way that loss of backup can be determined is during the RMS checkout or by the loss of main bus B.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule.

- B. RMS OPERATIONS IN SUPPORT OF HIGH PRIORITY TASKS CAN BE PERFORMED WITH ONLY ONE MODE OF OPERATING THE RMS AVAILABLE.

The RMS utilizes two power sources, primary and backup, and has multiple modes for driving the arm on primary power. The priority of operations is such that operations will continue with only one mode available to drive the RMS. EVA and jettison can be considered as redundancy for cradling the RMS or safing the payload bay.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule. ©[110900-7257]

A12-112 FIELD OF VIEW CONSTRAINT [CIL]

THE RMS SHALL NOT BE DRIVEN UNLESS THE CREW IS OBSERVING THE EXPECTED MOTION OF THE RMS/PAYLOAD STRUCTURE VIA WINDOW AND/OR CCTV VIEWS.

There are a considerable number of failure modes identified in the FMEA which can result in unannounced, uncommanded motion (e.g., two joints drive, wrong joint drives, hand controller fails at 56 percent of max command, etc.). If the operator is driving the arm in a configuration where the occurrence of one of these failure modes could not be observed, then the operator may not react to the failure by stopping the arm with the brakes (or whatever means are available) to avoid a collision with the orbiter/payload/EVA crewmember.

FLIGHT RULES

A12-113

AUTO MODE ENTRY CONSTRAINT [CIL]

AUTO MODES SHALL NOT BE ENTERED UNLESS THE PAYLOAD BAY AND PAYLOAD STRUCTURES ARE IN A CONFIGURATION FOR WHICH THE SEQUENCES HAVE BEEN VERIFIED. THE OPERATOR SHALL ONLY ENTER AN AUTO MODE IMMEDIATELY PRIOR TO SELECTION OF "PROCEED".

The first part of the rule requires that the payload bay be configured the way it was when the sequence was validated. This is simply to ensure that no appendages or other objects have been placed in the path of the sequence. Validation of the preflight designed auto sequences is accomplished by performing them on several of the available simulators and during crew training. Most of the operator-commanded auto sequences (OCAS) are also verified preflight in this way. However, in some cases, the crew may opt to develop a new OCAS real time. This OCAS can be verified by the ground flight controllers on their simulator or by the crew if the geometry is simple enough that they are confident that the procedure will run safely.

There are failure modes which can cause an auto sequence to begin prematurely (once the mode is entered), not stop at pause points, or not stop when "stop" is selected. By following this procedural rule, these failures will not place the crew in a hazardous condition. For operator-commanded auto sequences, care should be exercised in entering the desired position and attitude parameters because the sequence could begin with no operator command.

Rule {A12-114}, ORBITER PROXIMITY CONSTRAINTS [CIL], references this rule.

FLIGHT RULES

A12-114

ORBITER PROXIMITY CONSTRAINTS [CIL]

- A. IF THE MANIPULATOR CONTROLLER INTERFACE UNIT (MCIU) SAFING FUNCTION IS LOST, COMPUTER-SUPPORTED MODES SHALL NOT BE USED CLOSE TO (WITHIN APPROXIMATELY 5 FEET) STRUCTURE/PAYLOAD/EVA CREWMEMBER. WHILE BERTHING A PAYLOAD, ALL MODES CAN BE USED ONCE THE TRUNNIONS HAVE ENTERED THE V-GUIDES.

With this class of failure mode, MCIU safing will not automatically stop the arm if I/O with the GPC is erratic or interrupted while the arm is operating in a computer-supported mode. It is prudent to use only direct when close to any obstacles when MCIU safing is lost since direct is unaffected by these failure modes. Approximately 5 feet is considered sufficient since the runaway will be at the last commanded rate unlike other runaways which can result in maximum torque and joint rates. Once within the V-guides, any uncommanded motion is constrained by the physical guide. When the arm is not close to obstacles, all modes can be used since there is sufficient time for the operator to detect any uncommanded motion and apply the brakes.

- B. OPERATE AT/OR LESS THAN VERNIER RATES WHEN THE ARM/PAYLOAD IS CLOSE TO (WITHIN APPROXIMATELY 10 FEET) STRUCTURE/PAYLOAD/EVA CREWMEMBER. THE OPERATOR MUST CYCLE THE APPROPRIATE PANEL SWITCH WHEN DRIVING IN DIRECT OR BACKUP TO APPROXIMATELY MAINTAIN RATES AT OR LESS THAN VERNIER RATES.

There are many failure modes which result in uncommanded, unannunciated motion (e.g., hand controller fails, wrong joint drives, wrong joint direction, two joints drive, sluggish, or stalled joint, etc.) which the operator must detect and stop by applying the brakes. Many of these failure modes will run away at the last commanded rate or are joint rate limited so operating in vernier will limit the ultimate rates the failure can produce. The rest of the failure modes result in unexpected motion, uncommanded release, or derigidize. The detection and arresting of this motion or maneuvering the orbiter clear of a released payload will be less hazardous (i.e., give the crew more time to react) if the arm is operating at a slow rate.

- C. RATE HOLD SHALL NOT BE USED WHEN THE RMS/PAYLOAD IS CLOSE TO (WITHIN APPROXIMATELY 10 FEET) AND IS MOVING TOWARDS STRUCTURE/PAYLOAD/EVA CREWMEMBER EXCEPT WHEN CAPTURING A FREE FLYING PAYLOAD.

There are failure modes which result in the inability to cancel rate hold. If this occurs close to an obstacle, a collision could occur before the operator has enough time to detect and apply the brakes. Therefore, it is prudent not to use rate hold close to any obstacles. Rate hold may be used when capturing a free-flying payload since the payload/arm combination will be far from the orbiter.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-114 ORBITER PROXIMITY CONSTRAINTS [CIL] (CONTINUED)

- D. AUTO TRAJECTORIES SHALL BE DESIGNED SUCH THAT THE ARM/PAYLOAD DOES NOT PASS CLOSE TO (WITHIN APPROXIMATELY 5 FEET) STRUCTURE/PAYLOAD/EVA CREWMEMBER. @[111298-6744]

There are failure modes (e.g., sluggish and stalled joints) which result in undetected deviations from the intended auto trajectory. This requirement will allow the operator time to detect the failure and apply brakes. There is another rule (Rule {A12-113}, AUTO MODE ENTRY CONSTRAINT [CIL]) which governs use of auto mode (vice design). That rule prohibits using auto for unverified trajectories.

- E. THE RMS/PAYLOAD SHALL NOT BE MANEUVERED OR PARKED IN REGIONS WHERE IT CANNOT BE MANEUVERED TO A SAFE JETTISON POSITION WITH THE LOSS OF ANY SINGLE JOINT. @[111298-6744]

There are single point failure modes which result in the inability to drive an arm joint in either primary or backup modes. If any of these failures occurs and an EVA cannot be performed, the arm must be jettisoned prior to closing the PLBD. Therefore, since a joint failure may restrict arm mobility, the arm shall never be in a position where it cannot be maneuvered to a safe jettison position using only five of six joints.

The only single point failure modes which can result in the inability to drive all joints are in the power and arm select switches. These failure modes can be worked around by using an IFM pin kit. Final approval requires CIL change.

- G. EXCEPT FOR TRANSITORY MOTION (I.E., BERTHING/UNBERTHING, CRADLING/UNCRADLING, PAYLOAD DOCKING/UNDOCKING, OR PAYLOAD CAPTURE/RELEASE), THE RMS/PAYLOAD SHALL NOT BE MANEUVERED OR PARKED (CREW AWAKE) CLOSER THAN 60 CM (2 FT) FROM ORBITER STRUCTURE OR OTHER PAYLOADS. FOR APPLICATION OF THIS RULE, EVA CREWMAN IS NOT CONSIDERED ORBITER STRUCTURE OR PAYLOAD.

FLIGHT SPECIFIC EXCEPTIONS FOR HIGH PRIORITY OPERATIONS WILL BE IDENTIFIED IN THE FLIGHT SPECIFIC ANNEX.

Crew comfort, RMS and payload visibility, VRCS and ALT mode induced motion, RMS failures, and lack of task specific crew training become overriding concerns when maneuvering payloads in close proximity to orbiter structure. In cases where missions cannot be completed without violating this rule, the program incurs greater risk. As such, task specific assessment is required to document the risk and proposed methods, if any, to control it.

FLIGHT RULES

A12-115 **INOPERATIVE BRAKE CONSTRAINT [CIL]**

IF A BRAKE IS INOPERATIVE DUE TO A MECHANICAL FAILURE, THE RMS SHALL BE CRADLED IN SINGLE MODE AND LATCHED AS SOON AS POSSIBLE. IF THE WRIST ROLL BRAKE IS INOPERATIVE, UNLOADED RMS OPERATIONS MAY CONTINUE. PAYLOAD OPERATIONS WILL NOT CONTINUE WITH THE EXCEPTION OF COMPLETION OF BERTHING OPERATIONS IF THE PAYLOAD IS ALREADY WITHIN THE BERTHING GUIDES.

A failure mode exists which results in a brake pad mechanically not engaging. The motor drive amplifier (MDA) will still be inhibited when the brakes are electrically commanded on, so the failed joint will be free in both primary and backup modes. Single mode must be used to cradle the arm since it is the only remaining single joint mode that is still operative (uses position hold instead of brakes to maintain arm position). During unloaded operations, operations may continue with a known wrist roll brake problem since runaways on the wrist roll cannot result in any uncommanded translations of the arm.

Rule {A12-1001O} and P, RMS GO/NO-GO CRITERIA, reference this rule.

A12-116 **AUTO BRAKES CONSTRAINT [CIL]**

COMPUTER-SUPPORTED MODES SHALL NOT BE USED IF THE AUTO BRAKES FUNCTION HAS FAILED.

There are many failure modes which result in runaways (six or single joint) which are detected and automatically stopped by the auto brakes function. SPAR SIMFAC simulations have demonstrated that without these automatic checks a runaway in a computer-supported mode could travel as far as 18 feet before a crewmember could stop it by applying the brakes. Therefore, computer-supported modes should not be used after loss of this function.

Rule {A12-1001Q}, RMS GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A12-117 **CONTINGENCY STOP [CIL]**

THE BRAKES SHALL ALWAYS BE THE METHOD USED TO STOP THE RMS IF UNCOMMANDED MOTION OR UNUSUAL RMS BEHAVIOR OCCURS (INSTEAD OF SAFING, AUTO STOP SWITCH, OR RELEASING THE COMMAND). IF THE BRAKES ARE INOPERATIVE VIA THE PANEL SWITCH, THEY SHALL BE APPLIED BY TERMINATING PRIMARY POWER.

Use of the brakes is the most positive method of stopping the arm in emergency situations. It is preferred over safing since it inhibits the MDA at the joints which will stop a runaway joint caused by the servo or MDA (safing would not in many cases). It is also preferred over the stop switch during auto sequences since there are D&C failures which could prohibit the stop switch from operating.

A12-118 **POHS AND LEFT-HANDED COORDINATE SYSTEMS**

RMS POSITION AND ORIENTATION HOLD SELECT (POHS) MUST BE DISABLED FOR USE OF RMS PAYLOAD ID'S THAT ARE DEFINED USING A LEFT-HANDED PAYLOAD OPERATING COORDINATE FRAME. @[071494-1644]

POHS is a right-handed algorithm. It generates arm drive commands that are normal to the desired path which attempt to reduce off-axis deviations. Attempts to use it with left-handed defined payload operating systems results in unexpected motion by generating commands which are in a direction away from the desired trajectory. @[071494-1644]

A12-119 THROUGH A12-140 RULES ARE RESERVED

FLIGHT RULES

END EFFECTOR (EE) LOSS/FAILURE DEFINITIONS

A12-141 **EE BACKUP RELEASE**

EE BACKUP RELEASE IS CONSIDERED LOST IF SNARES DO NOT OPERATE SMOOTHLY TO THE FULLY OPEN POSITION.

Data from SPAR indicates that temperature has a significant effect on the time for the snares to open during the backup release check. Times on the order of minutes were seen at the lowest qualification test temperatures. With no grapple pin in the EE, the snares open quickly for the first 70-80 percent of travel then slow down at the end of travel. At the coldest flight conditions, during the on-orbit backup release check, the snares should fully open within 2 minutes, although 20-25 seconds has been typical. If the snares do not open smoothly and completely, there is a mechanical problem and backup release would be considered lost.

A12-142 **EE CAPTURE/RIGIDIZE**

EE CAPTURE OR RIGIDIZE FUNCTIONS ARE CONSIDERED LOST FOR AUTO AND/OR MANUAL IF THE CAPTURE TIME EXCEEDS 3 SECONDS OR THE RIGIDIZE TIME EXCEEDS 25 SECONDS.

The maximum capture specification time is 3 seconds and the maximum rigidize specification time is 25 seconds. Failure to meet these time constraints is indicative of binding in the drive mechanism or loss of one mode due to an electrical failure.

Rule {A2-112}, PDRS, references this rule.

A12-143 **EE RELEASE/DERIGIDIZE**

EE RELEASE OR DERIGIDIZE FUNCTIONS ARE CONSIDERED LOST FOR AUTO AND/OR MANUAL IF THE RELEASE TIME EXCEEDS 3 SECONDS OR THE DERIGIDIZE TIME EXCEEDS 25 SECONDS.

The maximum release specification is 3 seconds and the maximum derigidize specification time is 25 seconds. Failure to meet these constraints is indicative of binding in the drive mechanism or loss of one mode due to an electrical failure.

A12-144 THROUGH A12-160 RULES ARE RESERVED

FLIGHT RULES

END EFFECTOR SYSTEM MANAGEMENT

A12-161

PAYLOAD GRAPPLE CONSTRAINTS

- A. PAYLOADS SHALL NOT BE GRAPPLED AND UNBERTHED UNLESS BACKUP RELEASE AND ONE OF TWO METHODS TO CAPTURE AND RIGIDIZE (AUTO OR MANUAL) AND ONE OF TWO METHODS TO DERIGIDIZE AND RELEASE (AUTO OR MANUAL) ARE AVAILABLE.

The EE system is designed such that a single failure can result in the loss of both the auto and manual release capability. The backup release capability can also be lost with a single failure, but it is electrically isolated from auto and manual. As a rule, backup as well as one other release mode is required so that more than one failure has to occur before the arm must be jettisoned or the payload released via EVA. ©[110900-7257]

- B. LOADED OPERATIONS WILL CEASE AS SOON AS PRACTICAL IF BACKUP AND ONE OF TWO METHODS TO RELEASE (AUTO OR MANUAL) ARE NOT AVAILABLE.

If backup or both primary methods of releasing a payload are lost, then the RMS is one failure from being unable to release the payload. In a worst case situation this would lead to arm/payload jettison. It is unacceptable to continue operations when the system is one failure away from jettison.

Mission activities such as final release or berth may be completed under certain conditions with this failure.

- C. RMS OPERATIONS IN SUPPORT OF HIGH PRIORITY ACTIVITIES CAN BE PERFORMED WITH A SUSPECTED LOSS OF BACKUP RELEASE CAPABILITY.

There are three methods for opening the EE to release a payload (auto, manual, and backup). Without backup release capability, the EE is one failure away from the inability to release the payload. The priority of this mission is such that operations are allowed to continue with loss of two of the methods. ©[110900-7257]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A12-161 PAYLOAD GRAPPLE CONSTRAINTS (CONTINUED)

- D. RMS OPERATIONS IN SUPPORT OF HIGH PRIORITY ACTIVITIES CAN BE COMPLETED WITH A SUSPECTED LOSS OF END EFFECTOR (EE) DERIGIDIZE CAPABILITY. @[110900-7257]

Loss of derigidize capability does not preclude releasing of the grapple fixture; however, if the snares are opened without derigidizing, potential exists that tip-off rates may be induced. Additionally, without the capability to derigidize/extend the snare carriage, future capture capability is lost.

One alternative which may or may not be available is to install the RMS IFM Display and Control (D&C) kit to work around a D&C panel failure.

- E. A CAPTURE SHALL NOT BE ATTEMPTED WHILE IN A REACH LIMIT OR SINGULARITY. @[110900-7257]

The RMS does not respond normally to commands while in a reach limit or singularity. Also, excessive arm loads may result when a capture is attempted in a reach limit or singularity since one or more degrees of freedom are lost. With this loss the arm may not be able to conform to the payload if there are any EE/payload grapple fixture misalignments. If the arm cannot conform, significant forces may be applied to the EE/RMS structure.

Rules {A12-1001S}, T and U, RMS GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A12-162

EE MODE SWITCH CONSTRAINTS [CIL]

- A. THE EE MODE SWITCH SHALL ONLY BE TAKEN OUT OF THE "OFF" POSITION:
1. FOR FREE-FLYING PAYLOADS (I.E., PAYLOADS NOT ATTACHED TO THE RMS OR ANY ORBITER STRUCTURE) WHEN THE EE IS IN THE:
 - a. PRECAPTURE POSITION (I.E., THE POSITION THE RMS MAINTAINS ABOVE THE PLB DURING THE RENDEZVOUS PROCESS) JUST PRIOR TO CAPTURE,
 - OR
 - b. RELEASE POSITION.
 2. FOR BERTHED PAYLOADS WHEN THE EE IS IN THE:
 - a. CAPTURE ENVELOPE,
 - OR
 - b. RELEASE POSITION.
 3. DURING RMS CHECKOUT.

There are many failure modes that can cause the arm to limp unexpectedly or produce an uncommanded release or derigidize when the EE mode switch is in the manual or auto position. Therefore, the EE mode switch should only be taken out of the OFF position when it is safe to do so (i.e., when the arm is not moving and is far from obstacles or is in the process of moving the last few feet during the capture process of a free-flying payload).

- B. THE EE MODE SWITCH SHALL ALWAYS BE PLACED BACK IN THE "OFF" POSITION IMMEDIATELY AFTER THE NOMINAL CAPTURE/RIGIDIZE AND RELEASE/DERIGIDIZE TIMES HAVE ELAPSED.

There are many failure modes which can result in a continuously limped arm (e.g., incomplete rigidize sequence) or stalled EE drive motor (e.g., motor reversals, rigid microswitch fails low, etc., which lead to motor burnout in approximately 2 minutes) so that the microswitches never attain the proper state to complete an automatic EE capture or release. The effect of these failure modes can be nullified simply by turning the EE mode switch to off.

FLIGHT RULES

A12-163 CAPTURE AND RELEASE PROXIMITY CONSTRAINT [CIL]

DURING A CAPTURE OR RELEASE OF A FREE-FLYING PAYLOAD, THE EE SHALL BE FAR ENOUGH AWAY FROM ORBITER STRUCTURE/OTHER PAYLOADS/EVA CREWMEMBER THAT NO CONTACT COULD OCCUR REGARDLESS OF PAYLOAD ROTATIONS.

FLIGHT-SPECIFIC EXCEPTIONS FOR LARGE PAYLOADS OR TO MEET DAP STABILITY CONSTRAINTS WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX.

There are many failure modes which result in a payload being snared but only partially rigidized. When capturing a rotating payload, the payload could continue to rotate around the EE. If this occurs during release, gravity gradient and LVLH effects could result in payload rotation. This rule would procedurally prohibit any contact (other than the arm) for these failure scenarios. For payloads that cannot be positioned far enough from orbiter structure due to size or DAP constraints, an exception shall be identified in the flight-specific annex.

A12-164 PAYLOAD RELEASE DURING BERTHING

DURING BERTHING, A NOMINAL RELEASE OF A PAYLOAD WILL NOT BE PERFORMED UNTIL THE PAYLOAD IS VERIFIED BERTHED AND LATCHED.

If the payload was released without being latched, orbiter recontact could occur. The payload would have to be jettisoned per procedure unless EVA straps are available to strap a payload down for entry. Minimum payload latch configuration must be examined from a structural standpoint and may be different for on-orbit and entry/landing requirements. Reference flight-specific annex rules for the definition of the minimum payload latch configuration.

A12-165 THROUGH A12-180 RULES ARE RESERVED

FLIGHT RULES

RMS JETTISON SYSTEM MANAGEMENT

A12-181

JETTISON SYSTEM CONSTRAINT

- A. RMS OPERATIONS SHALL BE ALLOWED TO CONTINUE IF EITHER OF THE JETTISON SYSTEM BUSES MNB ML86B OR MNC ML86B IS LOST PROVIDED RMS DRIVE MODE REDUNDANCY, END EFFECTOR RELEASE MODE REDUNDANCY, AND MPM AND MRL STOW AND LATCH REDUNDANCY EXISTS. ©[113095-1809A]
- B. IF FLIGHT SPECIFIC ANNEX RULES ALLOW OPERATIONS TO CONTINUE FOR RMS SYSTEMS REDUNDANCY FAILURES, AN IFM WILL BE PERFORMED TO REGAIN A LOST JETTISON SYSTEM BUS WHEN CONVENIENT. THE IFM ONLY NEEDS TO BE PERFORMED UP TO THE POINT OF BEING INVASIVE TO THE ORBITER PANELS AND OTHER ORBITER SYSTEMS (I.E., RCS HEATERS).

With an RMS system redundancy failure and loss of a jettison system, the system is two failures away from a catastrophic situation in the event of an emergency deorbit. However, there is no means of verifying the current health of the alternate pyro system even though load and resistance tests were performed on turnaround. Therefore, if the Flight Specific Annex allows operations to continue in this posture, as much of the IFM should be performed as possible without impacting RCS heaters and by removing all but two of the panel A14 fasteners. With loss of RCS heaters, hotfiring of the affected RCS jets is the primary method to maintain thermal conditioning. A PRCS hotfire, if required, would be at odds with RMS operations. An additional 5 minutes will be required to complete the IFM should jettison subsequently be required. ©[113095-1809A] ©[110900-7257]

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule.

- C. IF AN RMS JETTISON SYSTEM BUS IS LOST PRIOR TO COMPLETION OF HIGH PRIORITY MISSION OBJECTIVES, OPERATIONS WILL CONTINUE WITHOUT JETTISON SYSTEM REDUNDANCY.

Operations may continue with the loss of a jettison system due to mission objective priorities. An IFM is available to restore a failed (short or open) jettison bus. This IFM will restore the jettison capability for any detected loss, but will impact other orbiter systems.

Rule {A12-1001}, RMS GO/NO-GO CRITERIA, references this rule. ©[110900-7257]

FLIGHT RULES

A12-182 **RMS/PAYLOAD JETTISON**

IF AN RMS/PAYLOAD COMBINATION MUST BE JETTISONED, THE RMS AND PAYLOAD SHALL BE JETTISONED AS A SINGLE UNIT, IF AT ALL POSSIBLE.

It is desirable to limit the number of free objects in space to avoid recontact problems by jettisoning the arm and payload as one unit.

RMS GO/NO-GO CRITERIA

NOTES:

- [1] CONTINUE OPERATIONS IF ONE FAILURE WILL NOT RESULT IN THE INABILITY TO LATCH AT LEAST TWO MRL'S.
- [2] ONE AT THE SHOULDER AND ONE AT EITHER THE MID OR AFT PEDESTAL IS REQUIRED.
- [3] OPERATIONS IN DIRECT AND BACKUP CAN CONTINUE WITH THE LOSS OF AUTOBRAKES.
- [4] RMS SYSTEM REDUNDANCY OR JETT REDUNDANCY IFM REQUIRED. @[113095-1809A]
- [5] CONTINUE OPERATIONS EVEN IF ONE FAILURE WILL RESULT IN THE INABILITY TO LATCH AT LEAST TWO MRL'S (ASSUMES CURRENTLY HAVE TWO-LATCH CAPABILITY). EVA CAPABILITY REQUIRED. @[110900-7257]
- [6] EVA CAPABILITY EXISTS FOR THE FOLLOWING CONTINGENCIES:
 - ? SHOULDER BRACE RELEASE
 - ? MPM DEPLOY/STOW
 - ? RMS STRAPDOWN
 - ? GRAPPLE FIXTURE (GF) RELEASE
- [7] ONE OF SINGLE, DIRECT, OR BACKUP REQUIRED FOR UNCRADLING. @[110900-7257]

FLIGHT RULES

SECTION 13 - AEROMEDICAL

ASCENT

A13-1 **ASCENT ABORT**

THERE ARE NO MEDICAL REASONS FOR ABORTING DURING THE ASCENT PHASE.

The powered flight phase is too short to allow an adequate evaluation of any medical problem that may develop and to call an abort would impose unacceptable risks on the remainder of the crew.

A13-2 **SPACEHAB SAFE ATMOSPHERE REQUIREMENTS - UNPOWERED ASCENT**

THE ATMOSPHERE FOR AN UNPOWERED SPACEHAB ON ASCENT IS CERTIFIED SAFE PREFLIGHT AND FOR INITIAL CREW ENTRY FOR 36 DAYS FROM THE TIME GROUND VENTILATION IS REMOVED IN THE ABSENCE OF PAYLOADS WITH HIGH OFFGASSING CHARACTERISTICS (T-VALUE > 0.2). SPACEHAB PAYLOADS WITH HIGH OFFGASSING CHARACTERISTICS SUCH THAT THE SAFE ENTRY TIME IS REDUCED WILL BE LISTED IN THE FLIGHT SPECIFIC ANNEX. ©[111501-4964A]

High offgassing characteristics are defined as any hardware with an index of toxicity (T-value) greater than 0.2. Off-gassing analyses by JSC Toxicology have shown that the atmosphere of a closed, unpowered Spacehab module develops unacceptably high levels of toxic gases after 36 days and may not be certified for crew ingress after 36 days. For missions that the Spacehab module is unpowered, the module is enclosed without ventilation or circulation from the time that ground ventilation is removed through launch, allowing a potential buildup of toxic offgas products. The level of these products remains below the maximum allowable for 36 days; therefore, there is no constraint to accessing the module on FD1 prior to crew sleep. There is no constraint for a powered Spacehab module on ascent because air circulation remains active.

Reference: Toxicology Group Memo 375, Safe Entry Into the Double and Single Spacehab Modules, dated February 25, 1998 and the Special Daily PRCB Presentation, Item No. 1 Spacehab Module Purge Evaluation (STS-101), dated May 11, 2000. ©[111501-4964A]

A13-3 THROUGH A13-20 RULES ARE RESERVED

FLIGHT RULES

ON-ORBIT

A13-21 EARLY FLIGHT TERMINATION

ANY FLIGHT TERMINATION DECISION RELATED TO CREW HEALTH WILL BE A REAL-TIME CALL AND WILL ONLY BE CONSIDERED IF ACCEPTABLE ON-ORBIT TREATMENT IS NOT AVAILABLE.

Early flight termination may be required for the onset of any condition that adversely affects crew safety or health and performance. Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule.

A13-22 ONBOARD MEDICAL KIT

THOSE ITEMS IN THE SHUTTLE ORBITER MEDICAL SYSTEM (SOMS) MEDICAL KIT LABELED "PHYSICIAN APPROVAL REQUIRED FOR USE" WILL BE USED BY NON-PHYSICIAN CREWMEMBERS ONLY AS DIRECTED BY THE FCR SURGEON OR AN ONBOARD ASTRONAUT PHYSICIAN. A COMPLETE LISTING OF ALL ONBOARD MEDICATIONS AND THEIR SIDE EFFECTS CAN BE FOUND IN THE MEDICAL CHECKLIST APPENDIX. ALL ITEMS USED FROM THE MEDICAL KIT WILL BE LOGGED IN FLIGHT ON INDIVIDUAL CARDS LOCATED IN THE SOMS KIT AND REPORTED TO THE SURGEON DURING THE POSTFLIGHT DEBRIEF.

Prescription drugs must be controlled by a physician during flight in the same manner that they are controlled on the ground. Drug control protects the crew by preventing inappropriate use of medications and unexpected side effects that could affect performance. Records of usage are required for reconstructing medical history and to assist in the refurbishment of the SOMS kits for subsequent flights.

FLIGHT RULES

A13-23

PRIVATE MEDICAL COMMUNICATION (PMC)

- A. A PMC MAY BE REQUESTED AS NEEDED BY THE CREW CDR, FCR SURGEON, OR FLIGHT DIRECTOR.

This rule reflects NASA Policy and Privacy Act of 1974 considerations regarding the privileged nature of doctor-patient communications.

- B. MEDICAL TREATMENT IN RESPONSE TO CREW REQUESTS MAY BE PRESCRIBED DURING NONPRIVATE COMMUNICATION PERIODS AT THE DISCRETION OF THE CDR AND THE FCR SURGEON.

The crew may discuss medical concerns and treatment over nonprivate air-to-ground loops if they choose to waive the privacy accorded them by the Privacy Act of 1974.

- C. A PMC WILL BE SCHEDULED PRIOR TO ANY EVA OR LANDING EARLIER THAN MET 72 HOURS EXCEPT WHEN LANDING ON LAUNCH DAY.

Early deorbit/landing or scheduled and unscheduled EVA's may be considered during flight. A PMC is necessary to accurately assess crew health during the first 72 hours MET when symptoms of motion sickness are greatest. (Reference Rule {A13-101B} and C, SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS, and rationale.)

- D. A PMC WILL BE SCHEDULED ON ALL FLIGHT DAYS. IT WILL USUALLY BE SCHEDULED DURING THE PRESLEEP PERIOD EXCEPT ON LANDING DAY WHEN IT WILL BE SCHEDULED PRIOR TO DEORBIT PREP, PREFERABLY IN THE POST SLEEP PERIOD.

FOR DUAL-SHIFT MISSIONS, PMC'S WILL BE SCHEDULED WHEN BOTH TEAMS ARE AWAKE, IF POSSIBLE.

This rule provides the opportunity for the surgeon to discuss health-related concerns with the crew and assist in the treatment of medical problems.

FLIGHT RULES

A13-24

CPHS PROTOCOLS

ALL LIFE SCIENCES EXPERIMENTS USING THE CREW AS TEST SUBJECTS WILL BE CONDUCTED ACCORDING TO PROTOCOLS APPROVED BY THE JSC COMMITTEE FOR THE PROTECTIONS OF HUMAN SUBJECTS (CPHS) AND OTHER PARTICIPATING MEDICAL BOARDS. DEVIATIONS IN FLIGHT TO THESE PROTOCOLS REQUIRE THE CONCURRENCE OF THE FCR SURGEON. ANY SAFETY RELATED ISSUES OR PROCEDURES ARE THE FINAL RESPONSIBILITY OF FCR SURGEON. @[092195-1797]

Life sciences experiments often involve hardware that requires detailed procedures, safety devices, and restraints to minimize the risk of injury to the participating crewmember(s). Data collection is not allowed until the JSC CPHS is satisfied that the experiment has been designed to minimize the risk of injury or illness for the crewmember. Therefore, deviation from approved protocols and procedures may compromise the safety of an experiment and expose the crewmember to an unacceptable level of risk for injury. @[092195-1797] @[ED]

A13-25

CREW AWAKE TIME CONSTRAINT

- A. ON ORBIT - THE MAXIMUM ON-ORBIT CREW AWAKE TIME IS 18 HOURS.
- B. LANDING DAY - THE MAXIMUM CREW AWAKE TIME ON LANDING DAY IS 18 HOURS FROM CREW WAKE-UP ON ORBIT TO THE SLEEP PERIOD AFTER LANDING, INCLUSIVE OF ALL POSTLANDING ACTIVITIES.

Fatigue represents a blend of factors resulting in a state of decreased ability. It has been shown to negatively impact both mental and physical performance, and fatigue-induced changes increase after 18 hours awake time. The strong relationship between sleep loss and the development of fatigue is well known.

For landing day, the post landing activities are described in the Crew Scheduling Constraints Document, Appendix K, Section 3.5 (JSC-22354). Post landing activities may be scheduled up to a maximum crew awake time of 18 hours inclusive of the presleep period.

FLIGHT RULES

A13-26

ACCELERATION RESTRICTIONS ON MEDICAL PROCEDURES

- A. THE FOLLOWING TYPES OF MEDICAL EXPERIMENTS WILL NOT BE PERFORMED DURING PRCS ATTITUDE HOLD, TRANSLATIONS, OR OMS FIRINGS: @[111094-1714A]
1. INVASIVE EXPERIMENTS THAT REQUIRE A DEVICE TO PENETRATE THE SKIN OF THE SUBJECT CREWMEMBER.
 2. APPLICATION OF ANY DEVICE TO THE SURFACE OF THE EYE.
 3. EXPERIMENTS THAT REQUIRE THE INSERTION OF ANY DEVICE INTO THE EAR, NOSE, OR MOUTH.
 4. EXPERIMENTS THAT REQUIRE THE USE OF A SYRINGE OR ANY SHARP-EDGED DEVICE.

Relative motion between an operator and subject will occur during OMS or RCS firings. This motion could lead to injury.

- B. THE CREW WILL INFORM THE ORBITER COMMANDER OR PILOT PRIOR TO PERFORMING DELICATE/INVASIVE MEDICAL OPERATIONS.

Delicate or invasive operations require that acceleration levels do not exceed those produced by the VRCS. In the case of the loss of VRCS, the crew needs to coordinate with the CDR or PLT to ensure that the orbiter is in free drift until the operation has been completed. This will prevent injury to the crew.
@[111094-1714A] @[ED]

FLIGHT RULES

A13-27

LOWER BODY NEGATIVE PRESSURE (LBNP)

A. A/G VOICE REQUIREMENTS

ELECTROCARDIOGRAM (ECG) TELEMETRY AND CONTINUOUS A/G VOICE COMMUNICATIONS ARE REQUIRED DURING PORTIONS OF THE LBNP RAMP TEST > 30 MMHG DECOMPRESSION.

B. A SECOND CREWMEMBER IS REQUIRED TO BE IN CLOSE PROXIMITY DURING ALL LBNP OPERATIONS WHILE A SUBJECT IS IN THE LBNP. THE SECOND CREWMEMBER MAY PERFORM OTHER EXPERIMENTS.

The second crewmember acts as an operator to assist the subject to egress the LBNP during rapid egress and in the event the subject becomes incapacitated (ref. SL-J Phase III Payload Flight Safety Review minutes). The second crewmember may operate other experiments but cannot be restrained or leave the immediate vicinity. The second crewmember must be physically in attendance (in close proximity) during ramp sessions.

C. LOSS OF CONSCIOUSNESS

FOR LOSS OF CONSCIOUSNESS BY SUBJECT DURING RAMP OR SOAK PROTOCOL, IMMEDIATELY RECOMPRESS LBNP BY BREAKING WAIST SEAL, OPENING THE MANUAL RELIEF VALVE, OR SEPARATING A QUICK DISCONNECT, AND CONTACT FLIGHT SURGEON. ©[ED]

FLIGHT RULES

A13-28

LBNP TEST TERMINATION CRITERIA

A. LBNP RAMP OPERATIONS ON A SUBJECT WILL BE TERMINATED FOR ANY ONE OF THE CRITERIA BELOW:

G - GROUND PERSONNEL CAN MAKE CALL

S - CREWMEMBER IN-FLIGHT CAN MAKE CALL

G	S	(1) DROP IN HEART RATE > 15 BEATS PER MINUTE IN 1 MINUTE
G	S	(2) DROP IN BLOOD PRESSURE (EITHER A SYSTOLIC DROP > 25 MMHG OR A DIASTOLIC DROP > 15 MMHG IN 1 MINUTE
G	S	(3) SYSTOLIC BLOOD PRESSURE ? 70 MMHG
G		(4) SIGNIFICANT CARDIAC ARRHYTHMIAS ? HEART RATE < 40 BPM FOR PERSONS WHOSE RESTING HEART IS > 50 BPM ? THREE OR MORE BEATS IN A ROW OF SUPRAVENTRICULAR OR VENTRICULAR TACHYCARDIA ? EVIDENCE OF HEART BLOCK OTHER THAN FIRST DEGREE ? PREMATURE VENTRICULAR COMPLEXES (PVC) WHICH MEET ANY OF THE FOLLOWING CRITERIA: - ? 6 PVC'S IN 1 MINUTE - PVC'S THAT ARE CLOSELY COUPLED (QR/QT < 0.85) - PVC'S THAT FALL ON THE T-WAVE OF THE PRECEDING BEAT (R ON T PHENOMENA) - PVC'S THAT OCCUR IN PAIRS OR IN RUNS - PVC'S THAT ARE MULTIFORMED
	S	(5) SEVERE NAUSEA, CLAMMY SKIN, PROFUSE SWEATING, LIGHTHEADEDNESS, TINGLING, DIZZINESS
	S	(6) SUBJECT REQUEST AT ANY TIME
G	S	(7) LOSS OF ECG AT THE SURGEON'S CONSOLE OR VOICE DOWNLINK DURING PORTIONS OF RAMP PROTOCOLS BELOW 30 MMHG OF DECOMPRESSION (- 40 MMHG AND - 50 MMHG)
G	S	(8) RESTING HEART RATE GREATER THAN THE MAXIMUM HEART RATE OBSERVED DURING PREFLIGHT PRE-SYNCO PAL LB NP TESTING

@[ED]

NOTE: FOLLOWING LBNP OPERATIONS TERMINATION, A PRIVATE MEDICAL CONFERENCE (PMC) WILL BE CONDUCTED IF NECESSARY. IF THE SITUATION IS TIME CRITICAL, THE SURGEON WILL INSTRUCT THE CREW DIRECTLY FROM THE CAPCOM CONSOLE. IF THE RAMP MUST BE TERMINATED DUE TO REACHING TERMINATION CRITERIA, THE LBNP WILL BE RECOMPRESSED TO AMBIENT PRESSURE. FOLLOWING A 5-MINUTE RECOVERY WITH ECG DOWNLINK AND A GO FROM MCC/POCC, THE SOAK TO - 30 MMHG MAY BE RESUMED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-29

NOISE LEVEL CONSTRAINTS (CONTINUED)

B. LBNP SOAK OPERATIONS ON A SUBJECT WILL BE TERMINATED FOR ANY ONE OF THE CRITERIA BELOW:

G	S	(1) SYSTOLIC BLOOD PRESSURE ? 70 MMHG
G		(2) SIGNIFICANT CARDIAC ARRHYTHMIAS ? HEART RATE < 40 BPM FOR PERSONS WHOSE RESTING HEART IS > 50 BPM ? THREE OR MORE BEATS IN A ROW OF SUPRAVENTRICULAR OR VENTRICULAR TACHYCARDIA ? EVIDENCE OF HEART BLOCK OTHER THAN FIRST DEGREE ? PREMATURE VENTRICULAR COMPLEXES (PVC) WHICH MEET ANY OF THE FOLLOWING CRITERIA: - ? 6 PVC'S IN 1 MINUTE - PVC'S THAT ARE CLOSELY COUPLED (QR/QT < 0.85) - PVC'S THAT FALL ON THE T-WAVE OF THE PRECEDING BEAT (R ON T PHENOMENA) - PVC'S THAT OCCUR IN PAIRS OR IN RUNS - PVC'S THAT ARE MULTIFORMED
	S	(3) SEVERE NAUSEA, CLAMMY SKIN, PROFUSE SWEATING, LIGHTHEADEDNESS, TINGLING, DIZZINESS
	S	(4) SUBJECT REQUEST AT ANY TIME
G	S	(5) RESTING HEART RATE GREATER THAN THE MAXIMUM HEART RATE OBSERVED DURING PREFLIGHT PRE-SYNCO PAL LB NP TESTING

NOTE: FOLLOWING LBNP OPERATIONS TERMINATION, A PRIVATE MEDICAL CONFERENCE (PMC) WILL BE CONDUCTED IF NECESSARY. IF THE SITUATION IS TIME CRITICAL, THE SURGEON WILL INSTRUCT THE CREW DIRECTLY FROM THE CAPCOM CONSOLE. IF THE RAMP MUST BE TERMINATED DUE TO REACHING TERMINATION CRITERIA, THE LBNP WILL BE RECOMPRESSED TO AMBIENT PRESSURE. FOLLOWING A 5-MINUTE RECOVERY WITH ECG DOWNLINK AND A GO FROM MCC/POCC, THE SOAK TO - 30 MMHG MAY BE RESUMED. @ED]

FLIGHT RULES

A13-29

NOISE LEVEL CONSTRAINTS

- A. IF THE 24-HOUR AVERAGE NOISE LEVEL (LEQ) IN ANY HABITABLE VOLUME (INCLUDING ORBITER FLIGHT DECK, MIDDECK, SPACELAB, SPACEHAB) IS GREATER THAN OR EQUAL TO 74 DBA AS MEASURED BY THE AUDIO DOSIMETER, ONE OR MORE OF THE FOLLOWING ACTIONS WILL BE TAKEN: ©[072795-1785A]
1. POWER OFF THE GREATEST NOISE PRODUCER(S). THE POCC/MCC MAY DECIDE ANY PRIORITIES IN THE POWERDOWN IF THERE IS MORE THAN ONE LOUD NOISE SOURCE. ©[ED]
 2. RESCHEDULE THE TIMELINE SO THAT ESPECIALLY NOISY EXPERIMENTS DO NOT OCCUR ON THE SAME DAY.
 3. WEAR HEARING PROTECTION DURING SLEEP TO ALLOW A RECOVERY PERIOD FROM THE NOISE.
 4. IN CONTINGENCY SITUATIONS ONLY, WEAR HEARING PROTECTION DURING THE DAY. ©[072795-1785A]

Exposure to noise levels of 74-76 dB for 10 days has been seen to cause fatigue, headaches, ringing in the ears and temporary threshold shifts of up to 20-25 dB. Exposure to these levels for even 24 hours led to complaints of the irritating effect of the noise. Each payload has been required to meet certain noise constraints. A number of payloads have not met those constraints and have been granted waivers. Any individual payload is not likely to cause difficulty but, in combination, may produce unacceptable noise levels. Powering off the loudest noise producers or rescheduling the time so that several loud experiments do not occur on the same day should lower the 24-hour noise exposure to an acceptable level. ©[072795-1785A]

Wearing hearing protection (e.g., foam ear plugs) during sleep provides a period of time to recover from the temporary threshold shift in hearing. The noise level during the day may still be irritating and fatiguing and may cause difficulty with communication. Wearing hearing protection during the day should eliminate the irritation and fatigue from the noise; however, communication among the crew, with the ground, and the ability to hear alert tones may be impacted.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-29

NOISE LEVEL CONSTRAINTS (CONTINUED)

- B. IF THE NOISE LEVEL, USING THE AUDIO DOSIMETER IN THE SOUND LEVEL METER MODE, EXCEEDS THE FOLLOWING LIMITS, STATEMENTS 1, 2, OR 4 OF PARAGRAPH A ABOVE MAY BE IMPLEMENTED. ©[072795-1785A]

76-80 DBA	5 MINUTES
81-85 DBA	1 MINUTE
? 86 DBA	NOT ALLOWED

At noise levels greater than 85 dBA, adequate communication with the ground would be extremely difficult, if not impossible, representing a potentially unsafe situation if urgent calls to the crew cannot be heard. Noise levels in the range from 76-85 dBA will make communication difficult both among the crew and between the crew and the ground. These time limits have been recommended by the Spacelab Payloads Acoustic Working Group and were approved by the Shuttle Program as a maximum time that this level of communication interference by an individual payload should be allowed.

- C. IF, AT ANY TIME, THE NOISE LEVELS ARE SUCH THAT THE CREW BECOMES UNCOMFORTABLE OR IS UNABLE TO COMMUNICATE WITH EACH OTHER OR THE GROUND ADEQUATELY, THE CREW MAY INSTITUTE CORRECTIVE ACTIONS PER PARAGRAPH A.

IF THE AUDIO DOSIMETER IS INOPERATIVE OR NOT AVAILABLE, THE SAME CORRECTIVE ACTIONS MAY BE IMPLEMENTED. NOISE LEVEL READINGS CAN BE TAKEN AT ANY TIME BY THE CREW, OR MAY BE REQUESTED BY THE FLIGHT DIRECTOR OR FCR SURGEON IF PREFLIGHT OR INFLIGHT CONCERN OVER NOISE LEVEL EXISTS.

Noise levels in paragraphs A & B are established as mandatory levels; however, the crew may experience fatigue, headaches, or other symptoms at lower noise levels or may encounter problems in communication with each other or the ground. The crew has the authority to make such judgment calls and use the above guidelines and priorities to achieve a workable environment to complete the mission safely and successfully. ©[012694-1601] ©[ED]

FLIGHT RULES

A13-30

IODINE REMOVAL REQUIREMENT

THE TOTAL AMOUNT OF IODINE AND IODIDE INGESTED BY CREWMEMBERS SHOULD BE LIMITED ON ALL SPACE FLIGHTS. IT IS HIGHLY DESIRABLE TO LIMIT IODINE CONSUMPTION TO 1.0 MG/DAY PER CREWMEMBER. THIS LIMIT INCLUDES IODINE FROM ALL SOURCES INCLUDING DIETARY INTAKE AND POTABLE WATER CONSUMPTION. @[090999-6996]

The Medical Operations Branch and a medical expert review panel agree that there is an insignificant risk of consuming 1.0 mg/day; however, excess iodine is suspected to cause long term adverse effects in people who are susceptible to thyroid problems. The shuttle supply water system is designed to iodinate drinking water to 3-4 ppm (mg/L). At normal crew consumption levels, this would equate to 6-8 mg of iodine ingested per day. The Galley Iodine Reduction Assembly (GIRA) will completely remove iodine from the cold water line and will provide approximately 0.7 mg of free iodine in 16 oz of hot water (1.5 mg/L of total iodine). The food will contribute approximately 0.3 mg/day. @[090999-6996]

A13-31

CREW CABIN TEMPERATURE LIMITS

TO MAXIMIZE CREW COMFORT AND PERFORMANCE, MISSION THERMAL ANALYSIS AND PLANNING SHALL KEEP THE CABIN TEMPERATURE AT OR BELOW THE FOLLOWING LIMITS: @[022201-7095A]

- A. PRE-LAUNCH: ? 80 DEGREES F
- B. ON-ORBIT: ? 80 DEGREES F

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-31

CREW CABIN TEMPERATURE LIMITS (CONTINUED)

C. ENTRY/LANDING: ? 75 DEGREES F

IF ATTEMPTING TO MEET THE ENTRY/LANDING CONSTRAINT OF 75 DEG RESULTS IN UNACCEPTABLY COLD TEMPERATURES DURING CREW SLEEP, THE 75 DEG LIMIT CAN BE INCREASED WITH CDR AND SURGEON CONCURRENCE. @092701-4860]

Excessive thermal stress can have a negative effect on crew health, safety, and performance. Exceeding these limits would be expected to result in an increased incidence of post-flight orthostatic intolerance, and an increased awareness and reporting of thermal discomfort by the crew. Liquid cooling for the ACES full-pressure suit was developed in response to crew complaints of thermal discomfort during the landing and post-landing period on flights STS-26 through STS-62. Post-flight medical data have shown that the incidence of orthostatic intolerance has been reduced since liquid cooling has been available to crews. The individual cooling units (ICU's) used during ascent/entry since STS-88 were designed to remove 340 BTU's/hr at an ambient temperature of 75 deg F, which is the metabolic heat load produced by a resting, minimally active crewmember. According to data provided by EC5, the ICUs are expected to become less efficient at removing heat at ambient temperatures above 75 deg F. An engineering evaluation of these units at higher ambient temperatures has not been performed to date. Orthostatic intolerance is mainly a concern during the entry/landing phase. Excessive heat load exacerbates orthostatic intolerance by increasing vasodilation and sweating. Therefore, the recommended temperature limits are more restrictive during this mission phase.

If CDR/surgeon determines that the temperature control measures to attain an entry/landing temperature of 75 deg F would compromise crew sleep by being too cold, per CDR and surgeon concurrence, the entry/landing target will be adjusted to ensure a comfortable sleep environment. A thermal assessment of the projected wake-up and landing temperatures will be provided to assist in making this decision. @092701-4860]

Measures to achieve the crew cabin temperature limits listed above are documented in Rule {A17-152}, CABIN TEMPERATURE CONTROL AND MANAGEMENT.

FLIGHT RULES

A13-32

INTENSE CYCLE EXERCISE

THIS RULE APPLIES TO EXPERIMENTAL/DSO EXERCISE PROTOCOLS, WHEN REQUIRED BY THE HRPPC, AND DOES NOT APPLY TO CREW OPTIONAL EXERCISE.

A. A/G VOICE REQUIREMENTS

WHEN FLOWN, INTENSE CYCLE EXERCISE REQUIRES ELECTROCARDIOGRAM (ECG) TELEMETRY AND CONTINUOUS A/G VOICE COMMUNICATIONS DURING PORTIONS OF THE CYCLE TEST (I.E., AT LEVELS > 80 PERCENT PREFLIGHT MAXIMUM HEART RATE) AND CONTINUING THROUGH THE RECOVERY PERIOD. THE RECOVERY PERIOD SHALL LAST A MINIMUM OF 5 MINUTES AND MAY BE EXTENDED AT THE FLIGHT SURGEON'S DISCRETION. THE SUBJECT SHALL CONTACT FLIGHT SURGEON IMMEDIATELY PRIOR TO BEGINNING THE EXERCISE PROTOCOL AND AGAIN IMMEDIATELY BEFORE PERFORMING EACH WORKLOAD INCREASE THAT EXCEEDS 80 PERCENT IN ORDER TO CONFIRM NO ORBITER LOSS OF SIGNAL (LOS).

B. ON FLIGHTS WITHOUT A TRAINED PHYSICIAN ASTRONAUT OR ONBOARD ECG MONITORING CAPABILITY, LOSS OF ECG/COMM WILL NECESSITATE LIMITING EXERCISE TO 80 PERCENT WORKLOAD OR REDUCING EXERCISE TO 80 PERCENT IF ALREADY ABOVE IT. @[072893-1517A]

C. IF ECG CAN BE MONITORED ONBOARD AND A TRAINED PHYSICIAN ASTRONAUT IS AVAILABLE, THE A/G VOICE REQUIREMENTS IN PARAGRAPHS A AND B ABOVE DO NOT APPLY. THE PHYSICIAN ASTRONAUT MUST CONTINUOUSLY MONITOR THE ECG DURING EXERCISE ABOVE THE 80-PERCENT WORKLOAD. THE PHYSICIAN ASTRONAUT MAY NOT PERFORM OTHER EXPERIMENTS AT THIS TIME AND MUST BE ABLE TO SEE THE ECG DATA.

The physician astronaut will be able to detect significant dysrhythmias since ECG is available onboard. The physician astronaut should be certified in advanced cardiac life support to assure capability in dysrhythmia recognition and intervention. Prior to exceeding the 80 percent workload, ECG downlink/comm should be confirmed. If downlink is available, the flight surgeon in the MCC will monitor the ECG data.

D. TEST TERMINATION CRITERIA @[072893-1517A]

INTENSE CYCLE EXERCISE OPERATIONS ON A SUBJECT WILL BE TERMINATED FOR ANY ONE OF THE CRITERIA LISTED BELOW:

G - GROUND PERSONNEL CAN MAKE CALL

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-32

INTENSE CYCLE EXERCISE (CONTINUED)

S - CREWMEMBER IN SPACE CAN MAKE CALL

- G 1. THE CARDIAC RHYTHM DISTURBANCES, LISTED BELOW, OCCUR: SUSTAINED ABNORMAL SUPRAVENTRICULAR TACHYCARDIA (I.E., PAROXYSMAL ATRIAL TACHYCARDIA, ATRIAL FIBRILLATION, ATRIAL FLUTTER, OR OTHER SUPRAVENTRICULAR TACHYCARDIA OF UNIDENTIFIED ETIOLOGY LASTING MORE THAN 10 SECONDS)
- a. VENTRICULAR TACHYCARDIA
 - b. EXERCISE INDUCED BUNDLE BRANCH BLOCK
 - c. R-ON-T PVC'S
 - d. UNEXPLAINED INAPPROPRIATE BRADYCARDIA
 - e. MULTIFOCAL PVC'S
 - f. ONSET OF SECOND OR THIRD DEGREE HEART BLOCK
 - g. INCREASING VENTRICULAR ECTOPY (>30 PERCENT OF TOTAL BEATS UNIFOCAL PVC'S DEFINED AS ABNORMAL)
- G S 2. A MAXIMUM HEART RATE VALUE GREATER THAN THAT EXPLAINABLE BY THE EXERCISE STIMULUS AND NORMAL PHYSIOLOGICAL VARIABILITY OCCURS. (IF THIS OCCURS AT LOW LEVELS, WITH NO SIGNS OF INTOLERANCE, CREWMEMBER SHOULD CHECK HEART WATCH AND CONFIRM HEART RATE WITH GROUND).
- S 3. SUBJECT EXPERIENCES CHEST PAIN, DIZZINESS, OR OTHER INAPPROPRIATE SYMPTOMS OF EXCEPTIONAL INTOLERANCE.
- S 4. SUBJECT REQUESTS TO STOP. ®[ED]

FLIGHT RULES

A13-33

EXERCISE REQUIREMENTS

- A. PRESCRIBED EXERCISE SHALL BE SCHEDULED FOR THE CDR, PLT, AND MS2 AT LEAST EVERY OTHER DAY FROM FD04 TO NOMINAL EOM-1. FOR FLIGHTS > 11 DAYS, EXERCISE FOR ALL OTHER CREWMEMBERS SHALL BE SCHEDULED AT LEAST EVERY 3 DAYS. EXERCISE STARTING ON FD03 IS HIGHLY DESIRABLE AND SHALL BE SCHEDULED IF CREW SPACE MOTION SICKNESS (SMS) SYMPTOMS PERMIT (CREW CALL). ©[022802-4887C]

Properly performed exercise results in improved condition of the crew on return to a 1-G environment. The parameters defining the specific components of the exercise prescription are based upon the findings of the Extended Duration Orbiter Medical Project and from evaluation of crews on Mir during Phase 1.

All shuttle crewmembers need to be capable of emergency egress, if required, and should possess the level of physical conditioning required to assist in the egress of returning long-duration crewmembers. The CDR, PLT, and MS2 must be capable of performing the necessary piloting tasks of a nominal landing, and therefore have priority in the scheduling of exercise. Exercise will be scheduled daily according to the Shuttle Crew Scheduling Constraints Document (SCSCD). These requirements are found in the Shuttle Crew Scheduling Constraints Document (NSTS-37326).

Prescribed aerobic exercise can be performed on the cycle ergometer, treadmill, or rowing device.

Specific components of the aerobic/anaerobic exercise protocol shall at a minimum include: exercise duration (exclusive of warm-up) ? 20 minutes; exercise frequency ? three times/seven flight days; exercise intensity performed at a level eliciting ? 70 percent of the individual crewmember's age-predicted maximum heart rate.

Aerobic/anaerobic exercise performed at an intensity, duration, or frequency lower than that listed above will result in insufficient training for maintenance of exercise capacity.

Strength training with resistive exercise hardware is also encouraged every 3 days, especially for CDR, PLT, and MS2.

Shuttle exercise will be briefed to the crew by the shuttle crew surgeon, prior to flight, and will be discussed when necessary via Private Medical Conference. ©[022802-4887C]

- B. FAILURE OF EXERCISE EQUIPMENT ALONE WILL NOT BE CAUSE TO SHORTEN THE FLIGHT. ©[022802-4887C]

If exercise hardware fails, exercise will be performed according to a workaround/contingency prescription from the surgeon.

ATMOSPHERE

A13-51

CABIN PRESSURE

A. MINIMUM CABIN PRESSURE:

1. IF THE PCS IS UNABLE TO MAINTAIN THE CABIN PRESSURE AT OR ABOVE 8.0 PSIA, THE FLIGHT WILL BE TERMINATED AT THE NEXT PLS.

The minimum cabin pressure of 8 psia is specified to provide adequate protection from decompression sickness (bends) for continued on-orbit operations. A decompression from 14.7 to 8 psia would produce an R value of 1.50. (The R-value is a measure of risk for developing decompression sickness and is the ratio of tissue nitrogen pressure prior to decompression to the final ambient pressure.) The risk of simple limb bends is estimated to be less than 10 percent and the risk of incapacitating bends less than 2 percent at this level. This level is more conservative than the EVA rule (ref. Rule {A13-103A}, EVA PREBREATHE PROTOCOL) because the crew could be exposed for many hours, and the cabin could not be repressurized above 8 psia should symptoms of bends develop.

Rule {A17-258}, LOSS OF CABIN INTEGRITY TMAX DEFINITION AND TIG SELECTION, references this rule. @[042594-ED]

2. MINIMUM PRESSURES BELOW 8 PSI - FOR CONTINGENCY PLANNING, IF POSSIBLE, PRESSURE REDUCTIONS BELOW 8 PSI WILL NOT EXCEED THE SPECIFIED LIMITS SHOWN BELOW.
 - a. 6.5 PSI FOR NO MORE THAN 90 MINUTES.
 - b. 3.5 PSI FOR NO MORE THAN 30 MINUTES.

The contingency limits on cabin pressure specified provide adequate protection from decompression sickness to allow safe return of crew to preferred recovery sites. Risk of decompression sickness is a complex function of many factors, including amount of pressure reduction, exposure time, and activity of the crewmembers. Based on available data, exceeding the specified limits in the shuttle environment would result in a risk of incapacitating bends of more than 5 to 10 percent and a risk of "pain only" bends of approximately 40 percent.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-51 CABIN PRESSURE (CONTINUED)

B. UNPLANNED REDUCTION IN CABIN PRESSURE:

1. ANY UNPLANNED REDUCTION OR PROJECTION OF CABIN PRESSURE BELOW 12.5 PSIA WILL REQUIRE THE CREW TO DON THE QUICK DON MASK (QDM) IMMEDIATELY. THE FINAL, STABILIZED CABIN PRESSURE WILL DETERMINE THE NEED FOR CONTINUED USE OF THE QDM. THE FCR SURGEON SHOULD BE CONSULTED FOR PLANNING OF ALL SUBSEQUENT CREW ACTIVITIES.

Reduction in cabin pressure and the resulting decrease in PPO₂ may result in hypoxia and increase the risk of decompression sickness in crewmembers. If the QDM is donned above a pressure of 12.5 psia, formation of microemboli in the blood may still be prevented. With a rapid loss of pressure, an understanding of the resulting cabin environment and the restrictions it may impose must be evaluated by the surgeon.

2. CREWMEMBERS MAY DISCONTINUE USE OF THE QDM WHEN THE FINAL, STABILIZED CABIN PRESSURE AND PPO₂ LEVELS ARE AT OR ABOVE THE FOLLOWING MINIMUM VALUES:

FOR TEMPERATURES WITHIN 70 DEG TO 85 DEG F, USE THE IN-RANGE VALUE. THE OUT-OF-RANGE VALUE IS USED FOR TEMPERATURES LESS THAN 70 DEG F OR GREATER THAN 85 DEG F.

CABIN PRESSURE (PSIA)	PPO ₂ (PSIA)		OXYGEN CONCENTRATION (PERCENT)			
		IN	OUT		IN	OUT
14.7	2.29	2.37	2.44	15.6	16.1	16.6
10.2	2.35	2.43	2.50	23.0	23.8	24.5
8.0	2.38	2.46	2.53	30.1	30.8	31.6

All of the cabin pressure-PPO₂ combinations provide the equivalent of an 8000-foot pressure altitude breathing air. The rationale of Rule {A13-53B}, MINIMUM PPO₂ CONSTRAINTS, applies. ©[ED 1

FLIGHT RULES

A13-52

PPCO₂ CONSTRAINT

A. TWO-GAS ENVIRONMENT (CABIN):

1. IF THE ATMOSPHERIC REVITALIZATION SYSTEM (ARS) IS UNABLE TO MAINTAIN THE PPCO₂ IN THE ORBITER CREW COMPARTMENT BELOW 15 MMHG, THE CREW WILL DON THE QDM. THE MISSION WILL BE TERMINATED AT THE NEXT PLS.

Deleterious physiological changes can be expected at PPCO₂ levels of 15 mmHg and above. These symptoms will be alleviated by using the QDM and breathing 100 percent O₂. If the ARS is unable to maintain PPCO₂ levels below 15 mmHg, the mission must be terminated as the cabin atmosphere is unsafe for routine crew activities without supplementary oxygen. Oxygen toxicity must be avoided with the prolonged exposure to 100 percent O₂ while using the QDM (ref. Rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT).

2. FOR PPCO₂ LEVELS BETWEEN 7.6 MMHG AND 15 MMHG, PLANNING FOR ALL CREW ACTIVITIES WILL REQUIRE EVALUATION BY THE FCR SURGEON.

A PPCO₂ of 7.6 mmHg is the maximum level that can be tolerated by the crew for long periods. Above 7.6 mmHg, physiological changes may occur that are unacceptable for crew safety, health, and performance. The length of exposure to levels above 7.6 mmHg and the planned crew activities will need to be reviewed by the FCR surgeon for consideration of physiological and performance effects.

B. ONE-GAS ENVIRONMENT (EMU):

1. FOR PPCO₂ LEVELS BETWEEN 3 AND 8 MMHG WITH SYMPTOMS INDICATIVE OF CO₂ EXPOSURE, THE CREWMEMBER WILL TERMINATE THE EVA, PROCEED TO THE AIRLOCK, AND CONNECT TO THE SERVICE AND COOLING UMBILICAL (SCU). @[ED]
2. FOR PPCO₂ LEVELS GREATER THAN 8 MMHG DURING EVA, IF IT CANNOT BE CONFIRMED THAT THE ELEVATED LEVELS ARE DUE TO A SENSOR ERROR, THE EVA CREWMEMBER WILL TERMINATE THE EVA, PROCEED TO THE AIRLOCK, AND CONNECT TO THE SCU. @[121197-6456A]
3. FOR LOSS OF PPCO₂ SENSOR, THE FLIGHT SURGEON MAY REQUEST PHYSIOLOGICAL STATUS CHECKS TO EVALUATE THE CREWMEMBER FOR SYMPTOMS OF HYPERCAPNIA. IF SYMPTOMS ARE DETECTED, THE EVA WILL BE TERMINATED. @[121197-6456A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-52

PPCO₂ CONSTRAINT (CONTINUED)

For a PPCO₂ indication of 3 to 8 mmHg, the actual level in the helmet can be 11 to 15 mmHg and may be as high as 19 to 23 mmHg, depending on the metabolic rate. If symptoms are associated with indicated values of 3 to 8 mmHg, this indicates a high level of CO₂ in the helmet, and the EVA should be terminated.

In order to avoid unnecessary termination of an EVA due to faulty high PPCO₂ readings, an evaluation of the PPCO₂ sensor should be performed if the indicated level is greater than 8 mmHg. The EVA cuff checklist outlines the procedure to be followed by the crewmember. Additional evaluation can be performed by ground personnel to determine the status of the sensor. If the indicated PPCO₂ level is greater than 8 mmHg, due to a confirmed sensor error, the crewmember may continue the EVA; but crewmember symptoms should be evaluated periodically. If symptoms are noted the EVA should be terminated, and the crewmember should proceed to the airlock and connect to the SCU. When the crewmember is connected to the SCU with the helmet purge valve open, the resultant O₂ flow alleviates danger of high PPCO₂ levels.

For CO₂ transducer loss, the ability to detect a high CO₂ level relies primarily on the crewmember's ability to detect physiological symptoms. Since one of the symptoms of hypercapnia is impaired judgment, the unaffected EVA crewmember, IV crewmember, and Flight Surgeon will assist in periodically monitoring the affected crewmember's physiological condition. The most common sign of CO₂ exposure is an increased breathing rate that will occur at 1 to 2 percent (7.6 to 15 mmHg). The pulse rate will increase at 3 to 5 percent (22 to 38 mmHg). Nonspecific symptoms experienced by the crewmember can be headache, dizziness, drowsiness, muscular weakness, etc. Note that the OSHA standard for an 8-hour workplace exposure is 0.5 percent (3.8 mmHg). The Flight Surgeon will continually monitor the downlinked ECG and metabolic data as well as the voice communications and breathing rate and may request physiological status checks be performed with the crewmember as necessary. The other EVA crewmember and the IV crewmember will monitor the affected crewmember's task performance and voice communications and should perform status checks every 30-60 minutes or as requested by the Flight Surgeon. If symptoms are detected, the EVA should be terminated. Thirty minutes was determined to be the minimum time it would take for the PPCO₂ levels to increase from 3 mmHg to 8 mmHg due to a LiOH breakthrough. ©[121197-6456A]

Rules {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT; {A15-102H}, EMU GO/NO-GO CRITERIA; {A17-106}, REGENERATIVE CO₂ REMOVAL SYSTEM (RCRS) LOSS DEFINITION; and {A17-301}, CABIN ATMOSPHERE MANAGEMENT; reference this rule. ©[ED 1]

FLIGHT RULES

A13-53

MINIMUM PPO₂ CONSTRAINTS

A. TWO-GAS ENVIRONMENT (CABIN):

1. THE PCS SHOULD MAINTAIN THE PPO₂ AT OR ABOVE THE FOLLOWING SPECIFIED CABIN PRESSURES:
 - a. FOR TEMPERATURES WITHIN 70 DEG TO 85 DEG F, USE THE IN-RANGE VALUE. THE OUT-OF-RANGE VALUE IS USED FOR TEMPERATURES LESS THAN 70 DEG F OR GREATER THAN 85 DEG F.

CABIN PRESSURE (PSIA)	PPO ₂ (PSIA)			OXYGEN CONCENTRATION (PERCENT)		
		IN	OUT		IN	OUT
14.7	2.29	2.37	2.44	15.6	16.1	16.6
10.2	2.35	2.43	2.50	23.0	23.8	24.5
8.0	2.38	2.46	2.53	30.1	30.8	31.6

- b. IF THE LEVEL OF PPO₂ CANNOT BE MAINTAINED AT THE ABOVE LEVELS, THE MISSION WILL BE TERMINATED AT THE NEXT PLS.

The PPO₂ minimum acceptable limits defined in the table are established to ensure adequate delivery of oxygen to the pulmonary alveoli. These limits represent the minimum PPO₂ required to maintain the alveolar pressure of oxygen equivalent to that of breathing air at an 8000-foot pressure altitude. Due to the saturation of breathing gases with water, PPO₂ limits must increase as cabin pressure decreases to maintain the same alveolar partial pressure of oxygen. For temperatures of 70 deg to 85 deg F, the maximum PPO₂ sensor error is ±0.08 psia. This error is added to the minimum acceptable true PPO₂ (8,000 feet altitude equivalent) to arrive at the minimum acceptable PPO₂ sensor reading (e.g., 2.29 + 0.08 = 2.37). For temperatures outside this range, the PPO₂ error is ±0.15 psia, and this error must be adjusted accordingly per OMRSD V61AJ0.141. Above a pressure altitude of 8,000 feet, deleterious changes in crew performance can occur from hypoxia and altitude sickness. Symptoms of altitude sickness can develop over several hours consisting of headache, lethargy, and reduced appetite in 15 to 20 percent of crewmembers. More serious symptoms of confusion, loss of coordination, and difficulty in breathing may occur. These more serious symptoms must be treated with oxygen and an immediate increase in ambient pressure. (Ref. Rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT).

©[ED]

Rules {A17-203}, PPO₂ CONTROL, and {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, reference this rule.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-53

MINIMUM PPO₂ CONSTRAINTS (CONTINUED)

2. FOR NEXT PLS LANDING, THE PPO₂ MAY BE ALLOWED TO DECREASE TO THE FOLLOWING LEVELS FOR NO MORE THAN 24 HOURS. THE LAUNCH/ENTRY SUIT (LES) SHALL BE DONNED 1 HOUR PRIOR TO LANDING WITH VISORS DOWN.

FOR TEMPERATURES WITHIN 70 DEG TO 85 DEG F, USE THE IN-RANGE VALUE. THE OUT-OF-RANGE VALUE IS USED FOR TEMPERATURES LESS THAN 70 DEG F OR GREATER THAN 85 DEG F.

CABIN PRESSURE (PSIA)	PPO ₂ (PSIA)			OXYGEN CONCENTRATION (PERCENT)		
		IN	OUT		IN	OUT
14.7	2.09	2.17	2.24	14.2	14.8	15.2
10.2	2.14	2.22	2.29	20.1	21.8	22.5
8.0	2.20	2.28	2.35	27.5	28.5	29.4

These PPO₂ levels represent a pressure altitude, breathing air of 10,000 feet. Rapid ascents to 10,000 feet cause a mild altitude sickness incidence of 20 to 40 percent. The risk of altitude sickness is increased principally from the reduced alveolar oxygen tension and to a lesser degree from the decrease in the ambient air pressure. High altitude pulmonary edema has been noted in the 15 to 25 percent of those exposed to a 14,000-foot pressure altitude for 24 hours and has occurred as low as 9,000 feet. Death from high altitude cerebral edema has been reported at 10,000 feet. The risk of altitude sickness at certain cabin pressures and PPO₂ levels must be balanced against system anomalies and difficulties generated from landing at a non-PLS site. Wearing the LES and breathing 100 percent oxygen 1 hour prior to landing will eliminate the subtle performance decrements that occur with hypoxia (ref. Rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT).

Rules {A17-203}, PPO₂ CONTROL; {A17-254}, CABIN O₂ CONCENTRATION; and {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, reference this rule. ©[ED]

3. FOR CONTINGENCY LANDING PURPOSES, IN A SITUATION WHERE THE PPO₂ CANNOT BE MAINTAINED AT THE LEVELS IN PARAGRAPH A.2, THE QDM SHALL BE DONNED. THE FINAL DETERMINATION OF QDM USE AND LES DONNING WILL DEPEND ON FINAL STABLE CABIN PRESSURE, PPO₂, AND TIG.

If the cabin cannot be maintained at the PPO₂ levels delineated in paragraph A.2, use of the QDM is necessary to prevent hypoxia and altitude sickness. Providing supplementary oxygen with the QDM or LES can prevent deleterious changes in crew performance from both hypoxia and altitude sickness.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-53

MINIMUM PPO2 CONSTRAINTS (CONTINUED)

4. CONSULT THE FCR SURGEON FOR THE TOTAL LENGTH OF TIME THAT THE CREW MAY WEAR THE QDM OR LES.

The next PLS opportunity may not occur for several hours. Some crewmembers may be able to remove their QDM or LES for brief periods of time during low activity and/or sleep periods. This removal will provide for greater crew comfort, increased mobility, and will prevent possible oxygen toxicity from breathing 100 percent oxygen (ref. Rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT). The FCR surgeon can estimate the pressure altitude, breathing air from the known cabin pressure and PPO2, and can estimate the length of time that the crew may safely remove their QDM or LES.

- B. ONE-GAS ENVIRONMENT (EMU) - IF THE PRESSURE IN THE SUIT FALLS BELOW 3.15 (3.3) PSI, THE EVA CREWMEMBER WILL ABORT THE EVA.
@[050400-7197A]

At 92 percent O₂, 3.15 (3.3) psia corresponds to a pressure altitude of 8000 feet and the rationale of paragraph A.1 applies. Exhaled nitrogen from the crewmember dilutes the oxygen atmosphere in the suit to 92 percent. @[050400-7197A]

Rule {A13-51B}.2, CABIN PRESSURE, references this rule.

FLIGHT RULES

A13-54

100 PERCENT OXYGEN USE CONSTRAINT

- A. THE MAXIMUM AMOUNT OF TIME A CREWMEMBER MAY BREATHE 100 PERCENT OXYGEN BY WEARING THE QDM OR LES AT VARIOUS CABIN PRESSURES IS:

CABIN PRESSURE	MAXIMUM QDM OR LES HELMET TIME
12-14.7 PSI	6 HOURS
10.2-12 PSI	12 HOURS
<10.2 PSI	INDEFINITELY

Breathing 100 percent oxygen at sea level pressure will result in physiologic changes due to oxygen toxicity after 6 hours minimum. Since oxygen toxicity is proportional to the oxygen partial pressure and not the percent gas, longer exposures of 100 percent oxygen can be tolerated at lower pressures. For 100 percent oxygen at sea level, physiologic changes begin as mild (2 to 5 percent) asymptomatic decreases in vital capacity (the largest volume of air which can be exhaled voluntarily) beginning with fully inflated lungs. After 12 hours, coughing, sore throat, and substernal soreness are usually seen, and after 24 hours, atelectasis, pulmonary edema, broncho-pneumonia, and further decrements in vital capacity may develop. Intermittent air breaks or lowering pressure may avoid such effects.

- B. CONTINGENCIES, SUCH AS FIRE OR SMOKE IN THE CABIN, HALON 1301 OR OTHER TOXIC COMPOUNDS SPILLED IN THE CABIN, MAY REQUIRE EXTENDED USE OF THE QDM OR LES BEYOND THE LIMITS STATED IN PARAGRAPH A. THE FCR SURGEON SHOULD BE CONSULTED FOR THE MAXIMUM LENGTH OF TIME THE QDM OR LES MUST BE WORN (REF. RULE {A13-52}, PPCO₂ CONSTRAINT).

After exposure of the shuttle cabin atmosphere to a toxic substance and subsequent cleanup, the atmosphere may need to be purged of residual toxic contamination based on the type of substance, amount released, relative toxic potential, and the ability of ARS to remove the substance.

The atmosphere is considered purged of residual toxic material that can be removed by the ARS after a six-fold cycle through the ARS.

Oxygen toxicity changes are usually mild at onset and may be considered less limiting than other considerations, including PLS availability and deorbit time requirements. Individual determination by the crew surgeon is required to balance cost/benefits for specific cases.

Rules {A13-52A.1}, PPCO₂ CONSTRAINT; and {A13-53A.2}, MINIMUM PPO₂ CONSTRAINTS, reference this rule.

A13-55 THROUGH A13-100 RULES ARE RESERVED

FLIGHT RULES

EVA OPERATIONS

A13-101 SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS

- A. NO SCHEDULED OR UNSCHEDULED EVA SHALL OCCUR PRIOR TO APPROXIMATELY 24 HOURS MET OF FLIGHT.
- B. NO SCHEDULED EVA SHALL OCCUR PRIOR TO APPROXIMATELY 72 HOURS MET UNLESS AN ASSESSMENT OF CREW HEALTH HAS BEEN ACCOMPLISHED BY THE FCR SURGEON DURING A PMC.

Symptoms of motion sickness are experienced by 73 percent of crewmembers on their first shuttle flight. Thirteen percent of them will have a severe case characterized by drowsiness, inability to concentrate, severe nausea and vomiting, and little or no food or water intake over 24 to 48 hours. The majority of susceptible crewmembers develop symptoms in the first 6 hours of flight, and all crewmembers graded as moderate or severe had symptom onset in the first 6 hours. Symptoms peak over 24 to 48 hours MET and resolve over 48 to 72 hours MET. During adaption to zero-g, movement (especially head movement) may provoke nausea and vomiting in susceptible crewmembers and potentially endanger the safety of the crewmember by decreased concentration, lethargy, or vomitus in the helmet.

- C. NO UNSCHEDULED EVA SHALL OCCUR PRIOR TO APPROXIMATELY 48 HOURS MET UNLESS AN ASSESSMENT OF CREW HEALTH HAS BEEN ACCOMPLISHED BY THE FCR SURGEON DURING A PMC.

An unscheduled EVA for mission success is a high priority EVA and may be performed after approximately 48 hours MET as many crewmembers will have resolving symptoms of motion sickness and will be less susceptible to provocative motion stimuli after 48 hours MET. The reduced risk of motion sickness is balanced against the prospective gain of a successful mission. The limitations elaborated in the Crew Scheduling document, Appendix K, recognize that the EVA may not be performed due to crew health concerns.

Rules {A13-23}, PRIVATE MEDICAL COMMUNICATION (PMC); and {A15-14}, SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS, reference this rule.

FLIGHT RULES

A13-102

MAXIMUM EVA DURATION CONSTRAINTS

EXTENSION OF ANY EVA BEYOND AN EVA PET 6.5 HOURS REQUIRES FLIGHT SURGEON APPROVAL BASED ON OBJECTIVE AND/OR SUBJECTIVE PHYSIOLOGICAL DATA AND PARAMETERS FOR EACH EV CREWMEMBER.

©[050400-7193A]

The energy level of the EV crewmember may be diminished after 6.5 hours. The average metabolic rate of an EV crewmember is approximately 800 BTU/hr (200 kcal/hr), with peak rates during heavy work periods of 1600 to 2000 BTU/hr (400 to 500 kcal/hr). While in the EMU, crewmembers do not have access to food. An increase in EVA duration could result in energy deficiency that begins to affect performance. Higher than average workloads will also affect the EV crewmember. Wearing the EMU suit and performing special EVA tasks could cause local fatigue in the hands, arms, and upper body. Free floating also requires more energy and produces greater cumulative fatigue than tasks utilizing foot restraints.

The body loses 6 to 8 ounces of water per hour during the EVA. This could cause an EV crewmember with a 32-ounce drink bag to be 1 percent dehydrated (thirsty) at the end of an 8-hour EVA. If the crewmember begins the EVA already at a 1 percent dehydration level, performance will be affected in the 6.5 to 8-hour period of the EVA.

Other factors that could lead to limiting EVA extension include, but are not limited to, residual Space Adaptation Sickness, uncertain hydration, nutrition, inadequate sleep/rest, poor thermal control of the Liquid Cooling Garment (leading to a hot crewmember losing excessive water), higher than normal metabolic rates, abnormal biomedical signs, and performance decrement.

FLIGHT RULES

A13-103

EVA PREBREATHE PROTOCOL

A. FOR SCHEDULED AND UNSCHEDULED EVA'S, PREBREATHING WILL BE ACCOMPLISHED USING THE PROTOCOL DEFINED IN PARAGRAPH A.1 (10.2 PSI CABIN) UNLESS THE PROTOCOL DEFINED IN PARAGRAPH A.2 (IN-SUIT) IS REQUIRED FOR A SPECIFIC FLIGHT.

1. 10.2 PSI CABIN OPTIONS:

a. EVA SCHEDULED WITHIN 36 HOURS OF CABIN DEPRESS TO 10.2 PSI:

INITIAL PREBREATHE	TIME AT 10.2 PSI	FINAL PREBREATHE
60 MINUTES	24 HOURS	40 MINUTES
60 MINUTES	20 HOURS	50 MINUTES
60 MINUTES	16 HOURS	60 MINUTES
60 MINUTES	12 HOURS	75 MINUTES

(1) THE INITIAL PREBREATHE MUST BE AN UNBROKEN PREBREATHE WITH > 95 PERCENT O₂, AT LEAST 45 MINUTES OF WHICH MUST BE ACCOMPLISHED PRIOR TO DEPRESSURIZATION BELOW 12.5 PSI. THE PREBREATHE WILL NOT BE TERMINATED UNTIL THE CABIN PRESSURE REACHES 10.2 PSI.

(2) THE FINAL PREBREATHE MUST BE AN UNBROKEN PREBREATHE IN THE SUIT OF 40 MINUTES (24-HOUR PROTOCOL) OR 75 MINUTES (12-HOUR PROTOCOL) IMMEDIATELY PRIOR TO EVA. THE FINAL PREBREATHE MAY BE GRADUALLY REDUCED FOR 10.2 PSI EXPOSURES LONGER THAN 12 HOURS BUT LESS THAN 24 HOURS. CONSULT THE FCR SURGEON FOR THE TOTAL TIME REQUIRED FOR THE FINAL PREBREATHE.

b. EVA SCHEDULED FOR LATER THAN 36 HOURS AT 10.2 PSI:

(1) IF THE EVA IS SCHEDULED FOR LATER THAN 36 HOURS AFTER CABIN DEPRESS TO 10.2, THE INITIAL PREBREATHE MAY BE ELIMINATED. THE FINAL PREBREATHE WILL BE 40 MINUTES.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-103

EVA PREBREATHE PROTOCOL (CONTINUED)

- (2) IF THE INITIAL PREBREATHE IS ELIMINATED, BUT THE EVA OCCURS PRIOR TO 36 HOURS AT 10.2 PSI, THEN 60 MINUTES WILL BE ADDED TO THE PREBREATHE.

2. IN-SUIT OPTION:

A MINIMUM OF 4 HOURS UNBROKEN PREBREATHE WITH > 95 PERCENT O₂ IS REQUIRED AT A CABIN PRESSURE ABOVE 12.5 PSI PRIOR TO ANY CABIN OR AIRLOCK DEPRESSURIZATION BELOW 8 PSI.

All prebreathe options in paragraphs A.1 and A.2 produce the same denitrogenation for all crewmembers (R=1.65-1.68) and these protocols or less conservative protocols have been verified in ground-based testing. The R-value is the ratio of tissue N₂ prior to decompression to the final ambient pressure. The R-value is a measure of risk for decompression sickness. The O₂ prebreathe displaces nitrogen from the tissues and blood thus lowering the risk for decompression sickness at low ambient pressure. The nitrogen displaced from the tissues will dilute the suit oxygen slightly (down to 92 percent), but supply oxygen > 95 percent will still provide adequate denitrogenation. The 10.2 cabin option is always preferred and will be used unless a specific flight carries equipment that cannot be exposed to a 10.2 psi cabin atmosphere and must continue to operate throughout the EVA. For off-nominal prebreathe situations, a calculated prebreathe time based on an R-value of 1.65 is highly desirable. Lack of ground-based support data for off-nominal prebreathe scenarios dictates a conservative approach in the prevention of DCS symptoms. ©[032395-1761]

Prebreathe protocols for 12 and 24 hours at 10.2 psi have been tested in ground-based studies and are the preferred operational protocols. Prebreathe exposures between 12 and 24 hours may be considered as necessary, but no ground-based test data has been obtained at intermediate exposures.

When an EVA is scheduled after 36 hours at 10.2, it is unlikely that any dispersed gas bubbles formed by the depressurization to 10.2 would remain beyond 36 hours. If the initial prebreathe was not performed, but an EVA becomes necessary prior to 36 hours, then the calculated final prebreathe will be extended by 60 minutes. It is estimated that the extra 60 minutes of final prebreathe would offset the reduced nitrogen washout capability that small persistent bubbles would cause.

B. FOR ANY CONTINGENCY EVA, PREBREATHING WILL BE ACCOMPLISHED AS FOLLOWS:

1. IF SUFFICIENT CREW TIME IS AVAILABLE DURING PREPARATION FOR A CONTINGENCY EVA, THE PREBREATHE PROTOCOLS OF PARAGRAPHS A.1 OR A.2 SHALL APPLY.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-103

EVA PREBREATHE PROTOCOL (CONTINUED)

2. IF EVA PREPARATION TIME IS CRITICAL TO CREW SAFETY, A MINIMUM OF 2.5 HOURS UNBROKEN PREBREATHE WITH > 95 PERCENT O₂ IS RECOMMENDED AT A CABIN PRESSURE ABOVE 12.5 PSI PRIOR TO ANY CABIN OR AIRLOCK PRESSURE BELOW 8 PSI. THE FCR SURGEON SHALL BE CONSULTED FOR A RECOMMENDED PREBREATHE PROTOCOL FOR ANY CONTINGENCY EVA.

A minimum prebreathe of 2.5 hours will reduce the estimated risk of incapacitating bends to < 50 percent for an EVA up to 6 hours in duration. This recommended time is very approximate and should be extended if possible. A prebreathe < 2.5 hours would exceed a 50 percent risk of incapacitating bends, and the risk would increase as the prebreathe was progressively shortened. The FCR surgeon should be consulted on each contingency EVA situation for an estimate of the risk based on the proposed length of prebreathe time.

C. INTERRUPTION OF THE PREBREATHE PROTOCOL:

1. 10.2 CABIN OPTION:
 - a. NO MODIFICATION OF THE 10.2 PSI PREBREATHE PROTOCOL IS REQUIRED IF THE CABIN PRESSURE IS MAINTAINED BELOW THE MAXIMUM LIMIT OF 10.84 (10.6) PSI.
 - b. IF THE CABIN PRESSURE EXCEEDS 10.6 PSI INDICATED, THE EVA CREWMEMBERS WILL DON THE QDM IMMEDIATELY. CONSULT THE FCR SURGEON FOR THE REQUIRED MODIFICATION TO THE PREBREATHE PROTOCOL.

An increase in the cabin pressure above 10.6 psi indicated will cause the tissues and blood to reabsorb nitrogen. At an indicated cabin pressure of 10.6 psi, the true cabin pressure may be 10.84 psi. The indicated PPO₂ caution and warning limit of 2.55, 2.40 psi true, produces a worst case PPN₂ of 8.44 (10.84 - 2.40) psi. This maximum PPN₂ of 8.44 psi is acceptable for continued prebreathe without modification. For pressures above 10.6 psi indicated, wearing the QDM and breathing 100 percent oxygen can prevent renitrogenation and preserve the prebreathe protocol. (Ref. Rule {A17-301}, CABIN ATMOSPHERE MANAGEMENT.)

2. QDM/EMU OPERATIONS (100 PERCENT O₂ PREBREATHE)

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-103

EVA PREBREATHE PROTOCOL (CONTINUED)

- a. ANY INTERRUPTION OF THE PREBREATHE PROTOCOL WHICH OCCURS WHILE THE CREW IS WEARING THE QDM OR IS IN THE EMU WILL REQUIRE AN INCREASE IN THE TIME ON 100 PERCENT O₂ AT A RATIO OF 2 ADDITIONAL MINUTES FOR EACH 1 MINUTE INTERRUPTION OF PREBREATHE. @[021199-6806A]
- b. IF THE EMU IN-SUIT PREBREATHE IS INTERRUPTED AFTER COMPLETION OF THE SUIT PURGE, THE INTERRUPTION DURATION IS DEFINED AS THE TIME BREATHING CABIN ATMOSPHERE PLUS THE TIME BREATHING SUIT ATMOSPHERE PRIOR TO REINITIATION OF A SUBSEQUENT SUIT PURGE. THE SUBSEQUENT SUIT PURGE DURATION DOES NOT COUNT AS EITHER THE INTERRUPTION TIME OR THE ADDITIONAL PREBREATHE TIME.
- c. THE RESULTING PREBREATHE TIME (ADDITIONAL PREBREATHE PLUS REMAINDER OF ORIGINAL PREBREATHE) WILL NOT EXCEED THE ORIGINAL PREBREATHE TIME PER PARAGRAPH A.1 OR A.2. CONSULT THE FCR SURGEON FOR THE REQUIRED INCREASE IN LENGTH OF THE PREBREATHE PERIOD. @[021199-6806A]

Breathing nitrogen after the prebreathe has begun allows the tissues and blood to reabsorb nitrogen. Renitrogenation occurs at a more rapid rate than denitrogenation, and a break in the prebreathe will require extra prebreathe time to be added to the protocol.

D. FOR MULTIPLE EVA'S:

1. IF THE PROTOCOLS OUTLINED IN PARAGRAPH A.1 ARE USED, THE CABIN PRESSURE WILL BE MAINTAINED AT 10.2 PSI UNTIL COMPLETION OF THE FINAL EVA. EACH SUBSEQUENT EVA MUST HAVE AN UNBROKEN PREBREATHE OF AT LEAST 40 MINUTES IN THE SUIT IMMEDIATELY PRIOR TO EVA.
2. IF THE IN-SUIT PREBREATHE OPTION IS USED, EACH EVA WILL FOLLOW THE PROTOCOL OUTLINED IN PARAGRAPH A.2.

Rules {A2-107C}, EVA GUIDELINES; {A13-51}, CABIN PRESSURE; {A15-151}, DENITROGENATION; and {A17-309}, CABIN PRESSURE TIME AT 10.2 PSIA; reference this rule. @[012694-1600]

FLIGHT RULES

A13-104

DECOMPRESSION SICKNESS SYMPTOMS AND CREW DISPOSITION

A. CUFF CLASS 1: @[040899-6836A]

1. SYMPTOMS: MILD PAIN AT SINGLE OR MULTIPLE SITES AND/OR SINGLE EXTREMITY PARASTHESIA. SYMPTOMS THAT ARE DIFFICULT TO DISTINGUISH FROM SUIT PRESSURE POINTS. SYMPTOMS DO NOT INTERFERE WITH PERFORMANCE.
2. RESPONSE: CONTINUE EVA AND REPORT IN POST-EVA PMC.
3. NO IMPACT ON FUTURE EVA PLANS FOR THE AFFECTED CREWMEMBER OR ON MISSION DURATION.

The EMU can cause pressure points and pains that could be confused with DCS symptoms. However, the risk of mild pain of this nature progressing to a serious symptom is low. Because there is low concern with injury and the symptoms are expected to resolve during repress if they are DCS related, it is acceptable to continue the EVA and report the symptoms later in a PMC. It is specifically mentioned in the rule that there is no impact to future EVA to encourage cuff class 1 symptom reporting. This reporting is required to verify total DCS risk over time.

B. CUFF CLASS 2:

1. SYMPTOMS: MODERATE CUFF CLASS 1 SYMPTOMS THAT INTERFERE WITH PERFORMANCE.
2. RESPONSE: TERMINATE EVA FOR AFFECTED CREWMEMBER. UNAFFECTED CREWMEMBER TERMINATES EVA AFTER COMPLETING WORK SITE CLEANUP AND PAYLOAD BAY SAFING. REPRESS AIRLOCK AS SOON AS PAYLOAD BAY SAFING IS COMPLETE. CONDUCT PMC AFTER REPRESS.
3. NO IMPACT ON MISSION DURATION IF SYMPTOMS RESOLVE. SURGEON WILL DETERMINE CONSTRAINTS ON FUTURE EVA FOR AFFECTED CREWMEMBER CONSISTENT WITH NASA JSC DECOMPRESSION SICKNESS PROCEDURES AND GUIDELINES JPG 1800.3. @[040899-6836A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-104

DECOMPRESSION SICKNESS SYMPTOMS AND CREW DISPOSITION (CONTINUED)

This level of symptoms is distinguishable from EMU pressure points by a trained EVA astronaut. Because it represents confirmed DCS symptoms and pressure is one of the most effective treatments, the affected crewmember should be repressed as soon as practical. The overall risk is low enough to warrant work site cleanup and payload bay safing before repressing but not additional mission success tasks. The affected crewmember's activity should be minimized because continued joint loads can aggravate the symptoms. During the post-repress PMC, the Surgeon will determine specific treatment required. NASA JSC Decompression Sickness Procedures and Guidelines JPG 1800.3 documents the approved limits for return-to-duty and return-to-delta pressure operations. The responses in these flight rules are consistent with this document. ©[040899-6836A]

C. CUFF CLASS 3:

1. SYMPTOMS: SEVERE CUFF CLASS 1 SYMPTOMS OR MIGRATORY, TRUNKAL OR MULTIPLE SITE PARESTHESIA, OR SEVERE OR UNUSUAL HEADACHE.
2. RESPONSE: TERMINATE EVA FOR BOTH CREWMEMBERS. UNAFFECTED CREWMEMBER WILL ASSIST AFFECTED CREWMEMBER TO AIRLOCK THEN PERFORM PAYLOAD BAY SAFING. REPRESS AIRLOCK AS SOON AS PAYLOAD BAY SAFING IS COMPLETE. CONDUCT PMC AFTER REPRESS.
3. NO IMPACT ON MISSION DURATION IF SYMPTOMS RESOLVE. SURGEON WILL DETERMINE CONSTRAINTS ON FUTURE EVA FOR AFFECTED CREWMEMBER CONSISTENT WITH NASA JSC DECOMPRESSION SICKNESS PROCEDURES AND GUIDELINES JPG 1800.3.

These symptoms are more severe than cuff class 2 because they are a more generalized level of DCS and there is a higher risk of symptom progression. Because continued joint loads can aggravate the symptoms, the affected crewmember's activity should be restricted to airlock ingress and should be assisted as much as possible. Further, work site and payload bay cleanup should be limited to only those required to safe the payload bay for an expedited deorbit. The overall risk is low enough to warrant delaying repress until both crewmembers are in the airlock. During the post-repress PMC, the Surgeon will determine specific treatment required. NASA JSC Decompression Sickness Procedures and Guidelines JPG 1800.3 documents the approved limits for return-to-duty and return-to-delta pressure operations. The responses in these flight rules are consistent with this document. ©[040899-6836A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

**A13-104 DECOMPRESSION SICKNESS SYMPTOMS AND CREW
DISPOSITION (CONTINUED)**

D. CUFF CLASS 4: @[040899-6836A]

1. SYMPTOMS: CENTRAL NEUROLOGICAL OR CARDIOPULMONARY.
2. RESPONSE: ABORT EVA. UNAFFECTED CREWMEMBER WILL ASSIST AFFECTED CREWMEMBER TO AIRLOCK. AFFECTED CREWMEMBER WILL BE RERESSED IMMEDIATELY, WITH THE UNAFFECTED CREWMEMBER PERFORMING PAYLOAD BAY SAFING AND REPRESSING SEPARATELY IF REQUIRED. CONDUCT PMC AFTER REPRESSING THE AFFECTED CREWMEMBER.
3. SURGEON WILL DETERMINE CONSTRAINTS ON FUTURE EVA FOR AFFECTED CREWMEMBER CONSISTENT WITH NASA JSC DECOMPRESSION SICKNESS PROCEDURES AND GUIDELINES JPG 1800.3.

The absolute minimum time to repress the affected crewmember is essential because these symptoms pose a serious health risk and increase the probability of an emergency deorbit. Therefore, it is acceptable to repress the affected crewmember separately while the other crewmember safes the payload bay for an expedited deorbit. At this level, it is likely the affected crewmember will require assistance due to impairment, and continued joint loads can aggravate the symptoms. During the post-repress PMC, the Surgeon will determine specific treatment required. NASA JSC Decompression Sickness Procedures and Guidelines JPG 1800.3 documents the approved limits for return-to-duty and return-to-delta pressure operations. The responses in these flight rules are consistent with this document.

DOCUMENTATION: DCS Risk Definition and Contingency Plan Review, April 1998; NASA JSC Decompression Sickness Procedures and Guidelines JPG 1800.3.

*Reference Rule {A13-105}, DECOMPRESSION SICKNESS RESPONSE AND TREATMENT.
@[040899-6836A]*

FLIGHT RULES

A13-105

DECOMPRESSION SICKNESS RESPONSE AND TREATMENT

A. DEORBIT REQUIREMENTS: @[040899-6835B]

1. ANY EARLY MISSION TERMINATION AND DEORBIT FOR DCS PURPOSES WILL ONLY BE CONSIDERED TO A SITE DESIGNATED AS A PRIMARY HYPERBARIC CARE SITE.

Deorbit timeframe will be based on deorbit opportunities and Surgeon's evaluation of the severity of the specific symptoms. The additional risk of landing at an ELS will only be considered if the site has hyperbaric treatment capability since the most important treatment for DCS is increased pressure. The landing site list maintained by Flight Surgeon is annotated to show sites that medical operations has classified as primary hyperbaric care sites. This designation reflects the time to transport the injured crewmember to the chamber and the level of support available at the chamber.

2. FOR ALL LEVELS OF DCS THAT RESOLVE WITH TREATMENT, THERE IS NO REQUIREMENT FOR EMERGENCY DEORBIT.

If symptoms resolve with treatment, there is a low risk of recurring symptoms and injury to the crewmember. Therefore, the risk of an emergency deorbit is not warranted. However, based on specific symptoms and response to treatment, Surgeon may request the affected crewmember be returned to Earth before the normal end of mission.

3. FOR ALL CUFF CLASS 1 SYMPTOMS, OR CUFF CLASS 2 AND 3 SYMPTOMS WHICH RESOLVE WITH TREATMENT, THERE IS NO REQUIREMENT FOR ANY EARLY MISSION TERMINATION.
4. EARLY DEORBIT WILL GENERALLY NOT BE CONSIDERED FOR UNRESOLVED NON-CUFF CLASS 4 SYMPTOMS UNLESS MEDICAL JUDGMENT DEEMS THE SYMPTOMS ARE PROGRESSING AND/OR ENDANGER CREW HEALTH AND SAFETY.

98.6 percent or more of non-Cuff Class 4 symptoms resolve with ground level O₂, so we would expect them to resolve with our on-orbit treatments. Additionally, we have data and experience that clearly suggests the suit creates residual symptoms, pain and paresthesia, that are consistent with non-Cuff Class 4 DCS. Also, data indicates there is no long-term injury associated with unresolved non-Cuff Class 4 symptoms.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-105

**DECOMPRESSION SICKNESS RESPONSE AND TREATMENT
(CONTINUED)**

5. FOR UNRESOLVED CUFF CLASS 4 SYMPTOMS, DEORBIT TO THE NEXT PRIMARY LANDING SITE OR WITHIN THE SCOPE OF NORMAL NPLS DEORBIT TIMING TO A LANDING SITE DESIGNATED AS A PRIMARY HYPERBARIC CARE SITE. BASED ON THE SPECIFIC MEDICAL SITUATION, DEORBIT WILL BE CONSIDERED TO THESE SITES AS EARLY AS 10 HOURS AFTER THE ONSET OF CUFF 4 SYMPTOMS.

@[040899-6835B]

After the full treatment flow, persistent Cuff Class 4 symptoms are life threatening. Even in this case, the additional risk of landing at an ELS will only be considered if the site has hyperbaric treatment capability since the most important treatment for DCS is increased pressure. Long-term risk to an affected crewmember is reduced if treatment is initiated within approximately 12 hours. Depending on the severity of the specific Cuff 4 symptoms, Surgeon may request an expedited deorbit. Considering the treatment available simply from cabin pressure and when the risk to the affected crewmember is weighed against the risk to the full crew and spacecraft, it was concluded that landing in less than 10 hours is not justified. @[040899-6835B]

- B. THE CAPABILITY OF THE AFFECTED CREWMEMBER TO RETURN TO DUTY AND TO EVA AFTER TREATMENT WILL BE DETERMINED BY THE SURGEON CONSISTENT WITH NASA JSC DECOMPRESSION SICKNESS PROCEDURES AND GUIDELINES JPG 1800.3.
- C. THE SUIT WILL REMAIN IN THE PRESS MODE OR AT BTA TREATMENT PRESSURE AS SUPPORTED BY SUIT CONSUMABLES. THE BTA CAN BE INSTALLED TO PROVIDE THE MAXIMUM PRESSURE IN THE SUIT FOR TREATMENT. @[071001-4742]

The BTA can now be installed without depressurizing the suit. The use of the BTA will pressurize the affected crewmember to 6 or 8 psi above ambient. Using the BTA to press the suit to 8 psi over ambient, renders the suit unusable for subsequent EVAs due to a need for re-certification of the suit seals. @[071001-4742]

- D. CABIN PRESSURE WILL BE MANAGED AS FOLLOWS:

1. FOR CUFF CLASS 2 OR 3 SYMPTOMS THAT DO NOT RESOLVE WITHIN 20 MINUTES OF AIRLOCK REPRESS, THE CABIN WILL BE REPRESSURIZED TO 14.7 PSI. FOR CASES THAT DO NOT RESOLVE WITH 14.7 TREATMENT, THE CABIN WILL BE FURTHER PRESSURIZED TO THE HIGHEST PRESSURE SUPPORTABLE BY CONSUMABLES AND OXYGEN CONSTRAINTS UP TO 15.56 PSI.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-105

DECOMPRESSION SICKNESS RESPONSE AND TREATMENT (CONTINUED)

2. FOR CUFF CLASS 4 SYMPTOMS, THE CABIN WILL BE REPRESSURIZED TO 14.7 PSI BEFORE OR DURING AIRLOCK REPRESS. FOLLOWING CABIN/AIRLOCK REPRESS, THE CABIN WILL BE FURTHER PRESSURIZED TO THE HIGHEST PRESSURE SUPPORTABLE BY CONSUMABLES AND OXYGEN CONSTRAINTS UP TO 15.56 PSI. @[040899-6835B]
3. FOR CUFF CLASS 2, 3 AND 4 SYMPTOMS, THE AFFECTED CREWMEMBER WILL NOT BE EXPOSED TO A REDUCED CABIN PRESSURE FOR AT LEAST 72 HOURS AFTER DCS TREATMENT UNLESS REQUIRED FOR DEORBIT, CONSUMABLES MANAGEMENT, OR OXYGEN CONSTRAINTS. FOR CASES WITH THE CABIN PRESSURE RAISED ABOVE 14.7 PSIA, THE CABIN PRESSURE WILL BE ALLOWED TO BLEED DOWN TO 14.7 PSIA. @[040899-6835B]

In all cases, the most effective immediate treatment is repressurization. The total pressure reached at cabin pressure with the suit in PRESS mode suffices for cuff class 2 and 3 symptoms. If the symptoms resolve, there is no need to increase the cabin pressure above the pressure at ingress. However, if Cuff Class 2 and 3 symptoms do not resolve with the initial treatment in a 10.2-psi cabin, the additional 4.5 psi is the most effective next step and the cabin will be repressed to 14.7 psi.

Due to the severity of cuff class 4 symptoms, the cabin will immediately be repressed to at least 14.7 psi to maximize the initial treatment pressure. Total pressure will be raised as high as 15.56 psi if supported by consumables and oxygen constraints. This pressure provides 0.24-psi margin (cabin pressure sensor measurement error) below the positive pressure relief valve (PPRV) cracking pressure based on a relief pressure of 15.8 psi for OV-105. 15.8 psia is the lowest PPRV cracking pressure of the fleet. The other vehicle's PPRV cracking pressures are as follows: OV-102 and OV-103 - 15.9 psia, OV-104 - 15.95 psia.

To prevent recurring symptoms, the affected crewmember will not be exposed to cabin pressure reductions for at least 72 hours. Surgeon may require a longer period based on specific symptoms and response to treatment.

The cabin pressure may be raised to 15.56 psia while treating severe symptoms. However, at the end of the treatment, the crewmember will be removed from the EMU that is providing the majority of the additional pressure during the treatment. Therefore, it is acceptable to allow the cabin pressure to bleed down over time to 14.7 psia in order to return to automatic atmosphere maintenance using the O₂/N₂ cabin regulators.

DOCUMENTATION: NSTS 16007 LCC Rev G (ECL-05), DCS Risk Definition and Contingency Plan Review, April 1998; NASA JSC Decompression Sickness Procedures and Guidelines JPG 1800.3, OMI V1217 Test Data.

FLIGHT RULES

HAZARD MANAGEMENT

A13-151 **HOT CABIN ATMOSPHERE**

IN THE EVENT OF LOSS OF CABIN COOLING CAPABILITY AND TIG IS GREATER THAN 2.5 HOURS, THE FOLLOWING MEASURES SHOULD BE TAKEN:

- A. MONITOR AND RECORD CREW AND CABIN TEMPERATURE AND HUMIDITY CHANGES USING AVAILABLE SENSORS INCLUDING MEDICAL KIT THERMOMETERS.
- B. BEGIN IMMEDIATE FLUID LOADING, WITH 8 OUNCES OF WATER EVERY 15 MINUTES AND ONE SALT TABLET EVERY 30 MINUTES.
- C. DON QDM FOR CREWMEMBER DISCOMFORT (I.E., ESTIMATED CABIN TEMPERATURE GREATER THAN 90 DEG F AND HUMIDITY GREATER THAN 90 PERCENT) WITH CONTINUED WEAR UNTIL RESOLUTION OF THE COOLING PROBLEM. DEORBIT TO AN EMERGENCY LANDING SITE MAY BE REQUIRED PRIOR TO PLS AS DETERMINED REAL TIME BY CREW, FLIGHT DIRECTOR, AND CREW SURGEON.
- D. WEAR LES DURING ENTRY. INFLATION OF G-SUIT PORTION OF THE LES TO 1.5 PSI REQUIRED AT EI.

A hot cabin may quickly reach crew tolerance limits and impair crew performance/health prior to PLS opportunities, and monitoring of the cabin and crew may be very limited due to the powerdown. Crew tolerances may be near limits when their skin temperature increases greater than 2.5 deg F (1 deg F core) or if pulse is greater than 140, but precise prediction of crew tolerances and time constraints for entry is not possible. Stepwise preventive measures, including water and salt intake, QDM use (for respiratory cooling with low humidity oxygen), and LES wear with G-suit use (to increase effective blood volume by preventing blood pooling in lower extremities) are necessary to provide maximum protection from the environment. Cabin purges may also be used for cooling. An emergency landing may be required to prevent crew incapacitation during certain situations, and preparations for such landings must begin well in advance. Such a determination will be a real-time call depending on the situation due to the numerous factors involved.

FLIGHT RULES

A13-152

CABIN ATMOSPHERE CONTAMINATION

- A. PLANNED OR ACCIDENTAL DISCHARGE OF EITHER A FIXED AVIONICS BAY FIRE EXTINGUISHER OR A PORTABLE FIRE EXTINGUISHER INTO AN AVIONICS BAY WITH NO SMOKE/FIRE DETECTED: @[090894-1682A]
1. THE CREW MAY BE EXPOSED TO THE CABIN ATMOSPHERE FOR 72-100 HOURS FROM THE TIME OF DISCHARGE WITHOUT IMPACT.
 2. THE CREW WILL CONTACT MCC TO DETERMINE THE MAXIMUM ALLOWABLE EXPOSURE TIME ON-ORBIT. THE SURGEON WILL MAKE A DECISION AS TO WHEN THE CREW MAY DON THE QDM'S OR LES'S AND BREATHE 100 PERCENT OXYGEN TO INCREASE MISSION DURATION.
 3. THE CDR, PLT, AND FLIGHT ENGINEER WILL CLOSE VISORS ON THE LES'S AND BREATHE 100 PERCENT OXYGEN FOR 60 MINUTES PRIOR TO LANDING AND THROUGH LANDING ROLLOUT.

REAL-TIME DISCUSSION OF MISSION DURATION OR EXTENSION WILL BE DEPENDENT UPON SUCH FACTORS AS CREW SYMPTOMS, PERFORMANCE, AND/OR INITIATION OF A DEDICATED AVIONICS BAY PURGE.

The above criterion was established based upon information from NASA's Halon 1301 Human Inhalation Study (reference JSC-23845, August 1989), the National Research Council (NRC), and JSC Toxicology Group. The human study involved exposing 8 volunteers to Halon 1301 for a period of 24 hours at a concentration of 1.0 percent (10,000 ppm). The effects on both physiology and performance were studied using a computerized battery of tests on reaction time, decision-making, etc. No significant changes in any physiological parameters were noted. There were no alterations of any blood counts or chemistries, no pulmonary function changes, no cardiac dysrhythmias, and no mental status changes. There were no significant decrements in performance recorded from the pre-exposure baselines. Based on this study, exposure of crewmembers to Halon concentration levels is limited to 1.0 percent. @[021600-7170]

As a result of research done in the "Documentation of the Spacecraft Maximal Allowable Concentration Values on Bromotrifluoromethane" (White Paper), the NRC approved revised SMAC levels for Halon 1301 on November 18, 1993. These guidelines state that for 24-hour exposure, the SMAC level is 0.35 percent (3500 parts per million), and for 7-day exposure, the SMAC level is 0.18 percent (1800 ppm). The JSC Toxicology Group sponsored the mentioned study and proposed SMAC levels to the NRC.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A13-152****CABIN ATMOSPHERE CONTAMINATION (CONTINUED)**

Approximately 50 percent of Halon 1301 discharged from a fire extinguisher into the avionics bay will diffuse into the cabin atmosphere within 50 hours, and 100% of it will diffuse in 100 hours. Halon 1301 is poorly absorbed by the charcoal in the LiOH canisters as well as the Ambient Temperature Catalytic Oxidizer (ATCO) canister. Thus, it cannot be effectively removed from the cabin atmosphere. ©[090894-1682A]

Discharge of one portable fire extinguisher into an avionics bay would produce a Halon 1301 concentration of approximately 0.3 percent (3000 ppm) at equilibrium. Discharge of one fixed avionics bay fire extinguisher would produce a concentration of approximately 0.4 percent (4000 ppm) at equilibrium. These concentrations were calculated on the assumption that complete equilibration of Halon 1301 with the cabin atmosphere occurs after 100 hours. ©[090894-1682A]
©[021600-7170]

Provided sufficient consumables are available, the mission duration may be extended by having the crew don the QDM's or LES's and breathe 100 percent oxygen for up to 6 hours at 12.0-14.7 psia without risk of oxygen toxicity (reference rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT). The Surgeon and EECOM shall coordinate their efforts to derive a plan that can increase mission duration after the crew has been exposed to Halon 1301.

Data shows that the half-life of Halon 1301 in non-fatty tissues (primarily blood) is 5 minutes; whereas, the half-life of Halon 1301 is approximately 200 minutes in fat (Halon is lipid soluble). Breathing 100 percent oxygen for 60 minutes prior to landing should significantly reduce the blood and brain levels of Halon 1301 and further protect crew performance during critical performance periods (i.e., de-orbit preparation, landing, landing rollout). Due to O2 concentration limits, three crewmembers can breathe 100 percent O2 for 1 hour, or seven crewmembers can breathe 100 percent O2 for 30 minutes.

A real-time decision is to be made by the Flight Director, Surgeon, EECOM, IFM, and any other disciplines involved with the decision-making process to perform a landing after the crew has been exposed to Halon 1301. The range of 72-100 hours is to be used as a guideline. The actual mission duration or extension is dependent upon such factors as crew symptoms, performance, and/or initiation of a dedicated avionics bay purge.

B. PLANNED OR ACCIDENTAL DISCHARGE OF A PORTABLE FIRE EXTINGUISHER INTO A PANEL OR INTO THE OPEN CABIN ATMOSPHERE, OR DETECTION OF A LEAKING PORTABLE FIRE EXTINGUISHER, WITH NO SMOKE/FIRE DETECTED:

- 1. THE CREW MAY BE EXPOSED TO THE CABIN ATMOSPHERE FOR 24-48 HOURS FROM THE TIME OF DISCHARGE OR DETECTION OF A LEAKING BOTTLE WITHOUT IMPACT.**

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A13-152 CABIN ATMOSPHERE CONTAMINATION (CONTINUED)**

2. THE CREW WILL CONTACT MCC TO DETERMINE THE MAXIMUM ALLOWABLE EXPOSURE TIME ON-ORBIT. THE SURGEON WILL MAKE A DECISION AS TO WHEN THE CREW MAY DON THE QDM'S OR LES'S AND BREATHE 100 PERCENT OXYGEN TO INCREASE MISSION DURATION. @[090894-1682A]
3. THE CDR, PLT, AND FLIGHT ENGINEER WILL CLOSE VISORS ON THE LES'S AND BREATHE 100 PERCENT OXYGEN FOR 60 MINUTES PRIOR TO LANDING AND THROUGH LANDING ROLLOUT. @[090894-1682A]

REAL-TIME DISCUSSION OF MISSION DURATION OR EXTENSION WILL BE DEPENDENT UPON SUCH FACTORS AS CREW SYMPTOMS, PERFORMANCE, AND/OR DETERMINATION OF THE AMOUNT OF HALON LEAKED/DISCHARGED INTO THE CABIN.

Discharge of a fire extinguisher into a panel or into the open cabin will produce a rapid equilibration with the cabin atmosphere. A Halon 1301 level of approximately 0.3 percent (3000 ppm) will be rapidly achieved, and the maximum allowable crewmember exposure time at this level is in the range of 24-48 hours based on the SMAC levels for Halon 1301 in paragraph A's rationale.

Provided sufficient consumables are available, the mission duration may be extended by having the crew don the QDM's or LES's and breathe 100 percent oxygen for up to 6 hours at 12.0-14.7 psia without risk of oxygen toxicity (reference Rule {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT). The Surgeon and EECOM shall coordinate their efforts to derive a plan that can increase mission duration after the crew has been exposed to Halon 1301.

Breathing 100 percent oxygen for 60 minutes prior to landing should significantly reduce the blood and brain levels of Halon 1301 and further protect crew performance during critical performance periods (i.e., de-orbit preparation, landing, landing rollout). Due to O2 concentration limits, three crewmembers can breathe 100 percent O2 for 1 hour, or seven crewmembers can breathe 100 percent O2 for 30 minutes.

A real-time decision is to be made by the Flight Director, Surgeon, EECOM, and any other disciplines involved with the decision-making process to perform a landing after the crew has been exposed to Halon 1301. The range of 24-48 hours is to be used as a guideline. The actual mission duration or extension is dependent upon such factors as crew symptoms, performance, and/or determination of the amount of Halon leaked/discharged into the cabin. Reference Flight Rule {A17-54}, MANAGEMENT FOLLOWING HALON DISCHARGE WITHOUT FIRE CONFIRMATION. @[090894-1682A] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-152 CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

- C. SMOKE OR FIRE DETECTED AND CONFIRMED VIA VISUAL OBSERVATION, TWO SMOKE DETECTORS, OR CREW SYMPTOMS.
1. IMMEDIATELY DON THE QDM'S AND INITIATE O2 FLOW. @[090894-1673A]
 2. INSTALL TWO FRESH LIOH CANISTERS IN THE ARS, OR ONE FRESH LIOH CANISTER AND THE FRESHEST CHARCOAL CANISTER IF THE RCRS IS FLOWN. @[090894-1673A]
 3. TURN CABIN TEMPERATURE CONTROLLER TO FULL COOL. @[090894-1673A]
 4. ACTIVATE THE WASTE MANAGEMENT SYSTEM (WMS) AIR SCRUBBER.
 5. UNSTOW CSA-CP AND TAKE READINGS IN VICINITY OF THE FIRE. @[021600-7170]
 6. WHEN HCL < 5 PPM OR TIG < 3 HOURS, REPLACE ONE LIOH CANISTER WITH THE ATCO CANISTER.

To protect crewmembers from toxicological injury, noncontaminated breathing gases must be provided immediately following a fire since even small concentrations of some combustion products can be lethal. Combustion products of Halon, polyvinyl chloride, Teflon, and Kapton can include hydrogen fluoride (HF), hydrogen chloride (HCl), hydrogen cyanide (HCN), hydrogen bromide (HBr), fluorine and bromine gases, carbonyl fluoride (COF₂), and carbon monoxide (CO). @[021600-7170]

HF, HCl, and HBr act instantaneously on the mucous membrane of the eye and respiratory tract causing temporary blindness, coughing, and wheezing. Bronchitis and pneumonia can develop hours later. High levels of HCN and CO may become an immediate danger to life and health.

Protection of the eyes and respiratory tract is achieved by donning the QDM. The QDM is recommended over the LES since the QDM can be donned more quickly. Donning the full LES will be considered later. Continuous use of the QDM or LES will rapidly use the gaseous N₂ reserves to maintain the cabin O₂ concentration within limits (the QDM or LES put O₂ into the cabin and diluting it with N₂ is the only way to prevent the O₂ concentration from rising above the maximum allowable limit; reference Rule {A17-254}; CABIN O₂ CONCENTRATION). The total N₂ available will be insufficient to last more than 10.5 hours with seven crewmembers on the QDM or LES (assuming an average O₂ concentration of 40 percent, 216 lb usable N₂, 3 lb O₂/hr/crewmember introduced into the cabin due to QDM or LES use). For the worst case redline value of 80 lb usable N₂, the time decreases to approximately 4 hours.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-152

CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

HF, HBr, HCl, fluorine, and bromine are absorbed by the LiOH canisters. The CO is removed only by the ATCO canister. HCN is only effectively removed by the activated charcoal in the LiOH canister, the charcoal canister (flown on RCRS flights), the WMS Odor Bacteria Filter, or the ATCO canister.

One LiOH canister should be changed out every 15 minutes for HCN scrubbing. Since there is only 1/4 lb of charcoal in the LiOH canisters, its capability to scrub HCN is limited to approx. 15 min. The charcoal canisters contain 5 lbs of activated charcoal and by comparison should last for up to 2 hours. LiOH canister changeout should continue until the HCN concentration reaches acceptable levels or stabilizes, at which time the preflight changeout schedule can be reimplemented. ©[090894-1673A]

Two fresh LiOH canisters are immediately installed to remove the acid gases (primarily HCl) that can degrade the platinum catalyst in the ATCO canister and therefore inhibit the effect of CO removal. When HCl concentration drops below 5 ppm, the ATCO canister can be installed without significant risk of degradation. 5 ppm is based upon engineering judgment. At tested HCl levels of 500 ppm, the ATCO canister was completely degraded, and conversely HCl levels of 1 ppm resulted in no measurable degradation. In the interest of beginning CO scrubbing as quickly as possible, a level of 5 ppm was determined to pose no significant risk of degradation and allowed the ATCO to be installed earlier by several hours as compared to 1 ppm HCl. If TIG < 3 hrs, the ATCO should be installed regardless of the detected HCl levels. By analysis, the worst case CO levels will be scrubbed out of the cabin atmosphere in approx. 4 hrs; therefore, the ATCO is installed to provide the maximum CO scrubbing capability prior to touch down. ©[090894-1673A] ©[021600-7170]

Turning the cabin temperature controller to the full-cool mode will maximize the air-flow rate through the cabin heat exchanger and therefore increase the amount of contaminants removed by the humidity separator.

The WMS air scrubber contains activated charcoal and can assist in the removal of acid gases due to its high flow rate and large capacity.

The Compound Specific Analyzer-Combustion Products (CSA-CP) should be used to measure the levels of the toxic target compounds (CO, HCN, HCl) in the crew cabin and to follow trends in these levels as cleanup efforts continue. ©[021600-7170]

Documentation: Combustion Product Removal From Cabin Air (OFTP #109 minutes, dated 8/90) Phase I Combustion Products Test Results (OFTP # 113 minutes, dated 1/09/91), Phase II Combustion Products Test Results (OFTP #120 minutes, dated 8/21/91), LESC memo 053-52-BR1, Suggested Flight Procedures in Response to an Accidental Burning of Wire in the Orbiter, dated 9/12/90. ©[090894-1673A]

FLIGHT RULES

A13-152

CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

7. THE MCC WILL ASSIST IN EVALUATING THE CABIN CONCENTRATION OF THE COMBUSTION PRODUCTS. THE CREW WILL REMOVE QDM'S ONLY ON MCC CALL. THIS DECISION WILL BE BASED UPON THE FOLLOWING: @[090894-1682A]
- a. CREW SYMPTOMS
 - b. SMOKE DETECTORS RESPONSE
 - c. CSA-CP RESPONSE @[021600-7170]
 - d. MATHEMATICAL MODEL OF ARS REMOVAL @[090894-1682A]
 - e. CREW INPUT ON AMOUNT & TYPE OF MATERIAL BURNED @[090894-1682A]

Collectively, these will provide only an estimate of the total toxicity hazard in the cabin. If crew symptoms like temporary blindness, coughing, and wheezing are noted, QDM's should remain donned. Crew will remove QDM's based on coordinated communication with the Flight Director, Surgeon, and EECOM. QDM's will be donned if any symptoms are incurred. QDM's can stay doffed if all crewmembers remain symptom-free for greater than 10 minutes.

Medical Operations cannot recommend that crewmembers discontinue breathing noncontaminated gases unless there is satisfactory evidence that the cabin concentration of combustion products is within safe limits. However, the risk of breathing contaminated gases must be weighed against the risks of an ELS, or exceeding cabin O2 limits. These risks were assessed by the community and have been considered in sections 8, 9, and 10 of this flight rule.

Smoke detector readings will be evaluated by EECOM for safe levels. QDM's should remain donned if visible indication of smoke remains in the cabin.

A real-time decision-making process, using the CSA-CP, will be based upon the initial post-fire readings compared with the decreasing trend in contaminant concentrations measured by the CSA-CP. The Surgeon, EECOM, and Toxicology Group will be consulted in these decisions. These baseline readings will be compared with the following contaminant levels (SMAC is Spacecraft Maximum Allowable Concentrations): CO < 55 ppm (1-hour SMAC); HCN < 8 ppm (1-hour SMAC); HCl < 5 ppm (1-hour SMAC). Depending on the profile of changing contaminant concentrations, the following 24-hour SMAC may be used as guidelines: CO < 20 ppm; HCN < 4 ppm; HCl < 2 ppm. The fact that irritant gases (HCl and HF) act additively will be considered. The criteria for determining a safe cabin or removing QDM's will not be based solely on CSA-CP readings. @[021600-7170]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-152 CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

The mathematical models of ARS removal of toxic compounds will be utilized to predict the rate of decrease in cabin concentrations. These predictions will be correlated with real-time CSA-CP data.

Crew input on the amount and type of materials burned will determine the potential thermal degradation and/or toxic byproducts.

8. IF EVALUATION SHOWS THE CABIN ATMOSPHERE PRESENTS A DEFINITE SHORT-TERM HAZARD:
 - a. ALL CREWMEMBERS WILL REMAIN ON QDM'S.
 - b. LES'S WILL BE USED WITH VISORS DOWN FOR ENTRY AND ORBITER EGRESS. @[090894-1682A]
 - c. AN ELS OR NEXT PLS LANDING WILL BE PERFORMED BASED ON N2 CONSUMABLES AND THE TIME TO THE NEXT PLS. @[090894-1682A]

If the cabin atmosphere is clearly hazardous, there is no choice but to protect the crew by wearing the QDM's and LES's. An ELS may be required.

9. IF EVALUATION OF THE CABIN ATMOSPHERE SHOWS A MODERATE PROBABILITY OF BEING HAZARDOUS: @[021600-7170]
 - a. A NEXT PLS/CONUS LANDING WILL BE PERFORMED.
 - b. THE QDM'S MAY BE REMOVED, IF REQUIRED, TO PREVENT EXHAUSTING ALL N2 PRIOR TO THE NEXT PLS LANDING.
 - c. IF POSSIBLE, CDR AND PLT WILL REMAIN ON QDM'S.

IF, AFTER DOFFING QDM'S, THE CABIN ATMOSPHERE IS CONFIRMED TO BE HAZARDOUS:

- d. QDM'S WILL BE RE-DONNED BY ALL CREWMEMBERS.
- e. AN ELS OR NEXT PLS LANDING WILL BE PERFORMED BASED ON N2 CONSUMABLES AND THE TIME TO THE NEXT PLS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-152

CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

- f. LES'S WILL BE USED WITH VISORS DOWN FOR ENTRY AND ORBITER EGRESS.

If the assessment of the inhalation hazard of combustion products is inconclusive or the range of uncertainty in the assessment is such that some risk still exists that the atmosphere may be hazardous, the risk to the crew is real and a next PLS or CONUS landing is justified. Although the potential risk to crew health with the QDM's removed is recognized, in the assessment of the overall community, there is a greater risk associated with an ELS landing or exceeding cabin O2 concentration limits (fire risk). If it becomes necessary to remove the QDM's to minimize N2 consumption, ensuring a PLS or CONUS landing, the CDR and PLT should remain on noncontaminated breathing gases to assure their peak performance throughout entry and landing. @[090894-1682A]

10. IF EVALUATION SHOWS THE CABIN ATMOSPHERE IS CLEARLY SAFE, THE SOURCE OF THE FIRE CAN BE LOCATED AND SAFED (I.E., A SHORT THAT CAN BE UNPOWERED), AND A HALON BOTTLE HAS NOT BEEN DISCHARGED: @[090894-1682A]

- a. QDM'S WILL BE REMOVED.
- b. A NOMINAL DURATION MISSION MAY BE PERFORMED.

IF A HALON BOTTLE HAS BEEN DISCHARGED, PARAGRAPHS A OR B OF THIS RULE WILL APPLY.

If the cabin atmosphere can be shown to be safe, there is no reason to shorten the flight

- D. IF A FREON-TO-WATER-LOOP LEAK OCCURS IN THE HEAT EXCHANGER AND, SUBSEQUENTLY, A WATER LOOP LEAK INTO THE CABIN DEVELOPS:
1. QDM'S WILL BE DONNED BY ALL CREWMEMBERS.
 2. CABIN ATMOSPHERE CONTAMINATION BY FREON 21 MAY REQUIRE MISSION TERMINATION AT THE NEXT PLS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-152 CABIN ATMOSPHERE CONTAMINATION (CONTINUED)

3. LES'S WILL BE USED WITH VISORS DOWN FOR ENTRY AND ORBITER EGRESS.

Freon 21 detection, concentration determination, and toxic effects will be difficult to determine in orbit and require conservative management. Although concentration and SMAC limits at various time intervals have been established for Freon 21, accurate in-flight determination is not possible at present. In chronic exposures and low concentrations (0.02 percent or 200 ppm for 7 days), Freon 21 may cause liver damage, with mental impairment expected at 0.05 percent (500 ppm) and cardiac arrhythmias at 0.5 percent (5000 ppm) during acute exposures. Cardiac arrhythmias and pulmonary effects are progressively worsened at higher levels and are potentiated by increased epinephrine levels. The potential cabin concentration upon release of 3.0 gm. is 11.0 ppm; there is nearly 272 kg. of Freon 21 onboard the orbiter. For each 0.45 kg. of charcoal in the ARS LiOH canisters, Freon 21 concentration will only be lowered approximately 12.5 ppm. Given the larger number of toxic compounds carried on the orbiter and in experiments, early recognition and response in atmosphere contamination contingencies are essential for crew safety.

*Rule {A17-51}, MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION, references this rule.
©[090894-1682A]*

A13-153 BROKEN GLASS/HAZARDOUS SUBSTANCE CONSTRAINT

- A. IF BROKEN GLASS OR A HAZARDOUS SUBSTANCE SPILLS INTO A CLOSED VOLUME AREA, THAT VOLUME AREA WILL NOT BE OPENED TO THE HABITABLE ENVIRONMENT. FLIGHT-SPECIFIC EXCEPTIONS WILL BE LISTED IN THE FLIGHT-SPECIFIC ANNEX.

This will prevent the introduction of the hazardous substance into the crew's environment.

- B. RELEASE OF BROKEN GLASS IN THE CABIN ENVIRONMENT IS A LEVEL 2 HAZARDOUS SPILL. REFERENCE RULE {A13-155C}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE, FOR CREW ACTIONS.

Free-floating glass particles represent a hazard to the eyes and respiratory tract. Cleanup may be attempted with the crew wearing protective equipment as noted for a level 2 hazardous spill.

FLIGHT RULES

A13-154

HAZARDOUS SPILL LEVEL DEFINITIONS

HAZARDOUS SPILL LEVELS ARE DEFINED BY THE FOLLOWING HAZARDOUS SPILL LEVEL DEFINITION TABLE.

COLOR/ LEVEL	STATE	FLAMMABILITY	SYSTEMIC/ INTERNAL DAMAGE	IRRITANCY	CRIT	SUMMARY OF HAZARD LEVEL
RED ? ? ? 4 ? ? ? ?	GAS, VOLATILE LIQUID, OR FUMES THAT ARE NOT CONTAINABLE BY A CLEANUP CREW. THE ARS WILL BE USED TO DECONTAMINATE. THE 5-MICRON SURGICAL MASKS WILL NOT PROTECT THE CREW. EITHER THE QUICK DON MASKS OR THE SEBS ARE REQUIRED.	MAY BE CAPABLE OF PRODUCING FLAMMABLE VAPORS OR FINE MIST IN SUFFICIENT QUANTITY TO PRODUCE A HAZARD.	APPRECIABLE EFFECTS ON COORDINATION, PERCEPTION, MEMORY, ETC., OR POTENTIAL FOR LONG TERM (DELAYED) SERIOUS INJURY (E.G., CANCER) OR MAY RESULT IN INTERNAL TISSUE DAMAGE.	MODERATE TO SEVERE IRRITATION THAT HAS THE POTENTIAL FOR LONG-TERM CREW PERFORMANCE DECREMENT (FOR EYE ONLY HAZARDS, THERE MUST BE A RISK OF PERMANENT EYE DAMAGE). NOTE: WILL REQUIRE THERAPY IF CREW IS EXPOSED.	[1]	IT IS A CATASTROPHIC HAZARD (CAPABLE OF CAUSING DISABLING INJURY) THAT IS NOT CONTAINABLE BY A CLEANUP CREW AND HAS THE POTENTIAL FOR SYSTEMIC TOXICITY, MODERATE-TO-SEVERE IRRITANT, TISSUE DAMAGE, OR CAN PRODUCE FLAMMABLE VAPORS. THE SURGICAL MASKS WILL NOT, COMBINED WITH GOGGLES AND GLOVES, PROTECT THE CREW. EITHER QUICK DON MASKS OR SEBS ARE REQUIRED TO BE WORN WHILE THE ARS DECONTAMINATES. NO PROVISION HAS BEEN MADE FOR SEVERE SKIN IRRITATION OR ABSORPTION. EXAMPLE: METAL VAPOR LIKE MERCURIC IODIDE.
ORANGE ? ? ? 3 ? ? ? ?	EITHER A SOLID OR NONVOLATILE LIQUID. CAN BE CONTAINED BY A CLEANUP CREW AND DISPOSED OF. SURGICAL MASKS AND GLOVES WILL NOT PROTECT THE CREW. EITHER QUICK DON MASKS OR SEBS AND SILVER SHIELD GLOVES ARE REQUIRED.	MAY BE CAPABLE OF PRODUCING FLAMMABLE VAPORS OR FINE MIST IN SUFFICIENT QUANTITY TO PRODUCE A HAZARD.	APPRECIABLE EFFECTS ON COORDINATION, PERCEPTION, MEMORY, ETC., OR THE POTENTIAL FOR LONG-TERM (DELAYED) SERIOUS INJURY (E.G., CANCER) OR MAY RESULT IN INTERNAL TISSUE DAMAGE.	THERE MAY BE IRRITATION THAT ACCOMPANIES THE SYSTEMIC TOXICITY CONCERNS; HOWEVER, IRRITANCY ALONE WOULD NOT DRIVE YOU TO A LEVEL 3. NOTE: WILL REQUIRE THERAPY IF CREW IS EXPOSED.	[1]	IT IS A CATASTROPHIC HAZARD (CAPABLE OF CAUSING DISABLING INJURY) THAT IS CONTAINABLE BY A CLEANUP CREW AND HAS THE POTENTIAL FOR SYSTEMIC TOXICITY, OR IS CAPABLE OF PRODUCING FLAMMABLE VAPORS, OR COULD CAUSE INTERNAL TISSUE DAMAGE. THE 5-MICRON SURGICAL MASKS, GLOVES, AND GOGGLES ARE NOT SUFFICIENT TO PROTECT THE CREW. THEREFORE, EITHER QUICK DON MASKS OR SEBS ARE REQUIRED TO BE WORN BY ALL CREWMEMBERS. ONLY THE CLEANUP CREW WILL BE REQUIRED TO WEAR SILVER SHIELD GLOVES. EXAMPLE: ACETONITRILE.

FLIGHT RULES

A13-155

ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE

THE FLIGHT-SPECIFIC ANNEX WILL LIST ALL LEVEL 4 THROUGH LEVEL 1 PAYLOAD HAZARDOUS SUBSTANCES. REFERENCE RULE {A13-154}, HAZARDOUS SPILL LEVEL DEFINITIONS. THE FOLLOWING ACTIONS WILL BE TAKEN IN THE EVENT THAT A HAZARDOUS SUBSTANCE IS RELEASED INTO THE ORBITER ATMOSPHERE.

A. LEVEL 4

1. ALL CREWMEMBERS WILL DON AND ACTIVATE QUICK DON MASKS. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS:
 - a. SET CABIN TEMPERATURE CONTROLLER TO FULL COOL.
 - b. TURN ON THE WASTE COLLECTION SYSTEM.
 - c. TURN OFF THE REGENERATIVE CO₂ REMOVAL SYSTEM (RCRS) (IF APPLICABLE).
2. THE CREW SHALL PERFORM A CABIN DEPRESS TO 8 PSI AND A CONTINUOUS CABIN PURGE AT 8 PSI IF REQUIRED TO CONTROL PPO₂. (REFERENCE RULE {A17-254}, CABIN O₂ CONCENTRATION). ©[090894-1673A]
3. THE FLIGHT CONTROL ROOM SURGEON SHOULD BE CONSULTED FOR THE MAXIMUM LENGTH OF TIME THE QUICK DON MASKS CAN BE WORN. (REFERENCE RULE {A13-54}, 100 PERCENT OXYGEN CONSTRAINT.)

A level 4 hazardous substance is defined as either a gas, a volatile liquid, or fumes that are not containable by the crew. Crew exposure could result in systemic toxicity, severe irritation, and/or tissue damage. The driving factor that distinguishes a level-4 substance from a level 3 substance is noncontainability.

The immediate priorities for a level 4 spill are to prevent crew exposure to the substance and to configure the ARS to scrub the environment. All crewmembers will don and activate QDM's to avoid any debilitating effects.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-155

ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

The ARS configuration steps were determined to provide maximum decontamination. Setting the cabin temperature to full cool will provide maximum removal of water soluble or particulate hazardous substances through the humidity separator as condensate. Other atmospheric scrubbing can be accomplished with the use of the odor/bacterial filter of the WCS and the LiOH and/or charcoal canisters that are already installed. The most recently installed LiOH canisters may have exhausted CO₂ removal capability; however, the LiOH/CO₂ product, Li₂CO₃, and existing charcoal still have scrubbing potential. For flights that use the RCRS, the RCRS must be unpowered to prevent contamination of the solid amine.

A cabin depress to 8 psi and continuous purge at 8 psi will manage O₂ concentrations below maximum levels as well as decrease the concentration of the level 4 substance. This action could extend the time on orbit so as to avoid an ELS entry. ©[090894-1673A]

B. LEVEL 3

1. ALL CREWMEMBERS WILL DON AND ACTIVATE QUICK DON MASKS AND SILVER SHIELD GLOVES. THE FLIGHT DECK CREW WILL TURN OFF THE CABIN AND IMU FANS ONE CREWMEMBER WILL CONTINUOUSLY MONITOR THE SPILL. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS:
 - a. ATTEMPT TO CLEAN UP THE SPILL.
 - b. BAG, LABEL AND STOW IN WET TRASH.
2. IF CLEANUP ATTEMPT FAILS, THE HAZARDOUS SPILL WILL BE UPGRADED TO A LEVEL 4.

A level-3 hazardous substance is defined as a solid or nonvolatile liquid that is containable by the cleanup crew. It is this containability that separates a level-3 substance from a level 4.

Crew exposure to a level-3 substance could result in systemic toxicity, severe irritation, and/or tissue damage. It is this severity of effects on exposure that separates a level-3 substance from the levels 2, 1, and 0 substances. All crewmembers must wear QDM's to protect themselves during the cleanup.

During the cleanup, all airflow is halted by deactivating the cabin and IMU fans to prevent dispersion of the spilled substance. The maximum time that a cabin fan can be deactivated in an off-nominal situation is 20 minutes (ref. SODB, Volume 3, Rev. A, Table 4.5.0-1, Display Driver Unit). The maximum time that an IMU fan can be deactivated in an off-nominal situation is 45 minutes, (ref. SODB, Volume 3, Rev. A, Table 4.5.0-1, Inertial Measuring Unit).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-155

ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE (CONTINUED)

By definition, a level-3 hazardous spill is catastrophic and containable. If the level-3 cleanup fails, this spill will be upgraded to a level 4, and level-4 cleanup actions shall be implemented.

C. LEVEL 2

1. ALL CREWMEMBERS WILL DON GOGGLES, SURGICAL MASKS, AND SILVER SHIELD GLOVES. THE FLIGHT DECK CREW WILL TURN OFF THE CABIN AND IMU FANS. THE CLEANUP CREW WILL TAKE ACTIONS 1.a AND 1.b LISTED IN PARAGRAPH B ABOVE. @ED]
2. IF CLEANUP ATTEMPT FAILS, THE HAZARDOUS SPILL WILL BE UPGRADED TO A LEVEL 4.

A level-2 substance is either a solid or a nonvolatile liquid that is containable by the cleanup crew. Crew exposure could result in moderate to severe irritation that has the potential for long-term crew performance decrement. All crewmembers will be adequately protected by the 5-micron surgical masks, goggles, and silver shield gloves.

See paragraph B, level-3 rationale, for the reason for stopping the airflow in the spill area.

Even though a level-2 substance causes less severe effects than a level-3 substance, a level-2 spill is defined as catastrophic and containable. If the level-2 cleanup fails, this spill will be upgraded to a level-4, and level-4 cleanup actions shall be implemented.

D. LEVEL 1

ALL CREWMEMBERS WILL DON GOGGLES AND SURGICAL MASKS. THE FLIGHT DECK CREW WILL TURN OFF THE CABIN AND IMU FANS. THE CLEANUP CREW WILL DON SURGICAL GLOVES AND TAKE ACTIONS a AND b LISTED IN PARAGRAPH B.

A level-1 hazardous substance may or may not be containable by the crew. Crew exposure will result only in slight to moderate irritation. All crewmembers will be protected by surgical masks and goggles.

See paragraph B, level-3 rationale, for the reason for stopping the airflow in the spill area.

If the spill is not containable by the crew, the MCC will determine other procedures for containment or for a workaround.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-155

ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

E. LEVEL 0

THE FLIGHT DECK CREW WILL TURN OFF THE CABIN AND IMU FANS.
THE CLEANUP CREW WILL TAKE ACTIONS a AND b LISTED IN
PARAGRAPH B.

A level-0 substance may or may not be containable by the crew. Crew exposure would result in only slight transient (less than 30 minutes) irritation.

No protective gear is required.

See paragraph B, level-3 rationale, for the reason for stopping the airflow in the spill area.

If the spill is not containable by the crew, the MCC will determine other procedures for containment or for a workaround.

All payload substances are reviewed by the Payload Safety Review Panel; those not listed as level-4 through 1 are considered nonhazardous (level 0).

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE

@[092701-4872]

THE FLIGHT-SPECIFIC ANNEX WILL LIST ALL EXPERIMENT/SAMPLES CONTAINING LEVEL-4 THROUGH LEVEL-1 PAYLOAD HAZARDOUS SUBSTANCES. REFERENCE RULE {A13-154}, HAZARDOUS SPILL LEVEL DEFINITIONS. THE FOLLOWING ACTIONS WILL BE TAKEN IN THE EVENT THAT A HAZARDOUS SUBSTANCE IS RELEASED INTO THE SPACEHAB/ORBITER ATMOSPHERE. @[111501-4971]

A. LEVEL 4

1. ORBITER

REFERENCE RULE {A13-155A}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. THE CREW SHALL SAFE AND ISOLATE THE SPACEHAB MODULE PER RULE {A2-329}, SPACEHAB DEACTIVATION/ENTRY PREP. @[ED]

A level-4 hazardous substance is defined as either a gas, a volatile liquid, or fumes that are not containable by the crew. Crew exposure could result in a systemic toxicity, severe irritation, and/or tissue damage. The driving factor that distinguishes a level-4 substance from a level-3 substance is noncontainability.

The immediate priorities for a level-4 spill in the orbiter are prevention of crew exposure to the substance and configuration of the atmospheric revitalization system (ARS) for environmental scrubbing. All crewmembers will don and activate Quick Don Masks to avoid any detrimental effects.

The Spacehab module cannot be used as a safe haven for the crew because the module ARS is incapable of controlling humidity, O₂, N₂, and CO₂ concentrations.

2. SPACEHAB MODULE

IF HAZARDOUS SPILL OCCURS IN THE SPACEHAB MODULE, EVACUATE ALL CREWMEMBERS TO THE ORBITER EXCEPT THE SAFING CREW. THE FLIGHTDECK CREW WILL TURN OFF ALL SPACEHAB FANS. THE EVACUATING CREW WILL CLOSE THE MAN PL ISOL VLV. THE SAFING CREW WILL PERFORM THE FOLLOWING ACTIONS: @[021600-7102A]

- a. DON/ACTIVATE SEBS
- b. OPEN CABIN DEPRESS VALVE (CDV)
- c. EVACUATE THE MODULE
- d. CLOSE THE SPACEHAB HATCH

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

e. CLOSE AND CAP EQUALIZATION VALVES @[111501-4971]

NOTE: MODULE ISOLATION IS NECESSARY BECAUSE THE MODULE ARS DOES NOT HAVE THE CAPABILITY TO SCRUB THE CONTAMINATED AIR. ALL EXPERIMENTS/SAMPLES CONTAINING LEVEL-4 PAYLOAD HAZARDOUS SUBSTANCES ARE LISTED IN THE FLIGHT SPECIFIC ANNEX. @[021600-7102A] @[111501-4971]

Reference the rationale for paragraph 1 for a definition of level-4 hazardous substances.

The immediate priorities for a level-4 spill in the module are crew evacuation to the orbiter and isolating Spacehab. Nonessential crew will evacuate to the orbiter to limit crew exposure to the hazardous substance. The ARS and cabin/HFA fans are temporarily deactivated by the flightdeck crew to halt air exchange within the transfer tunnel while the Spacehab hatch is still open. The MAN PL ISOL VLV is closed to stop air exchange between Spacehab and the orbiter through the transfer tunnel ducting. Since the Spacehab will remain powered, the CDV is being opened to protect the option to depress the module in case of a fire or to reduce the level of the hazardous spill concentration.
@[021600-7102A]

The safing crew will don and activate SEBS to avoid systemic effects while they secure the module.

B. LEVEL 3

1. ORBITER:

REFERENCE RULE {A13-155B}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS FAN.

A level-3 hazardous substance is defined as a solid or nonvolatile liquid that is containable by the cleanup crew. It is this containability that separates a level-3 substance from a level-4.

Crew exposure to a level-3 substance could result in systemic toxicity, severe irritation, and/or tissue damage. It is this severity of effects on exposure that separates a level-3 substance from the level-2, 1, and 0 substances. Since O₂/N₂, CO₂, and humidity control are not available in the module for an orbiter spill, all crewmembers must don and activate Quick Don Masks and don chemically resistant silver shield gloves.

During the cleanup, all airflow in the spill area is halted to prevent dispersion of the spilled substance. For an orbiter spill, this requires deactivating the cabin and IMU fans and turning off the Spacehab ARS fan, which will halt air exchange between the orbiter and Spacehab. If the hazardous spill is such that total isolation of the Spacehab module is required, the MAN PL ISOL VLV and the Spacehab hatch will be closed. @[111501-4971]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

2. SPACEHAB MODULE:

ALL CREWMEMBERS EXCEPT THE CLEANUP CREW WILL EVACUATE THE MODULE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS AND CABIN/HFA FANS. THE EVACUATING CREW WILL CLOSE THE MAN PL ISOL VLV. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS: @[111501-4971]

- a. DON/ACTIVATE SEBS AND SILVER SHIELD GLOVES
- b. DEACTIVATE AFT MODULE FAN (LDM ONLY) @[021600-7102A]
- c. ATTEMPT TO CLEAN UP THE SPILL
- d. BAG, LABEL, AND STOW IN WET TRASH

NOTE: IF CLEANUP FAILS, THIS SPILL WILL BE UPGRADED TO A LEVEL-4. ALL EXPERIMENTS/SAMPLES CONTAINING LEVEL-3 PAYLOAD TOXIC MATERIALS ARE LISTED IN THE FLIGHT SPECIFIC ANNEX.

See rationale from paragraph 1 for a definition of a level-3 hazardous spill.

The cleanup crew must use SEBS along with chemically resistant silver shield gloves to protect themselves while they perform the cleanup.

During the cleanup, all airflow in the spill area is halted by closing the MAN PL ISOL VLV and by deactivating all Spacehab subsystem fans. Unlike for a level-4 spill, the aft module fan is deactivated from inside the module by the cleanup crew because an item entry by the flightdeck crew would turn off the aft module lights, reducing module illumination for the cleanup crew. @[021600-7102A]

If the initial module PPCO₂ level is 7.15 mmHg at the time the SH ARS fan is deactivated, it will take 23.7 minutes to reach a level of 7.6 mmHg and 378 minutes to reach 15 mmHg (reference TM-SPACEHAB-91003, April 1991) in a Spacehab single module configuration. Times will be greater for Spacehab double module (LDM/RDM) configurations.

By definition, a level-3 hazardous spill is catastrophic and containable. If the level-3 cleanup fails, this spill will be upgraded to a level-4, and level-4 cleanup actions will be implemented. @[111501-4971]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

C. LEVEL 2 @[111501-4971]

1. ORBITER:

REFERENCE RULE {A13-155C}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS FAN.

2. SPACEHAB MODULE:

ALL CREWMEMBERS EXCEPT THE CLEANUP CREW WILL EVACUATE THE MODULE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS AND CABIN/HFA FANS. THE EVACUATING CREW WILL CLOSE THE MAN PL ISOL VLV. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS.

- a. DON SURGICAL MASKS, GOGGLES, AND SILVER SHIELD GLOVES
- b. DEACTIVATE AFT MODULE FAN (LDM ONLY)
- c. ATTEMPT TO CLEAN UP THE SPILL
- d. BAG, LABEL, AND STOW IN WET TRASH

NOTE: IF CLEANUP FAILS, THIS SPILL WILL BE UPGRADED TO A LEVEL-4. ALL EXPERIMENTS CONTAINING LEVEL-2 PAYLOAD TOXIC MATERIALS ARE LISTED IN THE FLIGHT SPECIFIC ANNEX.

A level-2 hazardous substance is either a solid or a nonvolatile liquid that is containable by the cleanup crew. Crew exposure could result in moderate-to-severe irritation that has the potential for long-term crew performance decrement. All crewmembers will be adequately protected by the 5-micron surgical masks, goggles, and silver shield gloves.

Reference paragraph B, level-3 rationale for the reason for stopping airflow in the spill area.

Even though a level-2 substance causes less severe effects than a level-3 substance, a level-2 hazardous spill is defined as catastrophic and containable. If the level-2 cleanup fails, this spill will be upgraded to a level-4, and level-4 cleanup actions shall be implemented. @[111501-4971]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-156

SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE
(CONTINUED)

D. LEVEL 1 @[111501-4971]

1. ORBITER:

REFERENCE RULE {A13-155D}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS FAN.

2. SPACEHAB MODULE:

ALL CREWMEMBERS EXCEPT THE CLEANUP CREW WILL EVACUATE THE MODULE. THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS AND CABIN/HFA FANS. THE EVACUATING CREW WILL CLOSE THE MAN PL ISOL VLV. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS.

- a. DON GOGGLES AND SURGICAL MASKS AND GLOVES
- b. DEACTIVATE AFT MODULE FAN (LDM ONLY)
- c. ATTEMPT TO CLEAN UP THE SPILL
- d. BAG, LABEL, AND STOW IN WET TRASH

A level-1 hazardous substance may or may not be containable by the crew. Crew exposure could result only in slight-to-moderate irritation. All crewmembers will be protected by surgical masks and goggles. Also, the cleanup crew will need to use surgical gloves. @[111501-4971]

Reference paragraph B, level-3 rationale for the reason for stopping the airflow in the vicinity of the spill. Reference Rule {A13-154}, HAZARDOUS SPILL LEVEL DEFINITIONS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-156 **SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE**
(CONTINUED)

E. LEVEL 0 @[111501-4971]

1. ORBITER:

REFERENCE RULE {A13-155E}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE. NO SPACEHAB ACTIONS ARE REQUIRED.

2. SPACEHAB MODULE:

THE FLIGHTDECK CREW WILL DEACTIVATE THE SPACEHAB ARS AND CABIN/HFA FANS. THE CLEANUP CREW WILL TAKE THE FOLLOWING ACTIONS:

- a. DEACTIVATE AFT MODULE FAN (LDM ONLY)
- b. ATTEMPT TO CLEAN UP THE SPILL
- c. BAG, LABEL, AND STOW IN WET TRASH

A level-0 substance is assumed to be containable by the crew. Crew exposure would result in only slight transient (less than 30 minutes) irritation. No protective gear is required. Reference paragraph B, level-3 rationale for the reason for stopping the airflow in the vicinity of the spill.

All payload substances are reviewed by the Payload Safety Review Panel; those not listed as level-4 through 1 are considered non-hazardous (level-0). @[111501-4971]

A13-157 THROUGH A13-200 RULES ARE RESERVED @[022802-4887C]

FLIGHT RULES

ENTRY

A13-201

ANTI-G SUIT PROTOCOL (ANTI-ORTHOSTATIC
COUNTERMEASURE) @[ED] @[102501-4885]

- A. WHEN PREPARING FOR ENTRY, EACH CREWMEMBER WILL DON THE LES. IF THE CREWMEMBER ELECTS TO INFLATE THE ANTI-G BLADDERS, THE BLADDERS WILL REMAIN INFLATED UNTIL LANDING. IF THE CREWMEMBER ELECTS TO DEFLATE THE ANTI-G BLADDERS PRIOR TO EGRESS, DEFLATION WILL BE ACCOMPLISHED PROGRESSIVELY OVER AT LEAST A 10-MINUTE PERIOD.

Normal adaptation to zero-g results in a condition equivalent to a 10-percent loss of blood volume. During entry (re-exposure to gravity), blood tends to pool in the lower extremities and a "light headedness" or visual symptoms may result. Inflation of the anti-g bladders prevents blood pooling and increases blood return to the heart. Gradual deflation of the bladders after landing minimizes symptoms by reducing blood pooling.

- B. FOR FLIGHTS GREATER THAN 11 DAYS (COMMANDER FLIGHT DAYS) OF PLANNED MISSION LENGTH, ANTI-G SUITS MUST BE INFLATED TO 0.5 PSI AFTER ENTRY INTERFACE AND TO AT LEAST 1.0 PSI AT 1 G. THE ANTI-G SUITS MUST REMAIN INFLATED UNTIL AT LEAST WHEEL-STOP.

Anti-G suit inflation needs to occur prior to occurrence of symptoms. This will be especially important to help prevent orthostatic problems after longer duration flights. @[102501-4885]

FLIGHT RULES

A13-202

FLUID LOADING

- A. FLUID LOADING IS REQUIRED BY ALL CREWMEMBERS PRIOR TO DEORBIT. CREWMEMBERS WILL INITIATE FLUID LOADING 1 HOUR BEFORE DEORBIT TIG AND SHOULD BE COMPLETED BY EI. EACH CREWMEMBER WILL CONSUME 8 OUNCES OF WATER AND TWO SALT TABLETS OR 8 OUNCES OF OTHER APPROVED SOLUTION EVERY 15 MINUTES, ACCORDING TO THE FOLLOWING TABLE:
 ©[030994-1608] ©[011801-7187A]

FLUID LOADING AMOUNTS FOR ENTRY BASED ON BODY MASS:

PREFLIGHT CREWMEMBER MASS	NUMBER OF 8 OZ DRINK CONTAINERS	AND	NUMBER OF SALT TABLETS	OR	APPROVED SOLN (OZ)
<120 LBS	3		6		24
120-155	4		8		32
156-190	5		10		40
>190 LBS	6		12		48

©[050400-7187]

THE CREWMEMBERS WILL BE INSTRUCTED ON THE PROPER AMOUNTS PRIOR TO LAUNCH. REMINDERS CAN BE GIVEN DURING THE ENTRY DAY PMC, IF NECESSARY.

- B. IF THERE IS A ONE ORBIT WAVE-OFF AND THE FLUID-LOADING PROTOCOL DESCRIBED IN PARAGRAPH A WAS COMPLETED, THE PROTOCOL SHOULD BE REPEATED TO A TOTAL OF ONE-HALF OF THE PRESCRIBED AMOUNT DETERMINED IN PARAGRAPH A, TO BE COMPLETED BY EI. IF THERE IS A GREATER THAN ONE ORBIT WAVEOFF OR A PARTIAL FLUID LOAD WAS COMPLETED ON THE PREVIOUS DEORBIT ATTEMPT, THE ENTIRE PROTOCOL DESCRIBED IN PARAGRAPH A SHOULD BE REPEATED.
 ©[011801-7187A]
- C. IF A CREWMEMBER IS PARTICIPATING IN A FLUID-LOADING DSO, THE PROTOCOL AND ITS METHOD OF IMPLEMENTATION WILL BE DETAILED PREFLIGHT BY THE INVESTIGATOR AND THE CREW SURGEON. THE PROTOCOL WILL ALSO BE DOCUMENTED IN THE MISSION-SPECIFIC FLIGHT RULES ANNEX.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A13-202

FLUID LOADING (CONTINUED)

Oral fluid loading with a salt/water mixture similar to body fluids has been shown to significantly reduce detrimental heart rate and blood pressure changes during orthostatic stress post flight. Basing the amount of salt and water (in a proper ratio) or other approved solution on the crewmember's body mass helps to assure the fluid loading is adequate for larger crewmembers and possibly not too much for smaller crewmembers. ASTROADE® and other tested isotonic solutions provide plasma volume expansion similar to salt tablets/water and may be easier for some crewmembers to ingest. Flight Surgeons must approve these alternate solutions for individual use prior to flight. ©[030994-1608]

The basis for initiating fluid loading 1 hour prior to TIG includes the amount of time it takes for fluid to leave the stomach, enter the intestine, and be absorbed to affect the plasma volume. A plot for gastric emptying (i.e., the time to leave the stomach and enter the intestine) showed that it takes approximately 60 minutes for nearly all of an isotonic solution consumed to enter the intestine (approximately 20 minutes for 80 percent, approximately 40 minutes for 95 percent, approximately 60 minutes for 98 percent, and approximately 80 minutes for 100 percent). Furthermore, it takes approximately 2 hours from initiation of fluid loading for the change in plasma volume to plateau (at approximately 5 percent). Since landing occurs 1 hour after TIG, change in plasma volume will peak at landing if fluid loading is initiated 1 hour prior to TIG.

From a wave-off perspective, the desire is to delay fluid loading as close to TIG as possible since weather wave-offs often occur just minutes prior to TIG. However, consuming too much too fast can cause gastric discomfort and vomiting.

If fluid loading is initiated 1 hour prior to TIG but deorbit is subsequently delayed, the impact is crew discomfort and increased WCS usage. Although this is undesirable, it is not a safety issue. However, if fluid loading is delayed and the reduction in the change in plasma volume at landing is significant, then crewmembers may feel faint or dizzy upon return to 1g and may not be able to egress unassisted. This can be a safety concern for crewmembers involved with landing the vehicle and for all crewmembers in an emergency egress scenario. ©[011801-7187A]

FLIGHT RULES

A13-203

TANK B WATER CONTINGENCY USE

TANK B WATER SHOULD ONLY BE USED AS A POTABLE WATER SOURCE IN A CONTINGENCY. IF IT BECOMES NECESSARY FOR CREWMEMBERS TO CONSUME TANK B WATER, DIRECT FLOW OF TANK B WATER THROUGH THE AUXILIARY WATER PORT MICROBIAL CHECK VALVE (MCV) AND WAIT 10 MINUTES TO ALLOW THE IODINE SUFFICIENT TIME TO KILL THE BACTERIA. TANK B WATER MUST NOT BE MIXED WITH ANY FLAVORING ADDITIVES DURING THE 10-MINUTE PERIOD.

Tank B water is unsafe for crew consumption without additional preparation. Although it is iodinated prior to launch, it is nominally utilized for FES operations soon after orbital insertion. Tank B subsequently receives water directly from the fuel cell without being iodinated by an MCV. Therefore, while on orbit, tank B water is subject to bacterial growth and should be considered contaminated. In order to ensure the crew does not drink contaminated water, tank B water should be iodinated for an appropriate period of time prior to consumption. An IFM procedure will be utilized to divert flow of tank B water through the auxiliary water port MCV. The water must not be consumed for 10 minutes after passing through the MCV, allowing the iodine sufficient time to kill bacteria. In addition, water flavoring additives (lemonade, tea, etc.) should not be added to the recently iodinated tank B water. These additives will bind with iodine and prevent its antibacterial activity. ©[ED]

FLIGHT RULES

SECTION 14 - SPACE ENVIRONMENT

The Flight Rules of the Space Environment Section deal specifically with ionizing radiation and are intended to provide assurance that crew radiation exposure during Space Shuttle operations will be maintained as low as reasonably achievable (ALARA), as required by the Code of Federal Regulations for Safety and Health.. In this context, Space Shuttle operations include crew activities for EVA and IVA for the orbiter and any habitable payload (Spacelab, Spacehab, etc.). JSC Space and Life Sciences personnel (Flight Surgeon, Radiological Health Officer, and the Space Radiation Analysis Group) are responsible for prelaunch, orbit, and postflight assessment of all shuttle mission crew radiation hazard/health issues. ©[ED]

DEFINITIONS

A14-1 **UNCONFIRMED ARTIFICIAL EVENT DEFINITION**

AN UNCONFIRMED ARTIFICIAL EVENT IS DEFINED AS AN ARTIFICIAL EVENT NOT CONFIRMED BY THE PROPER SUPPORT DATA SOURCE.

This definition is self-explanatory. It is included to minimize the influence on space shuttle operations of rumor or speculation from unofficial sources.

Reference Rule {B14-1}, UNCONFIRMED ARTIFICIAL EVENT DEFINITION.[R] ©[032901-7266A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; {A14-55}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENC; and {B14-1}, UNCONFIRMED ARTIFICIAL EVENT DEFINITION.[R], reference this rule.

A14-2 **CONFIRMED ARTIFICIAL EVENT DEFINITION**

A CONFIRMED ARTIFICIAL EVENT IS DEFINED AS AN ARTIFICIAL EVENT THAT IS REPORTED BY THE PROPER SUPPORT DATA SOURCE.

Reference Rule {B14-2}, CONFIRMED ARTIFICIAL EVENT DEFINITION.[R] ©[032901-7266A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; {A14-55}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY; and {B14-2}, CONFIRMED ARTIFICIAL EVENT DEFINITION.[R], reference this rule.

FLIGHT RULES

A14-3

SOLAR PARTICLE EVENT WARNING DEFINITION ©[032901-7265] ©[032901-7271A]

A SOLAR PARTICLE EVENT (SPE) WARNING IS DEFINED AS AN SPE WARNING GENERATED BY NOAA. NOAA WILL GENERATE THIS WARNING BASED ON THEIR PROJECTIONS THAT CURRENT CONDITIONS ARE SUCH THAT THERE IS A HIGH PROBABILITY THAT AN SPE (10 PROTONS (>10 MEV)/CM²-S-STER AT GEOSYNCHRONOUS ALTITUDE) IS LIKELY.

NOAA solar models take into account many different factors to determine that a solar particle event is likely. NOAA will also provide a window of time that the onset of the SPE may be observed. This warning replaces the previous alert criterion based on X-ray events, magnitude >M5, as an indicator that an SPE is possible. This will help reduce the number of alerts.

Reference Rule {B14-3}, SOLAR PARTICLE EVENT WARNING DEFINITION.[R] ©[032901-7271A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION and {B14-3}, SOLAR PARTICLE EVENT WARNING DEFINITION [R], referencethis rule.

A14-4

SOLAR PARTICLE EVENT DEFINITION

A SOLAR PARTICLE EVENT IS DEFINED AS AN INCREASE IN THE NEAR-EARTH PROTON RADIATION ENVIRONMENT RESULTING FROM SOLAR FLARE ACTIVITY. THRESHOLD LEVEL IS 10 PROTONS (>10 MEV)/CM²-S-STER AT GEOSYNCHRONOUS ALTITUDE. THRESHOLD LEVEL FOR AN ENERGETIC SPE IS 1 PROTON (>100 MEV)/CM²-S-STER AT GEOSYNCHRONOUS ALTITUDE. ©[032901-7267A]

A distinction is made between "ordinary" SPE's and energetic SPE's. Ordinary SPE's are mostly a concern for EVA astronauts. Energetic SPE's include particles with sufficient energy to penetrate the shuttle and thus is a concern for both IVA and EVA crewmembers.

Reference Rule {B14-4}, SOLAR PARTICLE EVENT (SPE) DEFINITION. .[R] ©[032901-7267A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; {A14-55}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY; and {B14-4}, SOLAR PARTICLE EVENT (SPE) DEFINITION .[R], reference this rule.

FLIGHT RULES

A14-5 GEOMAGNETIC STORM DEFINITION @[032901-7272A]

A GEOMAGNETIC STORM IS DEFINED AS A CHANGE FROM NORMAL LEVELS IN THE HORIZONTAL COMPONENT OF THE MAGNETIC FIELD AT THE SURFACE OF THE EARTH AS MEASURED BY MAGNETOMETERS AT BOULDER, CO. MAJOR GEOMAGNETIC STORM THRESHOLD IS $A_B = 50-99$ OR $K_B = 6$. SEVERE GEOMAGNETIC STORM THRESHOLD IS $A_B \geq 100$ OR $K_B \geq 7$.

Reference Rule {B14-5}, GEOMAGNETIC STORM DEFINITION..[R]. @[032901-7272A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; and {A14-55}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY; reference this rule.

A14-6 OTHER RADIATION EVENT DEFINITION @[032901-7268A]

OTHER RADIATION EVENT IS DEFINED AS INCREASED RADIATION RATES PRODUCED BY ANY SOURCE OTHER THAN SOLAR, GEOMAGNETIC OR ARTIFICIAL EVENT ACTIVITY. THRESHOLD LEVEL IS ANY INCREASE ABOVE THE NOMINAL MISSION RATE PROJECTIONS.

This definition is included to cover any natural or manmade exposure enhancement from radiation sources not listed in the definitions above. For example, geomagnetic storms can inject or accelerate particles in the Earth's trapped charged particle belts resulting in an increased ambient radiation environment surrounding the shuttle. These enhancements can last from days to weeks. Occasionally, during severe geomagnetic activity, new radiation belts that may persist for lengthy periods can be formed apart from the existing belts, and may increase shuttle crew exposure, particularly during EVA's.

Reference Rule {B14-6}, RADIATION BELT ENHANCEMENT DEFINITION.[R] @[032901-7268A]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; and {A14-55}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY, reference this rule.

FLIGHT RULES

A14-7

RADIATION ENVIRONMENT CONDITION DEFINITION

CONDITION	DEFINITION
NOMINAL	NO ADVERSE ENVIRONMENTAL CONDITION EXISTS.
ALERT	A CONDITION WHERE AN IMMINENT INCREASE IN CREW RADIATION EXPOSURES IS POSSIBLE. A RADIATION ALERT IS INITIATED WHEN ANY OF THE FOLLOWING EVENTS OCCUR: 1. UNCONFIRMED ARTIFICIAL EVENT (REF. RULES A14-1), UNCONFIRMED ARTIFICIAL EVENT DEFINITION); 2. SOLAR PARTICLE EVENT WARNING (REF. RULE {A14-3}, SOLAR PARTICLE EVENT WARNING DEFINITION); 3. SOLAR PARTICLE EVENT (REF. RULE {A14-4}, SOLAR PARTICLE EVENT DEFINITION); 4. GEOMAGNETIC STORM (REF. RULE {A14-5}, GEOMAGNETIC STORM DEFINITION); OR 5. OTHER RADIATION EVENT (REF. RULE {A14-6}, OTHER RADIATION EVENT DEFINITION));
CONTINGENCY	A CONFIRMED INCREASE IN RADIATION EXPOSURE LEVELS TO THE CREW THAT MAY REQUIRE ACTIVE INTERVENTION TO MINIMIZE THE EFFECTS FROM THE ENHANCED ENVIRONMENT. 1. FOR >45-DEGREE INCLINATION FLIGHTS, >100 PFU (>100 MEV PROTONS) AS MEASURED FROM GOES; 2. FOR >45-DEGREE INCLINATION FLIGHTS AND IF SIGNIFICANT MISSION OBJECTIVES ARE TO BE PERFORMED EVA, IF $K_b > 8$ OR A SIGNIFICANT SHIFT IN THE ELECTRON BELTS HAS OCCURRED; 3. IF IN THE JUDGMENT OF THE RADIATION CONSOLE OPERATOR, ENVIRONMENTAL CONDITIONS WILL PRODUCE LOCAL DOSE RATES > 5 MRADS/MIN; 4. A CONFIRMED ARTIFICIAL EVENT (REF. RULE {A14-2}, CONFIRMED ARTIFICIAL EVENT DEFINITION);

©[032901-7273A]

Space weather events may trigger substantial changes in the near-Earth radiation environment. Close monitoring of the radiation environment is required to detect trends that could lead to unacceptable increases in crew radiation exposure. Radiation environment enhancements may become significant enough to warrant actions by the crew to reduce radiation exposures in order to remain within crew exposure limits (Ref. Rule {A14-11}, SHUTTLE ADMINISTRATIVE LIMIT [HC]) and/or comply with ALARA (Ref. Rule {A14-9}, ALARA DEFINITION).

Reference Rule {B14-7}, RADIATION ENVIRONMENT CONDITIONS. [R] (TBR FOR RUSSIAN CONCURRENCE) ©[032901-7273A]

FLIGHT RULES

A14-8

PROJECTED OPERATIONAL DOSE LIMIT VIOLATION DEFINITION ©[032901-7268A]

PROJECTED OPERATIONAL DOSE LIMIT VIOLATION IS DEFINED AS A DOSE EXTRAPOLATION THAT VIOLATES AN OPERATIONAL LIMIT (RULE {A14-51}, CREW RADIATION EXPOSURE LIMITS [HC]) BASED UPON ANALYTICAL PROJECTIONS WITH ACCUMULATION RATES CONFIRMED BY ONBOARD DOSIMETRY READOUT.

This definition is self-explanatory. ©[032901-7268A]

Rules {A14-10}, LEGAL EXPOSURE LIMITS [HC] and {A14-53}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS - ON ORBIT [HC], reference this rule.

A14-9

ALARA DEFINITION

ALARA, AS LOW AS REASONABLY ACHIEVABLE, REFERS TO A RADIATION PROTECTION PRINCIPLE THAT REQUIRES ANY ADDITIONAL RADIATION EXPOSURE BE SUBJECT TO A RISK-VERSUS-GAIN ANALYSIS REGARDLESS OF THE MAGNITUDE OF ADDITIONAL EXPOSURE. THE MAXIMUM PERMISSIBLE LEVELS, OR LIMITS, ARE NOT TO BE CONSIDERED AS "ACCEPTABLE," BUT INSTEAD, THEY REPRESENT THE LEVELS THAT SHOULD NOT BE EXCEEDED.
©[032901-7275A]

NASA is required by the Occupational Safety and Health Administration (OSHA) to maintain a risk-limitation system for all activities that involve radiation exposure. This risk-limitation system includes the need to minimize cumulative radiation exposures for all crewmembers. Since OSHA classifies crewmembers as radiation workers, these federally mandated rules apply.

Reference Rule {B14-8}, ALARA DEFINITION.[R] ©[032901-7275A]

Rules{A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; {A14-10}, LEGAL EXPOSURE LIMITS [HC]; {A14-51}, CREW RADIATION EXPOSURE LIMITS [HC]; {A14-52}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS – PRELAUNCH, {A14-53}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS – ON ORBIT [HC], and {A14-54}, GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC], reference this rule.

FLIGHT RULES

A14-10 LEGAL EXPOSURE LIMITS [HC]

THE FOLLOWING OPERATIONAL CREW IONIZING RADIATION EXPOSURE LIMITS SHALL BE ADHERED TO: @[032901-7274B]

TABLE A14-10-I - EXPOSURE LIMITS (REM (SIEVERT))

EXPOSURE PERIOD	BLOOD FORMING ORGAN (BFO)	EYE	SKIN
30 DAYS	25 (0.25)	100 (1.00)	150 (1.50)
ANNUAL	50 (0.50)	200 (2.00)	300 (3.00)

Space shuttle crew radiation exposure limits recommended to NASA by the National Council on Radiation Protection and Measurements, "Guidance on Radiation Received in Space Activities," NCRP Report No. 98, July 31, 1989, have been legally adopted as the agency's supplementary standard in accordance with 29 CFR 1960.18. Space shuttle flights are nominally constrained to the 30-day exposure limits that are conservatively set to minimize mission impact (ref. Rule {A14-8}, PROJECTED OPERATIONAL DOSE LIMIT VIOLATION DEFINITION). The practice of ALARA is part of NASA's legal requirement to regulate crew exposures just as much as the maximum exposure limits.

Reference Rule {B14-9}, JOINT EXPOSURE LIMITS.[R] @[032901-7274B]

Rules {A14-51}, CREW RADIATION EXPOSURE LIMITS [HC]; {A14-54}, GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC]; and {B14-9}, JOINT EXPOSURE LIMITS [R], reference this rule..

A14-11 SHUTTLE ADMINISTRATIVE LIMIT [HC]

THE SHUTTLE ADMINISTRATIVE LIMIT IS 0.5 RAD (SKIN) ABOVE THE PREFLIGHT MISSION EXPOSURE LEVELS. @[032901-7276B]

This rule is applied by the EVA go/no-go rule to establish a threshold when EVA's are required to be rescheduled to reduce exposure. Below this threshold, normal ALARA practices govern EVA exposure control. The administrative limit includes all additional exposures (IVA and EVA) resulting from the enhanced radiation environment, from the beginning of the mission projected through the next EVA.

Reference Rule {B14-11}, CREW EXPOSURE ADMINISTRATIVE LIMITS. [R] (TBR FOR RUSSIAN CONCURRENCE) @[032901-7276B]

Rules {A14-7}, RADIATION ENVIRONMENT CONDITION DEFINITION; {A14-53}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS – ON ORBIT [HC]; and, {A14-54}, GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC], reference this rule., reference this rule.

FLIGHT RULES

A14-12 HIGH DOSE RATE LIMITS [HC]

A HIGH DOSE RATE CONDITION IS DEFINED AS A DOSE PROJECTED FOR 1 DAY THAT EQUALS OR EXCEEDS ONE OF THE FOLLOWING: @[032901-7277B]

- A. 2.5 RAD BFO/DAY (0.025 GRAY)
- B. 10 RAD EYE/DAY (0.10 GRAY)
- C. 15 RAD SKIN/DAY (0.15 GRAY)

The National Council on Radiation Protection, in making their recommendation for the legal radiation exposure limits, defines 5 rem BFO in 1 day as the threshold for acute exposure. For uniformity, the "rem" values are converted to "rad" using an assumed quality factor of 2.0. This quality factor is an estimate of the expected value during a large solar proton event. Dose rates above this threshold will result in additional risk compared to a similar exposure delivered over a longer period of time (e.g., protracted/chronic exposure). Eye and skin values are extrapolated from the legal limits based on the BFO exposure.

Reference Rule {B14-12}, HIGH DOSE RATE LIMITS.[R] @[032901-7277B]

Rule {A14-54}, GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC], references this rule.

A14-13 THROUGH A14-50 RULES ARE RESERVED

FLIGHT RULES

MANAGEMENT

A14-51 **CREW RADIATION EXPOSURE LIMITS [HC]** @[032901-7269B]

THE FOLLOWING OPERATIONAL CREW IONIZING RADIATION EXPOSURE LIMITS SHALL BE ADHERED TO:

- A. LEGAL EXPOSURE LIMITS (REF. RULE {A14-10}, LEGAL EXPOSURE LIMITS [HC])
- B. ALARA: FLIGHT MANAGEMENT SHALL EXERCISE REASONABLE EFFORTS TO MAINTAIN CREW EXPOSURES AS LOW AS REASONABLE ACHIEVABLY (REF. RULE {A14-9} ALARA DEFINITION).

Space shuttle crew radiation exposure limits recommended to NASA by the National Council on Radiation Protection and Measurements, "Guidance on Radiation Received in Space Activities," NCRP Report No. 98, July 31, 1989, have been legally adopted as the Agency's Supplementary Standard in accordance with 29 CFR 1960.18. Space shuttle flights are nominally constrained to the 30-day exposure limits that are conservatively set to minimize mission impact. The practice of ALARA is part of NASA's legal requirement to regulate crew exposures. @[032901-7269B]

Rules {A14-51}, CREW RADIATION EXPOSURE LIMITS [HC] and {A14-52}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS – PRELAUNCH, reference this rule.

FLIGHT RULES

A14-52

ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS - PRELAUNCH ©[032901-7265] ©[032901-7278A]

- A. NOMINAL OR ALERT - GO FOR LAUNCH
- B. CONTINGENCY -
 - 1. CONSIDERATION SHALL BE MADE TO DEFER THE FLIGHT UNTIL RADIATION LEVELS HAVE DECLINED.
 - 2. CONFIRMED ARTIFICIAL EVENT (ONLY):
 - a. PRIOR TO L-31 SECONDS, THE FLIGHT DIRECTOR WILL REQUEST A LAUNCH HOLD.
 - b. AFTER L-31 SECONDS, GO FOR LAUNCH. FURTHER ACTION WILL BE GOVERNED BY ON-ORBIT (REF. RULE {A14-53}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS - ON ORBIT) [HC].
 - 3. OTHERWISE, GO FOR LAUNCH.

During alert or contingency conditions, substantial changes in the near-Earth radiation environment may be initiated. Close monitoring of the radiation environment is required to detect trends that could lead to unacceptable increases in crew radiation exposure. Radiation environment enhancements may become significant enough to warrant actions by the crew to reduce radiation exposures in order to remain within crew exposure limits (ref. Rule {A14-51}, CREW RADIATION EXPOSURE LIMITS [HC] and/or comply with ALARA (ref. Rule {A14-9}, ALARA DEFINITION).

For Artificial events: If prior to L-31 seconds, it is better to hold/terminate than to risk exposing the crew to a potentially hazardous radiation environment. After L-31 seconds, it is safer to continue a nominal ascent and subsequently order deorbit if required. After achieving orbit, further action will be governed by orbit flight phase rules. Dosimeter readings are needed to confirm exposure and rate of exposure so that valid projections can be determined. This rule will minimize crew exposure from the potentially very high dose rates that can be produced before stabilization of the enhanced trapped electron belts.

A. ALERT

1. ENSURE SHUTTLE TEPC IS OPERATING.
 - a. OBTAIN A BASELINE TEPC CALLDOWN IF NOT OBTAINED IN LAST 24 HRS.
 - b. IF THE TEPC IS INOPERABLE, OBTAIN BASELINE MEASUREMENTS FROM THE RADIATION DOSIMETER ASSEMBLY.
2. PERFORM SHUTTLE TEPC DISPLAY CALL-DOWNS DAILY.

B. CONTINGENCY

1. ENSURE SHUTTLE TEPC IS OPERATING.
 - a. OBTAIN A BASELINE TEPC CALLDOWN IF NOT OBTAINED IN LAST 24 HRS.
 - b. IF THE TEPC IS INOPERABLE, OBTAIN BASELINE MEASUREMENTS FROM THE RADIATION DOSIMETER ASSEMBLY.
2. PERFORM SHUTTLE TEPC DISPLAY CALLDOWNS AT LEAST TWICE DAILY.
3. INFORM CREW. RECOMMEND REMAINING IN THE AIRLOCK DURING INTERVALS OF HIGH RISK ORBITAL ALIGNMENTS.
4. CONFIRMED ARTIFICIAL EVENT (ONLY):
 - a. THE FLIGHT DIRECTOR WILL NOTIFY THE CREW AND REQUEST THE CREW TO TAKE AND REPORT DOSIMETER READINGS AT SPECIFIED INTERVALS.
 - b. EVA CREWMEMBER WILL RETURN TO THE AIRLOCK ASAP. GO/NO-GO FOR CONTINUATION OF EVA WILL BE BASED ON PROJECTED RADIATION EXPOSURE LEVELS. ©[032901-7279B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A14-53

ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS - ON ORBIT [HC] (CONTINUED)

5. IF AN OPERATIONAL DOSE LIMIT VIOLATION HAS BEEN PROJECTED (REF. RULE {A14-8}, PROJECTED OPERATIONAL DOSE LIMIT VIOLATION DEFINITION), THE FLIGHT DIRECTOR WILL BE NOTIFIED. @[032901-7279B]
 - a. THE FLIGHT DIRECTOR WILL NOTIFY THE CREW OF THE PROJECTED DOSE LIMIT VIOLATION.
 - b. BASED ON THE PROJECTED RADIATION EXPOSURE LEVELS AND TIME REMAINING TO REACH THE DOSE LIMIT, CONSIDERATION WILL BE GIVEN TO:
 - (1) RESTRICT CREW LOCATION WITHIN THE ORBITER.
 - (2) CHANGE ORBITER ALTITUDE/ATTITUDE IF IT DECREASES CREW EXPOSURES.
 - (3) DEORBIT NEXT PLS.
 - (4) DEORBIT NEXT DAY PLS.

During alert or contingency conditions, substantial changes in the near-Earth radiation environment may be initiated. Close monitoring of the radiation environment is required to detect trends that could lead to unacceptable increases in crew radiation exposure. Radiation environment enhancements may become significant enough to warrant actions by the crew to reduce radiation exposures in order to remain within crew exposure limits (ref. Rule {A14-11}, SHUTTLE ADMINISTRATIVE LIMIT [HC]) and/or comply with ALARA (ref. Rule {A14-9}, ALARA DEFINITION). Higher shielded locations are based on analysis conducted by SRAG. Unplanned exposures will be evaluated in real time by the surgeon to determine risk of medical implications and weighed against other mission risks prior to making recommendations on crew actions. Communications with the Flight Director concerning crew actions will be coordinated with the surgeon.

Reference Rule {B14-103}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS. [R] (TBR FOR RUSSIAN CONCURRENCE) @[032901-7279B]

Rule {A14-52}, ACTIONS REQUIRED FOR RADIATION ENVIRONMENT CONDITIONS - PRELAUNCH, references this rule.

FLIGHT RULES

A14-54

GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC] ©[032901-7265] ©[032901-7280B]

THE FOLLOWING WILL BE DONE ONLY TO REDUCE CREW EVA EXPOSURES:

- A. FOR PREDICTED EVA EXPOSURE LESS THAN SHUTTLE ADMINISTRATIVE LIMIT (REF. RULE {A14-11}, SHUTTLE ADMINISTRATIVE LIMIT [HC]):
1. CONSIDER DELAYING OR ACCELERATING EGRESS 1-2 REVS IF THIS WILL REDUCE THE EXPOSURE WHILE ACCOMPLISHING MISSION OBJECTIVES CONSISTENT WITH NORMAL CREW GROUND RULES AND CONSTRAINTS, AND TIMELINE CHANGES ARE LIMITED TO A SINGLE FLIGHT DAY.
 2. AN EVA IN PROGRESS WILL CONTINUE. CONSIDER NOT ADDING UNSCHEDULED ITEMS TO EXISTING TIMELINE IF THIS RESULTS IN ADDITIONAL EVA CREW EXPOSURE.

While performing EVA's, crewmembers have reduced levels of shielding against radiation environments compared with IVA operations. The reduced shielding can result in significantly higher exposures to the radiation sensitive organs of EVA crewmembers compared with the IVA crew. Avoiding EVA's or rescheduling EVA's when possible during enhanced radiation environment conditions is in compliance with the federally mandated ALARA principle. To meet mission objectives, complete avoidance of radiation exposure may not be possible. Actions are based on combining the best estimate on the current mission dose with the projected EVA dose and comparing that value against the administrative limit for that time in the mission.

Even for crew exposures below the admin limit, the flight control team will consider rescheduling airlock egress in order to shift out of high radiation areas, if this can be done while still accomplishing all mission objectives. Based on the levels of exposure below the admin limit, this replanning is limited to a 1-2 rev change in egress time in order to preclude significant subsequent replanning, crew scheduling groundrule violations, etc. Unscheduled tasks will not be added for the next EVA if they will result in additional elevated exposures. ©[032901-7280B]

The risk from additional radiation exposures below the admin limit compared with the risk incurred by going EVA is low enough to support continuing an EVA already in progress. Unscheduled tasks added at the end of the EVA will be evaluated against additional exposures. Due to the structure of the radiation environment, certain geographic regions may produce significant fractions of the total exposure. In most cases, the phasing will be such that little additional risk is added from performing extra tasks and, therefore, the tasks could be added. Potentially, a significant exposure could be phased at the end of the EVA that would merit avoiding the unscheduled task in lieu of continuing. (Ref. Rule {A14-9}, ALARA DEFINITION.) ©[032901-7280B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A14-54

GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE [HC] (CONTINUED)

The admin limit is in place to regulate mission actions to minimize risk. The mortality risk associated with this limit is comparable to the risk of EMU suit penetration/depressurization. It is also comparable to the average total radiation risk for shuttle flights. The maximum mission exposure for the shuttle remains at the 30-day legal limit values (e.g., 25 rem BFO, etc.).

- B. PREDICTED CREW MISSION EXPOSURE GREATER THAN SHUTTLE ADMINISTRATIVE LIMIT AT THE END OF THE EVA (REF. RULE {A14-11}, SHUTTLE ADMINISTRATIVE LIMIT [HC]):
1. DELAY OR ACCELERATE EGRESS 1-2 REVS TO REDUCE EXPOSURES OR DELAY 1 DAY TO RESCHEDULE IN A LOWER EXPOSURE EVA PATH.
 2. IF AN ISS MISSION, CONSIDER TRANSFERRING TASKS TO A STATION-BASED EVA TO BE PERFORMED AT A LATER DATE.
 3. AN EVA IN PROGRESS WILL CONTINUE. CONSIDER EXPEDITING TASKS NOT REQUIRED FOR PRIMARY MISSION OBJECTIVES.

For crew mission exposures above the admin limit, replanning will be more aggressive, including accepting more downstream timeline impacts, crew scheduling groundrule violations, etc. Since shuttle operations are typically time constrained, the first option is to delay or accelerate by 1-2 revs to shift out of the enhanced radiation areas. The EVA may also be conducted with a lower exposure by delaying the EVA up to 1 day to allow the increased radiation environment to decay or to select a trajectory that has shifted out of the high radiation areas. ©[032901-7280B]

The risk from this level of radiation exposure/risk compared to the risk incurred by going EVA is low enough to support continuing an EVA already in progress. However, consideration of expediting or deleting tasks shall be made to aid in minimizing the radiation risk consistent with mission objectives and the associated risk of being EVA. If an ISS mission, consider transferring tasks to a station-based EVA. A later station based EVA may result in completing the task with a lower exposure. ©[032901-7280B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A14-54

GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION
EXPOSURE [HC] (CONTINUED)

- C. PREDICTED CREW EXPOSURE GREATER THAN THE HIGH DOSE RATE LIMITS (REF. RULE {A14-12}, HIGH DOSE RATE LIMITS [HC]):
1. A PLANNED EVA SHALL BE RESCHEDULED AS REQUIRED TO REDUCE THE EXPOSURE TO BELOW THE HIGH DOSE RATE LIMIT.
 2. AN EVA IN PROGRESS SHALL CONTINUE ONLY IF NO INCREASED ADDITIONAL DOSE IS PROJECTED FOR THE REMAINDER OF THE EVA. OTHERWISE, EXPEDITE THE EVA BY DELETING TASKS NOT REQUIRED FOR PRIMARY MISSION OBJECTIVES.

The high dose rate limits are daily exposure limits that meet the bounding assumptions used as a basis for the U.S. legal limits and, therefore, require replanning using similar options described in paragraph B. This replanning will ensure the predicted exposure is below the high dose rate limit and that the crewmember's mission exposure is below the legal exposure limit, if possible, or as low as practical above the admin limit if exposure history is currently in the restricted range, to preclude additional replanning.

The risk of this level of radiation warrants ending the EVA early. Since some risk has already been incurred by going EVA, an EVA in progress will be expedited by completing only the tasks required for minimum mission success. Remaining tasks will be replanned for a subsequent EVA. ©[032901-7280B]

- D. PREDICTED CREW EXPOSURE GREATER THAN THE LEGAL EXPOSURE LIMITS (REF. RULE {A14-10}, LEGAL EXPOSURE LIMITS [HC]):
©[032901-7280B]
1. A PLANNED EVA SHALL BE RESCHEDULED AS REQUIRED TO REDUCE THE CREWMEMBER'S MISSION EXPOSURE TO BELOW THE LEGAL EXPOSURE LIMIT.
 2. AN EVA IN PROGRESS SHALL BE TERMINATED.

The short-term and long-term health risks incurred with exposures above the legal exposure limits require replanning the EVA to reduce the radiation exposure, despite any long-term planning impacts that result. Replanning will be done in a manner that ensures the predicted EVA exposure is as low as possible to preclude additional replanning.

The risk of this level of radiation warrants terminating an EVA in progress as early as safely possible. Only tasks required for crew and vehicle safety will be performed.

Reference Rule {B14-106}, GO/NO-GO CRITERIA FOR EVA BASED ON RADIATION EXPOSURE.[HC] [R] ©[032901-7280B]

FLIGHT RULES

A14-55

DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY

A. AN ALERT IS CANCELED WHEN: @[042601-7281A]

1. SPE WARNING: THE TIME PROJECTED BY NOAA HAS EXPIRED.
2. SPE: FLUX LEVELS HAVE BEEN REDUCED BELOW EVENT THRESHOLD CRITERIA FOR THREE CONSECUTIVE READINGS AND SHOW A CLEAR TREND DOWN. SUBSEQUENT MINOR FLUCTUATIONS WILL NOT CONSTITUTE A NEW ALERT UNLESS LEVELS INCREASE OVER DEFINED SPE THRESHOLDS FOR THREE CONSECUTIVE READINGS (REF. RULE {A14-4}, SOLAR PARTICLE EVENT (SPE) DEFINITION).
3. GEOMAGNETIC STORM: GEOMAGNETIC K_B OR A_B LEVELS ARE REDUCED BELOW EVENT THRESHOLD LEVELS (REF. RULE {A14-5}, GEOMAGNETIC STORM DEFINITION).
4. OTHER RADIATION EVENT: REGRESSION TO NOMINAL ENVIRONMENTAL CONDITIONS IS AT THE DISCRETION OF THE RADIATION CONSOLE OPERATOR (REF. RULE {A14-6}, OTHER RADIATION EVENT DEFINITION).
5. UNCONFIRMED ARTIFICIAL EVENT: WILL BE EVALUATED ON A CASE BY CASE BASIS FOR DOWNGRADING (REF. RULE {A14-1}, UNCONFIRMED ARTIFICIAL EVENT DEFINITION).
@[042601-7281A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A14-55 DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY (CONTINUED)

- B. A CONTINGENCY IS DOWNGRADED TO NOMINAL WHEN: ©[042601-7281A]
1. SPE: FLUX LEVELS HAVE BEEN REDUCED BELOW EVENT THRESHOLD CRITERIA FOR THREE CONSECUTIVE READINGS AND SHOW A CLEAR TREND DOWN. SUBSEQUENT MINOR FLUCTUATIONS WILL NOT CONSTITUTE A NEW ALERT UNLESS LEVELS INCREASE OVER DEFINED SPE THRESHOLDS FOR THREE CONSECUTIVE READINGS (REF. RULE {A14-4}, SOLAR PARTICLE EVENT (SPE) DEFINITION).
 2. GEOMAGNETIC STORM (FOR EVA CONSIDERATION): GEOMAGNETIC K_B OR A_B LEVELS ARE REDUCED BELOW EVENT THRESHOLD LEVELS AND TRAPPED ELECTRONS ARE NOT AT ELEVATED LEVELS (REF. RULE {A14-5}, GEOMAGNETIC STORM DEFINITION).
 3. OTHER RADIATION EVENT: REGRESSION TO NOMINAL ENVIRONMENTAL CONDITIONS IS AT THE DISCRETION OF THE RADIATION CONSOLE OPERATOR (REF. RULE {A14-6}, OTHER RADIATION EVENT DEFINITION).
 4. CONFIRMED ARTIFICIAL EVENT: WILL BE EVALUATED ON A CASE BY CASE BASIS FOR DOWNGRADING (REF. RULE {A14-2}, CONFIRMED ARTIFICIAL EVENT DEFINITION).

An alert indicates a change in the environment that threatens to increase crew exposures. This rule provides guidelines when conditions are no longer indicative of escalating environmental conditions (SPE/Geomagnetic Storm/Artificial Event) or an assessment of re-planning (belt enhancement). Likewise, contingency conditions will also be downgraded. During big events, downgrading may only be temporary due to re-initiation of activity of events.

*Reference Rule {B14-109}, DOWNGRADING TO NOMINAL FROM ALERT OR CONTINGENCY [R]

FLIGHT RULES

SECTION 15 - EXTRAVEHICULAR ACTIVITY (EVA)

GENERAL

A15-1

EVA TIME DEFINITION

A. EMU TIME

EMU TIME STARTS WHEN THE EMU IS SWITCHED TO INTERNAL POWER, ENDS WHEN THE EMU IS SWITCHED TO ORBITER POWER.

EMU time represents the time that the EMU is operating on internal power. The EMU primary life support subsystem (PLSS) provides consumables for a duration of 7 hours. In order to provide a 30-minute reserve of primary consumables, EVA operations should be scheduled to be completed within a phase elapse time (PET) of 6 hours 30 minutes. This time includes all overhead activities (such as airlock egress/ingress and payload bay setup/cleanup) in addition to the EVA task itself.

B. EVA PHASE ELAPSE TIME

EVA PET STARTS WHEN THE EMU IS SWITCHED TO INTERNAL POWER, ENDS WHEN AIRLOCK REPRESSURIZATION IS INITIATED.

EVA PET represents the time that the EMU is exposed to vacuum. Some EVA scenarios require the EVA crew to return to the airlock and wait for some other operation to be completed (e.g., a payload deployment) before resuming EVA tasks or before initiating airlock repressurization. Since the EMU is operating on orbiter power during this time, EVA PET may be significantly longer than EMU time. EVA PET will be used when tabulating historical mission data.

A15-2

TERMINATE EVA DEFINITION

TERMINATE EVA MEANS TO CEASE EVA ACTIVITIES, CLOSE OUT PAYLOAD BAY, TRANSFER TO ORBITER AIRLOCK, INGRESS, AND REPRESSURIZE AIRLOCK.

NOTE: IF EMU PROBLEM CAN BE STABILIZED/CORRECTED BY USING SERVICE AND COOLING UMBILICAL (SCU), CREWMEMBER WITH PROBLEM MAY REMAIN ON SCU AT VACUUM FOR POSSIBLE RESCUE/ASSIST, WHILE OTHER CREWMEMBER COMPLETES EVA.

FLIGHT RULES

A15-3 **ABORT EVA DEFINITION**

ABORT EVA MEANS TO IMMEDIATELY TRANSFER TO ORBITER AIRLOCK, INGRESS, AND REPRESSURIZE AIRLOCK.

A15-4 **SCHEDULED EVA DEFINITION**

A SCHEDULED EVA IS DEFINED AS ANY EVA INCORPORATED INTO THE NOMINAL FLIGHT PLAN. @[041896-1868]

A15-5 **UNSCHEDULED EVA DEFINITION**

AN UNSCHEDULED EVA IS USED TO ACHIEVE/ENHANCE THE MISSION OBJECTIVES OF THE ORBITER OR ITS PAYLOADS. IT IS NOT PART OF THE FLIGHT PLAN. @[041896-1869]

A15-6 **CONTINGENCY EVA DEFINITION**

A CONTINGENCY EVA IS DEFINED AS AN EVA REQUIRED TO EFFECT THE SAFE RETURN OF THE CREW AND THE ORBITER.

A15-7 **MINIMUM RF COMMUNICATIONS DEFINITION**

IN ORDER TO COMMIT TO OR CONTINUE A SCHEDULED OR UNSCHEDULED EVA, EACH EVA CREWMEMBER MUST HAVE TWO-WAY COMMUNICATIONS WITH THE ORBITER, EITHER DIRECTLY OR VIA THE OTHER EVA CREWMEMBER (REF. RULE {A11-6}, MINIMUM COMMUNICATIONS REQUIREMENTS FOR SCHEDULED EVA). @[ED]

Rules {A15-102E}, EMU GO/NO-GO CRITERIA; and {A15-155}, MANIPULATOR FOOT RESTRAINT (MFR) AND PFR ATTACHMENT DEVICE (PAD) GUIDELINES, reference this rule. @[090894-1669A]
@[ED]

FLIGHT RULES

A15-8 **OPERATIONAL CAUTION AND WARNING SYSTEM (CWS)** **DEFINITION**

THE EMU CWS IS DETERMINED TO BE OPERATIONAL IF EITHER OF THE FOLLOWING TWO CONDITIONS ARE SATISFIED: ©[090894-1668]

- A. THE ABILITY TO MONITOR THE OPERATIONAL INTEGRITY OF THE EMU (AT LEAST STATUS LIST) BY THE EVA CREW.
- B. THE ABILITY FOR MCC TO MONITOR THE EMU STATUS WITH THE EVA CREW MONITORING CWS ALERT TONES AND THE DISPLAYS AND CONTROL MODULE (DCM) SUIT PRESSURE GAUGE.

The EMU CWS is operational if the EVA crew can monitor at least the DCM status list to determine EMU failures. If the crew cannot monitor the DCM status list, then MCC will have to monitor EMU status while the EVA crew monitors the CWS alert tones and the DCM suit pressure gauge. If a CWS alert tone was to occur with a non-functional DCM display, the EVA crew would check the suit pressure gauge and check with MCC to determine the type of failure and action.

Reference Rule {A15-102K}.2, EMU GO/NO-GO CRITERIA. ©[090894-1668] ©[ED]

A15-9 **TWO/ONE-CREWMEMBER EVA GUIDELINES**

REFERENCE RULE {A2-107}, EVA GUIDELINES.

A15-10 **EVA CREWMEMBER(S) SUPPORT**

AT ALL TIMES DURING EVA, AT LEAST ONE INTRAVEHICULAR (IV) CREWMEMBER WILL BE DEDICATED TO SUPPORTING THE EVA CREWMEMBERS. ©[021199-6747B]

IV crewmember is responsible for recording EMU status, monitoring the timeline, and providing orbiter support.

FLIGHT RULES

A15-11 SAFETY TETHER REQUIREMENTS

- A. AT ALL TIMES DURING EVA, EXCEPT WHEN INSIDE A CLOSED AIRLOCK, EACH EVA CREWMEMBER WILL BE ATTACHED TO THE ORBITER VIA A SAFETY TETHER. FLIGHT-SPECIFIC EXCEPTIONS TO TETHERING TO THE ORBITER WILL BE IDENTIFIED IN THE FLIGHT-SPECIFIC ANNEX. ©[021199-6747B]

Prevent loss of crewmember and resulting rescue scenarios. For some missions, it may be desirable for the crewmember to be attached (to a certified tether point) to the payload secured in the payload bay rather than the orbiter.

- B. EVA TOOLS WILL BE TETHERED TO THE CREWMEMBER AT ALL TIMES DURING THEIR USE.

Prevents loss of tools. Free-floating tools could impact orbiter causing orbiter damage.

A15-12 HAZARDOUS EQUIPMENT SAFING

POTENTIALLY HAZARDOUS EQUIPMENT WILL BE VERIFIED SAFE IN THE EVENT OF EVA.

Potentially hazardous equipment will be verified safe in the event of an EVA to minimize chances for injury to the EV crewmember.

A15-13 AIRLOCK CONFIGURATION

AN EVA CREWMEMBER SHALL NOT BE LOCKED OUT OF A PRESSURIZED AIRLOCK EXCEPT IN THE CASE OF AN "ABORT EVA" WHERE THE EV CREWMEMBERS ARE SIGNIFICANTLY SEPARATED AND REPRESSURIZATION TIME IS CRITICAL. ©[021199-6747B]

In the case of a serious EMU failure (i.e., loss of suit pressure), the EV crewmember must have immediate access to the airlock. This includes an abort scenario where the other EV crewmember is significantly separated from the airlock. In this case, the separated crewmember still has the capability to depressurize the airlock for ingress via the outer hatch equalization valves. ©[021199-6747B]

FLIGHT RULES

A15-14

SCHEDULED AND UNSCHEDULED EVA CONSTRAINTS

A. NO SCHEDULED EVA WILL BE PERFORMED PRIOR TO MET 72 HOURS.

During adaptation to zero-g conditions, moving about may provoke symptoms of illness. The activity associated with putting on a suit would increase the chance of an EVA crewmember being ill and potentially endanger the crewmember with vomitus in the suit.

B. UNSCHEDULED EVA'S:

1. NO UNSCHEDULED EVA SHALL OCCUR DURING THE FIRST 24 HOURS OF FLIGHT.
2. AN UNSCHEDULED EVA MAY BE PERFORMED PRIOR TO MET 72 HOURS ONLY IF AN ASSESSMENT OF CREW HEALTH HAS BEEN ACCOMPLISHED BY THE FCR SURGEON AND APPROVED BY THE FLIGHT DIRECTOR.

Asymptomatic crewmembers may be able to safely perform an unscheduled EVA before MET 72 hours. An accurate assessment of the health status of the EVA crew can be made by the FCR surgeon during a private medical conference.

C. NO SCHEDULED OR UNSCHEDULED EVA SHALL BE PERFORMED ON ENTRY DAY.

1. FOR A FLIGHT USING A SINGLE CREW SHIFT, A SCHEDULED OR UNSCHEDULED EVA MAY BE PERFORMED ON THE DAY BEFORE ENTRY ONLY IF AIRLOCK INGRESS IS COMPLETED NOT LATER THAN CREW SLEEP MINUS 7 HOURS.
2. FOR A FLIGHT USING DUAL SHIFT OPERATIONS, A SCHEDULED OR UNSCHEDULED EVA MAY BE PERFORMED ON THE DAY BEFORE ENTRY ONLY IF AIRLOCK INGRESS IS COMPLETED NOT LATER THAN CREW SLEEP (NONENTRY TEAM) MINUS 4.5 HOURS.

An EVA may be done on the day before entry if there is adequate time post-EVA to perform required activities. These activities include airlock repress, post-EVA, EMU maintenance recharge, post-EVA entry prep, cabin stow, and presleep. Seven hours is considered the minimum amount of time to accomplish these activities for a single shift flight. FCS C/O, RCS hot fire, and cabin repress activities must also be performed but can be overlapped with post-EVA and cabin stow activities. For an unscheduled EVA on the day before entry, it will be necessary to perform this EVA as a "quick response" EVA (i.e., the EMU C/O and cabin depress will need to be done on the day prior to the EVA). For a dual shift flight, 4.5 hours is considered the minimum due to cabin stow occurring on entry day for the nonentry team.

FLIGHT RULES

A15-15 **CONTINGENCY EVA PROTECTION**

A SCHEDULED OR UNSCHEDULED EVA WILL NOT BE CONDUCTED IF IT JEOPARDIZES FUTURE CONTINGENCY EVA CAPABILITY (E.G., INSUFFICIENT CONSUMABLES FOR RECHARGE).

Must always preserve the capability to perform a contingency EVA to bring the orbiter home safely. Reference Rule {A2-107A}, EVA GUIDELINES.

A15-16 **EVA TERMINATION FOR CABIN LEAK**

A SCHEDULED OR UNSCHEDULED EVA WILL BE TERMINATED FOR A CABIN LEAK WHICH CAUSES LOSS OF HIGHER PRIORITY FLIGHT OBJECTIVES OR COMPROMISES SAFE ENTRY.

This rule assumes that the leak is in the inner hatch and became evident after the start of the EVA.

A15-17 **PAYLOAD BAY CONFIGURATION POST-EVA**

AT THE END OF AN EVA, THE PAYLOAD BAY WILL BE LEFT IN A CONFIGURATION WHICH DOES NOT REQUIRE A SUBSEQUENT EVA FOR DEORBIT. EXCEPTIONS:

- A. ABORT THE EVA.
- B. A SPECIFIC PAYLOAD HAS THE CAPABILITY TO BE JETTISONED OR STOWED BY REMOTE ACTION.

It can never be assumed that there will be the time or consumables available for a subsequent EVA to clean up the payload bay:

- a. *The first exception is the case when an EVA must be aborted because an EV crewmember's life might be in jeopardy. In that case, repressurization of the airlock is the immediate priority.*
- b. *The second exception is allowed since the payload in question has the capability to be jettisoned or stowed remotely (e.g., cabin switch or ground command) if a subsequent orbiter condition would preclude a second EVA for entry safing.*

FLIGHT RULES

A15-18

PAYLOAD OPERATION/DEPLOY GUIDELINE

PAYLOADS OPERATIONS THAT REQUIRE AN UNSCHEDULED EVA AS A THIRD LEVEL OF REDUNDANCY MAY OPERATE PRIOR TO 48 HOURS ASSUMING THE UNSCHEDULED EVA CAN BE DELAYED UNTIL AFTER 48 HOURS. PREFLIGHT-IDENTIFIED EXCEPTIONS WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC FLIGHT RULES, SECTION 2.

Due to the possibility that the crew may be disabled by SAS, payload operations which would require a quick mandatory response EVA should not be started prior to 48 hours. Unscheduled EVA's will be defined preflight as to the nature of the response time required. Certain payloads may require an unscheduled EVA earlier than 48 hours. These payloads will have processed exemptions to the generic EVA rules and each will have a rule in the Flight Specific Annex to govern the conduct of unscheduled EVA.

A15-19

UNSCHEDULED EVA PREPARATION

IF A FAILURE HAS OCCURRED IN A PAYLOAD THAT WOULD PLACE CONTINUED OPERATION/DEPLOYMENT ONE FAILURE AWAY FROM AN UNSCHEDULED EVA, THE FLIGHT DIRECTOR MAY DELAY PAYLOAD OPERATIONS UNTIL EMU CHECKOUT AND THE 10.2 EVA PREBREATHE PROTOCOL ARE COMPLETED TO SET UP FOR THE POTENTIAL UNSCHEDULED EVA. CASES IDENTIFIED PREFLIGHT WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC FLIGHT RULES, SECTION 2.

Based on the nature of the payload failure and the current condition of orbiter systems, it may be appropriate to delay payload operations or a deployment until preparations can be completed to accomplish an unscheduled EVA. Certain payload operations are allowed to continue even though we may be one failure away from an EVA. This is due to: (1) confidence in the remaining system, (2) the payload may be jettisonable, (3) there is already a scheduled EVA available, or (4) continuing to deploy is safer than waiting (e.g., TDRS).

A15-20

ECG TELEMETRY CHECKOUT

IF POSSIBLE, ECG TELEMETRY SIGNAL QUALITY WILL BE CHECKED PRIOR TO EVA.

The rule allows for troubleshooting of hardware or adjusting of sensors prior to EVA if no signal is received. Biomed is not a requirement for any EVA.

Rule {A15-102N}, EMU GO/NO-GO CRITERIA, references this rule. ©[090894-1669A] ©[ED]

FLIGHT RULES

A15-21 **LEAKING RCS THRUSTER/APU AVOIDANCE**

AN EVA CAN BE PERFORMED DURING A KNOWN RCS JET OR APU LEAK. THE EVA CREWMEMBER WILL AVOID THE IMMEDIATE VICINITY OF THE LEAKING JET OR APU.

For RCS or APU leaks, the propellant tends to sublime very quickly and is not considered to be a threat to the crewmember as long as he stays out of the vicinity. The propellant has no effect on the EMU in small quantities.

A15-22 **RCS/APU THRUSTER PLUME AVOIDANCE**

AN EVA CREWMEMBER SHALL NOT BE POSITIONED WITHIN THE FOLLOWING DISTANCES OF AN RCS THRUSTER WITH DRIVER POWER ON OR THE EXHAUST PORT OF AN OPERATING APU (ALONG PRIMARY AXIS). @[021199-6747B]

PRCS - 27 FEET

VRCS - 3 FEET

APU - 3 FEET

These distances are conservative estimates based on the thermal effects of the jets on the EMU, particularly the visor, which is most sensitive to thermal extremes. These numbers were generated from analytical tests which modeled the heat flux from the respective jets and the thermal characteristics of the visor. Crew injury/EMU damage may result from hydrazine brought into the cabin after being picked up from an operating APU. Flight Rule {A6-151A}, RCS JET DRIVER MANAGEMENT [CIL], requires primary RJD's to be powered off while the crew is outside the payload bay envelope. The EVA checklist "CONTINGENCY DAP/JET CONFIG" directs the crew as to which jets to inhibit or power off based on EVA crew location.

A15-23 **EV CREW IN VICINITY OF ACTIVE PAYLOAD RETENTION LATCH ASSEMBLIES**

WHEN PAYLOAD RETENTION LATCH ASSEMBLIES MUST BE OPERATED AND EV CREWMEMBERS MAY BE WITHIN REACH, THEN THE EV CREW SHALL STAY CLEAR OF THE LATCHES AT THE TIME OF ACTUATION AND THE EV CREWMEMBERS SHALL GIVE THE GO FOR LATCH OPERATION.

Latch actuation without regard for EVA crewmembers constitutes a potential pinch hazard. The path traced by the motion of a latch is sufficiently localized for EV crewmembers to avoid when they are warned and properly positioned during the actuation.

FLIGHT RULES

A15-24

EVA OPERATIONS IN THE GENERIC PAYLOAD BAY ENVELOPE

EVA OPERATIONS MAY BE CONDUCTED IN ANY REGION OF THE GENERIC PAYLOAD BAY ENVELOPE. THE GENERIC PAYLOAD BAY ENVELOPE IS DEFINED AS THOSE REGIONS OF THE PAYLOAD BAY ACCESSIBLE TO THE UNAIDED EVA CREWMEMBER (E.G., NOT ATTACHED TO THE RMS, ETC.) WITH THE FOLLOWING EXCEPTIONS: ©[021199-6747B]

- A. FOR $X_0 = 576$ TO $X_0 = 596$, THE CREWMEMBER MUST REMAIN BELOW THE LEVEL OF THE PAYLOAD BAY DOOR MOLD LINE.
- B. FOR $X_0 = 576$ TO $X_0 = 815$, THE CREWMEMBER MUST REMAIN ON THE INBOARD SIDE OF THE STARBOARD EVA SLIDEWIRE.

THIS AREA WILL BE PROTECTED FROM S-BAND PER RULE {A11-8}, ORBITER S-BAND OPERATIONS DURING EVA, AND KU-BAND PER RULE {A11-7}, KU-BAND OPERATIONS DURING EVA. ©[ED]

EVA operations for the unaided crewmember in the payload bay are constrained by potential RF radiation exposure from only two sources. Those sources are represented by the restrictions in paragraphs A and B.

S-band radiation from the orbiter S-band PM antennas creates the restriction in paragraph A. This limit means that the crewmember must stay below the mold line for the first 20 inches aft of the 576 bulkhead. This requirement is based upon the need to remain 1 meter away from all S-band antennas.

Paragraph B is created by the need to maintain a reasonable level of Ku-band communications while not overly restricting EVA mobility. This limit implies that the crewmember must stay on the inboard side of the starboard slidewire for the first 20 feet of its length. This limitation will allow the use of a 0-degree Beta mask and a Beta-only operating mode for the Ku-band system. It should be understood that this rule does not require the use of any specific Beta mask, only that the volume was designed with Beta = 0 degree as an acceptable value. This requirement is based on the need to prevent Ku-band exposures for the EVA crewmember from exceeding the 20 V/M certification limit for the EMU at Ku-band. If there are no planned EVA operations outboard of the starboard slidewire, then the normal Ku-band operating mode of Beta + mask with Beta = 21 degrees may be used. ©[ED]

FLIGHT RULES

A15-25

ORBITER EVA OPERATIONS NEAR S-BAND ANTENNAS

EVA OPERATIONS MAY NOT BE CONDUCTED WITHIN 1 METER OF ANY ORBITER S-BAND ANTENNA UNLESS STEPS HAVE BEEN TAKEN TO PREVENT THAT ANTENNA FROM RADIATING.

An S-band dipole antenna's "near field" is generally considered to extend approximately 1 meter from the antenna in all directions. Within this near field, exact field intensities cannot be computed and as such could exceed the acceptable level for the EMU (120 V/M). If an antenna is totally inhibited (e.g., PI turned OFF or S-band FM forced to the lower antenna by crew switch), then the EVA crewmember is not at risk in approaching these antennas. Since an S-band PM antenna could begin radiating without warning, the crewmember must stay 1 meter away to ensure his/her safety

Reference Documentation: United Technology/Hamilton Standard Engineering Memorandum EMUM-604, April 30, 1992.

FLIGHT RULES

A15-26

KEEPOUT ZONE FOR EVA OPERATIONS NEAR THE ORBITER UHF PAYLOAD BAY ANTENNA

- A. WHEN THE SPACE-TO-SPACE ORBITER RADIO (SSOR) IS IN HIGH POWER MODE, THE EVA KEEPOUT ZONE IS 0.3 METER (1.0 FT) OVERHEAD AND FROM THE SIDE OF THE UHF PLB ANTENNA RADOME SURFACE. @[040899-6873A] @[121400-3856B]
- B. WHEN THE SSOR IS IN LOW POWER MODE, THE EVA KEEPOUT ZONE IS 0.1 METER (0.33 FT) OVERHEAD AND FROM SIDE OF THE UHF PLB ANTENNA RADOME SURFACE.

The SSOR and UHF PLB antenna are required for EVA communications with the crew, and the EV crew will nominally translate in close proximity to the UHF PLB antenna. During EVA, the SSOR nominally operates in low power mode (UHF PWR AMP off) and a smaller keepout zone precludes exposure of the EMU to excessive RF radiation (recommended exposure limit of 60 V/m rms which includes 6dB of safety margin). If the SSOR operates in high power mode (UHF PWR AMP on), the keepout zone increases. If the EV crew violates the keepout zone in low power mode, a potential exists to temporarily bias the EMU SOP transducer high and cause RF interference to the SSER (momentary ratty or broken comm). If the KOZ is violated in high power, potential exists to cause the EMU CWS to malfunction, trip EMU current limiters, damage the SSER, and exceed the physiological limit (102 V/m).

The SSOR operating frequency also affects the EMU. If the SSOR is in 414.2 MHz (nominal frequency) and inadvertently switches from low to high power mode while the crew maintains the low power keepout zone, sufficient margin still remains to protect the crewmember and EMU from harm. In 417.1 MHz, the EMU margin is still sufficient but is reduced, resulting in greater susceptibility to CWS and EMU current limiter malfunctions.

Provided that the crew maintains the specified keepout zones, the physiological limit (72 V/m) will not be exceeded. The analysis showed that no physiological impacts would be incurred when at the physiological limit (72 V/m). In low power mode, the physiological limits are reached at the radome top surface and at 0.0766 meter (3 inches) from the side. In high power, the limits are reached at 0.2 meter (9 inches) from the radome top surface and 0.19 meter (7.5 inches) from the side. These values are based on a 60 V/m output and are therefore conservative for an actual 72 V/m keepout zone.

The following telemetry will be used to determine whether the SSOR is in high or low power mode before the EV crew approaches the UHF PLB antenna: UHF POWER AMP (V74S2016E), SSOR POWER LEVEL (V74E2045A), and SSOR POWER STATUS (V74C2047A). @[121400-3856B]

A15-27 THROUGH A15-100 RULES ARE RESERVED

FLIGHT RULES

LOSS/FAILURE DEFINITIONS

A15-101 EVA CAPABILITY

EVA CAPABILITY IS CONSIDERED LOST IF UNABLE TO DEPRESSURIZE/REPRESSURIZE THE AIRLOCK WHILE MAINTAINING CABIN INTEGRITY.

The inability to depressurize/repressurize the airlock while maintaining cabin integrity resolves to a leaking airlock hatch. If either hatch leaks at greater than 0.2 psi/min airlock pressure decay rate, the EVA capability is lost.

A15-102 EMU GO/NO-GO CRITERIA

THE EMU CAPABILITIES LISTED IN THE EMU GO/NO-GO MATRIX ARE CONSIDERED LOST IF ONE OF THE FOLLOWING CONDITIONS ARE MET:
@[090894-1669A]

- A. SUIT PRESSURE INTEGRITY - EMU PRESSURE DECAY > 0.3 PSI/MIN DURING INTEGRITY CHECK. @[090894-1669A]

A leak > 0.3 psi/min can no longer be considered a worst case for EMU specification leakage (i.e., seal leaks and metabolic use). At greater than 0.3 psi/min, there is some other leak that could possibly propagate. @[090894-1669A]

The automated leak check will report failure when the pressure drop is 0.3 psi or greater for 1 minute. A 2-minute, manual leak check is performed during EMU checkout where failure is determined by a pressure drop of 0.3 psi or greater.

For loss of suit pressure integrity, if the failure occurs prior to EVA, the EMU is considered to be non-fail-safe and is therefore NO-GO for EVA. If the failure occurs during EVA, the SCU may provide a safe configuration if the leak (minor leak) does not allow the suit pressure to drop below the caution and warning SUIT P LOW limit (4.05 psid). If this is the case, then a TERMINATE EVA (i.e., enter airlock, connect SCU) is required for the affected crewmember. If the suit leak allows the suit pressure to drop below the CWS limit (major leak), an ABORT EVA (i.e., both crewmembers enter airlock and perform emergency repress) is required. @[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

- B. PRIMARY O₂ TANK PRESSURE INTEGRITY - PRIMARY O₂ PRESSURE DECAYS AT A RATE > 110 PSI/24 HRS FROM A FULLY CHARGED STATE, AND LEAK RATE IS SUCH THAT IT WILL PRECLUDE SAFE COMPLETION OF THE INTENDED EVA TASK. @[090894-1669A]

The primary O₂ tanks are considered fully charged when they are pressurized > 850 psi. Leak rates > 110 psi/24 hrs are indicative of a significant primary tank leak. An excessive external leak of the primary O₂ tanks will cause the primary O₂ supply to be depleted at a higher than normal rate. However, in the case where an excessive external leak is detected, real-time analysis may indicate that the leak will not preclude an EVA for the intended tasks. Further testing may determine that the leak is internal to the suit volume, which may not impact the O₂ use rate during EVA.

The EMU is considered NO-GO for EVA for a major leak. A major leak is a leak rate that is too high to support on the SCU (i.e., requires more O₂ than can be provided by the orbiter, case specific). If a major leak happens during EVA, then an ABORT EVA is required, since the EMU is no longer capable of remaining at vacuum. A minor leak is a leak rate that can be supported on the SCU. The EMU is considered GO for EVA if the leak is minor and if periodic recharges do not interfere with completing the EVA tasks. The EMU is considered GO to remain on the SCU if the leak is a minor leak and if frequent recharges interfere with completing the EVA tasks. If this happens during EVA, then a TERMINATE EVA is required for the affected crewmember. Leak propagation is not a concern with primary O₂ tank leaks because the seals in this system are hard/static seals.

- C. PRESSURE REGULATION - SUIT PRESSURE CANNOT BE MAINTAINED IN A RANGE ABOVE THE SOP REGULATION PRESSURE AND BELOW THE POSITIVE PRESSURE RELIEF VALVE (PPRV) CRACKING PRESSURE.

If the primary suit regulator cannot maintain suit pressure above SOP regulation pressure, the SOP will flow during the EVA and the emergency oxygen supply will be consumed, eventually making the SOP incapable of supporting 30 minutes of DCM purge flow. If the primary suit regulator cannot regulate below the positive pressure relief valve (PPRV) cracking pressure, the PPRV will open during the EVA and primary oxygen will be depleted more rapidly than normal.

The operational specification for the primary regulator with the O₂ actuator in PRESS or EVA is 4.2 to 4.4 psid. Checkout values outside of this range warrant further investigation to ensure that the requirements of this rule will be met. If the primary regulator is determined to be stable between 4.05 - 4.55 psid, then SOP flow and PPRV cracking should not be a concern since the specifications of the SOP regulator and PPRV will not overlap this range. If the primary regulation pressure is outside of the 4.05 to 4.55 psid range, real-time analysis considering the preflight performance of the specific EMU will be required. @[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

The specification for SOP regulation is 3.33 to 3.9 psid (dependent on flow rate). The specification for the minimum cracking pressure for the PPRV is 4.7 psid. A "SUIT P LOW" message occurs when sensed suit pressure is less than 4.05 psid. A "SUIT P EMERG" message occurs when sensed suit pressure is less than 3.10. A "SUIT P HIGH" message will occur when sensed suit pressure is 4.55 psid or greater. ©[090894-1669A]

For scheduled or unscheduled EVA's, the EMU is considered to be non-fail-safe and is therefore NO-GO. For contingency EVA's, the EMU is considered GO for SCU ops to be available for rescue/assist scenarios. For either types of EVA's, if a pressure regulation failure happens during EVA, a TERMINATE EVA is required for the affected crewmember.

D. OPERATIONAL SECONDARY OXYGEN PACK (SOP) :

1. SOP BOTTLE PRESSURE (AT IV AMBIENT TEMPERATURES) < PRESSURE NEEDED TO PROVIDE A MINIMUM OF 30 MINUTES SECONDARY O₂.

The SOP must be capable of supporting (with DCM purge valve open) a minimum of 30 minutes. The design specification for the EMU SOP bottle pressure is ? 5800 psig (at ambient IV temperatures) which guarantees a minimum of 30 minutes secondary O₂. However, engineering analysis has shown that the performance characteristics of a specific EMU may permit a minimum of 30 minutes secondary O₂ for bottle pressures < 5800 psig. If the bottle pressure is < 5800 psig, calculations must be performed based on the performance of the specific EMU to determine the actual minimum (30-minute) bottle pressure.

For scheduled or unscheduled EVA's, the EMU is considered to be non-fail-safe and is therefore NO-GO. For contingency EVA's, the EMU is considered GO for SCU ops to be available for rescue/assist scenarios.

2. SOP REGULATOR IS NOT CAPABLE OF MAINTAINING SUIT PRESSURE ABOVE 3.33 PSI AND BELOW PRIMARY O₂ REGULATION PRESSURE FOR 30 MINUTES DURING EMERGENCY DCM PURGE.

The operational specification for the SOP regulator is 3.33 to 3.9 (dependent on flow rate). SOP checkout values outside of this range warrant further investigation to ensure that the requirements of this rule will be met. Emergency DCM purge is representative of the worst case oxygen demand that could occur during an EVA. The SOP must be capable of maintaining suit pressure at a safe level (> 3.33 psi) during an emergency purge configuration (DCM purge valve open). An SOP that is regulating above the specification limit of 3.9 is satisfactory as long as it is regulating below the regulation pressure of the primary regulator. If the SOP regulates above the primary regulator pressure, the SOP oxygen will be consumed instead of primary oxygen. If this occurs during EVA, a TERMINATE EVA is required for the affected crewmember. ©[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

For scheduled or unscheduled EVA's, the EMU is considered to be non-fail-safe and is therefore NO-GO. For contingency EVA's, the EMU is considered GO for SCU ops to be available for rescue/assist scenarios.

3. SOP FIRST STAGE REGULATION PRESSURE CANNOT BE MAINTAINED BELOW 600 PSIG AS MEASURED BY THE INTERSTAGE GAUGE DURING SOP CHECKOUT. ©[090894-1669A]

The primary intent of the interstage gauge (located between the first- and second-stage pressure regulators) is to detect excessive leakage or failed open conditions related to the SOP first-stage regulator. Preflight processing also uses this gauge as a reference point for first-stage regulation. The 600 psig value is based on nominal first-stage regulation of 200 psig added to the +400 psig gauge tolerance. Due to the inaccuracy of the gauge at the low end (+400/-200 psig), detection of regulator shifts is difficult. However, gauge readings are worthwhile for comparison with pre-flight data. A failed SOP first-stage regulator followed by a failed SOP second-stage regulator will result on rapid suit overpressurization and rupture.

For scheduled or unscheduled EVA's, the EMU is considered to be non-fail-safe and is therefore NO-GO. For contingency EVA's, the EMU is considered GO for SCU ops to be available for rescue/assist scenarios.

- E. MINIMUM RF COMMUNICATIONS (REF. RULE {A15-7}, MINIMUM RF COMMUNICATIONS DEFINITION)

For crew safety, two-way voice (including relay) communication must be available. Crewmembers must preserve the availability to vocally communicate in case assistance or aid is necessary in areas where the crewmember might not be able to maintain visual contact.

For scheduled or unscheduled EVA's, the EMU is considered to be non-fail-safe and is therefore NO-GO. For contingency EVA's, the EMU is considered GO for SCU ops to be available for rescue scenarios. For either types of EVA's, if the failure happens during EVA, a TERMINATE EVA is required for the affected crewmember.

- F. POSITIVE PRESSURE RELIEF VALVE - FAILS CLOSED DURING DEPRESS

This failure is only detected during depressurization. The EMU is considered NO-GO for EVA if the valve cannot be opened, because the EMU is not fail-safe for overpressurization. ©[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102 EMU GO/NO-GO CRITERIA (CONTINUED)

- G. VENTILATION FLOW - INSUFFICIENT FLOW (< 4.0 acfm) TO PROVIDE CO₂ REMOVAL FROM THE HELMET OR DEFOGGING CAPABILITY.

@[090894-1669 A]

The vent flow sensor detects low flow at less than 4.0 acfm, and the CWS message (NO VENT FLOW) is triggered when vent flow drops below this level. This is the minimum flow required to adequately remove CO₂ from the helmet. CO₂ buildup in the helmet will lead to hypercapnia (excess CO₂ in the blood stream) which increases heart and respiration rate and can impair a crewmember's judgment and ability to perform the EVA task. Hypercapnia will eventually lead to an unconscious crewmember. Normal ventilation flow is 6 to 8 acfm. Helmet purge valve may be used to provide alternate vent flow if EMU consumables can be managed to support this.

Insufficient ventilation flow will also increase the fogging of the visor. This will hinder the crewmember's vision and will impair their ability to perform the EVA task. Under this condition while EVA, the crewmember is in a safe configuration while attached to the SCU. The EMU is somewhat degraded, but operational, for a possible crewmember assist/rescue scenario.

- H. CO₂ CONTROL - PPCO₂ LEVEL CANNOT BE MAINTAINED BELOW 8.0 MMHG.

For PPCO₂ indication of 8 mmHg by the CWS, the actual level in the helmet may be 15 mmHg or higher depending on metabolic rate. Problems arise if the crewmember's symptoms coincide with this PPCO₂ level and the contaminant control cartridge cannot be replaced. This PPCO₂ level will cause physiological changes (hypercapnia) that can impair the crewmember's judgment and ability to perform the EVA task. Reference Rule {A13-52B}, PPCO₂ CONSTRAINT. @[ED]

Under this condition, the crewmember is in a safe condition while attached to the SCU with the helmet purge valve open. The EMU is somewhat degraded, but operational, for a possible crewmember assist/rescue scenario.

- I. BATTERY POWER - EMU BATTERY IS NOT CAPABLE OF PROVIDING POWER.

The EMU battery provides power for all EMU systems once off of the SCU. At cabin pressure, the battery may be replaced by a spare and the EMU is GO-For-EVA. If a spare is unavailable, the EMU will be able to remain on the SCU for a possible crewmember assist/rescue scenario. @[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

- J. THERMAL CONTROL - THERMAL CONTROL CANNOT BE MAINTAINED IN A TOLERABLE RANGE THROUGHOUT ALL SUITED OPERATIONS WHILE STILL PROVIDING AN ADEQUATE LEVEL OF WATER VAPOR REMOVAL.

©[090894-1669 A]

Thermal control must be maintained throughout all EMU suited operations. If water vapor produced by the crewmember and as a byproduct of the chemical reaction of CO₂ with LiOH is not removed, excessive water vapor levels in the EMU will cause fogging of the visor, degrading crewmember visibility. If cooling control is lost, it may be possible, if the crewmember is too cold, for the crewmember to manage cooling by periodically opening and closing the feedwater shutoff valve. Another option, if the crewmember is too hot, involves opening one of the two available purge valves on the suit. The feasibility of utilizing these options is case dependent.

If thermal control is lost via the SCU, the EMU is considered GO for EVA, since cooling will be restored once at vacuum when the sublimator is activated. If this is the case, when not on the sublimator, cooling must be provided through the DCM purge valve, assuming that the SCU can support the purge flow for the required time or by swapping SCU's if possible. If the failure happens during EVA, the EMU is considered GO to continue EVA. If thermal control is lost via the EMU (i.e., failure in either sublimator or LCVG), the EMU is considered GO to remain on the SCU, since cooling will be provided via the SCU (for sublimator failure) or will be provided with the DCM purge valve (for LCVG failure), assuming the SCU can support the purge flow for the required time. If the failure happens during EVA, a TERMINATE EVA is required for the affected crewmember.

K. CRITICAL INSTRUMENTATION:

1. LOSS OF EVA CREW'S CAPABILITY TO MONITOR BOTH SUIT PRESSURE SENSOR AND DISPLAY AND CONTROL MODULE (DCM) SUIT PRESSURE GAUGE.

The capability must exist to monitor suit pressure via either the pneumatic gauge or the pressure transducer at all times during the EVA

With the loss of both suit pressure transducer and gauge, there is no indication to the crewmember of suit pressure. For a scheduled or unscheduled EVA, the EMU is considered NO-GO. Since a third failure has to occur before the crewmember's life is in danger, the EMU is considered GO for SCU ops for a contingency EVA so that the crewmember is available for rescue ops. ©[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102 EMU GO/NO-GO CRITERIA (CONTINUED)

2. LOSS OF OPERATIONAL CWS: @[090894-1669A]

Reference Rule {A15-8}, OPERATIONAL CAUTION AND WARNING SYSTEM (CWS) DEFINITION.

- a. BITE LIGHT ILLUMINATED UNLESS "LIMITS BAD" MESSAGE PRESENT.

The built-in test equipment (BITE) light is illuminated when the BITE circuitry has detected either a hardware or software problem within the CWS. If, upon inspection, the status list can be verified to be functioning properly, the CWS is considered operational. If the status list cannot be verified to be operating normally, the CWS is not considered to be operational. If the BITE is illuminated and LIMITS BAD message is present, the CWS is considered to be operational because the BITE circuitry has already verified that the status list is good and the problem resides in PROMS which contains only CWS limits.

- b. CREWMEMBER OR MCC DETERMINES INSUFFICIENT RELIABLE DATA AVAILABLE.

For the loss of operational CWS, the crewmember is in a safe condition while attached to the SCU. The EMU is somewhat degraded, but operational, for a possible crewmember assist/rescue scenario.

3. DCM DISPLAY - CREWMEMBER IS UNABLE TO READ DCM DISPLAY AND MCC CANNOT MONITOR EMU DATA VIA REAL-TIME DATA SYSTEM.

EMU is considered GO (fail-ops) if MCC is capable of monitoring EMU status via the EMU Real-Time Data System (RTDS). EMU is considered GO to remain on the SCU if MCC monitoring capability is not available. If the failure happens during EVA, EMU is considered GO to continue EVA, unless MCC monitoring capability of EMU data is lost. If MCC monitoring capability is lost, then a TERMINATE EVA is required by the affected crewmember. @[090894-1669A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

- L. SINGLE COMPONENT INSTRUMENTATION - LOSS OF ONE OF THE FOLLOWING SENSORS: @[090894-1669A]

SUIT PRESSURE XDUCER XDUCER	SUBLIMATOR PRESSURE XDUCER SOP PRESSURE XDUCER
VENT FLOW SENSOR	SOP INTERSTAGE GAUGE
CO ₂ XDUCER	H ₂ O GAS PRESSURE XDUCER
BATTERY VDC XDUCER	H ₂ O WATER PRESSURE XDUCER
BATTERY AMP XDUCER	H ₂ O TEMPERATURE XDUCER
O ₂ PRESSURE XDUCER	

EMU is considered GO (fail-ops). For the loss of any one sensor or transducer, the integrity of the system monitored by the failed sensor can be monitored via other sensors. A failure in that system will be manifested by a warning message from another sensor or by some other noticeable indication. For CO₂ transducer loss, the ability to detect a high CO₂ level relies entirely on the crewmember's ability to detect physiological symptoms and take appropriate action as required, such as purge valve activation (Rule {A13-52B}, PPCO₂ CONSTRAINT, rationale indicates symptoms of CO₂ exposure). For SOP interstage gauge loss, there is no other instrumentation device available in flight to verify SOP first-stage regulation. For any single sensor loss, consider using EMU 3 (if available) to regain full operational capability, depending on the extent of resizing necessary to accommodate the affected crewmember.

- M. SCU POWER - NO POWER PROVIDED TO EMU THROUGH SERVICE AND COOLING UMBILICAL.

The EMU is considered fully operational on battery power. Battery may need to be changed out prior to depressurization to preserve full EVA time capability. EMU is considered GO-for-EVA under this condition.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102 **EMU GO/NO-GO CRITERIA (CONTINUED)**

N. ECG TELEMETRY - NO ECG TELEMETRY IS PROVIDED TO MCC.

The EMU is considered fully operational. Reference Rule {A15-20}, ECG TELEMETRY CHECKOUT. ©[090894-1669A]

O. LOSS OF OPERATIONAL EMU HEATED GLOVE(S) IS NOT A CONSTRAINT TO PERFORMING AN EVA. ©[111298-6755A]

1. FOR A FAILURE OF HEATED GLOVES PRE-EVA AND THERMAL ANALYSIS INDICATING SKIN TEMPERATURE VIOLATIONS WITHOUT USE OF HEATED GLOVES BY THE CREW, ACTION WILL BE TAKEN TO RESTORE HEATED GLOVE POTENTIAL OR ESTABLISH CREW LIMITS WITHIN MISSION CAPABILITIES.

The actions for a failure are: EVA flights fly backup heated gloves for EV crewmembers which should be used for a heater element failure; replacement of batteries; identify to the crew potential keep-out areas or limit handling of items for durations as specified in the EMU Glove Palm Certification Curves if capability is not restored (i.e. scheduled use of items listed in paragraph 2 of rule); swapping to backup EMU components (i.e. PLSS/HUT or arm segments) for a harness failure. The last action may place an EV crewmember in a non-optimum sized EMU and is the least preferred action and will be decided real time.

The EMU is considered GO for a failure of EMU heated glove(s) before the EVA. Reasonable effort will be made to restore the capability so that heated gloves will be available to the EV crewmember if preflight thermal analysis deems likely the use of heated gloves. Need for heated gloves depends on mission attitude, timelines, locations of EVA tasks, and initial hand temperatures. The heated glove system for the EMU is a simple wire harness connecting a battery to the heater elements in the glove fingertips through connectors and toggle switches routed along the outside of the PLSS and arms. For the 3-volt system, a single failure will result in the loss of only one heated glove because each has a separate wire harness and battery.

Reference Documentation: JSC-39116 (CTSD-SS-1621) EMU Phase VI Glove Thermal Vacuum Test and Analysis Final Report, "Glove Palm Certification Limits" graphs, August 20, 1998.

2. FOR LOSS OF OPERATIONAL HEATED GLOVE DURING THE EVA, THE FOLLOWING OPTIONS, LISTED IN PRIORITY, ARE AVAILABLE TO THE EV CREW:
 - a. NOTIFICATION TO CREW OF POTENTIAL COLD AREAS TO AVOID, IF POSSIBLE, BASED ON THERMAL ANALYSIS.
 - b. FOR SINGLE GLOVE FAILURE, USE OF NON-AFFECTED HAND FOR GRASPING AND HANDLING COLD OBJECTS. ©[111298-6755A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-102

EMU GO/NO-GO CRITERIA (CONTINUED)

- c. USE OF BRT (OR OTHER RESTRAINT DEVICE) TO ALLOW HANDS-FREE OPERATION. @[111298-6755A]
- d. USE OF ADJUSTABLE THERMAL MITTENS.
- e. USE OF OTHER EV CREWMEMBER FOR OPERATIONS THAT ARE DEEMED TOO COLD BY THE AFFECTED EV CREW OR LIMIT HAND CONTACT DURATION.
- f. USE OF EMU LCVG BYPASS.
- g. CREW WOULD NOT WORK DURING NIGHT PASSES.
- h. EV CREW MAY MOVE TO SUN SIDE TO WARM HANDS AFTER TASK.

For a failure of the EMU heated gloves during the EVA, the EMU is GO to continue. The loss may require the affected EV crewmember to modify his/her operations as deemed necessary by that crewmember. For the 3-volt system, a single failure will result in the loss of only one heated glove because each has a separate wire harness and battery.

Restraint devices can be used to hold ORU's or restrain crewmembers to handrails. Thermal mittens may be used as an added layer to the EMU gloves but will reduce dexterity of the hands. The other EV crewmember may be used for cold tasks. Least preferred options include; EMU LCVG bypass may be used in an attempt to warm the crewmember's core temperature in an effort to warm the arms and hands, not working during night passes, or having the affected crewmember warm hands on the sun side as required.

The crewmember shall be reminded to preclude affected hand(s) from becoming too cold in the first place. Once the hands are cold, it will invalidate the crewmember's sense of temperature and lower their "threshold" of comfort. The affect is that the crewmember's hand does not need to warm as much to give the sensation of being comfortable; therefore, the hand will start at a colder initial temperature the next time it is exposed. Iterations of this process over the EVA duration could lead to tissue damage without the crewmember being aware.

Reference Documentation: JSC-39116 (CTSD-SS-1621), EMU Phase VI Glove Thermal Vacuum Test and Analysis Final Report, "Glove Palm Certification Limits" graphs, August 20, 1998. @[111298-6755A]

FLIGHT RULES

SYSTEMS MANAGEMENT

A15-151 DENITROGENATION

DENITROGENATION OF THE EVA CREWMEMBER WILL BE ACCOMPLISHED IN ACCORDANCE WITH AEROMED RULE {A13-103}, EVA PREBREATHE PROTOCOL.

Proper denitrogenation is required to prevent bends in the EV crewmember.

A15-152 EMU CONSUMABLES WITH REAL-TIME EMU DATA DOWNLINK @[050400-7199A]

EVA CREWMEMBERS MUST BE COMPLETE WITH AIRLOCK INGRESS AND CONNECTED TO THE SERVICE AND COOLING UMBILICAL (SCU) WHEN 30 MINUTES REMAIN OF ANY EMU CONSUMABLE AS DETERMINED BY MCC.

Thirty minutes is considered the redline for primary consumables (O₂, power, LiOH and water). This 30-minute reserve is necessary to prevent bringing the non-replenishable redundant oxygen system (SOP) on-line. If real-time data capability with MCC is available, the flight control team can use this information to determine which consumable will reach the 30-minute limit first. MCC consumables calculations can be more realistic due to the use of flight specific initial loading data rather than the standard minimum required values used by the EMU Caution and Warning System (CWS). A/G voice must be available for MCC to alert crew when they are approaching the 30-minute limit. If A/G voice capability is available, but is interrupted by periods of LOS, MCC can confirm consumables status with the crew prior to LOS. The affected crewmember(s) must be complete with airlock ingress and pre-repress when 30 minutes remain of any consumable. If consumables allow, the other crewmember will continue with remaining EVA tasks and will complete sortie cleanup. Timeline management will ensure that the EVA sortie cleanup, airlock ingress, and pre-repress is completed prior to the last crewmember reaching the 30-minute redline. Translation time back to the airlock will be determined by either Neutral Buoyancy Laboratory (NBL) or Virtual Reality (VR) Laboratory crew training. EVA tasks will be modified or deleted real time to ensure that the EV crewmember is connected to the SCU within the timeframe necessary to maintain the 30-minute reserve. Connection to the SCU is considered a safe configuration because the SCU can support the loss of any EMU consumable. Battery and LiOH have a finite capacity; however, opening the helmet purge valve while on the SCU compensates for the loss of LiOH, and configuring the EMU to accept airlock power compensates for the loss of battery. In the event that airlock power is not available, opening the helmet purge valve while on the SCU can compensate for the loss of the battery. Oxygen and water are rechargeable at vacuum. If the 30 minute consumable is oxygen or water, the crewmembers can connect to the SCU, recharge the consumables, and return to EVA tasks. This rule is considered an operational constraint.

DOCUMENTATION: Hamilton Sundstrand Engineering Memorandum EMUM1-0404 "Consumable Tracking During EVA," March 15, 2000, and engineering judgment. @[050400-7199A]

FLIGHT RULES

A15-153

EMU CONSUMABLES WITHOUT REAL-TIME EMU DATA DOWNLINK

- A. IF NO A/G VOICE CAPABILITY, AN EVA CREWMEMBER WILL TERMINATE THE EVA WHEN THE CAUTION AND WARNING SYSTEM (CWS) ISSUES A 30-MINUTE ALERT FOR ANY EMU CONSUMABLE. @[050400-7200A]

If A/G voice and real-time EMU data capability with MCC are not available, the EMU CWS will be used to determine which consumable will reach the 30-minute limit first. If the EV crewmember has no ability to communicate with MCC, the only insight into the EMU consumables is via the CWS. The EV crewmember will rely on the CWS to display a message when 30 minutes remain of any EMU consumable. The CWS consumable messages are more conservative than real-time consumables data. Oxygen and water are rechargeable at vacuum. If the 30-minute consumable is oxygen or water, the crewmembers can connect to the SCU, recharge the consumables, and return to EVA tasks. This rule is considered an operational constraint.

- B. IF A/G VOICE CAPABILITY, AN EVA CREWMEMBER WILL TERMINATE THE EVA WHEN THE CAUTION AND WARNING SYSTEM (CWS) ISSUES A 30-MINUTE ALERT FOR OXYGEN, LIOH, OR WATER CONSUMABLES. THE EVA CREWMEMBER MUST BE COMPLETE WITH AIRLOCK INGRESS AND CONNECTED TO THE SERVICE AND COOLING UMBILICAL (SCU) WHEN 30 MINUTES OF POWER REMAIN AS DETERMINED BY MCC THROUGH PERIODIC REPORTS OF EMU STATUS.

If A/G voice is available but real-time EMU data is not available, the EMU CWS will be used to determine which consumable (oxygen, LiOH, or water) will reach the 30-minute limit first. However, battery power can be tracked on the ground with a periodic status, because the power usage is relatively constant during the EVA as compared with other consumables. The EV crew will give an hourly EMU status for the first 6.5 hours followed by an increase in status calls to every 10 minutes so that MCC can track more closely the battery performance towards the lower end of its capacity. Oxygen, LiOH and water calculations depend on crewmember metabolic rate requiring more frequent status checks to get an accurate estimate of use rate. The CWS messages for these consumables are more conservative than real-time consumables data. The battery 30-minute limit will be calculated by the ground using the periodic status checks. Oxygen and water are rechargeable at vacuum. If the 30-minute consumable is oxygen or water, the crewmembers can connect to the SCU, recharge the consumables, and return to EVA tasks. This rule is considered an operational constraint.

DOCUMENTATION: Hamilton Sundstrand Engineering Memorandum EMUM1-0404 "Consumable Tracking During EVA," March 15, 2000, and engineering judgment. @[050400-7200A]

FLIGHT RULES

A15-154 **EMU CONSUMABLES PRE-EVA**

SUFFICIENT CONSUMABLES MUST BE AVAILABLE TO SUPPORT THE COMPLETE EVA TIMELINE PLUS 15 MINUTES OF EVA EGRESS ACTIVITIES, 15 MINUTES OF INGRESS ACTIVITIES, AND A 30-MINUTE RESERVE. @[050400-7201]

This rule is provided as an operational guide in planning EVA timelines based on consumable constraints. For purposes of EMU certification, this rule assumes 6 hours of EVA operations, with 5 minutes for post depress, 10 minutes for egress, 10 minutes for ingress, 5 minutes of pre-repress and 30 minutes of reserve to make a total of 7 hours EVA time. In addition, a 30-minute emergency oxygen supply is provided. @[050400-7201]

A15-155 **MANIPULATOR FOOT RESTRAINT (MFR) AND PFR ATTACHMENT DEVICE (PAD) GUIDELINES**

- A. ONLY MINIMUM COMMUNICATIONS FOR EVA BETWEEN THE RMS OPERATOR AND THE MFR/PAD OPERATOR ARE REQUIRED. (REF. RULE {A15-7}, MINIMUM RF COMMUNICATIONS DEFINITION.)

The EVA crewmember on the MFR/PAD has the best vantage point from which to direct the operator of the RMS to and about the worksite. Communications between the RMS operator and the MFR/PAD operator will maximize safety. Minimum communication is two-way communication with the orbiter even if relayed through the other EVA person.

- B. VISUAL VERIFICATION OF MFR/PAD POSITION/CLEARANCE IS REQUIRED.

This is to preclude contact and possible damage to payloads and structures in the payload bay imparted by the RMS and MFR/PAD.

- C. MFR/PAD WILL BE OPERATED ONLY IN THOSE AREAS WHERE THE RMS CANNOT IMPART EXCESSIVE LOADS TO THE EMU.

In certain configurations, the arm can impart excessive loads to the EMU and the EVA crewmember. The PLSS (the part of the EMU least tolerant to impact forces) is certified for a maximum 400-lb impact force on a 2-inch diameter sphere at a 2 ft/sec velocity before impact. The RMS will be kept out of regimes where impact loads of this type are possible to minimize the possibility of damage to the EMU.

A15-156 THROUGH A15-200 RULES ARE RESERVED

FLIGHT RULES

EXTERNAL AIRLOCK

A15-201

EXTERNAL AIRLOCK HATCH THERMAL COVER

DURING EVA, THE EXTERNAL AIRLOCK HATCH THERMAL COVERS FOR THE UPPER AND AFT HATCHES SHOULD REMAIN CLOSED. IF EITHER COVER OPENS DURING EVA, AN EVA CREWMEMBER WILL RETURN TO THE AIRLOCK TO CLOSE IT AT THE NEXT CONVENIENT OPPORTUNITY. @[061297-4904]

This rule is constrained by the orbiter cold case attitude (+XSI, PLB to space, beta = 90, or -XLV, PLB north, beta = -75). Design analysis that considered a closed hatch and thermal cover indicated that the water lines will approach freezing temperatures during the EVA period, even with the heaters enabled (for the analysis, the EVA period was defined as 10 hours with the airlock depressurized).

The airlock internal water lines are thermally insulated from the airlock structure by fiberglass standoffs. The segments of the internal water lines that have a direct view of deep space when both hatch and thermal cover are opened, will decrease more rapidly than the airlock structure. Therefore, there is a potential of the internal water lines freezing if the hatch thermal cover remains open during the EVA period.

Analysis indicates that when the airlock is pressurized, there is no concern for water line freezing regardless of the position of the hatch thermal cover.

DOCUMENTATION: Rockwell OER Presentation Charts September 18, 1996, and November 6, 1996, Rockwell IL 270-200-97-007, engineering judgment. @[061297-4904]

FLIGHT RULES

A15-202

EXTERNAL AIRLOCK LCG PRESSURE AND TEMPERATURE MANAGEMENT USING THE EMU

IN THE EVENT THE EXTERNAL AIRLOCK LIQUID COOLING GARMENT (LCG) FLUID LINES EXPERIENCE AN UNEXPECTED PRESSURE OR TEMPERATURE INCREASE (REF RULE {A18-62}, EXTERNAL AIRLOCK WATER LINE OVERPRESSURE/TEMPERATURE MANAGEMENT), THE FOLLOWING CONSTRAINTS AND ACTIONS APPLY: @[070899-6889A]

- A. IF THE SERVICE AND COOLING UMBILICAL (SCU) IS DISCONNECTED FROM THE EMU:

WITH THE EMU O₂ VALVES CLOSED AND THE TCV IN MAX "C," THE SCU CAN BE CONNECTED TO THE EMU AND THE EMU FAN/PUMP TURNED ON FOR A MAXIMUM OF 2 MINUTES, IF THE EMU WATER TANKS CONTAIN THE NOMINAL ULLAGE AND BEFORE THE LCG WATER LINE TEMPERATURES IN EITHER ZONE EXCEED 92 DEGREES F.

The external airlock EMU Liquid Cooling Garment (LCG) lines are routed externally to the airlock/orbiter and are susceptible to pressure (MSID V64P0170A {EV1}) and V64P0171A {EV2}) and temperature (MSID V64T0182A {ZN1} and V64T0185A {ZN2}) increases due to a "hot" orbiter attitude or failed on line heaters. There are no accumulators, shutoff valves, or regulators in the LCG loops, which are in a hydraulic lockup condition when disconnected from the EMU. In the EMU, the LCG loop is connected to the water tanks through the bypass of the EMU Coolant Isolation Valve. The EMU water tanks, with nominal 1 pound ullage, will act as an accumulator for the LCG lines through the bypass of the EMU Coolant Isolation Valve.

The O₂ valves must remain closed because the maximum thermal limit for O₂ supplied to the EMU is 90 deg F. LCG2 water line temperatures ? 92 deg F in both zones ensure that all sections of the LCG water lines are below the EMU thermal limit of 100 deg F. The maximum limit for the EMU water line vent tube assembly (WLVTA) is 100 deg F. Anytime the EMU TCV is out of the max "H" position, water will flow through the WLVTA.

Although not designed for this purpose, the EMU can be used as a contingency device for lowering the pressure (and temperature) in the LCG lines by using the EMU fan/pump to circulate the LCG water to the orbiter LCG HX for cooling. The EMU fan/pump should not be on for longer than 2 minutes without O₂ pressurization of the EMU water tanks due to potential cavitation and damage of the pump. Calculations show the LCG supply "hot" water flows through the LCVG water loop in 45 seconds with the TCV in max "C." Two minutes will ensure that the water can pass through the LCG HX at least twice for cooling.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-202

EXTERNAL AIRLOCK LCG PRESSURE AND TEMPERATURE MANAGEMENT USING THE EMU (CONTINUED)

It is preferable to change orbiter attitude if possible to lower the pressure (temperature) of the LCG fluid lines. ©[070899-6889A]

DOCUMENTATION: Hamilton Standard Engineering Memorandums EMUM1-0085 and EMUM1-0195, "STS-88 Hot External Airlock Return Temperatures & Revisions," and engineering judgment. ©[070899-6889A]

- B. IF THE SERVICE AND COOLING UMBILICAL (SCU) IS CONNECTED TO THE EMU:
1. THE EMU FAN/PUMP WILL BE TURNED ON FOR A MAXIMUM OF 2 MINUTES BEFORE THE LCG LINE PRESSURE REACHES 18 (16.6) PSIG FOR UNEXPECTED AND INCREASING PRESSURE.
 2. A NOMINAL EMU WATER TANK ULLAGE DUMP MUST BE PERFORMED AFTER AN UNEXPECTED PRESSURE INCREASE OR IF THE LCG PRESSURE DID NOT DECREASE AFTER SCU CONNECTION.

A steady pressure increase in either of the LCG lines (MSID V64P0170A {EV1} or V64P0171A{EV2}) with the SCU connected, EMU fan/pump and O₂ actuator off, indicates the EMU water tanks no longer contain any nominal ullage and are no longer acting as an accumulator for the LCG lines. In the EMU, the LCG loop is connected to the water tanks through the bypass of the EMU Coolant Isolation Valve. At 19.0 ±1.0 psig, the EMU Feedwater Relief Valve will open and vent water from the EMU water tanks into the airlock (ref Rule {A18-61}, EXTERNAL AIRLOCK LCG FLUID LINE LOSS DEFINITION).

Although not designed for this purpose, the EMU can be used as a contingency device for lowering the pressure (and temperature) in the LCG lines by using the EMU fan/pump to circulate the LCG water to the orbiter LCG HX for cooling. Therefore, the EMU pump will be turned on prior to reaching 18 psig (16.6 psig indicated) which will prevent the LCG loop pressure from reaching the Feedwater Relief Valve lower regulation of 18 psig. The EMU fan/pump should not be on for longer than 2 minutes without O₂ pressurization of the EMU water tanks due to potential cavitation and damage of the pump.

If the LCG line water has been cooled using the EMU fan/pump to stop a pressure increase, or if the pressure did not decrease after SCU connection, approximately 1 pound of water must be dumped from the EMU water tanks before reaching the Feedwater Relief Valve lower regulation of 18 psig to restore the capability for the EMU to act as an accumulator for the LCG lines through the bypass of the EMU Coolant Isolation Valve. In place of using the EMU, it is preferable to change orbiter attitude if possible.

DOCUMENTATION: Reference Hamilton Standard, EMUM-1337; Hamilton Standard Engineering Memorandums EMUM1-0085 and EMUM1-0195, "STS-88 Hot External Airlock Return Temperatures & Revisions;" and engineering judgment. ©[070899-6889A]

FLIGHT RULES

A15-203

CABIN ATMOSPHERE DECONTAMINATION FOLLOWING EVA

@[021199-6821A]

- A. FOLLOWING A NEGATIVE DRAGER TUBE READING, THE CABIN AIR WILL BE TREATED UNDER THE ASSUMPTION THAT THE AIRLOCK VOLUME IS CONTAMINATED TO THE MINIMUM SENSITIVITY LEVEL FOR THE SPECIFIC DRAGER TUBE (250 PPB FOR HYDRAZINES AND AMMONIA, AND 500 PPB FOR NO₂). @[021199-6821A]

This rule assumes that contamination of the EMU was either suspected or confirmed and action was taken to eliminate the contaminants from the affected EVA crewmember (such as bakeout) prior to performing airlock repress. Under these conditions, a Drager tube reading is required.

Because the Drager tubes are not sensitive enough to detect acceptable SMAC levels, lack of a reading does not verify that the contamination level is below the 7-day SMAC. The assumed contamination level is the minimum sensitivity of the specific Drager tube. The minimum sensitivities of the hydrazine/ammonia and nitrogen dioxide tubes are 250 ppb and 500 ppb, respectively.

DOCUMENTATION: Drager-Tube Handbook, 1994.

- B. THE FOLLOWING ACTIONS WILL BE TAKEN IN AN ATTEMPT TO REDUCE THE ASSUMED CONTAMINANT CONCENTRATION BELOW THE DESIGNATED 7-DAY SMAC LEVELS AND TO PROTECT THE CREW DURING ATMOSPHERE SCRUBBING:
1. IMMEDIATELY PRIOR TO AIRLOCK HATCH OPENING, THE IV CREW WILL DON QDM'S AND BREATHE O₂. THE IV CREW WILL REMAIN ON THE QDM'S FOR 20 MINUTES FOLLOWING HATCH OPENING.
 2. PRIOR TO AIRLOCK HATCH OPENING, PERFORM THE FOLLOWING ACTIONS AND CONTINUE FOR 3 HOURS AFTER AIRLOCK HATCH OPENING:
 - a. INSTALL TWO ATCO CANISTERS TO SCRUB HYDRAZINES AND AMMONIA FROM THE CABIN ATMOSPHERE.
 - b. PLACE CABIN TEMP CONTROLLER IN THE "FULL COOL" POSITION.
 - c. INITIATE AIR FLOW THROUGH WCS ODOR/BACTERIA FILTER.
 - d. IV CREW WILL DON LONG SLEEVES, LONG PANTS, AND GLOVES AS PRACTICAL. @[021199-6821A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-203

CABIN ATMOSPHERE DECONTAMINATION FOLLOWING EVA
(CONTINUED)

3. FOLLOWING AIRLOCK HATCH OPENING: @[021199-6821A]
 - a. EV CREW WILL REMAIN IN EMU'S FOR 20 MINUTES FOLLOWING AIRLOCK HATCH OPENING.
 - b. WIPE EMU'S AND AIRLOCK WALLS WITH WET TOWELS.
 - c. INSTALL/ACTIVATE BOOSTER FAN AND ASSOCIATED DUCTWORK AS SOON AS POSSIBLE.
- C. FOLLOWING A NEGATIVE READING AND COMPLETION OF THE ATMOSPHERE SCRUBBING ACTIVITIES (REF PARAGRAPH B), THERE ARE NO MISSION DURATION CONSTRAINTS.

Following EVA, the Drager test is performed with the airlock pressure at 5 psia. Repressurizing the airlock to 10.2 psia will reduce the contaminant concentration by a factor of 2 in the airlock (2.9 by repressurizing to 14.7 psia). This will bring the concentration below the 24-hour SMAC for all cases except MMH.

After airlock hatch opening and the atmospheres have mixed, the concentration will be further reduced by a factor of 7 (tunnel adapter) and 12 (airlock only) depending upon the specific volume configuration. This will bring the concentration below the 7-day SMAC for all cases except MMH.

The expected contamination level following dilution by volume equalization, assuming good atmospheric mixing, will be approximately 11 ppb (approximately 18 ppb with a tunnel adapter) for a 10.2 psia cabin. For a 14.7 psia cabin following equalization, the expected contamination level will be approximately 7 ppb (approx 12 ppb with a tunnel adapter).

The IV crew must remain on the QDM's and the EV crew must remain in the EMU for at least 20 minutes following hatch opening to allow time for the two atmospheres to mix and to allow any localized pockets of contaminants to dissipate. Twenty minutes was chosen as a time to allow effective mixing without requiring further action to control the O₂ concentration in the cabin. Donning long sleeves, long pants and gloves will minimize the amount of exposed skin and further protect the IV crewmembers from exposure to the toxic products following airlock hatch opening. This is listed as "as practical" because there is currently no requirement for crewmembers to select long pants and long-sleeved shirts as part of their in-flight wardrobe. @[021199-6821A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-203

CABIN ATMOSPHERE DECONTAMINATION FOLLOWING EVA (CONTINUED)

Two ambient temperature catalytic oxidizer (ATCO) canisters are installed to remove additional hydrazine, MMH, UDMH, and ammonia from the cabin atmosphere. In 2 to 3, hours it is expected that the cabin PPCO₂ levels will increase enough to require replacement of one of the ATCO canisters with a fresh LiOH canister. The other ATCO canister should remain in place as long as practical. The ATCO canister is 100 percent effective at neutralizing the contaminants from the air that passes through it. Based upon nominal cabin fan airflow, each ATCO canister will scrub the volume equivalent of the cabin atmosphere every 90 minutes. It is assumed that for each volume equivalent cycle through an ATCO can, approximately 63 percent of the remaining contaminants have been neutralized. Therefore, in 3 hours, assuming one ATCO is replaced with a LiOH after 2 hours, the entire cabin atmosphere will have passed through an ATCO canister at least three times and the concentration will be reduced to < 10 percent of the initial concentration. The 63 percent contamination reduction number is based upon analysis that shows for each complete volume equivalent cycle through a LiOH canister slot, because the atmospheric mixing is not ideal, only 63 percent vs 100 percent of the molecules of air in the cabin will actually flow across the catalyst bed in the ATCO canister. For all of the contamination compounds, including MMH, final concentration will be below the 7-day SMAC within 3 hours of airlock hatch opening and initial ATCO scrubbing. ©[021199-6821A]

Because hydrazines are water soluble, wiping the EMU's with wet towels will dilute the contaminant and transfer the contaminant to the towels and prevent additional off-gassing from the EMU. The contaminated towels can be placed in Ziplock bags. Also, due to the solubility of hydrazines, contaminants can be condensed out of the atmosphere and sent in solution to the waste water system. Therefore, the IV crew will place the cabin temp controller to the "FULL COOL" position thus maximizing airflow across the ARS condensing heat exchanger.

The WCS odor/bacteria filter is designed to remove ammonia (NH₃) from the airflow through the WCS. Activation of the WCS commode will initiate the maximum airflow through the odor/bacteria filter and aid in scrubbing ammonia from the cabin atmosphere. The volume equivalent of the cabin atmosphere will flow through the WCS odor/bacteria filter approximately every 60 minutes.

The booster fan is reinstalled and activated, with associated ductwork connected, as soon as possible to circulate the contaminated atmosphere from the airlock to the cabin in an attempt to dilute the overall concentration through mixing of the atmospheres and to send the contaminated atmosphere through the ARS as quickly as possible. ©[021199-6821A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-203

**CABIN ATMOSPHERE DECONTAMINATION FOLLOWING EVA
(CONTINUED)**

In all cases, the procedure governed by this rule meets the criteria listed in the following table with the exception of the 24-hour SMAC for MMH. Orbit Flight Techniques (November 12, 1998) deemed this acceptable based upon the ability to meet the 24-hour and the 7-day SMAC within 3 hours of cabin contamination. Additionally, White Sands personnel have been previously exposed to MMH at levels several orders of magnitude higher than the 24-hour SMAC with no deleterious effects. ©[021199-6821A]

The table below lists the SMAC levels informally proposed by the JSC Toxicology group.

TABLE A15-203-I - SMAC LEVELS (PPB)

CHEMICAL	DRAGER DETECTION LEVEL	1-HOUR	24-HOURS	7-DAYS
N ₂ H ₄	250	4,000	300	40
MMH	250	2	2	2
UDMH	250	NOT SET	NOT SET	100
N ₂ O ₄ (NO ₂)	500	NOT SET	NOT SET	500
NH ₃	250	30,000 (30 PPM)	20,000 (20 PPM)	10,000 (10 PPM)

DOCUMENTATION: EVA Console Handbook, Sec. 6.5 N₂H₄ Contamination (EVA/JSC-20597), engineering judgment. ©[021199-6821A]

FLIGHT RULES

A15-204

EXTERNAL AIRLOCK EMU SERVICING CONSTRAINTS

EMU SERVICING AND OPERATION IS CONSTRAINED BY THE FOLLOWING THERMAL LIMITS: @[070899-6890A]

A. O₂ SERVICING MAY BE PERFORMED WHEN EITHER OF THE FOLLOWING TWO CONDITIONS ARE SATISFIED:

1. THE O₂ SUPPLY TEMPERATURE IS ? 80 DEG F (INDICATED).
@[121400-3862A]
2. THE O₂ SUPPLY LINE TEMPERATURE SENSOR IS FAILED AND:
 - a. THE EXTERNAL AIRLOCK FLUID LINE HEATERS ARE CYCLING IN BOTH ZONES.

OR

- b. THE EXTERNAL AIRLOCK FLUID LINE HEATERS ARE NOT CYCLING AND THE LCG SUPPLY AND POTABLE SUPPLY TEMPERATURES ARE ? 72 DEG F (INDICATED).

O₂ servicing is defined as the period of time when the SCU is mated to the EMU and the airlock O₂ valves are open. Flow analyses were performed to ensure that all O₂ delivered to the airlock is less than 90 deg F since temperature gradients can exist between the sensor location and the rest of the line. Based on the analyses, an O₂ supply line temperature (MSID V64T0183A through STS-98; the MSID will be V64T0186A starting with STS-102) less than or equal to 80 deg F ensures the O₂ flow into the EMU is less than 90 deg F. If the O₂ supply temperature sensor fails, then heater cycling (MNA, MNB, or MNC heaters) on the fluid lines indicates a payload bay environment below 70 deg F and, therefore, environmental heating above the O₂ limit is not possible. Also, for a failed O₂ sensor, maintaining a supply water (MSID V64T0181A {ZN1} and V64T0184A {ZN2}) and LCG supply (MSID V64T0182A {ZN1} and V64T0185A {ZN2}) line temperature in both zones below 72 deg F with no heater cycling (implying that the 72 deg F is due to environmental heating and not heater operations) ensures that the O₂ line temperature is below 90 deg F. The O₂ limit of 90 deg F was chosen because all EMU safety analysis was performed with this limit. Impacts from exceeding this limit are unknown. There is also a 90 deg F maximum inlet temperature to the helmet that EMU must meet. There is currently no active method of cooling the O₂ line. @[121400-3862A]

Indicated values are used since the analyses have conservative assumptions that cover the instrumentation error. Applying instrumentation error to the conservative analysis values may unnecessarily constrain operations. @[121400-3862A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-204

EXTERNAL AIRLOCK EMU SERVICING CONSTRAINTS
(CONTINUED)

- B. LCG WATER MAY BE CIRCULATED THROUGH A MANNED SUIT IF THE EXTERNAL AIRLOCK LCG2 WATER LINE TEMPERATURE IN BOTH ZONES IS ? 92 DEG F.

LCG2 water line temperatures ? 92 deg F in both zones (MSID V64T0182A {ZN1} and V64T0185A {ZN2}) ensure that the all sections of the LCG water lines are below the EMU thermal limit of 100 deg F. The 100 deg F thermal limit for water circulated through a manned suit is defined by Hamilton Sundstrand to ensure crew comfort.

- C. LCG WATER MAY BE CIRCULATED THROUGH AN UNMANNED SUIT IF EXTERNAL AIRLOCK LCG2 WATER LINE TEMPERATURE IN BOTH ZONES IS ? 110 DEG F.

FOR AN UNMANNED EMU, IF THE EXTERNAL AIRLOCK LCG LINE TEMPERATURE IN EITHER ZONE IS < 110 DEG F BUT > 92 DEG F, THE EMU TCV MUST BE PLACED IN THE MAX "H" POSITION PRIOR TO INITIATING WATER CIRCULATION. @[070899-6890A]

LCG2 water line temperatures ? 110 deg F in both zones (MSID V64T0182A {ZN1} and V64T0185A {ZN2}) ensure that all sections of the LCG water lines are below the EMU thermal limit of 120 deg F. For an unmanned suit, the limit of 120 deg F comes from the EMU certification limit. The tubing in the HUT is molded at 120 deg F and may deform when exposed to this limit. Placing the TCV in MAX "H" (LCVG bypass) minimizes the EMU exposure to hot water. @[070899-6890A]

- D. WATER RECHARGE MAY BE PERFORMED IF THE EXTERNAL AIRLOCK SUPPLY WATER LINE TEMPERATURE IN BOTH ZONES IS ? 95 DEG F.
@[121400-3862A]

Supply water line temperatures ? 95 deg F in both zones (MSID V64T0181A {ZN1} and V64T0184A {ZN2}) ensure that all sections of the supply water line are below the EMU thermal limit of 100 deg F. The thermal limit of 100 deg F for water recharge protects the life of the SCU bacteria filter cartridge and minimizes the risk of having a high concentration of iodine in the feedwater bladders.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A15-204

EXTERNAL AIRLOCK EMU SERVICING CONSTRAINTS
(CONTINUED)

E. BATTERY RECHARGE IS NOT CONSTRAINED BY EXTERNAL AIRLOCK LINE THERMAL LIMITS.

Battery recharge has no thermal constraints because the airlock O₂ valves are closed to isolate O₂ flow, and no water is supplied to or circulated through the EMU.

F. EMU O₂ SERVICING SHALL BE AVAILABLE FOR THE DURATION OF AN EVA PER CONSTRAINTS IN PARAGRAPH A. EMU LCG COOLING SHALL BE AVAILABLE FOR THE DURATION OF AN EVA PER CONSTRAINTS IN PARAGRAPH B.

To protect for early termination of an EVA due to EMU failures, and provide vehicle consumables, the EMU O₂ supply must be available at all times during an EVA to provide immediate O₂ resupply/flow through the Service and Cooling Umbilical (SCU). The LCG supply line temperatures must be maintained ? 92 deg F in both zones (MSID V64T0182A {ZN1} and V64T0185A {ZN2}) during the EVA in order to provide cooling to the EV crew in the case of an EMU cooling failure.

FLIGHT RULES

A15-205

EMU DECONTAMINATION DURING EVA

- A. IF CHEMICAL CONTAMINATION OF THE EMU IS CONFIRMED BY VISUAL OBSERVATION OR CHEMICAL DETECTION EQUIPMENT, THEN THE HYDRAZINE DECONTAMINATION PROCEDURE WILL BE EXECUTED.
©[070899-6869A]

For confirmed contamination, the decontamination procedure is designed to reduce the hydrazine, ammonia, or oxidizer levels to safe values based on analysis.

Use of consumables and impact to the crew timeline for airlock depress and bakeout are significant mission impacts and will not be performed unless contamination of the EMU is confirmed by visual inspection or chemical detection equipment.

- B. DRAGER TUBES WILL ONLY BE UTILIZED WHEN EMU CONTAMINATION IS SUSPECTED.

EMU CONTAMINATION IS SUSPECTED WHEN THE EMU WAS IN THE VICINITY OF A THRUSTER OR AMMONIA SYSTEM COMPONENT WITH A VISUALLY OR TELEMETRY DETECTED LEAK.

Because there is a limited supply of drager tubes on board, they will only be used if contamination is suspected.

Suspected EMU contamination must be investigated further with the hydrazine detection equipment to either confirm or disprove the suspected contamination before it presents a hazard to the IV crew.

FLIGHT RULES

SECTION 16 - POSTLANDING

GENERAL

A16-1 **CONVOY POSITIONING**

CONVOY POSITIONING WILL NOT BE CAUSE TO CONSTRAIN RUNWAY SELECTION.

A16-2 **VEHICLE SYSTEM RECONFIGURATION CONSTRAINT**

SYSTEM RECONFIGURATION WHICH WOULD RESULT IN DESTROYING VEHICLE TURNAROUND PROBLEM ANALYSIS WILL BE AVOIDED WHERE POSSIBLE.

A16-3 **PRECREW EGRESS TROUBLESHOOTING CONSTRAINT**

PRECREW EGRESS TROUBLESHOOTING WILL BE LIMITED TO REGAINING A CAPABILITY REQUIRED FOR POSTLANDING ACTIVITIES.

Emphasis will be on configuring the Orbiter in a safe configuration for crew egress. Activities that can be accomplished by the exchange crew will be delayed until crew egress in order to expedite the crew egress timeline.

A16-4 **VEHICLE SYSTEM MODING CONSTRAINT**

IF AN EMERGENCY POWERDOWN IS REQUIRED, NO VEHICLE SYSTEM MODING WILL BE ACCOMPLISHED TO PROTECT VEHICLE SYSTEMS DATA.

Emergency powerdown and crew safety have priority over vehicle systems data.

A16-5 **MEMORY RECONFIGURATION CONSTRAINT**

IF THE BFS IS ENGAGED PRIOR TO THE POSTLANDING G3-TO-G9 TRANSITION, GNC RECONFIGURATION TO A SIMPLEX PASS GNC 9 MEMORY CONFIGURATION WILL NOT BE ATTEMPTED.

Cause for the BFS engage is most likely a combination of LRU failures and GPC failures. No attempt at establishing a PASS computer will be performed in order to preserve data for failure reconstruction purposes. SSME repositioning will not be attempted since the capability is not supported in the BFS. Rule {A16-9}, SSME REPOSITIONING CONSTRAINT, references this rule.

FLIGHT RULES

A16-6

RECORDER DUMP

POSTLANDING RECORDER DUMPS WILL BE ACCOMPLISHED BY MCC SO AS NOT TO CONSTRAIN THE CREW EGRESS TIMELINE.

This rule clarifies that MCC is prime for recorder dumps and crew participation will be minimal. Should there be an unexpected need for onboard assistance, the dump will be delayed until the astronaut support crew is available.

A16-7

GOM HANDOVER

- A. NOMINAL HANDOVER TO THE GOM WILL OCCUR AT CREW EGRESS OR GSE COOLING ACTIVATION, WHICHEVER OCCURS LATER.
- B. FOR LOSS OF MCC VOICE AND TELEMETRY, OR IF A MODE V OR VI EMERGENCY CONDITION IS DECLARED, HANDOVER TO THE GOM WILL BE ACCOMPLISHED ASAP; IF TOTAL LCC CAPABILITY IS LOST, NO CHANGE TO POSTLANDING ACTIVITIES WILL OCCUR, BUT HANDOVER TO THE GOM WILL BE DELAYED UNTIL THE CAPABILITY IS REGAINED OR THE ORBITER IS POWERED DOWN.
- C. HANDOVER TO THE GOM WILL OCCUR AT WHEELS STOP FOR LOSS OF MCC COMMUNICATIONS WITH THE VEHICLE.

LCC data monitoring is available to the Ground Operations Manager if loss of MCC systems insight and communication capability occurs. Handover will occur ASAP in order for normal postlanding operations to continue. If LCC monitoring capability is lost, systems monitoring will continue to be supported by the MCC until no longer needed (vehicle powerdown or restoration of LCC capability).

FLIGHT RULES

A16-8

CREW EGRESS METHOD DETERMINATION (FOR MODE V EGRESS)

THE CREW WILL DETERMINE WHICH OF THE FOLLOWING MODE V EGRESS METHODS WILL BE USED: @[041196-1881A]

- A. HATCH ON MODE V - CREW MANUALLY OPENS SIDE HATCH. WHENEVER POSSIBLE, THE CREW WILL USE THIS TECHNIQUE.
- B. HATCH JETTISON MODE V - CREW PYROTECHNICALLY JETTISONS THE SIDE HATCH. A CREW WILL USE THIS TECHNIQUE ONLY UNDER THE FOLLOWING CONDITIONS:
 1. INTOLERABLE CABIN CONDITIONS DUE TO FIRE, SMOKE, TOXIC GASSES, OR HIGH TEMPERATURES PRESENT IN THE CREW CABIN AND NOT READILY ELIMINATED BY OTHER ACTIONS.
 2. IMMINENT THREAT TO LIFE AND SAFETY OF THE CREW AS DETERMINED BY THE CDR.
- C. ESCAPE PANEL MODE V - CREW PYROTECHNICALLY JETTISONS THE WINDOW 8 ESCAPE PANEL. THIS TECHNIQUE WILL BE USED ONLY UNDER THE CIRCUMSTANCES LISTED FOR HATCH JETTISON IN PARAGRAPH B ABOVE, AND THEN HATCH JETTISON IS PREFERRED. ESCAPE PANEL MODE V WILL BE PERFORMED ONLY IF SITUATIONS REQUIRING IMMEDIATE EGRESS WHEN THE SIDE HATCH IS (1) BLOCKED, (2) JAMMED, (3) STRUCTURALLY DEFORMED, (4) OTHERWISE SUSPECTED OF BEING UNABLE TO BE JETTISONED, OR (5) WHEN GROUND PERSONNEL ARE IN THE HAZARD ZONE AROUND THE SIDE HATCH.

PYROTECHNIC JETTISON WILL NOT BE UTILIZED WHEN AN EXPLOSIVE/FLAMMABLE ATMOSPHERE IS PRESENT. THE CREW SHOULD MAKE EVERY POSSIBLE ATTEMPT TO COORDINATE WITH GROUND PERSONNEL BEFORE PYROTECHNIC JETTISON.

The crew is in the best position to determine the safest egress mode. If time allows, it is preferable to reposition the egress slide on the side hatch and then open the hatch normally and inflate the slide. This prevents further damage to the vehicle. If the crew is in immediate danger, the side hatch may be jettisoned. In the case of a slide failure, the crew can still egress out the side hatch using the sky genie descent devices.. An egress through the overhead escape panel (window W8) is slower and more inherently dangerous and, therefore, should not be performed unless egress through the side hatch is impossible.

The crew should attempt to notify the crash/rescue crew of their intentions either by orbiter A/G, PRC-112 survival radio (Channel A), or light signals per the Entry Checklist. @[041196-1881A]

FLIGHT RULES

A16-9

SSME REPOSITIONING CONSTRAINT

A. SSME REPOSITIONING WILL NOT BE ATTEMPTED UNDER ANY OF THE FOLLOWING CONDITIONS: @[031500-7180]

1. OI MDM OA1, DSC OA1, OR BOTH PCMMU'S FAILED.

The GPC's depend on SSME actuator position feedback information transmitted through OI MDM OA1 and the PCMMU's to properly reposition the SSME's. The SSME actuator position feedback transducers receive power through DSC OA1.

2. MULTIPLE AEROSURFACE POSITION FEEDBACK FAILURES RESULTING IN ERRONEOUS OPS-9 SELECTED POSITION. REPOSITIONING CAN BE PERFORMED IF COMMFAULTING ONE OF THE FAILED FEEDBACKS WILL PROVIDE A GOOD SELECTED POSITION.

The OPS 9 aerosurface position feedback selection filter utilizes a mid-value selection scheme among the first three feedbacks, and only downmodes to use the channel 4 feedback when one of the first three is commfaulted by powering off the associated FA MDM (further commfaults would result in averaging the two available feedbacks or using the one available feedback). Feedbacks failed by OPS 3 or 6 RM, or deselected manually by the crew, are still considered available. If two of the feedbacks among channels 1, 2, and 3 are failed, a bad feedback will be selected and the subsequent AI Mode1 command will set the commands equal to this erroneous value causing a large step input to the actuator command. By commfaulting one of these failed feedbacks, the selection filter will use the channel 4 feedback and output a good selected feedback. Nominal repositioning can continue with this FA MDM and associated FCS channel off. (The performance of OPS 9 repositioning software with commfaulted FA MDM's was verified in formal SAIL testing on September 28-30, 1998. This testing confirmed that the repositioning software will function properly with up to three FA MDM's commfaulted.)

3. TWO APU'S/HYDRAULICS SYSTEMS UNAVAILABLE.

The loss of two APU's/hydraulic systems (due to system failures or failed-closed MPS/TVC isolation valves) will keep one of the SSME's from being repositioned since each engine only has two hydraulic systems available as shown below:

Center engine: Hydraulic systems 1 and 3.

Right engine: Hydraulic systems 2 and 3.

Left engine: Hydraulic systems 1 and 2.

The inability to reposition one engine will cause the repositioning sequence to fail. @[031500-7180]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-9

SSME REPOSITIONING CONSTRAINT (CONTINUED)

4. BODY FLAP ANOMALY ("HOLD, CYCLE, FAIL") THAT CANNOT BE ISOLATED. @[031500-7180]

The failure of the body flap to move as commanded during entry, which causes the messages of HOLD, CYCLE, or FAIL to occur, signifies a problem in the body flap drive system (messages due to FCS channel reconfigurations do not apply). In cases where the body flap happens to be in the up position, a recontact of the body flap with the SSME's may occur when the repositioning sequence is activated. If the condition is due to a failed command channel, the bad channel can be isolated by turning off the corresponding FCS channel for a failed ASA command, or by shutting down the corresponding APU for a failed pilot valve.

5. THE DIFFERENCE BETWEEN ANY SSME ACTUATOR COMMAND (AVERAGE OF THE ACTIVE ATVC DRIVER OUTPUTS) AND THE INDICATED POSITION IS GREATER THAN 2.0 DEGREES.

Application of full hydraulic pressure to ATVC's, with a command-actual position difference of greater than 2 degrees, risks damage (possible rupture) to the hydraulic lines and subsequent loss of that hydraulic system. The average of the active ATVC driver outputs are used in the differencing scheme (as opposed to the software command) to eliminate the uncertainties in the command path. The 2.0-degree constraint takes into account the transducer uncertainty (ref. SODB 3.4.5.1.h.1).

When the post-landing repositioning sequence is started, the MDM commands are first set equal to the indicated position feedbacks (AI mode 1). If an engine actuator position measurement is in error, the resulting Mode 1 command will likewise be in error by the same amount, resulting in a step change in position if the isolation valves are open. Should this step exceed 2.0 degrees, the possibility of rupturing hydraulic lines exists. Even if the hydraulic lines are not ruptured, the command/position delta (if caused by transducer failure) may result in an error code 103 being generated and displayed on SPEC 105 which in turn will prevent any further repositioning of the SSME's.

6. BFS ENGAGED

The BFS cannot perform SSME repositioning (ref. Rule {A16-5}, MEMORY RECONFIGURATION CONSTRAINT).

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-9 SSME REPOSITIONING CONSTRAINT (CONTINUED)

- B. IF SSME REPOSITIONING CANNOT BE PERFORMED, THE SPEEDBRAKE AND BODY FLAP WILL BE REPOSITIONED PROVIDED THE LANDING IS AT KSC AND THE SSME'S ARE IN THE CHUTE STOW POSITION.

The primary benefit of SSME repositioning is that it allows GSE access for the main engine turbopump bearing purges. To prevent a significant turnaround impact, these purges must begin within 48 hours of landing. Provided the landing is at KSC and the SSME's are in the drag chute stow position, adequate access for the purges is achieved by positioning only the body flap and speedbrake. In this case, the body flap is manually positioned full down, prior to the OPS 9 transition. For OI-28 and subsequent flights, fully closing (position of 15 percent) the speedbrake prior to the OPS 9 transition will provide adequate clearance for GSE in the OPF. For OI-27, a software K-load will not allow the speedbrake to be sufficiently closed prior to OPS 9. Therefore, the speedbrake must be closed using OPS 9 software and SPEC 113. If the landing is at a site other than KSC, or the SSME's are not in the drag chute stow position at touchdown, then full SSME repositioning is required to gain access for the turbopump purges. @[031500-7180]

A16-10 NORMAL POSTLANDING OPERATIONS

NORMAL POSTLANDING OPERATIONS WILL BE CONTINUED EXCEPT FOR THE FOLLOWING CONDITIONS:

- A. LIGHTNING WITHIN 5 MILES.

The KSC Ground Operations Safety Plan (GP-1098E) requires that all operations be terminated for lightning within 5 miles. However, if orbiter tow operations are underway, towing may continue if all personnel on foot enter a covered vehicle.

- B. LIQUID LEAKS, HYPERGOLIC VENTING, OR HAZARDOUS MATERIALS TOXICITY ABOVE ALLOWABLE LIMITS (REF. RULE {A16-301}, CONTAMINATION/FLAMMABILITY/TOXICITY).
- C. MMH, N₂O₄, OR HYDRAZINE CONCENTRATIONS WITHIN THE POD/AFT COMPARTMENT. (FOR MMH OR HYDRAZINE, REF. RULE {A16-11C}, EXPEDITED POWERDOWN.) (FOR N₂O₄, REF. RULE {A16-204}, WINDWARD APU OPERATION CONSTRAINT.)
- D. LOSS OF COMMUNICATION/SYSTEMS MONITORING CAPABILITY (REF. RULE {A16-11}, EXPEDITED POWERDOWN).
- E. ORBITER CONDITIONS REQUIRING EXPEDITED/EMERGENCY POWERDOWN (REF. RULE {A16-12}, EMERGENCY POWERDOWN).

FLIGHT RULES

A16-11

EXPEDITED POWERDOWN

AN EXPEDITED POWERDOWN IS DEFINED TO ALLOW ACCOMPLISHMENT OF ET DOOR OPENING (RTLIS/TAL ONLY), OMS/RCS-SAFING, NOMINAL GPC POWERDOWN FOLLOWED IMMEDIATELY BY AN EMERGENCY POWERDOWN. ©[012402-5079]

AN EXPEDITED POWERDOWN AND MODE V CREW EGRESS WILL BE ACCOMPLISHED FOR:

- A. LOSS OF ALL COMMUNICATIONS (INCLUDING VISUAL SIGNALS AND MCC RELAY) BETWEEN CREW AND CONVOY ELEMENTS.

NOTE: RULE {A16-8}, CREW EGRESS METHOD DETERMINATION (FOR MODE V EGRESS) GOVERNS THE MODE V EGRESS METHOD THE CREW WILL USE. ©[041196-1881A]

Crew safety could be compromised with the loss of communication between the crew and convoy personnel. Possible orbiter problems that occur during landing and rollout not reflected in orbiter systems would not be available to the crew (i.e., tire fire, explosive/flammable conditions, etc.).

- B. LOSS OF ALL TELEMETRY (MCC AND LCC) AND ONBOARD SYSTEMS MONITORING (BFS, C&W PANEL, AND FDA) VISIBILITY. IF COMM IS AVAILABLE TO CREW, MCC WILL DETERMINE IF MODE V IS REQUIRED.

As long as insight into critical vehicle systems and communication with the crew are maintained, normal postlanding operations can continue. Critical systems information is available at KSC (LCC) that allows the LCC to be an acceptable source for orbiter systems monitoring.

- C. A NONISOLATABLE OMS, RCS, OR APU FUEL LEAK OR FOR AN ISOLATED LEAK WHEN THERE HAS BEEN INSUFFICIENT TIME FOR FUEL SUBLIMATION (RTLIS, TAL, AOA, OR POST-DEORBIT IGNITION). FOR THESE CASES, A MODE V CREW EGRESS WILL BE IMPLEMENTED. RCS JET LEAKS AND APU SEAL CAVITY DRAIN LEAKS ARE EXEMPTED FROM THIS CATEGORY.

Leaking OMS, RCS, or APU fuel poses a toxicity and fire hazard. An expedited powerdown should be performed in order to minimize the danger to the flightcrew and ground operations personnel. If a fuel leak occurs and is isolated during an RTLIS, TAL, AOA, or post-deorbit ignition, there is insufficient time for the fuel to sublimate, and an expedited powerdown is prudent.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-11

EXPEDITED POWERDOWN (CONTINUED)

An isolated RCS jet leak does not pose a risk to the orbiter/crew with continued postlanding operations. In the event of an APU fuel pump seal failure, the APU seal cavity drain dumps hydrazine overboard. Once the APU is shut down, the leak is isolated.

Rules {A16-10C} and D, NORMAL POSTLANDING OPERATIONS, and {A6-206}, RCS MANIFOLD/LEG LEAK PRESSURIZATION, reference this rule. ©[ED]

D. A CONFIRMED OR SUSPECTED FIRE FOR WHICH A FIRE SUPPRESSION BOTTLE HAS BEEN DISCHARGED DURING ENTRY.

Vehicle damage can pose hazards to crew safety after a fire is extinguished, especially if its location is unknown. Wires melted together could cause any number of hazards (e.g., inadvertent GPC commanding causing fuel valves to open, etc.). In addition, if the fire occurred in an avionics bay several hours (minutes for a cabin fire) before landing, the crew should exit the vehicle to avoid breathing Halon and toxic combustion byproducts which slowly leak out of the avionics bay and panels.

E. A NON-ISOLATABLE H₂ LEAK GREATER THAN 6.5 LB/HR (5.5 LB/HR FOR SPACELAB/PAYLOAD RETURN).

Leaking H₂ poses a possible fire hazard in the midbody. An H₂ concentration of 4 percent represents the lower ignitable limit of H₂ (deflagrates or burns rapidly).

Rule {A16-205F}, EARLY APU SHUTDOWN, references this rule. ©[072398-6577]

Normally, KSC is prime for recommending an expedited powerdown/crew egress based on detected H₂ concentrations. For known H₂ leaks prior to touchdown, this rule identifies the H₂ leak rate criteria to be used by MCC in determining whether an expedited powerdown/crew egress should be performed prior to KSC assessment (i.e., for large leaks). These leak rates are based on a 4 percent concentration 35 minutes after wheels stop.

For leak rates below 6.5 (5.5) lb/hr, KSC is prime for determining whether or not an expedited powerdown is required, based on actual detection of H₂. The MCC H₂ leak rate prediction is based on the initial size of the leak once detected, a homogenous mixing in the midbody, and no consideration for venting or leakage of H₂ from the midbody at wheel stop.

DOCUMENTATION: ECLS Console Handbook, SCP 4.6.2, and KSC OMI S0026, Revision L.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-11

EXPEDITED POWERDOWN (CONTINUED)

- F. AN INCOMPLETE MPS LH₂ DUMP (NEGATIVE INERT) OR FAILURE TO PRESSURIZE THE MPS LH₂ MANIFOLD ABOVE ATMOSPHERIC PRESSURE ON AN RTLS OR TAL ABORT. ©[012402-5079]

Failure(s) in the MPS LH₂ system during the MPS dump and inert will result in an incomplete LH₂ dump (negative inert) on RTLS and TAL aborts. Analysis (reference Rockwell Internal Letter no. 287-100-94-186 dated October 12, 1994) has shown that the loss of a dump path or the loss of helium pressurization (during the MPS dump) will trap between approximately 0.8 to 40.8 pounds of LH₂ residuals in the MPS LH₂ manifold depending on the specific scenario. Loss of a dump path may be caused by failure of one of the following LH₂ valves: outboard or inboard fill/drain valve, backup dump valves, topping valve, pre valve, or SSME fuel bleed valve. Loss of helium pressurization may be caused by numerous reasons such as: relief isolation valve fails closed, relief valve fails open, inboard fill/drain fails open, clogged orifice, etc. In these failure cases, concern exists for crew and convoy safety because analysis (reference Boeing Internal Letter SHA0-01-043 dated April 26, 2001) predicts the MPS LH₂ manifold will exceed its relief setting and venting of hydrogen residuals (potentially explosive mixture) will occur as early as 10.8 minutes after touchdown. In addition, nominal leakage in the MPS system could lead to the buildup of an explosive mixture of hydrogen in or around the aft compartment.

©[012402-5079]

After discussion at the Ascent/Entry Flight Techniques Panel (AEFTP #168 on October 27, 2000) and subsequent discussions with KSC ground operations and KSC safety, it was decided that the appropriate action for MPS dump failures on RTLS and TAL aborts is to perform an expedited powerdown. Rationale for this decision is based on the potential hazard to the flight crew and ground personnel due to uncertainties in the hazards of the trapped hydrogen residuals. Although, residuals due to a failure in the MPS system on a TAL abort can be lower than the residuals on a nominal RTLS abort, an expedited powerdown will still be performed on the TAL because of the limited ground operations equipment available to assess and manage the situation at the TAL site. Expedited powerdown actions are not required for AOA aborts or nominal missions because sufficient time exists on orbit to fully inert the MPS LH₂ manifold of all LH₂ residuals.

©[012402-5079]

After discussion at the AEFTP Meeting (AEFTP #168 on October 27, 2000) and subsequent discussions with KSC ground operations and KSC safety, it was also decided that the failure to pressurize the MPS LH₂ manifold above atmospheric pressure on RTLS and TAL aborts would result in the ingestion of air into the LH₂ manifold resulting in the creation of an explosive mixture (reference Boeing Internal Letter SHA0-01-043 dated April 26, 2001). The hazards of an explosive mixture in the MPS manifold that the flight crew and ground operations personnel would be exposed to are difficult to quantify. However, these hazards represent an unnecessary risk, and, therefore, this scenario warrants an expedited powerdown.

Rules {A5-210}, ENTRY MPS PROPELLANT DUMP FAILURES, {A5-201}, MPS DUMP INHIBIT [CIL], and {A5-209}, ENTRY MPS HELIUM PURGING FOR CRITICAL VEHICLE POWER/COOLING, reference this rule. ©[030994-1604B] ©[030994-1617] ©[090894-1730A] ©[012402-5079]

©[ED]

FLIGHT RULES

A16-12

EMERGENCY POWERDOWN

AN EMERGENCY POWERDOWN WILL BE IMPLEMENTED POST-ROLLOUT FOR THE FOLLOWING CONDITIONS OR AS REQUESTED BY THE FLIGHT DIRECTOR OR CONVOY COMMANDER :

An emergency powerdown will be performed if Orbiter systems cannot support continued operations or if orbiter conditions compromise crew safety. The normal egress mode is preferred if allowed by system conditions. Loss of cooling will allow an orderly egress to continue.

If conditions exist that compromise crew safety (fire, smoke, explosive conditions, etc.), a MODE V egress is warranted. Based on knowledge of Orbiter conditions and systems indications, the Flight Director and Convoy Commander are able to recognize problems and recommend the appropriate action/egress mode.

A. NORMAL EGRESS (SIDE HATCH, CONVOY CREW ASSIST) :

1. LOSS OF BOTH FREON COOLANT LOOPS.

If both loops are lost, the emergency powerdown is required because there is absolutely no cooling of the vehicle. The fuel cell stack temperature will reach the specification limit of 250 degrees F within approximately 50 minutes. In addition, the electrolyte concentration will reach the 25 percent operational limit in approximately 75 minutes. At this point, continued operation of the fuel cells is questionable. This assumes a simultaneous purge of all three fuel cells and a 12.54 kWh (4.18 kWh/fuel cell) power level. If the failure occurred on orbit, the situation would be time-critical postlanding. Purging H₂ into the atmosphere should be avoided if at all possible (ref. Rule {A16-301}, CONTAMINATION/ FLAMMABILITY/TOXICITY). Without the purge, the fuel cells will flood in approximately 18 minutes based on an 8.0 kWh (2.67 kWh/fuel cell) power level (ref. Rules {A2-54}, RTLS, TAL, AND AOA ABORTS FOR SYSTEMS FAILURES [CIL]; and {A2-205}, EMERGENCY DEORBIT). Upon completion of the emergency powerdown, a normal crew egress can be performed.

DOCUMENTATION: Dual Freon Loop Failure Entry Analysis, Rockwell International IL 388-301-79-018, and SODB table 3.4.4.1-1.

2. LOSS OF BOTH H₂O COOLANT LOOPS.

If both loops are lost, the emergency powerdown is required because there is no cooling to water and air cooled equipment in the cabin. If the failure occurred on orbit, avionics equipment and GPC's would be cycled to their thermal limits in order to maintain as much redundancy as possible during critical mission phases. Since this failure scenario does not contain any hazard to the crew, an orderly, normal egress can be accomplished.

DOCUMENTATION: MDTSCO analysis 1.1-ECLSS-09, Dual Water Coolant Loop Failed Entry Contingency.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-12

EMERGENCY POWERDOWN (CONTINUED)

3. LOSS OF BOTH NH₃ SYSTEMS WHEN CRITICAL TEMPERATURES ARE (RULE {A16-51}, NO GROUND COOLING/EARLY VEHICLE POWER TERMINATION) EXCEEDED.

Postlanding, orbiter cooling is provided by the heat sink capacity remaining from the on-orbit radiator coldsoak, the NH₃ system, and the ground-cooling cart. In the event that the ground-cooling cart is not available, NH₃ must supply the cooling once the radiator coldsoak has been used. Therefore, subsequent loss of both NH₃ systems will eventually lead to loss of all vehicle cooling, and loss of all vehicle cooling has the same result as described in the loss of both Freon loops in paragraph A.1.

DOCUMENTATION: Engineering judgment.

B. MODE V EGRESS:

1. WHEEL WELL FIRE OR BRAKE FIRE THAT POTENTIALLY WILL PROPAGATE TO THE WHEEL WELL. EGRESS WILL BE BASED ON CONVOY COMMANDER RECOMMENDATION.
2. EXPLOSIVE/FLAMMABLE CONDITIONS (REF. RULE {A16-301}, CONTAMINATION/FLAMMABILITY/TOXICITY).
3. SMOKE, FIRE, OR OBVIOUS STRUCTURAL DAMAGE.
4. INTOLERABLE CABIN CONDITIONS.

NOTE: RULE {A16-8}, CREW EGRESS METHOD DETERMINATION (FOR MODE V EGRESS) GOVERNS THE MODE V EGRESS METHOD THE CREW WILL USE. @[041196-1881A]

It is preferable to perform a normal egress. However, if cabin conditions warrant, a MODE V egress may be performed. An emergency powerdown should be implemented for the conditions listed in paragraph B1, 2, 3 above in order to eliminate electrical ignition/isolate volatile propellant sources that could make the vehicle anomalous condition worse. A confirmed MPS LH₂ leak is considered to be an explosive/flammable condition (ref. rule {A5-201}, MPS DUMP INHIBIT [CIL]). @[030994-1604B]
 @[ED]

DOCUMENTATION: Engineering judgment.

Rule {A16-10E}, NORMAL POSTLANDING OPERATIONS, references this rule.

FLIGHT RULES

A16-13

SIDE HATCH OPENING CONSTRAINT

IF CABIN PRESSURE EXCEEDS LANDING SITE ATMOSPHERIC PRESSURE BY MORE THAN 3.2 PSID, THEN THE CABIN VENT VALVES WILL BE USED TO DEPRESSURIZE THE CABIN TO BRING THE PRESSURE DIFFERENTIAL BELOW 3.2 PSID BEFORE ATTEMPTING TO OPEN THE SIDE HATCH.

An unisolatable leak into the cabin could result in cabin pressure being as much as 16 psid greater than landing site atmosphere pressure (the cabin relief valves relieve at 16 psid). Rockwell International has verified side hatch structural capability to vent excess cabin pressure postlanding only as high as 3.2 psid. The 3.2 psid pressure differential was selected for verification because it is the maximum expected to be encountered at the highest altitude landing site (White Sands) under normal cabin pressure conditions.

DOCUMENTATION: Side Hatch Structural Capability to Release Cabin Pressure Following Rollout, Rockwell International Internal Letter No. 280-106-82-016, May 7, 1983.

A16-14 THROUGH A16-50 RULES ARE RESERVED

FLIGHT RULES

COOLING

A16-51 **NO GROUND COOLING/EARLY VEHICLE POWER TERMINATION**

POSTLANDING LOSS OF COOLING WILL BE DEFINED AS FOLLOWS: @[012694-1599]

- A. IF MCC VOICE AND TELEMETRY ARE AVAILABLE, COOLING WILL BE DECLARED LOST AND AN EMERGENCY POWERDOWN PERFORMED WHEN ANY OF THE FOLLOWING CONDITIONS OCCUR:
1. FUEL CELL COOLANT RETURN TEMP > 140 DEGREES (135 DEGREES) F OR LOCAL FUEL CELL KOH < 24 PERCENT (29 PERCENT)
 2. AVIONICS BAY AIR OUTLET TEMP EXCEEDS THE FOLLOWING LIMITS PRIOR TO ENT C/L "LRU DEACT":
 - a. AVIONICS BAY 1 OR 2 AIR OUTLET TEMP > 133 DEGREES (128 DEGREES) F
 - b. AVIONICS BAY 3 AIR OUTLET TEMP > 117 DEGREES (112 DEGREES) F
 3. AVIONICS BAY AIR OUTLET TEMP EXCEEDS THE FOLLOWING LIMITS POST ENT C/L "LRU DEACT":
 - a. AVIONICS BAY 1 OR 2 AIR OUTLET TEMP > 113 DEGREES (108 DEGREES) F
 - b. AVIONICS BAY 3 AIR OUTLET TEMP > 107 DEGREES (102 DEGREES) F
 4. CABIN TEMPERATURE > 95 DEGREES (90 DEGREES) F
 5. MIDBODY COLDPLATE OUTLET TEMP > 115 DEGREES (110 DEGREES) F
 6. AFT COLDPLATE OUTLET TEMP > 112 DEGREES (107 DEGREES) F

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-51

NO GROUND COOLING/EARLY VEHICLE POWER TERMINATION (CONTINUED)

The FCP coolant return temp is a direct indication of the status of the FCP cooling capability. Inadequate cooling of the fuel cell may result in fuel cell KOH concentrations < 24 percent, which indicate a wet fuel cell and impending fuel cell flooding.

Avionics bay temperatures above the listed limits indicate LRU outlet temperature > 130 degrees F limit. Cabin temperatures above 95 degrees F will cause overtemp conditions for flight deck avionics. The limits listed above will not result in hardware damage or certification violation if an emergency powerdown is executed when the limit is reached. @[012694-1599]

- B. FOR LOSS OF MCC VOICE OR TELEMETRY, AN EMERGENCY POWERDOWN PERFORMED WHEN ANY OF THE FOLLOWING CONDITIONS OCCUR: @[012694-1599]
1. FUEL CELL CONDENSER EXIT TEMP > 164 DEGREES F
 2. AVIONICS BAY AIR OUTLET TEMP EXCEEDS THE FOLLOWING LIMITS PRIOR TO ENT C/L "LRU DEACT" :
 - a. AVIONICS BAY 1 OR 2 AIR OUTLET TEMP > 133 DEGREES (128 DEGREES) F
 - b. AVIONICS BAY 3 AIR OUTLET TEMP > 117 DEGREES (112 DEGREES) F
 3. AVIONICS BAY AIR OUTLET TEMP EXCEEDS THE FOLLOWING LIMITS POST ENT C/L "LRU DEACT" :
 - a. AVIONICS BAY 1 OR 2 AIR OUTLET TEMP > 113 DEGREES (108 DEGREES) F
 - b. AVIONICS BAY 3 AIR OUTLET TEMP > 107 DEGREES (102 DEGREES) F

Postlanding cooling tests performed after STS-58 indicate that loss of the 508 GSE cooling cart will not result in violations of the above limits if the radiators are flowing, and PLB purge air is available. The purge air for this test was controlled to approximately 45 degrees F. If PLB purge is not available, or is insufficient, an emergency powerdown should be implemented when the appropriate thermal limit is violated.

DOCUMENTATION: MACDAC 1.1 ECLSS 122 and SODB 3.4.4.1.11, page 3.4.4.1-3, engineering judgment, and STS-58 Post Mission report.

Rule {A16-12A}.3, EMERGENCY POWERDOWN, references this rule. @[012694-1599]

FLIGHT RULES

A16-52 **EXTENDED COOLING**

ORBITER COOLING MAY BE EXTENDED AS FOLLOWS:

- A. MAINTAIN RADIATOR FLOW.
- B. POWERDOWN AS QUICKLY AS POSSIBLE PER THE NORMAL POST-ROLLOUT PROCEDURES (DEPENDING ON LANDING SITE AND OTHER FAILURE SITUATIONS).

It is highly desirable to hand over the vehicle in a powered condition in order to expedite turnaround operations. Crew requirements or vehicle systems management may dictate a need to operate the vehicle for a greater than normal amount of time without ground cooling.

DOCUMENTATION: Engineering judgment.

A16-53 **FREON LOOP CONFIGURATION**

THE FPV IN BOTH FREON LOOPS WILL BE PLACED TO THE "ICH" POSITION IF BOTH THE EVAPORATOR OUTLET TEMPERATURES ARE LESS THAN 32 DEGREES (34.4 DEGREES) F. IF THE PAYLOAD LOOP DOES NOT CONTAIN WATER, A REAL-TIME CALL WILL BE MADE TO PLACE BOTH FPV'S TO THE "P/L" POSITION.

Provided that both orbiter water loops and a payload water loop (if installed) are flowing, the ICH position provides orbiter water loop freeze protection for Freon temperatures as low as 6 degrees F and payload water loop protection for Freon temperatures as low as -30 degrees F (extrapolated). If left in the P/L position, the payload water loop would freeze at a Freon temperature of 32 degrees F and the orbiter water loops at -30 degrees F (extrapolated) Freon temperature. For payload flow rates < 150 lb/hr, the P/L water loop will freeze eventually, but is delayed if the FPV is placed in the ICH position.

DOCUMENTATION: Lockheed analysis, LEMSCO 19630.

FLIGHT RULES

A16-54

AMMONIA BOILER MANAGEMENT

THE AMMONIA BOILER WILL BE ACTIVATED WHEN THE FLASH EVAPORATOR OUTLET TEMPERATURE > 55 DEGREES F.

The standard orbiter entry cooling configuration is to utilize radiator heat sink capacity (cold soak) from 160k feet altitude until depletion. Normally this occurs post-rollout. At that time the ammonia boiler is activated to maintain thermal control. Upon ammonia activation, specification leakage past the primary control valves will result in ammonia boiler outlet temperatures dropping 17 degrees F. Delaying ammonia activation until flash evaporator outlet temperatures are greater than 55 degrees F protects downstream H₂O loop components from freezing.

DOCUMENTATION: Engineering judgment. SODB, volume 1, 4.6.3.11.2.b.6 and c.3

A16-55 THROUGH A16-100 RULES ARE RESERVED

FLIGHT RULES

ET UMBILICAL DOOR

A16-101 ET UMBILICAL DOOR POSITIONING

- A. FAILURE TO OPEN THE ET UMBILICAL DOOR WILL REQUIRE NO CHANGE TO NORMAL POSTLANDING PROCEDURES.

For normal postlanding, the ET doors are opened by the flightcrew to facilitate ground handling at KSC, EAFB, and NOR. If the doors cannot be opened by the crew, ground turnaround time of the vehicle will be extended somewhat. There are no safety concerns if this cannot be done.

- B. THE ET DOORS MUST BE OPENED ASAP POSTLANDING FOR TAL OR RTLS. FOR NORMAL EOM, AOA, OR CLS, THEY MUST BE OPENED ASAP IF THERE IS EVIDENCE OF POTENTIAL FOR H₂ BUILDUP.

Hydrogen poses an explosion hazard. Opening the ET doors as soon as possible after wheel stop will help to vent the trapped hydrogen into the atmosphere.

- C. WHEN OPENING IS REQUIRED, THE ET DOORS WILL BE DRIVEN TO THE POSTLANDING POSITION OF 110 + 30 DEGREES. THERE IS NO CONSTRAINT ON OPENING THE ET DOORS POSTLANDING FOR BLOWING DUST OR SAND.

The postlanding ET door position of 110 ± 30 degrees takes into consideration allowable tolerances for wind loads on door mechanism (stationary vehicle or while being towed) and tolerances on clearance for mounting the GSE jacks when used to prepare the vehicle for transport on the Shuttle carrier aircraft. It has been established that the doors can be opened regardless of blowing sand or dust (ref. Ascent/Entry Flight Techniques #5, 7/27/83).

A16-102 THROUGH A16-200 RULES ARE RESERVED

FLIGHT RULES

VENT DOORS

A16-151 **VENT DOOR POSITIONING**

- A. VENT DOOR POSITIONING IS NOT A CONSTRAINT TO NORMAL POSTLANDING OPERATIONS (REGARDLESS OF BLOWING SAND OR DUST).

KSC prefers to have the vent doors configured to the purge position (midbody vents closed; forward and aft vents in purge) in order to expedite vehicle turnaround time. However, if this cannot be accomplished, having the doors open, as is the case when the vehicle lands, all doors open is considered to be a safe configuration (hazardous gas buildup prevention). Hazardous gas protection is of higher priority than blowing sand or dust protection. Other normal crew-initiated postlanding procedures can continue since the procedures are unaffected by the position of the vent doors.

- B. IF PURGING CAN BE ACCOMPLISHED, THE VENT DOORS WILL BE CONFIGURED AS FOLLOWS:
1. ALL MIDBODY VENT DOORS CLOSED.
 2. ALL FORWARD AND AFT VENT DOORS IN THE PURGE POSITION.

These are the desired positions of the vent doors for vehicle purging.

- C. IF PURGING CANNOT BE ACCOMPLISHED OR IS LOST AFTER INITIATION, THE PREFERRED VENT DOOR POSITION IS OPEN (REGARDLESS OF BLOWING SAND OR DUST).

Reference rule rationale for paragraph A.

A16-152 THROUGH A16-200 RULES ARE RESERVED

FLIGHT RULES

APU/HYDRAULIC

A16-201**HYDRAULIC CIRCULATION PUMP OPERATION**

- A. FOLLOWING APU SHUTDOWN, HYDRAULIC CIRCULATION PUMPS WILL BE OPERATED IF ANY OF THE FOLLOWING BONDLINE TEMPERATURES EXCEED 245 DEGREES F UNTIL THE HYDRAULIC RETURN LINE TEMPERATURES HAVE PEAKED AND BEGUN TO DECREASE. LOSS OF ONE OR MORE OF THESE PUMPS WILL NOT CONSTRAIN NORMAL POSTLANDING OPERATIONS. SHOULD POWER PROBLEMS DICTATE, CIRCULATION PUMPS MAY BE OPERATED ONE AT A TIME IN 5-MINUTE INTERVALS; OTHERWISE, ALL THREE WILL BE OPERATED SIMULTANEOUSLY (MCC CALL):

V09T1006A LIB ELVN LWR BL Y-235 T (OV-102 ONLY).
 V09T1026A BODY FLAP LWR CL BL T (OV-102 ONLY).
 V09T1002A LWR L WING BL X 1278, Y-240 T.
 V09T1702A AFT FUS LWR CL BL T.
 V09T1004A TOP R WING BL X 1278, Y 240 T.
 V09T1624A CAB CL BL LWR X 560 T.

When vehicle bondline temperatures have exceeded 245 degrees F, heat soakback would cause temperatures to rise in the hydraulic fluid to the point where seals would degrade resulting in fluid leakage. Turning on the circulation pumps will help transport hotter fluid to cooler areas, thus reducing the chances of seal degradation.

If bus power problems arise such that it is desirable not to run all three circulation pumps at once, then each pump can be run at 5-minute intervals.

- B. MPS HELIUM WILL BE PROVIDED TO AN ENGINE PRIOR TO HYDRAULIC CIRCULATION PUMP OPERATION POSTLANDING IF THE ASSOCIATED MPS/TVC ISOLATION VALVE IS OPEN.

Maintaining helium pressure on the closed side of the engine valves will insure that the valves do not drift open when hydraulic circulation pump pressure is applied to the TVC actuators. Keeping the engine valves closed prevents engine contamination and reduces the number of helium regulator cycles.

©[072795-1786]

FLIGHT RULES

A16-202

APU REQUIREMENTS

POSTLANDING ACTIVITIES WITH APU'S OPERATING, IN ORDER OF PRIORITY, ARE:

- A. BODY FLAP REPOSITIONING (OPS 3). @[012402-5090A]
- B. SSME REPOSITIONING (OPS 9, PASS).
- C. SPEED BRAKE REPOSITIONING (OPS 9, PASS).
- D. HYDRAULIC LOAD TEST (OPS 3).

Body flap repositioning (full down) must be performed, in OPS 3, in preparation for a potential SSME repositioning failure. Even if SSME repositioning is NO-GO, this measure can help reduce the cost of turnaround operations and is desirable. SSME repositioning, available in PASS OPS 9, is required every flight to position the engines for ferry operations (Edwards/ Northrup) and to prevent rain from entering into the nozzle, possibly damaging engine components. In the event SSME repositioning is not accomplished and landing occurred at KSC, the speedbrake must be repositioned (in PASS OPS 9) in order to expedite and reduce the cost of turnaround operations. The hydraulic load test is performed in OPS 3 to test the capability of the APU's after the fifth flight of a particular APU. However, the load test can be rescheduled to another flight and is not critical to postlanding operations. @[012402-5090A]

A16-203

APU/HYDRAULIC LOAD TEST TERMINATION

AN APU/HYDRAULIC LOAD TEST WILL BE TERMINATED FOR ANY OF THE FOLLOWING:

- A. ANY PROBLEM REQUIRING AN EXPEDITED OR EMERGENCY POWERDOWN.
- B. INSUFFICIENT CONSUMABLES.
- C. INABILITY TO OBTAIN DATA (REAL TIME OR RECORDED).
- D. LESS THAN TWO GOOD APU/HYDRAULIC SYSTEMS.

The APU/hydraulic load test is conducted to gather data on APU catalyst bed roughness; i.e., the efficiency of fuel decomposition and hydraulic system main pump performance degradation. The test entails manually cycling the elevons, rudder, and body flap with hydraulic system 1 depressed and then system 2 depressed. The duration of motion is about 80 seconds. For the cases listed above, the load test should be terminated since the data being obtained is not critical and can be obtained during postlanding of a later flight.

FLIGHT RULES

A16-204

WINDWARD APU OPERATION CONSTRAINT

TO AVOID EXCEEDING VERTICAL TAIL STRUCTURAL TEMPERATURE LIMITS, THE WINDWARD APU(S) WILL NOT BE OPERATED LONGER THAN THE ALLOWABLE POSTLANDING APU RUN TIME, OBTAINED FROM THE POSTLANDING OPERATIONS PLOT.

If the postlanding run time exceeds the allowable run time, vertical tail overtemperature and subsequent structural damage can occur if the APU plume has ignited. There are no constraints to run time if the APU plume has not ignited; however, due to the difficulty in visually determining whether the plume is burning or not, the worst case is assumed.

Reference SPDB 3.2.1.1.

FLIGHT RULES

A16-205

EARLY APU SHUTDOWN

AN APU (OR APU'S) WILL BE SHUTDOWN ASAP POST-WHEEL STOP:

- A. IF A FUEL OR OXIDIZER LEAK IS SUSPECTED OR DETECTED IN THE MPS, OMS, RCS, OR ANY APU, EVEN IF THE LEAKS HAVE BEEN ISOLATED (DOES NOT APPLY FOR RCS JET LEAKS). ©[030994-1604B]

The requirements for APU operations postlanding, SSME repositioning, and hydraulic load test are not considered mandatory. In cases where fuel or oxidizer leaks are suspected or detected, the APU's should be shut down ASAP to reduce chances of the leak developing into a greater flammability hazard, brought on by the operation of hot, rotating machinery. Note that an APU fuel tank N₂ leak is considered a fuel leak.

APU's will not be shut down early for RCS jet leaks since these types of leaks are isolated and external to the orbiter. No flammability hazard exists for continued APU operations with known RCS jet leaks.

Rules {A5-201}, MPS DUMP INHIBIT [CIL], and {A6-206}, RCS MANIFOLD/LEG LEAK PRESSURIZATION, reference this rule. ©[030994-1604B] ©[ED]

- B. IF A FIRE IS OBSERVED IN A WHEEL WELL OR TIRE/BRAKE AREA. THE HYDRAULIC LANDING GEAR EXTEND AND BRAKE ISOLATION VALVES WILL BE CLOSED PRIOR TO SHUTTING DOWN THE APU'S.

A fire in the wheel well or landing gear area could involve hydraulic fluid. Closing the landing gear isolation valves will isolate the fluid from the gear area, thus preventing any further feeding of the fire. The APU's should be shut down in an effort to reduce high-pressure flow of hydraulic fluid to the gear area should an isolation valve fail to close.

- C. IF THERE IS A NON-ISOLATABLE LEAK IN ITS ASSOCIATED HYDRAULIC SYSTEM.

The APU should be shut down postlanding to minimize hydraulic leakage into the aft compartment. Postlanding operations requiring hydraulic power are not mandatory and can be performed if there are two remaining good systems.

- D. IF THE APU SHIFTS TO HIGH SPEED WITH NORMAL SPEED SELECTED.

The APU should be shut down postlanding to protect against a possible uncontained overspeed. Postlanding operations requiring the APU's are not mandatory and can be performed if there are two remaining good systems.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A16-205 EARLY APU SHUTDOWN (CONTINUED)

E. FOR INSUFFICIENT LUBE OIL OR HYDRAULIC COOLING.

The APU should be shut down postlanding to minimize bearing and gear wear due to degraded lubrication capability. Postlanding operations requiring the APU's are not mandatory and can be performed if there are two remaining good systems.

F. FOR A NON-ISOLATABLE H₂ LEAK GREATER THAN 6.5 LB/HR (5.5 LB/HR FOR SPACELAB/PAYLOAD RETURN). ©[072398-6577]

Leaking H₂ poses a possible fire hazard in the orbiter midbody. The leaking H₂ is lighter than air and may escape from the payload bay at the payload bay door (PLBD) aft bulkhead interface and from where payload bay doors interface along the centerline. Pressure seals are located at the PLBD/bulkhead interface as well as along the PLBD centerline. However, the integrity of the pressure seals to contain H₂ is unknown. The APU exhaust ducts are located at the base of the vertical tail and are in close proximity to the aft bulkhead/PLBD interface. The APU exhaust plume is assumed to be ignited, which could provide an ignition source for the H₂ in the payload bay.

Reference rule {A16-11E}, EXPEDITED POWERDOWN. ©[072398-6577]

A16-206 THROUGH A16-250 RULES ARE RESERVED

FLIGHT RULES

FUEL CELLS

A16-251 **FUEL CELL LIFETIME**

FUEL CELL LIFETIME CONSIDERATION WILL NOT BE A CONSTRAINT DURING POSTLANDING OPERATIONS THROUGH CREW EGRESS.

Fuel cell lifetime concerns will not preclude normal postlanding operations through crew egress because of the desire to perform nominal postlanding procedures. The additional time impact to fuel cell lifetime from touchdown through crew egress is insignificant.

A16-252 THROUGH A16-300 RULES ARE RESERVED

FLIGHT RULES

CONTAMINATION/FLAMMABILITY

A16-301 **CONTAMINATION/FLAMMABILITY/TOXICITY**

- A. THE CONVOY COMMANDER WILL NOTIFY THE FLIGHT DIRECTOR OF ANY EXPLOSIVE, FLAMMABLE, AND/OR TOXIC CONDITIONS THAT EXIST THAT PRECLUDE/DELAY NORMAL CREW EGRESS OPERATIONS.

- B. FOR EXTERNAL LEAKS OR HYPERGOLIC VENTING WHERE CONTAMINATION IS SUSPECT BUT BELOW MAXIMUM ALLOWABLE LIMITS, NORMAL POSTLANDING/CREW EGRESS OPERATIONS WILL BE CONTINUED.

Reference the postlanding Operational Maintenance Instructions (OMI) for contamination/flammability/toxicity limits. Convoy personnel are primarily responsible for the detection of hazardous substances that may preclude normal crew egress operations. Notification of explosive/ toxic limit violation is consistent with the Flight Director's responsibility to ensure adequate vehicle safing and allow normal crew egress. Postlanding operations will continue as long as hazardous substance concentrations are within acceptable limits (i.e., below established explosive/toxic limit criteria).

Contamination, flammability, and toxic limits have been identified in the KSC Ground Operations Safety Plan and are consistent with the most stringent OSHA/NIOSH standards.

Rules {A16-10B}, NORMAL POSTLANDING OPERATIONS; and {A16-12A}.1, and B.2, EMERGENCY POWERDOWN, reference this rule.

A16-302 **EMERGENCY OXYGEN SYSTEM REQUIREMENTS**

- A. THE CREW WILL ACTIVATE THE EMERGENCY OXYGEN SYSTEM FOR ANY UNAIDED EMERGENCY EGRESS.

For an unaided egress, the KSC Safety Assessment Team will not be available to test for the hazardous materials toxicity limits so the emergency oxygen system will be activated to protect against unknown contamination.

DOCUMENTATION: Engineering judgment.

- B. THE CREW WILL ACTIVATE EMERGENCY OXYGEN SYSTEM FOR ANY NONEMERGENCY EGRESS WHERE THE CABIN OR EXTERNAL ATMOSPHERE IS EITHER CONTAMINATED OR UNKNOWN.

This rule protects the crew from the hazards of toxic materials.

DOCUMENTATION: Engineering judgment.

SECTION 17 - LIFE SUPPORT

SMOKE DETECTION/FIRE SUPPRESSION LOSS DEFINITIONS

A17-1 **FIRE/POST-FIRE DEFINITIONS**

- A. FIRE SHALL BE DEFINED AS ONE OR MORE OF THE FOLLOWING:
1. CREW OBSERVANCE OF FLAME OR SMOKE
 2. FOR AN AVIONICS BAY, ANY ONE OF THE FOLLOWING: @[090894-1674]
 - a. TWO SMOKE DETECTOR CONCENTRATION LEVELS OVER 2000 UG/M**3 IN THE SAME COMPARTMENT
 - b. ONE CONCENTRATION LEVEL 2000 UG/M**3 AND INCREASING, AND THE ALTERNATE DETECTOR HAS FAILED SELF TEST
 - c. ONE CONCENTRATION LEVEL 2000 UG/M**3 AND INCREASING, AND CONFIRMATION BY ELECTRICAL DATA OF A SUSTAINED SHORT

*A confirmation is required to accurately detect a fire condition; this confirmation can be via a separate smoke detector indicating a concentration level over 2000 ug/m**3, or crew observations. In the event the alternate smoke detector fails a self test in an avionics bay, a fire condition will be assumed. Any indications of a sustained short in the affected avionics bay will also be considered as confirmation of a fire.*

In the event of a cabin fire, the crew will most likely react to olfactory sensing prior to the annunciation of a smoke detector(s), since the human nose is significantly more sensitive. Also, visual cues will most likely be used as confirmation of a fire condition rather than relying solely upon two smoke detector indications. For a cabin fire, the crew must locate the fire and therefore confirm its existence prior to discharging a Halon bottle. Without confirmation of the fire there can be no guarantee that the Halon was discharged in the appropriate place or had any affect on the fire. @[090894-1674]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-1 FIRE/POST-FIRE DEFINITIONS (CONTINUED)

B. POST-FIRE SHALL BE DEFINED AS THE FOLLOWING:

1. CREW OBSERVANCE THAT FIRE HAS BEEN SUPPRESSED
2. SMOKE DETECTOR CONCENTRATIONS INDICATE STABLE OR DECREASING
3. FOR AN AV BAY FIRE, A HALON BOTTLE HAS BEEN DISCHARGED AND THE AFFECTED LRU UNPOWERED. @[090894-1674]

If the crew continues to observe a fire or increasing smoke, the fire condition still exists. If a fire has been suppressed by either Halon discharge or removal of power, the smoke detector concentration indications should stabilize or decrease. An avionics bay fire is considered suppressed, when the avionics bay fans have been deactivated, Halon has been discharged into the bay, and the affected LRU's have been unpowered. @[090894-1674]

DOCUMENTATION: SODB 4.6.5.1.e; engineering judgment; and materials branch discussions.

FLIGHT RULES

A17-2

SMOKE DETECTION LOSS DEFINITION

- A. AVIONICS BAY SMOKE DETECTION SHALL BE CONSIDERED LOST FOR ANY ONE OF THE FOLLOWING REASONS:
1. ONE SMOKE DETECTOR FAILS BOTH PORTIONS OF THE CIRCUIT TEST AND THE OTHER SMOKE DETECTOR FAILS EITHER PORTION OF THE CIRCUIT TEST.
 2. POWER TO BOTH THE DETECTORS IN THAT AVIONICS BAY CANNOT BE MAINTAINED.
 3. LOSS OF AIR CIRCULATION (BOTH AVIONICS BAY FANS FAILED) IN THE BAY.
- B. CREW CABIN SMOKE DETECTION SHALL BE CONSIDERED LOST FOR ANY ONE OF THE FOLLOWING REASONS:
1. ALL THREE DETECTORS FAIL BOTH PORTIONS OF THE CIRCUIT TEST.
 2. POWER TO ALL THREE CABIN DETECTORS CANNOT BE MAINTAINED.
 3. LOSS OF AIR CIRCULATION (BOTH CABIN FANS FAILED) IN THE CREW CABIN.

Each smoke detector outputs two smoke detection indications (an alarm indication and a concentration measurement), and these two measurements are independent of one another except for a smoke detector hardware failure. The only hardware failure that can be detected by the circuit test is an air pump failure which would force the detector to fail both portions of the circuit test. If the smoke detector passes either portion of the circuit test, the air pump is then verified as operative, and the concentration readout sent to the GPC for FDA limit sensing is considered a valid indication.

Power is required for the smoke detectors to operate. Loss of air circulation prevents particulates from reaching the smoke detector in a timely manner if the combustion is not close to the smoke detector. If only one indication is left in an avionics bay, the system is considered suspect to the point of being unreliable.

DOCUMENTATION: R. I. Vendor drawings VS70-620109, V070-623420, and V70-960099. Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A17-3

FORWARD AVIONICS BAY FIRE SUPPRESSION

FORWARD AVIONICS BAY FIRE SUPPRESSION IS CONSIDERED LOST IF:

- A. THE "AGENT DISCHARGE" PBI IS ILLUMINATED WITH NO CONCURRENT AURAL CUE.

The system is suspect to the point of being unreliable. An AGENT DISCHARGE light indicates an "empty" bottle. Without an aural cue, it would not be known when or how fast the agent discharged.

- B. 50 HOURS HAS ELAPSED AFTER THE "AGENT DISCHARGE" PBI IS ILLUMINATED AND WITH A CONCURRENT AURAL CUE.

The avionics bays are not airtight and will allow the Halon 1301 fire suppressant to dissipate into the cabin over a period of time. However, the resultant concentration of Halon 1301 in an avionics bay from a fully charged bottle will stay above the required 4 percent needed to extinguish a fire for 50 hours.

DOCUMENTATION: SODB 4.6.5.2.A.2.R.

- C. FOR AV BAY 3A WITH ENHANCED MIDDECK COOLING AND ACTIVELY COOLED PAYLOADS: 28 HOURS HAS ELAPSED AFTER THE "AGENT DISCHARGE" PBI IS ILLUMINATED WITH A CONCURRENT AURAL CUE.
@[040899-2497]

Avionics bays that have been modified for enhanced middeck cooling, and have actively cooled payloads stowed in the bay, have a higher leakage rate than avionics bays that have not been modified. As such, Halon 1301 fire suppressant will dissipate into the cabin faster from the enhanced avionics bays. The resultant concentration of Halon 1301 in an enhanced avionics bay from a fully charged bottle will stay above the required 4 percent needed to extinguish a fire for 28 hours. If the av bay has enhanced cooling capability; however, no actively cooled payloads have been manifested, then paragraph B applies because the payload ducts have been capped.

DOCUMENTATION: BNA 287-200-098-017, Middeck Bay 3A Leakage Analysis. @[040899-2497]

A17-4 THROUGH 117-50 RULES ARE RESERVED

FLIGHT RULES

SMOKE DETECTION/FIRE SUPPRESSION MANAGEMENT

A17-51 MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION

A. AVIONICS BAY:

1. HALON DISCHARGE CRITERIA

DURING ANY PHASE OF FLIGHT, A HALON BOTTLE WILL BE DISCHARGED IF THERE IS EQUIPMENT FAILURE IN THAT AVIONICS BAY AND THE FAILURE IS ATTRIBUTED TO A SUSTAINED SHORT. IF THE MCC IS NOT AVAILABLE TO DETERMINE IF A SHORT WAS PRESENT, THE REMAINING EQUIPMENT IN THE BAY WILL BE POWERED DOWN UNTIL THE ASSESSMENT CAN BE MADE. A HALON BOTTLE WILL BE DISCHARGED IF SECONDARY CUES ARE PRESENT. ©[090894-1674]

An equipment failure due to a sustained short could provide an ignition source for a fire and should be considered a fire condition. A short that has cleared has effectively eliminated the ignition source and should not be considered a fire condition. If the MCC is not available when a piece of equipment fails, powerdown of the bay is considered the best compromise to safe the bay while not prematurely discharging Halon. If the crew confirms a fire condition with secondary cues such as simultaneous or subsequent equipment failure or crew observance of smoke, a Halon bottle will be discharged.

2. POWERDOWN MANAGEMENT FOR AVIONICS BAYS 1 AND 2

- a. FOR AVIONICS BAYS 1 AND 2, A POST-OMS-2 POWERDOWN OF ALL AIR-COOLED EQUIPMENT AND THE AVIONICS BAY FAN IN THE AFFECTED AVIONICS BAY SHALL BE ACCOMPLISHED. ALL THIS EQUIPMENT MAY BE POWERED UP FOR ENTRY.

Air-cooled equipment and avionics bay fan will be powered down to (1) prevent the propagation of any fire by removing the convection currents that would feed O₂ to the fire and (2) eliminate friction generated by the fan as a potential ignition source. This action safes the avionics bay from any combustion except for arc tracking during the critical time of powering up equipment required for entry.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-51

MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION
(CONTINUED)

- b. PRIOR TO POWERUP OF EQUIPMENT IN THE AFFECTED AVIONICS BAY FOR ENTRY, A HANDHELD HALON BOTTLE WILL BE DISCHARGED IN THAT BAY.

The affected avionics bay will be safed by Halon discharge because the possibility exists that a fire condition could occur without proper and timely fire suppression since smoke detection is lost. Firing of a handheld bottle is preferred since it allows the crew the option of firing the remotely controlled Halon bottle during entry, if it becomes necessary and the remote bottle is still available. ©[090894-1674]

3. AVIONICS BAY 3 MANAGEMENT:

- a. FOR AVIONICS BAY 3, A POST-OMS-2 POWERDOWN OF ALL AIR-COOLED EQUIPMENT (EXCEPT COMMUNICATIONS EQUIPMENT, CAUTION AND WARNING EQUIPMENT, AND THE AVIONICS BAY FAN) SHALL BE ACCOMPLISHED. ALL OF THIS EQUIPMENT MAY BE POWERED UP FOR ENTRY. A LOCKER IN FRONT OF AVIONICS BAY 3 WILL BE REMOVED TO EXPOSE THE BAY TO THE CABIN ENVIRONMENT FOR SMOKE DETECTION. ©[090894-1674]

The communication and caution and warning equipment (air-cooled equipment) in avionics bay 3 is required for flight and cannot be unpowered. This precludes fire suppression by lack of convection currents because the fan is still running. Removal of a locker in front of avionics bay 3 will expose the bay to the cabin environment, thus allowing the cabin smoke detectors and the crew to monitor the powered equipment for evidence of a fire. The alternative would be to leave the locker in place and discharge a handheld Halon bottle to safe the bay since air-cooled equipment remains powered up. This action would cause possible early mission termination due to Halon discharge constraints (ref. Rule {A13-152A}, CABIN ATMOSPHERE CONTAMINATION).

- b. PRIOR TO POWERUP OF EQUIPMENT IN AVIONICS BAY 3 FOR ENTRY, ANY PREVIOUSLY REMOVED LOCKERS WILL BE REINSTALLED AND A HANDHELD HALON BOTTLE WILL BE DISCHARGED IN THE BAY.

The avionics bay 3 will be safed by Halon discharge prior to entry because the possibility exists that a fire condition could occur without proper and timely fire suppression since smoke detection is lost. Firing of a handheld bottle is preferred since it allows the crew the option of firing the remotely controlled Halon bottle during entry, if it becomes necessary, and the remote bottle is still available. ©[090894-1674]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-51 **MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION**
(CONTINUED)

B. CREW CABIN

A CREWMEMBER MUST REMAIN AWAKE AT ALL TIMES FOLLOWING LOSS OF SMOKE DETECTION IN THE CREW CABIN TO MONITOR FOR SMOKE/FIRE.

A crewmember must be available for monitoring the cabin since a sleeping crew may not be awakened by a smoke/fire condition.

C. MINIMAL SMOKE DETECTION MANAGEMENT

IF ONLY TWO SMOKE DETECTION INDICATIONS REMAIN IN THE CABIN OR AVIONICS BAY, THE CIRCUIT TEST SHALL BE PERFORMED EVERY DAY UNTIL EOM.

Each smoke detector has two separate indications (hardware alarm and GPC concentration readout). Thus, nominally, the cabin has six indications, and each avionics bay has four indications. If only two of these indications are available in an area, the circuit test should be performed every day to verify that the minimum requirement is still met.

Note: The risk of an avionics bay fire is extremely low due to the design of the vehicle. The design limits ignition sources and provides little fuel for a fire. Any ignition that did occur would most likely be due to wire bundle arc tracking on which Halon has no effect.

Note: The powerdown of the air-cooled equipment causes little procedural impact on orbit but is a severe impact during dynamic flight phases (ascent through OMS-2, deorbit prep through landings).

Note: The discharge of a handheld Halon bottle in the avionics bay has little postlanding turnaround impact.

DOCUMENTATION: Engineering judgment; Flammability Requirements, NHB 8060.1b, p. 1-1; and Halon 1301 Fire Extinguishment in Avionics Bays, M. Pedley.

Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A17-52

MANAGEMENT FOLLOWING LOSS OF FIRE SUPPRESSION IN
AN AVIONICS BAY

FOR LOSS OF FIRE SUPPRESSION IN AN AVIONICS BAY, NO ACTION WILL BE TAKEN UNLESS THE SMOKE DETECTORS IN THE AFFECTED AVIONICS BAY INDICATE A FIRE CONDITION. AT THAT TIME A HANDHELD HALON BOTTLE WILL BE DISCHARGED INTO THE AVIONICS BAY.

A HANDHELD HALON BOTTLE WILL BE DISCHARGED INTO THE AFFECTED AVIONICS BAY PRIOR TO SEAT INGRESS IF ONE HAS NOT BEEN PREVIOUSLY DISCHARGED INTO THE AVIONICS BAY.

If a fire condition exists in an avionics bay, then the handheld Halon bottles will be used to suppress the fire. During deorbit, however, the crew may not be able to reach the affected bay to discharge a handheld Halon bottle to suppress a fire; therefore, it is prudent to discharge a handheld Halon bottle in the avionics bay prior to seat ingress to prevent the ignition and/or propagation of a fire. This action has no adverse turnaround impacts.

DOCUMENTATION: Engineering judgment.

Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A17-53

FIRE AND POST-FIRE ACTIONS

A. AVIONICS BAY FIRE ACTIONS

IF A FIRE CONDITION IS DETECTED IN THE AVIONICS BAY DURING ANY PHASE OF FLIGHT, THE FOLLOWING ACTIONS WILL BE ACCOMPLISHED AS SOON AS POSSIBLE:

1. AN AVIONICS BAY HALON BOTTLE WILL BE DISCHARGED IN THAT AVIONICS BAY.
2. THE AVIONICS BAY FAN WILL BE TURNED OFF.
3. THE CREW WILL DON THE HRA/LES HELMETS WITH VISORS DOWN.

B. CREW CABIN FIRE ACTIONS

IF A FIRE CONDITION IS DETECTED IN THE CABIN DURING ANY PHASE OF FLIGHT, THE FOLLOWING ACTIONS SHALL BE ACCOMPLISHED AS SOON AS POSSIBLE:

1. THE CABIN FAN SHALL BE TURNED OFF.
2. THE CREW SHALL DON HRA/LES HELMETS WITH VISORS DOWN.
3. THE CREW SHALL DISCHARGE THE HANDHELD HALON BOTTLE IN THE APPROPRIATE FIRE PORT.

A Halon discharge should save the avionics bay from any further combustion except for arc tracking upon which Halon has no effect. In the case of a cabin fire, the HRA/LES helmets protect the crew from breathing potentially toxic gases; donning of the LES will be considered later if appropriate. The discharged Halon should suppress the fire in most conditions. Also the cabin fan and avionics fan produces convection air currents that will feed oxidizer to a fire. Without convection currents a fire should extinguish itself due to a lack of oxidizer and also localize toxins in the vicinity of combustion until the crew has donned protective gear.

DOCUMENTATION: Materials Processing in Space: Early Experiments, NASA SP-443.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-53

FIRE AND POST-FIRE ACTIONS (CONTINUED)

C. AVIONICS BAY POST-FIRE ACTIONS

FOLLOWING A FIRE CONDITION FOR WHICH A HALON BOTTLE HAS BEEN DISCHARGED INTO AN AVIONICS BAY:

1. IN ORDER TO MINIMIZE ELECTRICAL AND FRICTIONAL IGNITION SOURCES, A POWERDOWN OF ALL EQUIPMENT IN THAT AVIONICS BAY SHALL BE ACCOMPLISHED WITH THE EXCEPTION OF THE IMU FANS, INSTRUMENTATION REQUIRED FOR THE CREW AND MCC TO ASSESS POST-FIRE SAFETY STATUS, AND COMMUNICATIONS EQUIPMENT WHICH WILL BE POWERED DOWN ONLY IF INDICATIONS SHOW IT HAS FAILED. @[090894-1673A]
 - a. THE POWERED DOWN EQUIPMENT IN THE AFFECTED AVIONICS BAY WILL BE DECLARED LOST UNTIL PROVEN GO FOR GO/NO-GO CRITERIA.
 - b. THE ONLY EQUIPMENT TO BE CONSIDERED FOR REACTIVATION WILL BE EQUIPMENT REQUIRED TO RESTORE SINGLE-FAULT TOLERANCE FOR ENTRY. @[090894-1673A]

Without direct insight into the affected bay, the damage to the equipment is unknown. Some of the equipment may not have been in use during the fire or may have suffered failures not immediately detectable; therefore, the equipment must be considered NO-GO for all GO/NO-GO purposes. For avionics bay 1, IMU fans (located in the avionics bay) must remain operating since the IMU's (not located in avionics bays) cannot operate for more than 30 minutes without cooling. If a fan has failed, a redundant fan will be activated immediately. For avionics bay 3, communication is considered too important during the entry phase of flight to allow it to become unpowered without a confirmed failure. For all three avionics bays, in order to maintain insight into the health of the remaining systems and to implement the post-fire cabin depress and purge at 8 psi, the instrumentation equipment is required. Instrumentation is required in order to properly limit the rate of the cabin depress such that a positive delta pressure is maintained on the avionics bay while a dedicated avionics bay purge is in place. The positive delta pressure on the avionics bay will ensure that the toxic combustion products from the fire are not forced into the cabin.

Repowered equipment in the affected avionics bay should be restricted to that required to achieve single-fault tolerance to entry systems so exposure to the source of the fire can be minimized. The health of the systems and/or crew cannot be guaranteed following a fire; therefore, entry may be necessary following cabin evaluation.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-53

FIRE AND POST-FIRE ACTIONS (CONTINUED)

2. AFTER THE DISCHARGE OF A HALON BOTTLE IN AN AVIONICS BAY, AN OVERBOARD PURGE OF THAT BAY WILL BE INITIATED. IF COMBUSTION PRODUCTS ARE DETECTED IN THE CABIN, THE CREW WILL REMAIN ON THE QDM'S AND A CABIN DEPRESS TO 8 PSI FOLLOWED BY A CONTINUOUS CABIN PURGE AT 8 PSI WILL BE PERFORMED. THE PURGE WILL BE TERMINATED AND THE CREW ALLOWED TO BREATHE CABIN AIR ACCORDING TO THE CRITERIA OUTLINED IN RULE {A13-152C}.7, CABIN ATMOSPHERE CONTAMINATION.

Post-fire, a cabin depress to 8 psia and continuous purge at 8 psia will manage O₂ concentrations below maximum levels as well as decrease the concentration of discharged Halon and any toxic gases that were produced by a fire. This action will extend the time on orbit so as to potentially avoid an ELS entry by effectively reducing the amount of N₂ needed to control O₂ concentrations. Since in an 8 psi cabin condition, the O₂ concentration is allowed to reach 40 percent which increases the flammability potential, the crew should make sure that the fire has been fully extinguished before initiating the depress to prevent flares. If sufficient N₂ is available to reach a PLS, it is not necessary to go to 8 psi. ©[090894-1673A]

A cabin depress without first purging the affected avionics bay directly overboard, would create a negative pressure differential between the cabin and avionics bay that would draw any Halon and/or toxic combustion products from the avionics bay into the cabin. Therefore, the 50-hour period between the Halon discharge in an avionics bay and the diffusion of a potentially hazardous level of Halon into the cabin (ref. Rule {A13-152A}, CABIN ATMOSPHERE CONTAMINATION) could not be guaranteed following a cabin depress without first initiating an avionics bay purge. A dedicated avionics bay purge of at least 3 lb/hr directly overboard will maintain a positive delta pressure on the avionics bay with respect to the cabin during a controlled cabin depress to 8 psi, thus ensuring that any Halon and/or combustion products would not be drawn into the cabin. In order to maintain the positive delta pressure on the affected avionics bay, the cabin EQ dP/dT must be controlled to below a maximum of -0.1 psi/min during the transition from the current cabin pressure to 8 psi.

In the case of a fire following the depletion of all available Halon, lowering of the O₂ concentrations to 15 percent could be used as an alternative means of fire suppression.

Note: A safe level of toxicity in the cabin cannot be guaranteed following a fire condition, but a cabin depress without initiating a dedicated avionics bay purge would quicken the diffusion rate of toxins into the cabin. ©[090894-1673A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-53

FIRE AND POST-FIRE ACTIONS (CONTINUED)

3. THE RCRS WILL BE MANUALLY SHUT DOWN FOLLOWING AN ORBITER AVIONICS BAY FIRE.

See Rule {A17-156}, RCRS MANUAL SHUTDOWN CRITERIA, for rationale.

DOCUMENTATION: Engineering judgment

D. CREW CABIN POST-FIRE ACTIONS

POST-FIRE THE FOLLOWING ACTIONS SHALL BE ACCOMPLISHED:

1. THE CREW WILL POWER DOWN SUSPECT EQUIPMENT.

The crew should power down suspect equipment because the equipment health cannot be guaranteed and is a potential ignition source.

2. THE CREW SHALL PERFORM A FLIGHT DECK AVIONICS CHECKOUT FOR SUSPECT EQUIPMENT AND/OR EQUIPMENT REQUIRED FOR ENTRY.

If required for entry, the equipment should be checked out before use.

3. FOLLOWING A FIRE/HALON BOTTLE DISCHARGE, IF COMBUSTION PRODUCTS ARE DETECTED IN THE CABIN, THE CREW WILL REMAIN ON THE QDM'S. THE CREW SHALL PERFORM A CABIN DEPRESS TO 8 PSI AND A CONTINUOUS PURGE AT 8 PSI WILL BE PERFORMED. THE PURGE MAY BE TERMINATED AND THE CREW ALLOWED TO BREATHE CABIN AIR ACCORDING TO THE CRITERIA OUTLINED IN RULE {A13-152C}.7, CABIN ATMOSPHERE CONTAMINATION. @[090894-1673A]

Post-fire, a cabin depress to 8 psi and continuous purge at 8 psi will manage O₂ concentrations below maximum levels as well as decrease the concentration of discharged Halon and any toxic gases that were produced by a fire. This action will extend the time on orbit so as to potentially avoid an ELS entry by effectively reducing the amount of N₂ needed to control O₂ concentrations.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-53

FIRE AND POST-FIRE ACTIONS (CONTINUED)

Following a fire condition, the health of the systems and/or crew cannot be guaranteed; therefore, following a cabin atmosphere evaluation, entry may be necessary. Since in an 8 psi cabin condition, the O₂ concentration is allowed to reach 40 percent which increases the flammability potential, the crew should make sure that the fire has been fully extinguished before initiating the depress to prevent flares. If sufficient N₂ is available to reach a PLS, it is not necessary to go to 8 psi.

In the case of a fire following the depletion of all available Halon, lowering of the O₂ concentrations to 15 percent could be used as an alternative means of fire suppression. ©[090894-1673A]

DOCUMENTATION: SODB 4.6.5.2.a.2.r; engineering judgment; and Halon 1301 Fire Extinguishment in Avionics Bays, M. Pedley.

4. THE RCRS WILL BE MANUALLY SHUT DOWN FOLLOWING AN ORBITER CABIN FIRE.

See Rule {A17-156}, RCRS MANUAL SHUTDOWN CRITERIA for rationale.

DOCUMENTATION: Engineering judgment

Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, references this rule.

FLIGHT RULES

A17-54 MANAGEMENT FOLLOWING HALON DISCHARGE WITHOUT FIRE CONFIRMATION

A. AVIONICS BAY: @[090894-1673A]

FOLLOWING A BOTTLE EMPTY INDICATION, AN AVIONICS BAY PURGE WILL BE PERFORMED. IF THE TIME OF DISCHARGE CAN BE ACCURATELY DETERMINED, EARLY MISSION TERMINATION CRITERIA AS SPECIFIED IN RULE {A13-152A}, CABIN ATMOSPHERE CONTAMINATION, MAY BE WAIVED ON MCC CALL. IF THE TIME OF DISCHARGE OF THE HALON BOTTLE CANNOT BE DETERMINED, A WORSE CASE TIME OF DISCHARGE AT LIFT-OFF WILL BE APPLIED.

A dedicated overboard purge of the affected avionics bay will begin to decrease the concentration of Halon in the bay and ensure that it does not migrate into the cabin. The purge should be initiated as soon as possible in order to avoid potential mission termination due to toxic concentrations of Halon in the cabin. If the time of discharge cannot be accurately determined, it must be assumed that the bottle began leaking at the worst case time of lift-off. The MCC indication of an empty bottle provides no insight into the start of a potential leak or the time of discharge. A 140 db audible cue and a rapid rise in smoke concentrations are the only indications to determine time of discharge and this only applies to a bottle discharging all of its contents within a matter of seconds. Reference Rule {A13-152}, CABIN ATMOSPHERE CONTAMINATION, for EOM determination due to Halon concentrations from an avionics bay Halon bottle.

B. CABIN:

IF THE START OF A LEAK FROM A HANDHELD BOTTLE CAN BE ACCURATELY DETERMINED, THE REMAINING CONTENTS OF THE BOTTLE WILL BE DISCHARGED OVERBOARD THROUGH THE AIRLOCK DEPRESS VALVE.

Discharge of the remaining contents of a handheld Halon bottle directly overboard will reduce the concentration of Halon in the cabin and potentially minimize the EOM impacts. The time of the start of the leak is critical because, coupled with the discharge duration through the depress valve, there is no other way to effectively determine how much Halon has leaked into the cabin. The nominal discharge time for a handheld Halon bottle is 15 - 19 seconds. Neither the crew nor the MCC have insight into an empty or leaking handheld bottle unless the crew can audibly detect a leak. Reference rule {A13-152B}. CABIN ATMOSPHERE CONTAMINATION for EOM determination due to Halon concentrations from a handheld Halon bottle.

Another option for disposal of a leaking handheld bottle is to place it in the airlock and expose it to vacuum. However, since there is no effective way to determine the leak rate of the bottle, it is not possible to determine how much Halon has leaked into the cabin or how long the bottle must be exposed to vacuum before it is completely empty. @[090894-1673A]

A17-55 THROUGH 17-100 RULES ARE RESERVED

FLIGHT RULES

ATMOSPHERE REVITALIZATION SYSTEM (ARS) AIR LOSS DEFINITIONS

A17-101

CABIN FAN

A CABIN FAN IS CONSIDERED LOST IF THE FAN DELTA PRESSURE IS <4.20 (4.49) INCHES H₂O OR >6.80 (6.51) INCHES H₂O AND CREW DETECTS LOSS OF AIR FLOW.

With a delta P of 4.2 inches H₂O (low on the portion of performance band) the flow is approximately 1575 lb/hr. This is considered to be the maximum flow available with low delta P with intact systems (no leakage; therefore, proper cooling to all areas).

The minimum required flowrate for proper cooling is 1400 lb/hr (at the high portion of the performance band); the delta P required to maintain the flow is 6.8 inches H₂O. A delta P higher than this will not meet the required minimum cooling.

Measurement accuracy is ± 3.6 percent of full scale (0.036 x 8 inches H₂O = 0.288).

FLIGHT RULES

A17-102

CABIN ATMOSPHERIC CONTROL

CABIN ATMOSPHERIC CONTROL IS CONSIDERED LOST IF:

- A. UNABLE TO MAINTAIN CABIN TEMPERATURE CONTROL AT <95 DEG (90 DEG) F.

Temperatures above 95 deg F would cause an overtemperature condition in the avionics on the flight deck. The lower limit for the flight deck avionics is 40 deg F which cannot be achieved if the vehicle is in the full, on-orbit avionics configuration. From analysis and flight experience, the water pump outlet temperature will run 8 deg to 10 deg F below cabin temperature; therefore, a 39 deg F cabin temperature would result in a water pump outlet temperature below the freezing point of water.

DOCUMENTATION: SODB 4.6.1.3.4-1.1, 1.1-ECLSS-122

- B. UNABLE TO SATISFY BIOMED CONSTRAINTS ON PPCO₂ (REF. RULE {A13-52}, PPCO₂ CONSTRAINT).

See Rule {A13-52}, PPCO₂ CONSTRAINT, rationale.

DOCUMENTATION: SODB 3.4.6.1 and SODB 4.6.1.3.1-C.

- C. HUMIDITY CONTROL

1. UNEXPLAINED DECREASE IN THE WASTE WATER TANK FILL RATE (NORMALLY 6 ±1 LB/DAY-CREWMEMBER).

The increase in waste tank quantity is used in determining status of humidity control instead of change in the humidity level. On STS-5 when fan separator B became degraded due to blockage at the separator inlet, the humidity level did not change. The failure was detected by the flight controllers when the waste quantity increase became a slower rate. From past flights, the combined waste water quantity fill rate from metabolic production and the LiOH-CO₂ reaction has been about 0.25 lb/hr-crewmember (6 lb/day-crewmember). If the waste quantity is increasing only from the crew's use of the WCS (3.49 lb/day-crewmember), the crew will inspect the crew module for condensation.

DOCUMENTATION: SODB 4.6.2.2.4, 1.3-TM-DF86T50-54.

2. VISUAL CONDENSATION ON THE STRUCTURE OR THE EQUIPMENT.

If humidity control fails, moisture in the air will condense on equipment and/or parts of the vehicle structure with a corresponding temperature below the dewpoint.

DOCUMENTATION: Flight experience and SEH-SETO-87-014.

FLIGHT RULES

A17-103

LOSS OF AVIONICS BAY FAN

A. AV BAY COOLING @[040899-2498A]

AVIONICS BAY FAN SHALL BE CONSIDERED LOST IF THE FAN DELTA PRESSURE IS < 2.5 INCHES OF H₂O OR > 4.3 INCHES OF H₂O.

A delta pressure of 2.5 inches of H₂O is considered the minimum value which provides adequate airflow required for avionics bay cooling. This minimum value corresponds to the estimated fan delta pressure of two-phase fan operation. This delta pressure should also provide adequate cooling flow in the case of duct leakage or degraded fan performance.

The maximum delta pressure which provides minimum airflow for required cooling is 4.3 inches of H₂O. This maximum delta pressure/minimum airflow is based on a temperature violation of the GPC's. A delta pressure > 4.3 inches of H₂O will not meet the required minimum flowrate for adequate cooling. A delta pressure exceeding this value would be indicative of possible duct blockage or filter blockage.

The minimum and maximum delta pressure values are in general agreement with current LCC and OMRSD limits which are based on analytical predictions of flowrates as described in reference documentation.

Fan delta pressure is a coarse representation of avionics bay cooling performance. Other indicators to determine the effectiveness of the cooling are avionics bay air outlet, active water coolant loop heat exchanger inlet and outlet temperatures, and H₂O flowrate. Therefore, measurement error for delta pressure will not be used to determine the loss of an avionics bay fan.

DOCUMENTATION: RI-D IL-287-203-91-003, IL-287-203-90-86, and engineering judgment. (SODB request submitted.)

B. UPGRADED AV BAY FANS FOR ENHANCED MIDDECK COOLING: @[040899-2498A]

AN UPGRADED AV BAY FAN SHALL BE CONSIDERED LOST IF THE FAN DELTA PRESSURE IS < 4.5 INCHES OF H₂O OR > 7.8 INCHES OF H₂O.

The new upgraded av bay fans are identical to the current cabin fans, with the exception of the housing. As of January 1999, the new av bay fans are currently installed in Av Bay 3A of OV-104. OV-103 and OV-105 will receive the upgraded fans sometime in the future; however, the Shuttle Program has not determined when that will be. OV-102 is not scheduled to receive the upgraded fans.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-103

LOSS OF AVIONICS BAY FAN (CONTINUED)

A delta pressure of 4.5 inches of H₂O is considered the minimum value which provides adequate airflow required for avionics cooling. This minimum value corresponds to the estimated fan delta pressure of two phase fan operation. This delta pressure should also provide adequate cooling flow in the case of duct leakage or degraded fan performance.

The maximum delta pressure which provides minimum airflow for required cooling is 7.8 inches of H₂O. The maximum delta pressure/minimum airflow is based on temperature violation of the GPC's. A delta pressure of 7.8 inches of H₂O will not meet the required minimum flow rate for adequate cooling. A delta pressure exceeding this value would be indicative of duct blockage or filter blockage.

Fan delta pressure is a coarse representation of avionics cooling performance. Other indicators to determine the effectiveness of the cooling are avionics bay outlet, active water coolant loop heat exchanger inlet and outlet temperatures, and H₂O flowrate. Therefore, measurement error for delta pressure will not be used to determine the loss of an avionics bay fan.

DOCUMENTATION: BNA Memo No. 287-200-098-019, Bay 3A Enhanced Avionics Fan Delta Pressure Limit. @[040899-2498A]

FLIGHT RULES

A17-104

IMU FAN

AN IMU FAN IS CONSIDERED LOST IF:

- A. FAN DELTA PRESSURE IS < 3.70 (3.94) OR > 4.95 (4.71) INCHES H_2O .

The minimum required flowrate for proper cooling is 144 lb/hr which is supplied by a maximum delta P of 4.95 inches H_2O (temperature dependent value). A delta P any higher than this would not be able to supply the air flowrate required for proper cooling.

A delta P of 3.7 inches H_2O produces a flow of approximately 185 lb/hr. This is considered to be the maximum fan flow available for an intact system. Therefore, any lower delta P would have to be produced by a system with questionable integrity (leakage). Measurement accuracy is ± 3.4 percent of full scale (0.034×7 inches $H_2O = 0.238$).

- B. IMU FAN SPEED INDICATES ABNORMAL WHEN FAN IS SELECTED.

IMU fan speed range for normal speed indication is $10,000 \pm 240$ to $12,720 \pm 700$ rpm. Fan speeds outside this range indicate degraded fan operations not producing the necessary flow for cooling or a breach of system integrity.

DOCUMENTATION: Hamilton Standard Component Data Handbook SP01T80, Specification Number SVHS 6416.

FLIGHT RULES

A17-105

AVIONICS BAY COOLING

AVIONICS BAY COOLING IS LOST IF:

A. ASCENT/ENTRY:

UNABLE TO MAINTAIN AVIONICS BAY AIR OUTLET TEMPERATURE < 130 DEG (125 DEG) F.

For a fully powered avionics bay, air outlet temperatures above 130 deg F would result in an overtemperature condition of the avionics in that avionics bay. @[030994-1609]

DOCUMENTATION: SODB 3.4.6.1.1.

B. ON-ORBIT:

1. FOR A 14.7 PSI CABIN, UNABLE TO MAINTAIN AVIONICS BAY AIR OUTLET TEMPERATURE BELOW: @[090894-1673A]
 - a. 120 DEG (115 DEG) F, IF TWO GPC'S IN RUN.
 - b. 108 DEG (103 DEG) F, IF ONLY ONE GPC IN RUN.
 - c. 100 DEG (95 DEG) F, IF NO GPC'S IN RUN.
2. FOR A 10.2 PSI CABIN, UNABLE TO MAINTAIN AVIONICS BAY AIR OUTLET TEMPERATURE BELOW:
 - a. 117 DEG (112 DEG) F, IF TWO GPC'S IN RUN.
 - b. 101 DEG (96 DEG) F, IF ONLY ONE GPC IN RUN.
 - c. 89 DEG (84 DEG) F, IF NO GPC'S IN RUN.
3. FOR AN 8 PSI CABIN, UNABLE TO MAINTAIN AVIONICS BAY AIR OUTLET TEMPERATURE BELOW:
 - a. 127 DEG (122 DEG) F, IF TWO GPC'S IN RUN (AV BAY 1, WITH COLLINS TACAN, ONLY).

122 DEG (117 DEG) F, IF TWO GPC'S IN RUN (AV BAY 1, WITH GOULD TACAN, ONLY).

119 DEG (114 DEG) F, IF TWO GPC'S IN RUN (AV BAY 2 ONLY).

FLIGHT RULES**A17-105****AVIONICS BAY COOLING (CONTINUED)**

- b. 109 DEG (104 DEG) F, IF ONLY ONE GPC IN RUN (AV BAY 1, WITH COLLINS TACAN, ONLY).
- 105 DEG (100 DEG) F, IF ONLY ONE GPC IN RUN (AV BAY 1, WITH GOULD TACAN, ONLY).
- 101 DEG (96 DEG) F, IF ONLY ONE GPC IN RUN (AV BAYS 2 & 3). @[090894-1673A]
- c. 87 DEG (82 DEG) F, IF NO GPC'S IN RUN (AV BAY 1 ONLY). @[090894-1673A]
- 83 DEG (78 DEG) F, IF NO GPC'S IN RUN(AV BAYS 2 & 3).

The airflow in each of the avionics bays is distributed such that each LRU has enough airflow to remain under its maximum operational temperature limit based upon a design requirement of 95 degrees F maximum avionics bay inlet temperature. Since the inlet temperature is not a measured parameter, the air outlet temperature sensor must be used to determine if adequate cooling is available to the individual LRU's. The measured avionics bay air outlet temperature is a mixed air temperature for all LRU's (active & inactive) in the respective bay and is therefore an indication of the average heat load. When an LRU is powered off, its relatively cooler airflow will mix with the warmer air from the active LRU's, resulting in a mixed air temperature, in most cases, lower than that of an active LRU. For example, with a single active GPC, a mixed air outlet temperature of 130 degrees F would result in a GPC operating above its maximum operational limit of 130 degrees F. Consequently, a measured avionics bay air outlet temperature which corresponds to a maximum inlet temperature of 95 degrees F will be LRU configuration dependent. When set up for on-orbit operations (assuming nominal on-orbit configuration: TACAN, MLS, etc., are unpowered), the GPC is the largest heat load and each GPC affects approximately one-third of the airflow in that bay. Therefore, the configuration dependent air outlet temperature limit for on-orbit is driven primarily by the individual avionics bay's GPC configuration. The derived outlet temperature limits assume no airflow blockage within the avionics bay/LRU ducting.

Three different analyses were performed for cabin pressures of 14.7, 10.2, and 8.0 psia. The 14.7 psia case protects against the design requirement of 95 degrees F maximum avionics bay inlet temperature. Based upon the airflow distribution unique to each avionics bay, the individual GPC operating temperatures were derived to be 122 and 126 degrees F for avionics bays #1 and #2 respectively. The resulting mixed air temperatures (avionics bay air outlet temperature) is listed in section 1 of the rule since it is the monitored parameter. Consequently, there is between 4 and 8 degrees F margin depending on the specifics of the avionics bay.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-105

AVIONICS BAY COOLING (CONTINUED)

Since there are no design requirements for the 10.2 and 8.0 psia cases, the analyses were performed as follows:

In order to be consistent between the two nominal cases (10.2 and 14.7 psia), the 10.2 analysis protected the same individual GPC box outlet temperatures as the 14.7 psia case, and backed out an air inlet temperature of approximately 80 degrees F. From these two parameters, the mixed air outlet temperature was calculated and listed in section 2 of the rule. The analysis was performed taking into account the decrease in air flow due to the lower cabin pressure. The expected decrease in airflow at 10.2 psia is based upon a linear function of the airflow at 14.7 psia and the lower cabin pressure. ©[090894-1673A]

Since the 8.0 psia case is a contingency scenario, the analysis protected against the maximum GPC operating temperature of 130 degrees as opposed to the derived design limit used for the 14.7 and the 10.2 psia cases. Therefore, based upon a GPC operating temperature of 130 degrees F, the analysis calculated the mixed air outlet temperatures listed in section 3 of the rule. The 8.0 psi case has limits which are specific to the avionics bays as compared to the 10.2 and 14.7 psi cases. This is due to the fact that the lower pressure of 8.0 psi magnifies the impacts of the different avionics bay airflow configurations (including whether Gould or Collins TACAN's are installed in the avionics bay). For the higher pressure cases, the airflow differences did not cause a divergence in results significant enough to be considered separately. ©[090894-1673A]

Avionics bay airflow reconfigurations due to the installation of the new Collins TACAN's has no impact on the avionics bay air outlet temperature limits at either 8, 10.2 or 14.7 psi cabin pressures. ©[030994-1609]

C. BOTH FANS ARE LOST. ©[030994-1609]

If unable to get the required air flow, the avionics bay is considered lost.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A17-106 **REGENERATIVE CO2 REMOVAL SYSTEM (RCRS) LOSS**
DEFINITION

THE RCRS IS CONSIDERED LOST IF:

A. UNABLE TO MAINTAIN PPCO₂ BELOW 7.6 MM HG.

RCRS CO₂ removal capability will not be effective if the vacuum vent line isol valve closes the vacuum vent duct blocks, or for ARS duct leakage occurs.

RCRS operations are not possible if both controller A and B have failed since the RCRS requires an automatic controller (no manual RCRS override capability).

RCRS auto shutdown logic will shut down the RCRS if bed pressures, bed delta pressures, or compressor RPM and valve position indications are not acceptable.

Reference Rule {A13-52A}.2, PPCO₂ CONSTRAINT, rationale.

DOCUMENTATION: RCRS Critical Design Review, March 15-17, 1990.

B. UNABLE TO MAINTAIN PPCO₂ INSIGHT.

See Rule {A17-155B}.4, REGENERATION CO₂ REMOVAL SYSTEM (RCRS) MANAGEMENT, for rationale.

DOCUMENTATION: Engineering judgment.

A17-107 THROUGH A17-150 RULES ARE RESERVED

FLIGHT RULES

ARS AIR SYSTEM MANAGEMENT

A17-151 CABIN ATMOSPHERE CONTROL

- A. THE CABIN TEMPERATURE CONTROL BYPASS VALVE WILL BE AUTOMATICALLY DRIVEN TO THE "FULL COOL" POSITION FOR ASCENT AND ENTRY.

The heat load in the cabin is large enough to require full cool during these phases. Having the valve in full cool is SOP. This is done to protect against the high heat loads in the cabin during an 8 psi ascent or entry situation.

DOCUMENTATION: SEH-ITA-80-245.

- B. WHEN TIME PERMITS THE LIOH CANISTERS WILL BE REMOVED FOR AN 8 PSI ENTRY.

The canister removal increases the fan efficiency for cooling which is critical at a reduced pressure. One fan increases in flow from 820 lb/hr (with LiOH in) to 870 lb/hr (with LiOH out). This rule also assumes the crew is wearing launch/entry suit (LES) helmets or that the PPCO₂ level is under control before removing the canisters.

DOCUMENTATION: 1.2-TM-B1709-24.

- C. LIOH CANISTER(S) WILL NORMALLY BE REPLACED PRESLEEP AND POSTSLEEP OR WHEN PPCO₂ IS VERIFIED TO BE ≤ 7.6 (6.1) MMHG.

Changeouts are scheduled so normal housekeeping activities will not interfere with mission or payload operations. Single or dual canister changeouts are based on an analysis to maximize LiOH utilization as a function of crew size. Additionally, the rule specifies that a changeout will occur when PPCO₂ increases above 7.6 mmHG which is the level we will manage PPCO₂ to prevent possible physiological changes to the crew.

DOCUMENTATION: SEH-ITA-85-145, SODB 3.4.6.1, SODB 4.6.1.3.1-C.

- D. WINDOW SHADES MAY BE USED TO MINIMIZE LOCAL CABIN TEMPERATURE GRADIENTS.

The effects of solar heat loads transmitted through the windows to the cabin and flight deck can essentially be negated by installing the shades.

DOCUMENTATION: SEH-ITA-82-028T.

FLIGHT RULES

A17-151

CABIN ATMOSPHERE CONTROL (CONTINUED)

E. CABIN FANS WILL NOT BE CYCLED PRE-MECO. @[040899-2570]

The cabin fan large ac loads during the first stage are nearly at their maximum level. Cycling fans (8.0 amps startup) could create a voltage transient to the main engine controllers jeopardizing engine performance.

F. UPGRADED AVIONICS BAY FANS WILL NOT BE CYCLED PRE-MECO.

Upgraded avionics fans have been installed in OV-104 and will later be installed in OV-103 and OV-105 to provide additional cooling to middeck payloads. The startup transient currents associated with these fans are significantly larger than the older avionics fans (7.4 amps/phase vs 2.0 amps/phase). Cycling fans could create a voltage transient to the main engine controllers, jeopardizing engine performance.
@[040899-2570]

FLIGHT RULES

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT

CREW CABIN TEMPERATURE WILL BE MANAGED IN THE FOLLOWING MANNER:
@[022201-4146]

A. ASCENT:

THE CABIN TEMPERATURE CONTROL BYPASS VALVE WILL BE AUTOMATICALLY DRIVEN TO THE "FULL COOL" POSITION FOR ASCENT.

The heat load in the cabin is large enough to require full cool during this phase. Having the valve in full cool is SOP. This is done to protect against the high heat loads in the cabin during an 8 psi ascent situation.

DOCUMENTATION: SEH-ITA-80-245.

B. ON-ORBIT:

THE CREW MAY ADJUST THE CABIN TEMPERATURE CONTROLLER TO ANY DESIRED POSITION TO SATISFY CREW COMFORT, REGARDLESS OF THE TEMPERATURE INDICATED ON THE CABIN TEMPERATURE SENSOR. ONE EXCEPTION TO THIS IS THAT IF LOWERING THE CABIN TEMPERATURE IS REQUIRED TO MAINTAIN ACCEPTABLE ISS DEWPOINT LEVELS DURING DOCKED OPS, THIS WILL HAVE PRIORITY OVER CREW COMFORT. OTHER EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX. @[022201-4146]

1. THE FOLLOWING SENSORS MAY BE USED TO MEASURE CABIN TEMPERATURE: @[022201-4146]

INSTRUMENT
CABIN TEMP DUCER
MICRO-WIS
MULTIMETER

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT
(CONTINUED)

The cabin temperature transducer is normally used to measure cabin temperature. However, the cabin temperature transducer can be affected by ambient conditions immediately surrounding the transducer. In order to lessen the effects, the box surrounding the transducer is normally taped to minimize this influence, but STS-103 data indicated that this transducer could still be affected by other heat loads in the near vicinity. Furthermore, DTO 664, performed on STS-60, STS-62, STS-59, STS-64, and STS-66, showed that the cabin temperature could vary significantly throughout the cabin. For example, on STS-103, the cabin temperature transducer reading was approximately 7-11 deg F higher than multimeter readings taken at various locations. These data indicate that a difference between the cabin temperature transducer and the actual cabin temperature should not be discounted during flight. Therefore, if a more accurate temperature reading at the avionics inlet is required, other sources can be used.

2. IF THE CABIN TEMPERATURE IS TOO COLD, THE FOLLOWING ACTIONS WILL BE PERFORMED IN ORDER OF PRIORITY:
 - a. MANUALLY PIN CABIN HEAT EXCHANGER BYPASS VALVE IN THE REQUIRED POSITION.
 - b. POWERUP PANEL AND FLOOD LIGHTS.
 - c. POWERUP AIR COOLED EQUIPMENT.
 - d. OPERATE BOTH WATER LOOPS WITH FULL INTERCHANGER FLOW.
 - e. DEACTIVATE THE FES. @[022201-4146]
 - f. OPERATE THE RADIATOR CONTROLLER OUTLET TEMPERATURE IN "HI" (57 DEG ± 2 DEG F). @[022201-4146]

Each action will decrease the amount of heat rejected from the cabin or increase the cabin heat load, thus allowing an incremental temperature increase.

DOCUMENTATION: RI IL 287-203-91-025, SODB RI-1344.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT (CONTINUED)

3. IF PRE-FLIGHT OR REAL-TIME ANALYSIS PREDICTS A VIOLATION OF THE UPPER CABIN TEMPERATURE LIMIT DEFINED IN {A13-31}, CREW CABIN TEMPERATURE LIMITS, THE CABIN TEMP CNTLR BYP VLV WILL BE AUTOMATICALLY DRIVEN TO THE "FULL COOL" POSITION POSTSLEEP ON THE DAY OF THE EVENT. IF THE CREW THEN BECOMES UNCOMFORTABLE DUE TO THIS CONFIGURATION, THEY MAY ADJUST THE CABIN TEMPERATURE CONTROLLER TO ANY DESIRED POSITION TO SATISFY CREW COMFORT.

For each flight, BNA produces a Thermal Verification Analysis at the L-5 Month and L-1 Month time periods. An overall ATCS analysis, the Thermal Verification Analysis, provides the predicted cabin temperatures for each flight analyzed. Using this analysis, extensive preflight coordination is performed by EECOM and BNA to ensure the cabin temperature constraint is not violated. As part of this coordination, paragraph a will be used to provide a "cabin coldsoak" prior to any event that is foreseen as possibly causing the crew to be uncomfortably warm. Events that may require a cabin coldsoak include rendezvous, 10.2 psi operations, ISS ingress/egress operations, or other operations during which the ARS cannot react quickly enough to protect the upper limits. For most cases, ensuring the orbiter ATCS configuration is in the 10.2 Psi cabin configuration, in addition to paragraph a above, will ensure that the cabin temperature does not exceed the upper limit. ©[022201-4146]

4. IF THE INDICATED CABIN TEMPERATURE EXCEEDS: ©[022201-4146]

CABIN PRESSURE (PSIA)	HARDWARE UPPER LIMIT (DEG F)
14.7	95
10.2	85
INTERMEDIATE PRESSURE	$85 + (\text{CABIN P} - 10.2) \times 2.22$

THEN THE MCC MAY REQUEST THAT THE CREW OBTAIN ADDITIONAL TEMPERATURE DATA ON SPECIFIC AVIONICS BOXES TO CHARACTERIZE ANY POSSIBLE EFFECTS ON AVIONICS LIFETIME.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT
(CONTINUED)

The upper temperature limit for the avionics hardware is based on protecting the maximum air outlet temperature of 130 deg F for all flight deck avionics. Since outlet temperature cannot be measured directly, an inlet temperature limit is used to protect the outlet temperature constraint. At 14.7 psi, the SODB inlet temperature limit is 95 deg F. To derive the upper cabin temperature limit at lower cabin pressures, the 95 deg limit was scaled to account for the air density reduction and still protect the 130 deg outlet temperature limit. Since the previous limit (80 deg F) at 10.2 had been violated on occasion and the limit waived real time, a higher upper hardware limit was recommended (85 deg F). An analysis was performed by Boeing to assess the impact to the avionics lifetime of increasing the limit by 5 deg F. Per the aforementioned analysis, there is negligible impact to the reliability/lifetime of the avionics equipment so the hardware limit was changed to 85 deg F.

DOCUMENTATION: SODB 4.6.1.3.4-d, 4.6.1.4.3-a, and SD2-99-005, "Revised Cabin Temperature Requirements," OFTP#182. @[022201-4146]

5. IF, FOLLOWING AN AVIONICS TEMPERATURE CHARACTERIZATION, IT IS FOUND THAT THE AVIONICS LIMITS ARE BEING VIOLATED, THE FOLLOWING ACTIONS WILL BE CONSIDERED: @[022201-4146]
 - a. INCREASE AIRFLOW TO THE AVIONICS BY OPENING ACCESS DOORS IF INLET TEMPERATURES ARE WARMER THAN THE CABIN ENVIRONMENT.

Previous flight data have shown that the temperatures behind the panels can be higher than the cabin environment. Opening the access doors to the avionics is an easy way to improve mixing of the cooler cabin air with the air behind the panels and possibly reduce the inlet temperatures below the limit.

- b. USE WINDOW SHADES TO MINIMIZE LOCAL CABIN TEMPERATURE GRADIENTS.

Installing the shades can essentially negate the effects of solar heat loads transmitted through the windows to the cabin and flight deck. This action may be taken any time the crew desires to minimize temperature gradients.

DOCUMENTATION: SEH-ITA-82-028T. @[022201-4146]

- c. POWER DOWN SELECTED EQUIPMENT FROM THE FOLLOWING MATRIX. THE PRIORITY AND DEPTH OF POWERDOWN WILL DEPEND ON MISSION ACTIVITIES AND THE TRENDS IN CABIN TEMPERATURE. @[022201-4146]

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT (CONTINUED)

The matrix above lists selected equipment that will be powered off and includes the electrical load and the impact of powerdown. The priority of the equipment in the matrix depends on mission activities.

C. ENTRY:

CABIN TEMPERATURE WILL BE MANAGED AS FOLLOWS TO ENSURE ADEQUATE ENTRY TEMPERATURES IN ACCORDANCE TO RULE {A13-31}, CREW CABIN TEMPERATURE LIMITS:

1. PRE-SLEEP OF EOM-1, THE CABIN TEMP CONTROLLER WILL BE AUTOMATICALLY DRIVEN TO A POSITION TO ACHIEVE A CABIN TEMP OF 70 DEG F AT CREW WAKE ON ENTRY DAY.
2. PRE-SLEEP OF EOM-1, IF SLEEP TEMPERATURES WILL BE UNACCEPTABLY COLD, PER CDR AND SURGEON AGREEMENT, THE CABIN TEMP CONTROLLER POSITION CAN BE CONFIGURED TO PROVIDE A COMFORTABLE SLEEP ENVIRONMENT WHILE STILL STRIVING TO ACHIEVE THE OPTIMAL COLD SOAK. @[092701-4860]
3. THE CABIN TEMPERATURE CONTROLLER BYPASS VLV WILL BE AUTOMATICALLY DRIVEN TO THE "FULL COOL" POSITION, POST SLEEP OF ENTRY DAY.
4. ACTION WILL NOT BE TAKEN TO REDUCE CABIN TEMPERATURE IF THE D/O PREP TIMELINE HAS BEEN ENTERED.
5. FOR WAVEOFF DAYS, PREFLIGHT ANALYSIS WILL DICTATE THE LEVEL OF ACCEPTABLE POWER (EITHER GROUP B OR C POWERDOWN) TO OBTAIN CABIN TEMPERATURE CONCERNS. @[092701-4860]

Per Rule {A13-31}, CREW CABIN TEMPERATURE LIMITS, the Individual Cooling Units (ICU's), used during ascent/entry since STS-88, were designed to remove 340 BTU's/hr at an ambient temperature of 75 deg F, which is the metabolic heat load produced by a resting, minimally active crewmember. The actions above seek to ensure that the temperatures documented in the Section 13 rule are met and still provide comfortable temperatures for the crewmembers during the sleep period prior to entry day.

@[022201-4146]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-152

CABIN TEMPERATURE CONTROL AND MANAGEMENT (CONTINUED)

Flight data from several flights indicated that achieving a cabin temperature of 70 deg F, at crew wake on entry day, would satisfy the defined limits and still provide comfortable temperatures for the crewmembers during the sleep period prior to entry day. At the OFTP #176 in August 1999, the recommended position for the Cabin Temp Selector to achieve this temperature was approximately the 10 o'clock position. Flight demands may necessitate a different position for future flights. If other temperature data indicate that the cabin temperature transducer has a significant bias, the position of the cabin temperature controller selector can also be biased to target an actual temperature of 70 deg F, rather than a cabin temperature transducer indicated temperature of 70 deg F. ©[022201-4146]

Pre-sleep of EOM-1, if sleep temperatures will be unacceptably cold, per CDR and surgeon agreement, the cabin temp controller position can be configured to provide a comfortable sleep environment while still striving to achieve the optimal coldsoak. ©[092701-4860]

The Cabin Temperature Controller Bypass Valve will be driven to the "Full Cool" position, post-sleep, to continue the cabin coldsoak for entry.

Analyses produced by Boeing North America at the L-5 month and L-1 month milestones provide feedback to MOD on whether or not these temperature limits are met during the flight planning process. Predicted violations will be worked on a flight-by-flight basis, if required.

If a limit is violated during the Deorbit Prep/Entry timeframe, there are no easy actions remaining to reduce the cabin heat load. Powerdowns of orbiter or payload equipment would be necessary but are not desirable during this time period. The risks introduced by turning off entry-related equipment outweigh the slight increased risks to crew health that temps above 75 deg F may cause.

In order to produce water for additional entry attempts (for weather wave-off days, etc.), the Flash Evaporator is normally deactivated for weather extension days. This configuration, in conjunction with the nominal debris protect attitude of -ZLV -XVV, caused concerns that the entry cabin temperature constraints could not be met. BNA produced an analysis (November 3, 1999), in this configuration, with a Group B powerdown. Temperatures were found to be acceptable for an extension day with only a Group B powerdown in place. Temperatures were elevated for the actively cooled payload case, with a 3000 W payload allocation. Flights with actively cooled payloads will require additional analyses to ensure adherence to the entry cabin temperature limit. Because of this, the rule allows for either a Group B or C powerdown to be performed, dependent on the flight manifest.

FLIGHT RULES

A17-153

CABIN/AVIONICS BAY FAN MANAGEMENT

- A. FOR LOSS OF AN AVIONICS BAY FAN DELTA PRESSURE TRANSDUCER, THE SECOND FAN WILL BE TURNED ON AND LEFT ON UNTIL EOM.

Since the crew and the ground operator have lost insight into fan performance with the loss of a fan delta pressure transducer, two fans will be turned on to protect against a fan failing undetected. This rule still applies for upgraded avionics fans (cabin fans) installed in av bay 3A. Even though the fans are larger than regular avionics fans, the crew may not be able to detect a fan loss by sound as mentioned in paragraph B of this rule. Mission duration may be impacted due to a higher consumables usage with an additional fan powered on. ©[040899-2499B]

DOCUMENTATION: Engineering judgment.

- B. FOR LOSS OF A CABIN FAN DELTA PRESSURE TRANSDUCER, BOTH CABIN FANS WILL BE TURNED ON DURING SLEEP PERIODS.

Since the crew and the ground operator have lost insight into fan performance with the loss of a fan delta pressure transducer, two fans will be turned on during sleep periods to protect against a fan failing undetected while the crew is asleep. The crew can detect cabin fan loss (sound) during awake periods. Mission duration may be impacted due to a higher consumables usage with an additional fan powered on. ©[040899-2499B]

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A17-154

MANAGEMENT OF DEGRADED ROTATING EQUIPMENT

- A. ANY ROTATING EQUIPMENT (EXCEPT THE CABIN FAN) THAT LOSES A SINGLE PHASE WILL BE SWITCHED TO THE ALTERNATE EQUIPMENT.
@[032395-1752A]

All equipment with the exception of the cabin fan and the upgraded avionics fan can be restarted on two phases. @[040899-2500]

Since the lifetime of two-phase operations is confirmed to 168 hours (for new equipment) and the two-phase equipment operates below normal performance, it is prudent to switch from the two-phase equipment.

The JSC test and OV-101 fan test at Rockwell-Downey showed that when a cabin fan was started on two phases that it popped the 3 AMP cb's powering the fans.

If a cabin fan loses a phase, it is prudent to continue operating the two phase cabin fan since it may not be possible to restart that fan if it is turned off and loss of one cabin fan results in an MDF (reference Rule {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA). In the case of an upgraded avionics fan, which is the same as a cabin fan, it is not necessary to continue operating an upgraded av bay fan on two phases since the loss of one av fan has no mission duration impacts. Further, it is not recommended to continue operating the fan on two phases since two phase operation is below nominal performance and could cause damage to the fan. Should a second failure occur which causes loss of the remaining fan, there is an IFM to swap power supplies assuming the second failure is not a power supply failure.
@[040899-2500]

- B. FOR ROTATING EQUIPMENT THAT IS DEGRADED FROM NORMAL OPERATING LEVELS, BUT ABOVE LOSS DEFINITIONS FOR REASONS OTHER THAN LOSS OF A PHASE, THE FOLLOWING MANAGEMENT WILL BE APPLIED:
1. FOR EQUIPMENT THAT WOULD CAUSE EARLY MISSION TERMINATION IF THE EQUIPMENT COULD NOT BE RESTARTED, THE DEGRADED EQUIPMENT WILL CONTINUE TO BE OPERATED, PROVIDED NO SAFETY HAZARD EXISTS.

If equipment is degrading for reasons other than loss of a phase (bearing seizure, material failure, etc.) then restarting that piece of equipment could not be guaranteed (static friction being greater than dynamic friction). If the equipment is required GO for GO/NO-GO purposes, then it would have to be shown that it would restart once it was deactivated. This could cause early mission termination. Therefore, it would be prudent to remain on the degraded equipment until the performance violates its loss definition, provided no safety hazard exists. @[032894-1751A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-154

MANAGEMENT OF DEGRADED ROTATING EQUIPMENT
(CONTINUED)

2. FOR EQUIPMENT THAT WOULD NOT CAUSE EARLY MISSION TERMINATION IF IT COULD NOT BE RESTARTED, THE DEGRADED EQUIPMENT WILL BE SWITCHED TO THE ALTERNATE EQUIPMENT.
@[032894-1751A]

Since the equipment is not required GO for GO-NO/GO purposes, it would be prudent to switch from the degraded equipment. This would eliminate the risk/probability of a safety hazard while having no EOM impacts.

Documentation: SODB Vol. IV 4.1.6.3, 4.1.6.4, Hamilton Standard, SP 01TBO [Item SV 6405 (Avionics Fans), SV 6470 (Humidity Separator), SV 6416 (IMU fans)], MCR 6159 (Rockwell's pitch to the CCB on 10/12/79 about starting fans on two phases). Engineering judgment. @[032395-1751A]

FLIGHT RULES

A17-155

REGENERATIVE CO₂ REMOVAL SYSTEM (RCRS) MANAGEMENT

A. ASCENT/ENTRY OPERATIONS

THE RCRS WILL BE DEACTIVATED FOR ASCENT AND ENTRY.

The RCRS requires a vacuum source to operate properly. Since a vacuum source is not available during ascent and entry, the unit is deactivated. LiOH canisters provide PPCO₂ control during these periods. If the RCRS remains activated through entry, the loss of vacuum source will cause the RCRS to shut down and will not damage the RCRS.

DOCUMENTATION: Engineering judgment.

B. ORBIT OPERATIONS

1. ACTIVATION/DEACTIVATION

THE RCRS WILL BE ACTIVATED AS SOON AS PRACTICAL ONCE ON ORBIT POST-OMS 2 AND DEACTIVATED AS LATE AS PRACTICAL PRE-DEORBIT BURN.

The RCRS serves a highly critical PPCO₂ removal function. Without a successful RCRS activation, mission duration is limited by the number of LiOH canisters flown. Early on-orbit RCRS activation allows immediate determination of whether the unit is operating properly allowing the crew maximum utility of the remaining LiOH canisters for entry planning. Troubleshooting and failure impact can then begin as soon as this information is known.

Deactivating the RCRS late in the deorbit timeframe minimizes usage of the manifested LiOH canisters in the event the mission is waved off for weather or system failures. When the RCRS is deactivated, a fresh LiOH canister will have been installed to control CO₂ levels through the remainder of deorbit prep and through entry.

DOCUMENTATION: Engineering judgment.

2. REACTIVATION

IF THE RCRS HAS BEEN DEACTIVATED FOR DEORBIT PREP, THE RCRS WILL NOT BE REACTIVATED FOR WAVE-OFF ORBITS, BUT WILL BE REACTIVATED FOR A WAVE-OFF DAY IF CONSUMABLES PERMIT.

THIS RULE CONTINUED ON NEXT PAGE

A17-155

REGENERATIVE CO2 REMOVAL SYSTEM (RCRS) MANAGEMENT (CONTINUED)

For wave-off orbits, the RCRS is not reactivated since RCRS activation coupled with LiOH canister removal during the busy deorbit prep period creates an unacceptably high crew workload.

For wave-off days, the RCRS is reactivated to save LiOH but only if cryogenic consumables permit the additional power consumption. Generally, sufficient stowed LiOH cans will permit at least two days of mission extension. The LiOH canister installed for RCRS deactivation will be removed for later use.

DOCUMENTATION: Engineering judgment.

3. CABIN AND AIRLOCK DEPRESS

THE RCRS WILL BE DEACTIVATED DURING A CABIN DEPRESS OR AN AIRLOCK DEPRESS.

The RCRS controller logic will shut down during cabin depresses or during an airlock depress since the failure logic criteria will be satisfied due to vacuum vent line or cabin pressure inputs. When the unit shuts down, a fault summary message (S66 CO₂ RL SYS MALF) will be generated and a fault light (panel M051F) lit. Once shutdown has occurred, the unit must be powered down and repowered in an orderly fashion to regain RCRS operations. Due to the high probability of this shutdown occurring during a critical time period, it is preferred to manually shut down the unit during these events. After these time periods, the RCRS will be reactivated.

CO₂ removal during this period is of little concern since the deactivation duration is short (~20 minutes) and since the partial pressure of CO₂ will decrease simply from the reduction of cabin or airlock pressure.

4. FOR LOSS OF THE RCRS, LIOH CANS WILL BE INSTALLED AND WILL DETERMINE EOM.

When the RCRS is lost (loss of PPCO₂ insight or total functional loss (ref. Rule {A17-106}, REGENERATIVE CO₂ REMOVAL SYSTEM (RCRS) LOSS DEFINITION)), either proper evaluation of the RCRS CO₂ removal capability is not possible or CO₂ control is lost. Without PPCO₂ insight, the proper action is to install and remove LiOH cans on a regular basis to ensure adequate CO₂ control.

Similarly, installation of LiOH cans subsequent to a total RCRS functional loss is required to regain proper CO₂ control.

Due to the limited number of cans stowed, their number will determine EOM.

FLIGHT RULES

A17-156**RCRS MANUAL SHUTDOWN CRITERIA**

THE RCRS WILL BE MANUALLY SHUT DOWN FOLLOWING EITHER A CABIN OR AN AVIONICS BAY FIRE.

In the event of either an orbiter cabin or avionics bay fire, preserving the RCRS CO₂ removal capability is of primary importance due to the limited number of LiOH canisters flown. Fire/smoke contaminants will be removed from the orbiter atmosphere with either fresh or used LiOH/charcoal and ATCO canisters. Exposure of the RCRS solid amine beds to fire contaminants causes irreversible damage to the RCRS CO₂ removal capability. Of the most probable orbiter fire combustion products (CO₂, CO, COF₂, HF, HCL, HCN, SO₂, NO_x, CF₃Br), the HCL, HF, and HCN react irreversibly with solid amine. Once absorbed, these gases will not be removed on exposure to vacuum through normal operation but will remain on the surface adsorption sites, degrading RCRS CO₂ removal capability. Additionally, RCRS post-fire contaminant removal is inefficient due to the limited RCRS airflow. After the contaminants have been removed from the air environment via LiOH/ATCO canisters, the RCRS will be reactivated to continue CO₂ removal operations. Reference Flight Rule {A17-53C}.3 and D.4, FIRE AND POST-FIRE ACTIONS.

DOCUMENTATION: Engineering judgment.

A17-157**LiOH REDLINE DETERMINATION**

A MINIMUM OF 2 DAYS OF UNUSED LiOH CANS MUST BE HELD IN RESERVE FOR CONTINGENCY USE THROUGH PLANNED NOMINAL END OF MISSION. A MAXIMUM P_{PCO₂} OF 7.6 MMHG WILL BE PROTECTED, UNLESS MISSION-SPECIFIC PAYLOAD CONSTRAINTS (REFERENCE PAYLOAD ANNEX FOR THAT MISSION) DICTATE MORE RESTRICTIVE LIMITS. ©[032395-1749]

Since the capability of a used (bagged) can is assessed only through analysis and cannot be guaranteed, only unused LiOH cans will be counted towards the redline. Enough unused standard LiOH canisters should be held in reserve to allow a minimum of 2 days of CONUS landing site opportunities in the event the prime form of CO₂ removal is lost (i.e., CO₂ removal system, LiOH cans in excess of redline, ISS CO₂ removal system while docked). If a repair cannot be completed before using LiOH from the 2-day reserve, a next PLS should be declared. The only form of CO₂ removal after all LiOH is depleted would be to perform cabin air overboard purges which will support as little as 2 hours of CO₂ control (assumes seven crewmembers, start and maintain 7.6 mmHg CO₂, N₂ consumables at redline). As a guideline, the number of LiOH canisters required for 2 days at 7.6 mmHg equals the number of crewmembers on board (a LiOH canister provides CO₂ removal for approximately 50 man-hours). Real-time or mission-specific assessments may override this guideline. ©[032395-1749]

FLIGHT RULES

A17-158

MANAGEMENT OF LIOH CANS FOR ADDITIONAL DAYS

- A. WHEN ADDITIONAL MISSION DAYS ARE DESIRED, A CHANGEOUT PLAN UTILIZING A PPCO₂ LEVEL OF 7.6 MMHG MAY BE USED IF NEEDED TO CREATE LIOH MARGIN. IN ORDER TO ACHIEVE MAXIMUM MISSION DURATION AND TO MINIMIZE BAGGING AND REUSE OF CANS, 7.6 CHANGEOUT SCHEDULES SHOULD BE IMPLEMENTED AS SOON AS POSSIBLE. MISSION-SPECIFIC PAYLOAD CONSTRAINTS MAY DICTATE WHETHER THIS MAXIMUM PPCO₂ LEVEL (AND THEREFORE THE MISSION EXTENSION) CAN BE SUPPORTED. FLIGHT SPECIFIC EXCEPTIONS WILL BE DOCUMENTED IN THE ANNEX. ©[032395-1748A]
- B. WHEN EXTENSION OF MISSION DURATION REQUIRES USED (BAGGED) LIOH CANS, THE FOLLOWING GUIDELINES WILL APPLY:
1. NO BAGGED CAN WITH LESS THAN 1 LBM OF LIOH REMAINING WILL BE CONSIDERED.
 2. BAGGED CANS WILL BE USED AS EARLY AS POSSIBLE.
 3. ONE USED CAN WILL BE UTILIZED IN COMBINATION WITH ONE FRESH CAN.
 4. THE PPCO₂ WILL BE NORMALLY MANAGED BELOW 7.6 MMHG. ADDITIONAL PAYLOAD CONSTRAINTS MAY REQUIRE LOWER PPCO₂ LEVELS; HOWEVER, THESE LOWER LEVELS WILL MAKE RE-USE OF CANS LESS EFFECTIVE.

When mission days are added to a flight after pre-flight planning has already dictated the use of a "standard" LiOH changeout schedule (cue card), a "7.6 Changeout Schedule" is the preferred way to ensure desired mission extension. Utilizing fresh LiOH until a PPCO₂ level of 7.6 mmHg is reached maximizes the efficiency of each can. Analysis and implementation of such a plan is straightforward, since the amount of LiOH in each fresh (unused) can is always known. The amount of LiOH in previously used cans is not known. This amount is arrived at by analysis only and is subject to variables such as actual crew metabolic rates, exactly when a can has been changed out, and how well it has been sealed.

Whenever a 7.6 plan is being considered, it should always be implemented as soon as possible. The longer a decision is delayed about the use of a 7.6 plan, the greater the uncertainty (amount of LiOH in bagged cans). ©[032395-1748A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-158

MANAGEMENT OF LIOH CANS FOR ADDITIONAL DAYS
(CONTINUED)

Circumstances may be such that mission duration extension can only be achieved through the use of previously used LiOH cans. However, cans with less than 1 lbm of usable LiOH remaining do not have sufficient CO₂ removal capability to be of practical use. ©[032395-1748A]

Since the amount of LiOH in used cans is estimated, they should be used as much as possible before the end of the mission. Further, since CO₂ removal rate degrades substantially as the quantity of LiOH remaining decreases, it is not always possible to maintain acceptable CO₂ rates, even though LiOH is being consumed out of the can. Installing a used can with a fresh can allows the used can to completely deplete while the fresh can maintains control over CO₂ levels.

DOCUMENTATION: Engineering judgment. ©[032395-1748A]

A17-159 THROUGH A17-200 RULES ARE RESERVED

FLIGHT RULES

PRESSURE CONTROL SYSTEMS (PCS) LOSS DEFINITIONS

A17-201 CABIN PRESSURE INTEGRITY

CABIN PRESSURE INTEGRITY IS CONSIDERED LOST IF:

A. ASCENT:

1. A NONISOLATABLE LEAK > 0.15 PSIA/MIN WILL RESULT IN THE INTACT ABORT THAT WILL PROVIDE THE EARLIEST AVAILABLE RETURN AND LANDING TIME.
2. A NONISOLATABLE LEAK > 0.02 PSIA/MIN, AND ≤ 0.15 PSIA/MIN, WILL RESULT IN AN AOA ABORT (GROUND CALL).
3. FOR A NONISOLATABLE LEAK ≤ 0.02 PSIA/MIN, OR ANY LEAK WHICH OCCURS AFTER THE CLOSE OF THE AOA WINDOW, PARAGRAPH B WILL DETERMINE EOM.

NOTE: ALL DP/DT VALUES REFERENCED IN THIS RULE ARE ASSUMED TO BE AN EQUIVALENT DP/DT AT 14.7 PSI CABIN PRESSURE AND NEGATIVE IN SIGN.

The rationale for selecting one dp/dt on which to call an immediate abort comes from the assumption that any penetration through the cabin wall always has the possibility of propagating, thereby increasing the leak rate. The numbers contained in this rule and rationale are leak rates which confirm a cabin leak during the different phases of ascent. Additionally, the numbers include a margin to protect for an increase in the leak rate. The leak rate of 0.15 psia/min is the dp/dt limit for an orbit 3 deorbit opportunity which protects for an 8 psi cabin to the ground. In order to provide margin against an increase in the leak rate, the intact abort that results in the quickest return and landing will be selected for any cabin leak rate that remains above 0.15 psia/min (both on-orbit and ground call). ©[120894-1740]

The highest probability of the leak occurring is during the first few minutes of flight when the drop in atmospheric pressure creates a large delta in pressure across the cabin wall. However, during the first 2 minutes of flight, cabin stretch (by ≈ -0.07 psia/min) and LES flow (by $\approx +0.02$ psia/min) will bias any dp/dt that is associated with a true leak. By selecting a leak rate of 0.15 psia/min as the immediate abort call, a dp/dt of this size will provide positive indication of a cabin leak at any point during ascent. ©[120894-1740]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-201

CABIN PRESSURE INTEGRITY (CONTINUED)

A leak rate in the range $0.02 < dp/dt \leq 0.15$ will allow continuing to orbit and then performing leak isolation procedures to determine whether the leak can be stopped. A leak rate of -0.02 would allow a landing at the next PLS. However, an AOA will be performed to provide additional margin should the leak rate increase. This leak rate is small enough to allow conservatism, but also large enough to not be masked by the post-MECO transient (≤ -0.02) so that a NO-GO call for APU shutdown can be made for a real leak. [120894-1740] [ED]

The onboard AOA call will be 0.08 psia/min which will be used for crew loss of communication procedures. This leak rate trips the class 1 Klaxon alarm and, therefore, cues the crew to a possible cabin leak and to cross check with a cabin pressure decrease. The C&W dp/dt limit is set at 0.08 psia/min to prevent nuisance alarms during the period from lift off to MECO when cabin pressure is transient due to LES helmet flow, thermal and external pressure drop effects.

DOCUMENTATION: Engineering judgment. [120894-1740] [ED]

B. ON-ORBIT:

A NONISOLATABLE LEAK SUCH THAT O_2/N_2 CONSUMABLES CAPABILITY WILL NOT ALLOW A NEXT PLS ENTRY AT 14.7 (10.2 IF ALREADY IN 10.2 PSIA OPS) PSIA PLUS THE GREATER CONSUMABLE REQUIREMENT OF THE FOLLOWING:

1. A 48-HOUR FLIGHT EXTENSION AT 14.7 (10.2 IF ALREADY IN 10.2 PSIA OPS) PSIA BEYOND THE NEXT PLS OPPORTUNITY, OR
2. THE PLANNED CONSUMABLES FOR THE 165-MINUTE, 8 PSIA CONTINGENCY RETURN REQUIREMENT

Cabin pressure integrity for on-orbit operations is defined to be lost at the point where normal operations can no longer take place (i.e., 14.7 (10.2 if already in 10.2 psia ops) psia cabin plus all reserves remaining intact). The two reserves which must be included to define loss of cabin pressure integrity are: (1) The required consumables to maintain 14.7 (10.2 if already in 10.2 psia ops) psia for two mission extension days, or (2) Loss of the 165-minute, 8 psia contingency reserve which would not allow an emergency deorbit should one become necessary. Allowing for all three of the above named consumable requirements does not leave sufficient margin between loaded quantities and what is required for contingency. Therefore, only the greater of the two reserves is required in addition to the 14.7 (10.2 if already in 10.2 psia ops) psia cabin maintenance to the next PLS.

Rules {A2-301}, CONTINGENCY ACTION SUMMARY; and {A17-305}, 14.7 PSIA CABIN REPRESSURIZATION LIMITATION; {A9-251}, CRYO HEATER MANAGEMENT FOR ASCENT; and {A17-1001}, LIFE SUPPORT GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A17-202

8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY

THE 8 PSIA CABIN CONTINGENCY (165 MINUTES) RETURN CAPABILITY IS CONSIDERED LOST IF:

- A. AT LEAST 2.5 LB O₂/HR/CREWMEMBER CANNOT BE SUPPLIED TO THE LES HELMETS.

The 8 psia cabin may present an unacceptable atmosphere for normal breathing (PPO₂ can drop below 2.5 psia), in which case the LES helmets must be worn. A 20 lb/hr flowrate to the LES helmet manifold is necessary to provide eight LES helmets with 2.5 lb/hr O₂ (11.0 liters/minute). This means sufficient upstream pressure must be supplied from the cryo tanks to accommodate LES helmet flowrates during LES helmet operations. The 2.5 lb/hr can supply enough O₂ to allow regular breathing both at rest and during a state of excitement in a resting position.

DOCUMENTATION: (TWO-WAY MEMO RECEIVED FROM J. WALIGORA/SD5 DATED 2/2/87).

- B. TOTAL N₂ QUANTITY IS LESS THAN THE N₂ REDLINE. @[050400-7196]

The N₂ Redline (also defined as the 8 psia cabin contingency 165-minute return capability requirement) is determined by the summation of N₂ tank measurement error and residuals (MER) and the N₂ required to support the 8 psia cabin pressure maintenance duration following a bleed down to 8 psia.

1. FOR AN INITIAL CABIN PRESSURE OF 14.7 PSIA, THE N₂ REDLINE IS THE VOLUME-DEPENDENT AMOUNT SHOWN IN THE FOLLOWING TABLE. @[050400-7196]

THIS RULE CONTINUED ON NEXT PAGE

@[050400-7196]

The 8 psia cabin pressure maintenance duration requirement is based on the amount of N₂ required to support a cabin leak caused by a 0.45-inch diameter hole and a landing 165 minutes later. The 165 minutes consists of two distinct durations: 1) The volume-dependent time required for the cabin pressure to “bleed down” from an initial cabin pressure to 8 psia during which no N₂ is used, and 2) The duration at 8 psia where the emergency 8 psia cabin regulators flow N₂ (and O₂) to make up for the cabin air loss and to maintain the cabin pressure at 8 psia. The entire orbiter volume, including modules, will be used to support the cabin leak. Larger volumes allow for a longer bleed down time to 8 psia, and N₂ will not be used until the cabin pressure reaches 8 psia; as the total usable volume increases, the amount of N₂ required to make the balance of the 165-minute duration decreases.

@[050400-7196]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-202

8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY (CONTINUED)

The 165-minute contingency return requirement assumes an intermittent flow of 17 lbm/hr O₂ from the direct O₂ orifice and an intermittent flow of 23 lbm/hr O₂ from the cabin pressure regulator to manage O₂ levels in the cabin environment. It also assumes a starting cabin pressure of 14.7 psia, PPO₂ of 3.20 psia, and temperature of 70 deg F. The actual amount of N₂ required to support the 8 psia cabin maintenance duration is shown in the table below. ©[050400-7196]

VEHICLE CONFIGURATION	VOLUME (ft ³)	8 PSIA MAINTENANCE REQ'T (LBM N ₂)
<i>Orb + Int Arlk</i>	2475	85.2
<i>Orb + Int Arlk + Tnl Adptr</i>	2605	82.3
<i>Orb + Int Arlk + Tnl Adptr + Short Tnl + Single Hab</i>	3718	58.0
<i>Orb + Int Arlk + Tnl Adptr + Short Tnl + Double Hab</i>	4824	34.3
<i>Orb + Int ArLk + Tnl Adptr + Long Tnl + Single Hab</i>	3921	53.8
<i>Orb + Int Arlk + Tnl Adptr + Long Tnl + Double Hab</i>	5027	29.5
<i>Orb + Ext Arlk</i>	2703	80.4
<i>Orb + Ext Arlk + Tnl Adptr</i>	2833	77.1
<i>Orb + Ext Arlk + Tnl Adptr + Short Tnl + Single Hab</i>	3946	52.9
<i>Orb + Ext Arlk + Tnl Adptr + Short Tnl + Double Hab</i>	5052	29.6
<i>Orb + Ext ArLk + Tnl Adptr + Long Tnl + Single Hab</i>	4149	49.1
<i>Orb + Ext Arlk + Tnl Adptr + Long Tnl + Double Hab</i>	5255	24.2

N₂ tank measurement error (4.05 lbm/tank RSS'd) and residuals (6.5 lbm/tank) are shown in the table below. Nominal management of the N₂ systems (ref Rule {A17-257}, N₂ SYSTEM MANAGEMENT) has both N₂ systems being used as one system. Therefore, MER determination should be based on all N₂ tanks being used to supply N₂ to the cabin.

	N ₂ (LBM)						
	2 TKS	3 TKS	4 TKS	5 TKS	6 TKS	7 TKS	8 TKS
<i>Measurement Error</i>	5.7	7.0	8.1	9.1	9.9	10.7	11.5
<i>Residuals</i>	13.0	19.5	26.0	32.5	39.0	45.5	52.0
<i>MER (TOTAL)</i>	18.7	26.5	34.1	41.6	48.9	56.2	63.5

©[050400-7196]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-202

8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY (CONTINUED)

2. FOR AN INITIAL CABIN PRESSURE OF 10.2 PSIA, ADD THE FOLLOWING N₂ QUANTITY TO THE 14.7 PSIA REQUIREMENT IN PARAGRAPH 1 TO GET THE N₂ REDLINE (165-MIN CONTINGENCY RETURN CAPABILITY REQUIREMENT). @[050400-7196]

IF THE FOLLOWING VOLUME IS AT 10.2	ADD THIS QUANTITY TO THE 14.7 PSIA REDLINE (LBM N ₂)
ORB + INT ARLK	40.8
ORB + INT ARLK + TNL ADPTR	42.6
ORB + INT ARLK + TNL ADPTR + SHORT TNL + SINGLE HAB	56.7
ORB + INT ARLK + TNL ADPTR + SHORT TNL + DOUBLE HAB	69.7
ORB + INT ARLK + TNL ADPTR + LONG TNL + SINGLE HAB	59.5
ORB + INT ARLK + TNL ADPTR + LONG TNL + DOUBLE HAB	73.9
ORB + EXT ARLK	43.9
ORB + EXT ARLK + TNL ADPTR	46.3
ORB + EXT ARLK + TNL ADPTR + SHORT TNL + SINGLE HAB	59.1
ORB + EXT ARLK + TNL ADPTR + SHORT TNL + DOUBLE HAB	71.9
ORB + EXT ARLK + TNL ADPTR + LONG TNL + SINGLE HAB	62.6
ORB + EXT ARLK + TNL ADPTR + LONG TNL + DOUBLE HAB	76.2

If the orbiter volume is at 10.2 psia, the additional N₂ is the amount required to give the same 165-min return capability for a cabin leak at an initial cabin pressure of 10.2 psia as exists with an initial cabin pressure of 14.7 psia. Because the bleed down duration from 10.2 to 8 psia is shorter than the bleed down time from 14.7 to 8 psia, the 8 psia cabin pressure maintenance duration is longer; therefore, more N₂ is required. To determine the total 8 psia maintenance duration requirement for an initial pressure of 10.2 psia, the N₂ quantity from the table above should be added to the 8 psia maintenance N₂ requirement from the table in the Paragraph B.1 rationale.

DOCUMENTATION: DF7/93-39, Cabin Leak Analysis (0.45 in Hole in Cabin, 165-Minute Return Capability), 11/16/93; and Level B Groundrules and Constraints. @[121593-1597]

FLIGHT RULES

A17-203

PPO₂ CONTROL

PPO₂ CONTROL IS CONSIDERED LOST WHEN BOTH AUTOMATIC AND MANUAL METHODS OF CONTROLLING PCS OXYGEN SUPPLY CAN NO LONGER CONTROL THE AMOUNT OF OXYGEN FLOWING INTO THE CABIN.

The ability to control PPO₂ inside the crew module is dependent on the integrity of the oxygen supply lines, valves, sensors, and automatic controllers. Control is considered lost on the low side when oxygen can no longer be fed to the cabin. This will eventually result in the PPO₂ level inside the cabin dropping to unsafe limits due to crew metabolic consumption of oxygen and cabin leakage.

PPO₂ control is considered lost on the high side when an unisolatable oxygen leak occurs or the crew is required to wear their launch/entry suit helmets for a period of time which causes the percent oxygen level in the cabin to exceed the GO/NO-GO criteria for a PLS (ref. Rule {A17-1001D}.3, LIFE SUPPORT GO/NO-GO CRITERIA). Depending on the leak rate, early termination will probably be necessary due to high oxygen concentration within the cabin.

DOCUMENTATION: Engineering judgment.

Rules {A17-301}, CABIN ATMOSPHERE MANAGEMENT; and {A17-1001D}, LIFE SUPPORT GO/NO-GO CRITERIA, reference this rule.

FLIGHT RULES

A17-204

N2 SUPPLY

- A. THE PCS N₂ SUPPLY IS CONSIDERED LOST IF THE N₂ TANK PRESSURE IS < 200 (375) PSIA. [ED]

The N₂ regulators control the N₂ pressure to the cabin regulators to 200 ± 15 psig. If the N₂ tank pressure is < 200 psia, the N₂ regulator loses control and regulator flow may not be adequate to meet the demand of the 14.7 psi cabin regulator. Below 200 psia, the N₂ supply is, for all practical purposes, lost.

DOCUMENTATION: SODB 4.6.1.1.4.A.3.

MODULE

- B. LOST IF N₂ TANK PRESSURE IS <300 PSIA/20.7 BARS.

The operating range of the N₂ tank is 300 to 3306 psi. The N₂ tank residual is 7 pounds mass (lbm) at a tank pressure of 300 psia.

*Reference: SLODB 3.2.4 and MSFC Memorandum for Record, EP 45 (83-103), August 31, 1983,
Subject: Updated SL-1 O₂/N₂ Consumables Analysis Results. [ED]*

A17-205

PPO2 SENSOR LOSS DEFINITION

A SINGLE PPO₂ SENSOR WILL BE CONSIDERED LOST IF IT DEVIATES MORE THAN 0.15 PSI FROM THE NEAREST READING OF THE TWO SENSORS THAT ARE WITHIN 0.15 PSI OF EACH OTHER.

A SUBSEQUENT SENSOR FAILURE WILL BE DETERMINED BY ANALYSIS USING PREVIOUS SIGNATURES AND O₂ FLOWRATES.

The initial failure of a PPO₂ sensor will be determined by comparison with the readings of the other two sensors. The sensors that are reading within 0.15 psi (±3.0 percent full scale) of each other are assumed to be nominal and the deviant sensor (>0.15 psi from the nearest PPO₂ reading) will be considered failed based on this assumption.

Because there are only two remaining sensors, no “voting out” capability exists; so, subsequent PPO₂ sensor failures will have to be determined through the analysis of previous PPO₂ signatures from both the current and past flight data, by the frequency of O₂/N₂ controller cycles, and by O₂ flow rates.

Note that the PPO₂ sensors have different accuracy specifications based on ambient temperature. Between 70 deg and 85 deg F, the sensor accuracy is ±1.5 percent of full scale; outside this band the accuracy drops to ±3.0 percent of full scale. The greater error is assumed for this rule.

DOCUMENTATION: Engineering judgment and MCR 16202.

FLIGHT RULES

A17-206

LES O₂ SUPPLY SYSTEM LOSS DEFINITION

ONE (OF TWO) LES O₂ SUPPLY SYSTEMS IS LOST IF THE ASSOCIATED O₂ CROSSOVER VALVE OR ECLSS O₂ SUPPLY VALVE CANNOT BE OPENED, OR FOR ANY OTHER BLOCKAGE IN THAT LEG OF THE SYSTEM (E.G., CHECK VALVE FAILED CLOSED). ©[050495-1756B]

The LES manifold is required to support procedures for a fire or toxic spill case. For these cases, the crew immediately dons the LESH/QDM. At 14.7 (10.2) psia, the maximum crew breathing rate is 5.5 (3.8) lbm/hr/crewman. If this rate cannot be met then on the LESH, the anti-suffocation device will open allowing ambient air to be ingested, possibly subjecting the crew to harmful gases/combustion products. When the crew is on the QDM's, they may be starved of O₂, possibly forcing them to remove the masks. For a 5 to 8 man crew at 14.7 psia, this rate cannot be met by a single O₂ supply system (24 lbm/hr). For a 5 or 6 man crew at 10.2 psia, the safety tolerance is marginal.

For the cabin leak case, the crew dons the LESH/QDM's at a pressure below 10.2 psia; therefore, the breathing requirement is lowered (2.7 lb/hr/crewman) and one O₂ system can supply enough O₂ for this contingency. Also, it would be acceptable for the anti-suffocation valves to periodically open since there is not a contamination concern. ©[050495-1756B]

The 8 psia cabin may present an unacceptable atmosphere for normal breathing (PPO₂ can drop below 2.7 psia), in which case the LESH/QDM's must be worn. A 21.6 lb/hr flowrate to the LES helmet manifold is necessary to provide eight LESH/QDM's with 2.7 lb/hr O₂ (11.8 liters/minute). This means sufficient upstream pressure must be supplied from the cryo tanks to accommodate LESH/QDM flowrates during LESH/QDM operations. The 2.7 lb/hr can supply enough O₂ to allow regular breathing both at rest and during a state of excitement in a resting position. ©[050495-1756B]

The O₂ supply system can be obstructed by the O₂ XOVR valve, ECLSS O₂ SUPPLY valve, or CHECK valve failing closed, as well as a blockage.

DOCUMENTATION: Two-way memo received from J. Waligora/SD5, dated 2/2/87. ©[050495-1756B]

A17-207 THROUGH A17-250 RULES ARE RESERVED

FLIGHT RULES

PCS SYSTEMS MANAGEMENT

A17-251 NORMAL PCS CONFIGURATION

NORMAL PCS COMPONENT CONFIGURATION WILL BE AS FOLLOWS:

- A. PCS 1 WILL BE OPERATED FROM LIFT-OFF TO MISSION MIDPOINT.
PCS 2 WILL BE OPERATED FROM MISSION MIDPOINT TO EOM.

As part of the redundant component checkout that is normally performed midway through the mission, the PCS system will be reconfigured to the alternate PCS system to verify system health and maximize total operating lifetime. Additionally, PCS 2 will be selected since it is impractical for KSC to perform a redundant component checkout during ground turnaround.

DOCUMENTATION: Engineering judgment.

B. NORMAL PCS VALVE CONFIGURATION:

1. ASCENT/ENTRY:
 - a. BOTH PCS 1 AND 2 14.7 PSIA CABIN REGULATOR INLET VALVES - CLOSED.
 - b. PCS 1 O₂/N₂ CONTROL VALVE - OPEN.
 - c. PCS 2 O₂/N₂ CONTROL VALVE - CLOSED.
 - d. O₂ REGULATOR INLET VALVES - CLOSED.

(NOTE: 8.0 PSIA EMERGENCY REGULATORS CANNOT BE DISABLED.)

2. ORBIT:
 - a. PCS 1(2) 14.7 PSIA CABIN REGULATOR INLET VALVES - OP;
PCS 2(1) 14.7 CABIN REGULATOR INLET VALVES - CLOSED.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-251 NORMAL PCS CONFIGURATION (CONTINUED)

- b. PCS 1(2) O₂/N₂ CONTROL VALVE - AUTO;
 PCS 2(1) O₂/N₂ CONTROL VALVE - CLOSED.
- c. O₂ REGULATOR INLET VALVE 1(2) - OPEN;
 O₂ REGULATOR INLET VALVE 2(1) - CLOSED.

The above ascent/entry configuration is the desirable switch setup in the event of a cabin leak during these flight phases. This configuration and associated rationale is different from the orbit configuration for a cabin leak, since the crew, on orbit, has more time to react to the leak and they are able to move about and reach the necessary switches.

For ascent/entry, the cabin regulator inlet valves must be configured prior to entering these flight phases due to the crew not being able to reach these switches once in their seats. The configuration of the O₂/N₂ control valves allows for one PCS system to be active to respond to a cabin leak once cabin pressure reaches 8.0 psia. For large leaks (meaning a leak where the stabilization pressure is below 6.5 psia with only one system active), the crew will procedurally activate PCS system 2 upon reaching 6.5 psia cabin pressure, to gain a minimum of 75 lb/hr additional N₂ flow. For the smaller leaks (<75 lb/hr), only one PCS system active is the preferred configuration. The O₂ regulator inlet valves are closed to supply all O₂ flow to the crew and any extra O₂ will flow to the cabin, during a cabin leak, via the direct O₂ valve.

For orbit operations, paragraph A of this rule defines PCS system configuration for the mission. This determines which cabin regulator inlet valves and O₂/N₂ control valves apply in the orbit portion of this rule. Normally, while on orbit, only one PCS system is used to automatically control cabin atmosphere. Therefore, the active PCS system will have the 14.7 psia cabin regulator open to maintain a 14.7 psia cabin, the O₂/N₂ control valve in auto to automatically regulate oxygen/nitrogen partial pressure, and the O₂ regulator inlet valve open to allow O₂ flow during O₂ cycles.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A17-252

CABIN PRESSURE RELIEF VALVES

BOTH CABIN POSITIVE PRESSURE RELIEF VALVES WILL BE ENABLED DURING ALL FLIGHT PHASES.

The failure of a pressure relief valve to open will not be detected until an overpressure condition exists. Because of the potential for an overpressure condition with possible catastrophic results, the redundant pressure relief function is enabled at all times.

DOCUMENTATION: Engineering judgment.

DOCUMENTATION: Engineering judgment.

A17-253

CABIN VENT VALVES

THE CABIN VENT VALVES WILL BE CLOSED PRELAUNCH AND THE CB'S OPENED AFTER ASCENT. THE CB'S WILL REMAIN OPEN FOR THE REMAINDER OF THE FLIGHT THROUGH POSTLANDING HANDOVER.

The cabin vent valves are opened to vent the cabin after the prelaunch cabin leak check at T minus 30 minutes and closed at T minus 20 minutes. After ascent the circuit breakers are opened to prevent accidental opening of the valves. Circuit breaker opening is postponed until after ascent because they cannot be reached by the crew prior to lift-off or during powered flight.

FLIGHT RULES

A17-254

CABIN O₂ CONCENTRATION

CABIN O₂ CONCENTRATION WILL BE MAINTAINED WITHIN THE SPECIFIED LIMITS FOR THE FOLLOWING CABIN PRESSURES:

- A. FOR 14.7 PSIA OPERATIONS, THE CABIN O₂ CONCENTRATION LEVEL WILL BE MAINTAINED BELOW 25.9 PERCENT.

Orbiter cabin materials and all middeck payload/experiments are required to be compatible (non-fire-propagating) with 25.9 percent O₂ concentration and have been qualified by test. Any materials or payloads flown which do not meet O₂ concentration requirements as stated in the Shuttle/Payload Middeck Accommodations document must have a waiver from the program office prior to flight. Instrumentation error for percent O₂ is derived by dividing worst case (high) PPO₂ plus instrumentation error (0.075) by worst case (low) cabin pressure minus instrumentation error (0.24) and equating this value to 25.9 percent. Then the indicated values, without the instrumentation error, are divided to arrive at the percent O₂ error.

DOCUMENTATION: NHB 8060.1B and NSTS 21000-IDD-MDK.

- B. FOR 10.2 PSIA OPERATIONS, THE CABIN O₂ CONCENTRATION LEVEL WILL BE MAINTAINED BELOW 30.0 PERCENT.

Testing on orbiter cabin materials has demonstrated that orbiter materials are non-fire-propagating at O₂ concentrations up to 30 percent. Middeck payloads/experiments are required to be compatible with a 30 percent O₂ atmosphere at a cabin pressure of 10.2 psi. Currently, all planned scheduled/unscheduled and contingency EVA's will be performed at 10.2 psi, if possible. However, until the vehicle is certified for 10.2 psi operations, a waiver is required to allow O₂ concentrations up to 30 percent.

DOCUMENTATION: MCR 11891 and NSTS 21000-IDD-MDK.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-254

CABIN O₂ CONCENTRATION (CONTINUED)

- C. FOR 8.0 PSIA OPERATIONS, THE CABIN O₂ CONCENTRATION LEVEL WILL BE MAINTAINED BELOW 40 PERCENT IF REMAINING CONSUMABLES ALLOW LESS THAN 36 HOURS TO ACCOMPLISH A LANDING. IF GREATER THAN 36 HOURS EXISTS, 35 PERCENT WILL BE THE UPPER LIMIT WHILE AT 8.0 PSIA. @[090894-1673A]
1. FOR CABIN LEAK SCENARIOS, OR SITUATIONS WHERE IT IS POSSIBLE, AN UPPER LIMIT OF 30 PERCENT WILL APPLY TO THE TRANSITION FROM 14.7 PSIA OPERATIONS TO 8.0 PSIA OPERATIONS.
 2. WHEN A DEPRESS TO 8 PSI IS USED AS A METHOD TO CONTROL RISING O₂ CONCENTRATIONS, AN UPPER LIMIT OF 40 PERCENT WILL APPLY TO THE TRANSITION FROM 14.7 PSIA OPERATIONS TO 8.0 PSIA OPERATIONS.

The 8.0 psia cabin operations is a contingency situation only requiring a landing no further than the next PLS. The 30 percent limit during the transition represents an O₂ concentration which is considered acceptable at all operating cabin pressures (14.7, 10.2, 8.0) for contingency situations. However, for scenarios where the depress to 8 psi is required as a method for controlling rising O₂ concentrations below the maximum limits (such as when the crew is required to remain on the QDM. LES's for extended periods of time or during an unisolatable O₂ leak into the cabin), it is not possible or practical to maintain the O₂ concentration below 30 percent. Therefore, in these cases, the 8.0 psia upper limit of 40 percent will apply. For example, in an avionics bay fire case, a depress rate great enough to maintain 30 percent maximum O₂ concentrations will also result in a negative differential pressure on the avionics bay, with respect to the cabin, causing the Halon and toxic combustion products to be drawn into the cabin (reference the rationale for Rule{A17-53C}.2, FIRE AND POST-FIRE ACTIONS). For these cases, it is considered less risk to manage the O₂ concentration between 30 and 40 percent in order to extend on-orbit time and avoid exposing the crew to toxic gasses. The decision to manage oxygen concentration up to 40 percent while at 8.0 psia is based on several factors. First, Rule {A13-53A}.2, MINIMUM PPO₂ CONSTRAINTS, requires the minimum acceptable PPO₂ level for 8.0 psia operations to be 2.35 psi in order for the crew to remain off the launch/entry suit helmets (LESH)/Quick Don Masks (QDM's) in a contingency situation. This is equivalent to a 30 percent O₂ level which is equivalent to the limit to which cabin materials have been tested. If the crew were to don the LESH once PPO₂ dropped below 2.35 psi, the resulting excess flow of oxygen would not allow maintaining the O₂ concentration below 30 percent. Therefore, it is not possible to both maintain percent O₂ under acceptable limits (30 percent) and maintain an acceptable breathing atmosphere for the crew, without helmets, at 8.0 psia. Secondly, Halon 1301 effectively is degraded at O₂ percentages higher than 40 percent; however, test data shows it can extinguish a fire in 8.0 psia/40 percent O₂ concentration. Finally, 40 percent allows the crew more on-orbit stay time and less crew involvement with the direct O₂ valve than an upper limit less than 40 percent. @[090894-1673A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-254

CABIN O2 CONCENTRATION (CONTINUED)

The 36-hour decision point for which upper limit to apply to oxygen concentration at 8.0 psi is arbitrary. A reason for having two upper limits while at 8.0 psi is to avoid extended operations at high O₂ concentration levels. Leak rates which allow less than 36 hours will be large enough to keep the oxygen concentration from remaining above 35 percent for long periods of time. (Ref. Rule {A13-53A}.2, MINIMUM PPO2 CONSTRAINTS.). @[090894-1673A]

Documentation: PRCB PCIN 41004, NASA TR-255-001.

Rules {A17-53}, FIRE AND POST-FIRE ACTIONS; and {A13-152C}, CABIN ATMOSPHERE CONTAMINATION, reference this rule.

FLIGHT RULES

A17-255

8 PSIA EMERGENCY CABIN CONFIGURATION

THE 14.7 PSIA CABIN REGULATOR INLET VALVES WILL BE CLOSED AND THE CABIN WILL BE ALLOWED TO BLEED TO 8 PSIA ONLY IF: @[090894-1673A]

- A. CABIN LEAK: O₂/N₂ CONSUMABLES ARE INSUFFICIENT TO ALLOW THE ORBITER TO EFFECT A NEXT PLS ENTRY AT 14.7 (10.2 IF ALREADY IN 10.2 PSIA OPS) PSIA CABIN PRESSURE PLUS A 24-HOUR FLIGHT EXTENSION AT 8 PSIA.

Operation at 14.7 psia is preferred because, at 8 psia, a powerdown is required and the crew must wear the LES helmet. However, if inadequate consumables exist to allow both a 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin pressure to the next PLS opportunity and 1 extension day at 8 psia, the cabin will be immediately reconfigured to the 8 psia emergency configuration (i.e., 14.7 cabin regulators closed and associated powerdowns performed).

If it is determined that enough consumables exist to allow the 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin pressure to the next PLS plus the 24-hour extension day at 8 psia, then the 14.7 (10.2 if already in 10.2 PSIA ops) psia cabin will be maintained to the next PLS opportunity to attempt a normal entry. If entry cannot be performed at the PLS opportunity, then the cabin must be reconfigured to the 8 psia emergency configuration for the remainder of the mission and an entry performed prior to consumables depletion @[090894-1673A]

DOCUMENTATION: Engineering judgment.

Rule {A17-254}, CABIN O₂ CONCENTRATION, references this rule.

- B. CABIN/AV BAY FIRE OR LEVEL 4 HAZARDOUS SPILL: THE CREW IS REQUIRED TO WEAR THE LES/QD, FOR AN EXTENDED PERIOD OF TIME TO PROTECT THEMSELVES AGAINST A CONTAMINATED CABIN ATMOSPHERE. @[090894-1673A]

A cabin depress to 8 psi and continuous purge at 8 psi will manage O₂ concentration below maximum levels as well as decrease the concentration of discharged Halon and any potentially toxic gases that were produced by a fire or hazardous elements that were spilled into the cabin atmosphere. This action could extend the time on orbit so as to avoid an ELS entry (ref. Rule {A17-53}, FIRE AND POST-FIRE ACTIONS, and {A13-155}, ORBITER HAZARDOUS SUBSTANCE SPILL RESPONSE). @[ED]

DOCUMENTATION: Engineering judgment @[090894-1673A]

Rule {A17-254}, CABIN O₂ CONCENTRATION, references this rule.

FLIGHT RULES

A17-256**O₂ BLEED ORIFICE MANAGEMENT**

THE O₂ BLEED ORIFICE WILL BE INSTALLED IN AN LEH VALVE QUICK DISCONNECT (QD), PRESLEEP ON FLIGHT DAY 1, IF PPO₂ LEVELS ARE BELOW 3.20 PSIA AND REMOVED DURING DEORBIT PREPARATION ACTIVITIES ON ENTRY DAY.

The O₂ bleed orifice, sized specifically for metabolic consumption of O₂ based on crew size, is installed to keep the 14.7 cabin regulator inlets in the low flow region of the regulator. This eliminates nuisance O₂/N₂ FLOW HIGH alarms caused by WCS cycles and O₂/N₂ flow switchovers. Normally, the bleed orifice is installed presleep on flight day 1, if PPO₂ levels permit. Due to oxygen introduced into the cabin via LES flow during ascent, however, the PPO₂ may be elevated to such a degree that bleed orifice installation is not necessary until postsleep on flight day 2. Delaying the installation will allow metabolic consumption to lower PPO₂ to nominal levels.

The bleed orifice is not used during ascent/entry since the PCS system is deactivated and there is no concern of generating nuisance flow alarms.

DOCUMENTATION: Flight data.

A17-257**N₂ SYSTEM MANAGEMENT**

BOTH N₂ SYSTEMS WILL NORMALLY BE OPERATED AS ONE SYSTEM.

Nominal operations for N₂ systems 1 and 2 has both systems fully open (i.e., supply valves, regulator inlet valves, etc.) so N₂ will be depleted simultaneously from all tanks. One of the drawbacks of operating both nitrogen systems as a single system is the possibility of losing more than one system's nitrogen quantity in the event of a massive tank leak. However, by operating both systems fully open, the risk is removed of a supply valve failing closed and cutting off one N₂ system for the remainder of the mission. The likelihood of a supply valve failing closed is considered greater than the possibility of a massive tank leak, and therefore the system is operated to protect against failure of one, or both, of the N₂ supply valves failing closed. Also, by depleting nitrogen equally from both systems, the quantity of N₂ remaining in a good system is maximized.

DOCUMENTATION: Engineering judgment.

Rule {A17-202B}, 8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY, references this rule.

FLIGHT RULES

A17-258

LOSS OF CABIN INTEGRITY T_{MAX} DEFINITION AND TIG SELECTION

- A. T_{MAX} IS DEFINED AS THE LATEST DEORBIT TIG THAT WILL ALLOW A LANDING BEFORE THE DEPLETION OF N₂ CONSUMABLES. IF CONSUMABLES WILL BE DEPLETED BEFORE A PLS LANDING, AN ELS LANDING WILL BE EFFECTED.
- B. THE MINIMUM ACCEPTABLE CABIN PRESSURE PRIOR TO ATMOSPHERIC REPRESSURIZATION IS 8 PSIA. THE PCS SHALL BE CONFIGURED TO MAINTAIN 8 PSIA. NOTE: EXTENDED TIME ON ORBIT AT A LOWER CABIN PRESSURE WILL BE SACRIFICED TO MAINTAIN A CABIN PRESSURE OF 8 PSIA.
- C. A DEORBIT TIG FOR LOSS OF CABIN PRESSURE INTEGRITY SHALL OCCUR AT OR BEFORE T_{MAX}.

T_{max} is defined as the deorbit TIG that synchronizes touchdown with the depletion of N₂ consumables. Note that T_{max} is independent of landing site availability and does not account for cooling certification violations due to loss of cabin pressure.

The T_{max} prediction is based on an assumed 8-psia emergency regulator maximum flowrate of 125 lb/hr of N₂ each (while the spec max flow is 75 lb/hr, OMRSD testing shows that the actual average max flow is about 125 lb/hr). It also assumes that the time from TIG to touchdown is 60 minutes and that O₂ is managed between 2.2 and 3.0 psia (ref. Rules {A17-254}, CABIN O₂ CONCENTRATION, and {A13-53}, MINIMUM PPO₂ CONSTRAINTS). N₂ depletion is defined in Rule {A17-204}, N₂ SUPPLY, as tank pressure below 200 (375) psia. [ED]

The vehicle avionics are not certified to withstand cabin pressures below 8 psia due to cooling requirements. Also, a cabin pressure of 8 psia is the minimum pressure which will allow the crew to function normally for any length of time without a prebreathe. Reference Rule {A13-51A}, CABIN PRESSURE. For these reasons, maintaining 8 psia (if possible) is mandatory.

In maintaining 8 psia, N₂ supplies will be exhausted as necessary. No N₂ conservation steps that involve lowering the cabin stabilization pressure below 8 psia will be attempted. Therefore, the time on orbit that could be achieved if the cabin was allowed to stabilize at a lower pressure will be sacrificed to maintain 8 psia.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-258

LOSS OF CABIN INTEGRITY T_{MAX} DEFINITION AND TIG
SELECTION (CONTINUED)

Actual TIG determination will be based on T_{max} and not the cabin stabilization pressure. Obviously, TIG must occur at or before T_{max} so that N_2 consumables do not deplete before touchdown, thereby allowing the cabin to drop to near zero pressure.

If a PLS site is available at 8 psia, it would be the most desirable landing site. Landing site options at cabin pressures lower than 8 psia will be very limited (probably one, if any) due to the rapid depletion of N_2 (a leak would have to be over 250 lb/hr for cabin pressure to stabilize below 8 psia). Therefore, landing site selection at cabin stabilization pressures lower than 8 psia need not be addressed.

All other rules regarding acceptable PPO_2 levels for breathing and O_2 concentration levels in the cabin must be upheld during a cabin leak in order to effect a safe entry.

DOCUMENTATION: NASA memo from James M. Waligora/SD5 - 7/14/86, EVA Prebreathe N_2 vs. Decompression Sickness Risk Table, engineering judgment, and KSC 8-psia reg OMRSD ground checkout testing. @[050400-7196]

FLIGHT RULES

A17-259

LES O₂ SUPPLY SYSTEM LOSS MANAGEMENT

- A. IF AN O₂ SYSTEM IS LOST DUE TO AN O₂ XOVR VALVE FAILURE, CHECK VALVE FAILURE, OR BLOCKAGE, AN IFM TO RESTORE FLOW WILL BE PERFORMED. @[050495-1756B]

If an O₂ XOVR valve or check valve is failed closed, the ability to protect the crew from a contaminated cabin is probably lost. For the blockage case, the IFM will be performed if the blockage is in such a place that allows the IFM to be viable. The IFM will restore full functionality to the LES MANIFOLD.

- B. UNTIL THE IFM IS COMPLETE, MIDDECK EXPERIMENTS INVOLVING LEVEL 3 OR 4 TOXIC MATERIALS THAT HAVE FEWER THAN THE SAFETY PANEL APPROVED NUMBER OF LEVELS OF CONTAINMENT SHOULD NOT BE PERFORMED, UNLESS DOING SO CLEARLY DOES NOT INCREASE THE RISK FOR A SPILL.

Experiments involving Level 3 or 4 toxic materials that have fewer than the Safety Panel approved number of levels of containment have lost a level of containment. Performing these experiments while an LES O₂ SUPPLY SYSTEM is lost may subject the crew to unnecessary risk. Experiments in isolatable volumes (Spacehab, etc.) are not affected by this rule. @[050495-1756B] @[092701-4872]

- C. CONSIDERATION WILL BE GIVEN TO PERFORMING A REAL-TIME TEST OF THE LES MANIFOLD CAPABILITIES. IF THE SINGLE O₂ SYSTEM SUPPLIES ENOUGH O₂ TO PREVENT THE ANTI-SUFFOCATION VALVES FROM OPENING WHILE ALL CREWMEMBERS ARE BREATHING RAPIDLY, THEN THE LES O₂ SUPPLY SYSTEM MAY BE CONSIDERED GO. @[050495-1756B]

It is generally believed that each crewmember consumes approximately 5.5 lb/hr of O₂ while breathing on the LES or QDM's, which exceeds the capacity of a single O₂ supply system. However, usage varies with each crew, so it is possible that a single system could support.

Documentation: STS-26 flight data, engineering judgment.

Reference Rule {A17-206}, LES O₂ SUPPLY SYSTEM LOSS DEFINITION. @[050495-1756B]

FLIGHT RULES

A17-260

PCS O₂/N₂ CONTROLLER CHECKOUT

- A. THE IN-FLIGHT CHECKOUT OF THE PCS O₂/N₂ CONTROLLERS REQUIRES A SWITCHOVER IN EACH DIRECTION WHILE OPERATING AT A CABIN PRESSURE OF 14.7 PSIA WITH THE O₂/N₂ CONTROLLER SWITCH IN THE "AUTO" POSITION. ALTHOUGH NOT REQUIRED, CHECKOUT OF BOTH SYSTEMS IS DESIRABLE AND WILL BE ACCOMPLISHED ON A NON-INTERFERENCE BASIS WITH MISSION OBJECTIVES. ©[032901-4188] ©[ED]

Checkout of the PCS O₂/N₂ Controllers is performed in-flight due to impacts associated with performing the checkout during ground processing. Switchover is based on the change in sensed ppO₂ across the upper and lower set points of the controller. Observing switchovers from both O₂ to N₂ and from N₂ to O₂ verify that the O₂/N₂ Controller is operating properly in its control range. Both switchovers must be observed during the same flight in order to complete a controller checkout. Full vehicle checkout requires four switchovers: one in each direction, and on each controller while operating at a cabin pressure of 14.7 psia. The Space Shuttle Master Verification Plan (MVP) requires at least one PCS system performance to be verified each flight. The PCS is normally reconfigured mid-flight to provide checkout time on both systems. However, mission events may require reconfiguration to be delayed to obtain a full checkout on one controller.

DOCUMENTATION: OMRS File IX, DV611FC.030 and ARPCS Performance Verification.

- B. IF A "NATURAL" SWITCHOVER DURING AUTOMATIC 14.7 PSI OPERATIONS DOES NOT OCCUR, THE FOLLOWING STEPS WILL BE EXECUTED, IN PRIORITY ORDER, TO INDUCE A SWITCHOVER AND ENSURE THE CHECKOUT OF AT LEAST ONE CONTROLLER:
1. TERMINATE FLOW TO THE O₂ BLEED ORIFICE.
 2. PLACE THE O₂/N₂ CONTROLLER SWITCH IN THE "CLOSED" POSITION (O₂) DURING CREW SLEEP.

Nominally, during 14.7 psi operations, the O₂/N₂ Controller switch is in "AUTO" while the crew is awake and "OPEN" (N₂) during sleep (to preclude switchover from O₂ to N₂ which can cause an N₂ Flow Hi alarm). Some missions do not provide enough time in auto mode to satisfy a complete checkout of both controllers due to 10.2 psi operations, pressures above 14.7 psi due to ISS repress, etc. In addition, some crews' metabolic O₂ use is well matched to the makeup flow from the O₂ Bleed Orifice and therefore ppO₂ does not change enough to drive a switchover. Auto switchovers cannot be predicted preflight; predictions require trend data for the specific crew during several wake and sleep periods.

©[032901-4188]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-260

PCS O₂/N₂ CONTROLLER CHECKOUT (CONTINUED)

Terminating O₂ Bleed Orifice flow will cause ppO₂ to decrease more rapidly, increasing the likelihood of a switchover from N₂ to O₂. Similarly, configuring the O₂/N₂ control valve to flow O₂ during crew sleep will slow the decrease of PPO₂ and possibly cause PPO₂ to rise overnight. This action will expedite a switchover from O₂ to N₂ once the O₂/N₂ controller is configured back to "AUTO" during crew wake. In this case, O₂ will be managed prior to sleep to prevent alarms during sleep. These methods require ground analysis for prediction and additional crew switch throws. ©[032901-4188]

Switchovers observed during represses do not satisfy the PCS checkout requirement because the data gathered could be lower fidelity due to the transient PPO₂ levels and short time between switchovers during the variable pressure environment of a repress. Therefore, switchovers observed during represses will only be used for PCS checkout verification in the event that a 'natural' or 'induced' switchover has not been observed due to unexpected events.

If a complete in-flight PCS checkout of at least one O₂/N₂ Controller cannot be accomplished on a mission, then additional ground testing is required prior to the next flight of that vehicle. If a full in-flight checkout is not accomplished, ground personnel will document the specific switchovers that did not occur and will ensure that the PCS is placed in the appropriate configuration to achieve the required switchovers during the next flight of the vehicle.

A17-261 THROUGH A17-300 RULES ARE RESERVED

FLIGHT RULES

10.2 PSIA CABIN ATMOSPHERE OPERATION

A17-301 CABIN ATMOSPHERE MANAGEMENT

THE CABIN ATMOSPHERE WILL BE MANUALLY MANAGED TO MAINTAIN THE CABIN PRESSURE BETWEEN 10.0 AND 10.4 PSIA AND THE CABIN PPO₂ BETWEEN 2.55 AND 2.80 PSIA, INDICATED.

Operation at these conditions satisfies the 10.2 EVA protocol for bends prevention, provides adequate PPO₂, and maintains an acceptable O₂ concentration below 30 percent. The 10.0 psia cabin pressure minimum avoids a powerdown due to cooling requirements. The 10.4 psia cabin pressure avoids C&W alarms from being tripped. The C&W upper limit is set at 10.6 to avoid breaking the 8.44 PPN₂ limit for EVA prebreathe. A PPO₂ of 2.55 psia prevents the crew from having to don LES helmets for 2.50 psia minimum metabolic PPO₂ at a 10.2 psia cabin pressure. 2.80 psia PPO₂ is within the 30 percent O₂ concentration flammability limit during 10.2 psia operations (ref. Rule {A13-53A}.1, MINIMUM PPO₂ CONSTRAINTS).

Rule {A13-103C}.1, EVA PREBREATHE PROTOCOL, references this rule.

A17-302 10.2 PSIA CABIN DEPRESSURIZATION CONSTRAINTS

CABIN DEPRESSURIZATION WILL NOT BE PERFORMED IF ANY OF THE FOLLOWING CONDITIONS EXIST:

- A. CABIN PRESSURE TRANSDUCER HAS FAILED, OR THE CABIN PRESSURE TRANSDUCER HAS DRIFTED BEYOND ± 1.2 PERCENT FULL-SCALE AND NEITHER OF THE FOLLOWING IS AVAILABLE:
 1. UPLINK OF A PASS SM CABIN PRESSURE CALIBRATION COEFFICIENT REAL-TIME COMMANDER OR,
 2. AN EMU FEEDWATER PRESSURE SENSOR THAT CAN BE VERIFIED AS ACCURATE TO WITHIN ± 0.24 PSIA FOR USE AS AN ALTERNATE CABIN PRESSURE TRANSDUCER. @[111094-1687]

The available OI backup measurements to determine cabin pressure, airlock/overboard delta P, and the delta P between supply H₂O inlet P and H₂O regulator P are not accurate enough to keep the cabin within specified pressure and PPO₂ limits. The airlock/overboard delta P transducer can give as much as ± 2.0 psi inaccuracy on the true cabin pressure. Using the H₂O regulator inlet pressure transducers and the H₂O supply inlet pressure can give as much as ± 2.8 psi inaccuracy. Therefore, the depressurization should not be performed using only these since these transducers do not provide accurate means of determining cabin pressure and O₂ concentration. @[111094-1687]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-302

10.2 PSIA CABIN DEPRESSURIZATION CONSTRAINTS (CONTINUED)

One of the requirements for the 10.2 psi certification (PCIN 60154) was to ensure the cabin pressure transducer would be within ± 1.2 percent full-scale (± 0.24 psi) accuracy prior to launch. The OMRSD requires the transducer to be within ± 1.0 percent prior to the vehicle leaving the OPF. This allows for some drift to occur between OPF processing and launch. A single point check is then performed during PPO₂ sensor calibration approximately 2 weeks prior to launch. If the transducer is determined to have drifted beyond ± 1.2 percent during the single point check, then a SCALING COEFFICIENT SET UPDATE (OI-21 and subs) will be required for any 10.2 psi operations using the last seven-point calibration verification for that vehicle. ©[111094-1687]

The EMU feedwater pressure sensor is certified as Crit 1 flight instrumentation. The spec accuracy of the EMU feedwater pressure sensor is ± 0.4 psia (± 2.5 percent full-scale); however, actual performance of the sensor far exceeds the specifications during vacuum chamber testing. The actual sensor performance varies with each EMU and is calibrated prior to each mission. If the orbiter cabin pressure sensor were to fail, an EMU would be unstowed, powered up, and a reading made of the feedwater pressure (AIRLK P XX.X on the EMU DCM) with the feedwater shutoff valve closed (WATER - OFF). The downlinked value of feedwater pressure sensor is given to two decimal places; however, it requires that the EMU UHF comm be active. The reading should be taken as soon as possible (within 1/2 hour is preferred) after the failure of the cabin pressure sensor is detected. The reported EMU reading will be compared to the last valid reading of the orbiter cabin pressure sensor and the vacuum chamber feedwater pressure sensor calibration data to verify that ± 0.24 psia accuracy (the 10.2 certification requirement) can be met. ©[050400-7196]

Use of the EMU for monitoring cabin pressure will only be required during the depress to 10.2 psi and the 10.2 psi maintenance activities. It is not necessary for the EMU to remain powered continuously. This will not pose a constraint to missions where only two EMU's are manifested since the cabin atmosphere will be managed to preclude the need for a 10.2 psi maintenance during the EVA when no EMU's are available in the orbiter. If there are no other EVA's scheduled, the cabin can be repressed to 14.7 psi during the EVA. ©[050400-7196]

Additional methods are available to perform coarse checks of the EMU feedwater pressure reading without the orbiter cabin pressure sensor. These methods include comparisons of the airlock/overboard (cabin/airlock) delta pressures and the delta pressure between the supply H₂O inlet pressure and H₂O regulator pressure, and Fluke MultiCal Pressure Sensor. The Fluke MultiCal Pressure Sensor is currently not certified as Crit 1 hardware and is therefore not available for use as an alternate means of monitoring for 10.2 psi operations.

If 10.2 EVA protocol cannot be utilized, the EVA crew will be required to prebreathe for 4 hours (14.7 EVA protocol) prior to each EVA. The 10.2 EVA protocol requires only a 40-minute prebreathe. ©[111094-1687]

B. TWO OF THE THREE PPO₂ SENSORS ARE FAILED. @[090894-1455]

During the depress to 10.2 psia and while at 10.2 psia, the cabin atmosphere is maintained manually, using PPO₂ as one of the determining parameters. Because the PPO₂ transducers have a history of drifting and PPO₂ must be maintained within tight limits, one parameter is not sufficient to guarantee that PPO₂ will be maintained within limits; therefore, there needs to be at least one confirming sensor to insure an accurate PPO₂ and O₂ concentration reading.

If C&W/FDA limits cannot be annunciated for PPO₂, the crew will have to closely monitor it to maintain the proper atmosphere. @[090894-1455]

DOCUMENTATION: Engineering judgment.

C. TOTAL N₂ QUANTITY IS LESS THAN: @[050400-7196]

1. THE NOMINAL MISSION REQUIREMENT, PLUS
2. THE N₂ REDLINE REQUIREMENT (FROM THE TABLE IN PARAGRAPH B.1 OF RULE {A17-202}, 8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY), PLUS
3. IF NOT INCLUDED IN THE NOMINAL MISSION REQUIREMENT, THE VOLUME-DEPENDENT AMOUNT REQUIRED TO REPRESS THE CABIN FROM 10.2 TO 14.7 PSIA, PER THE FOLLOWING TABLE. (NOTE: ONLY THE VOLUME THAT IS ACTUALLY BEING RERESSED SHOULD BE USED.) @[050400-7196]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-302

10.2 PSIA CABIN DEPRESSURIZATION CONSTRAINTS (CONTINUED)

CONFIG (VOLUMES TO BE DEPRESSED)	VOLUME (FT ³)	REPRESS REQ'T (LBM)
ORB + INT ARLK	2475	54.8
ORB + INT ARLK + TNL ADPTR	2605	57.7
ORB + INT ARLK + TNL ADPTR + SHORT TNL + SINGLE HAB	3718	82.4
ORB + INT ARLK + TNL ADPTR + SHORT TNL + DOUBLE HAB	4824	106.9

ORB + EXT ARLK + TNL ADPTR	2833	62.8
ORB + EXT ARLK + TNL ADPTR + SHORT TNL + SINGLE HAB	3946	87.4
ORB + EXT ARLK + TNL ADPTR + SHORT TNL + DOUBLE HAB	5052	111.9
ORB + EXT ARLK + TNL ADPTR + LONG TNL + SINGLE HAB	4149	91.9
ORB + EXT ARLK + TNL ADPTR + LONG TNL + DOUBLE HAB	5255	116.4

@[050400-7196]

If the 10.2 depress had been scheduled preflight, the amount of N₂ required to repress the cabin would be contained in the Nominal Mission Requirement.

The repress requirement listed in the above table assumes a cabin temp of 70 deg F and a repress of N₂ only, which is conceivable though conservative.

Some volumes may have requirements against operating at 10.2 psia. It may also be advantageous to preserve N₂ by isolating volumes prior to depressing to 10.2 psia. Only the volumes to be repressed from 10.2 psia should be used.

DOCUMENTATION: Engineering judgment. @[050400-7196]

FLIGHT RULES

A17-303 **CABIN REPRESSURIZATION PRIOR TO DEORBIT**

PRIOR TO DEORBIT, THE CABIN WILL BE REPRESSURIZED BACK TO 14.7 PSIA.

An entry at a cabin pressure less than 14.7 psia would require a powerdown (loss of cabin pressure, 8 psi powerdown) which is undesirable during entry. A concern also exists about the structural integrity of some components exposed to cabin pressures less than 14.7 psi during entry. These components would require a postflight structural analysis to determine if they should be replaced prior to next flight, resulting in extended turnaround time and unnecessary cost to the program.

DOCUMENTATION: Minutes of Initial 10.2 psia Certification meeting, August 18, 1986.

A17-304 **10.2 PSIA CABIN PRESSURE MANAGEMENT FOR MULTIPLE EVA'S**

FOR MULTIPLE EVA'S, THE CABIN WILL REMAIN AT 10.2 PSIA UNTIL THE LAST SCHEDULED EVA HAS BEEN COMPLETED.

Cabin repressurization from 10.2 to 14.7 psia requires 45 lb of N₂ and 11 lb of O₂. Repressurizing the cabin, knowing that another EVA is pending, would cause an unnecessary use of consumables.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A17-305

14.7 PSIA CABIN REPRESSURIZATION LIMITATION

CABIN REPRESSURIZATION WILL NOT BE PERFORMED IF A CABIN LEAK OF UNKNOWN ORIGIN OCCURS WHILE THE CABIN PRESSURE IS BEING MANAGED AT 10.2 PSIA.

By repressing the cabin with a declared unknown leak in the pressurized module, a structural pressure cycle will be imparted on the cabin which could cause the leak to enlarge. If the leak is of known origin and the source of the leak ensures the hole will not become larger by repressing the cabin to 14.7 psia, then a cabin repressurization may be performed if it can be done within the consumables guidelines of Rule {A17-201B}, CABIN PRESSURE INTEGRITY.

DOCUMENTATION: *Engineering judgment.*

A17-306

10.2 PSIA CABIN TEMPERATURE CONSTRAINT

CABIN REPRESSURIZATION TO 14.7 PSIA WILL BE PERFORMED IF THE CABIN TEMPERATURE CANNOT BE MAINTAINED < 80 DEG F.

The maximum air outlet temperature for all flight deck avionics is 130 deg F. At a 10.2 psia cabin pressure, the avionics have a 50 deg F delta temperature across the LRU. Therefore, the flight deck avionics must have an air inlet of less than or equal to 80 deg F so that the avionics will not overtemp. This rule is designed to protect the IMU's which cannot be powered down and are flight-critical avionics.

DOCUMENTATION: *SEH-ITA-83-179T.*

Rule {A17-308}, ATCS (10.2 PSIA CABIN) CONFIGURATION, references this rule.

A17-307

PAYLOAD 10.2 PSIA CABIN OPERATIONS

PAYLOADS WITHIN THE CREW MODULE THAT HAVE NOT BEEN CERTIFIED TO OPERATE IN A 30 PERCENT O₂ ENVIRONMENT WILL BE POWERED OFF DURING 10.2 PSIA CABIN OPERATIONS.

The Orbiter Middeck/Payload Standard Interface Control Document (ICD) gives a requirement that payloads must be compatible with a 31 percent O₂ environment at 10.2 psia cabin pressure. This avoids creating an ignition source in a high oxygen concentrated environment. This rule applies to payloads which may have a waiver or some other reason for being manifested on a flight with a scheduled cabin depress.

DOCUMENTATION: *Orbiter Middeck/Payload Standard ICD, ICD 2-1 M001, March 1984.*

FLIGHT RULES

A17-308 ATCS (10.2 PSIA CABIN) CONFIGURATION

ATCS CONFIGURATION WILL BE AS FOLLOWS:

- A. WITH ONLY ONE FLOW PROPORTIONING VALVE (FPV) IN THE INTERCHANGER (ICH) POSITION, A FES PRIMARY CONTROLLER MUST BE ACTIVATED. ©[ED]

With only one FPV in the ICH position, the FES is required to maintain cabin temperature < 80 deg F and the avionics bay air outlet temperatures < 130 deg F (per Rule {A17-306}, 10.2 PSIA CABIN TEMPERATURE CONSTRAINT). ©[ED]

- B. WITH BOTH FPV'S IN THE ICH POSITION, THE FES MAY BE DEACTIVATED IF ORBITER ATTITUDES ALLOW THE RADIATORS TO CONTROL THE EVAP OUT T < 52 DEG F. ©[ED]

This should maintain cabin temperature < 80 deg F and the avionics bay air outlet temperatures < 130 deg F (per Rule {A17-306}, 10.2 PSIA CABIN TEMPERATURE CONSTRAINT). However, the FES is normally activated during 10.2 psia operations to minimize fluctuations in cabin temperature and cabin pressure.

During periods when the orbiter attitude allows sunlight into the orbiter windows, the cabin temperature may experience fluctuations that exceed 80 deg F. For those cases, the window sunshades should be installed on the affected windows to minimize the thermal impact.

DOCUMENTATION: SEH-ITA-83-179T; flight data (STS-7, STS-41D, STS-31).

A17-309 CABIN PRESSURE TIME AT 10.2 PSIA

TIME AT 10.2 PSIA WILL BE MINIMIZED AS MUCH AS PRACTICAL.

Operations at 10.2 psia run closer to the flammability and cooling limits (than at 14.7 psia) as well as putting the orbiter in an off-nominal configuration for emergency deorbit. For these reasons, time at 10.2 psia should be minimized. However, the prebreathe protocol that requires the crew to be at 10.2 psia for 36 hours prior to an EVA should have priority over these concerns. The 36-hour period is required to avoid the initial 1-hour prebreathe prior to/during cabin depress.

Documentation: SEH-ITA-83-179T, Minutes of Initial 10.2 psia Certification meeting, August 18, 1986.

A17-310 THROUGH A17-350 RULES ARE RESERVED

FLIGHT RULES

WASTE COLLECTION SYSTEM (WCS) / VACUUM VENT LOSS DEFINITIONS

A17-351 **WCS SEPARATOR**

THE WCS SEPARATOR IS CONSIDERED LOST IF:

- A. UNABLE TO ESTABLISH DC OR AC POWER TO THE WCS SEPARATOR.
- B. THE SEPARATOR IS FLOODED AND CANNOT BE CLEARED.

The primary function of the WCS separator is to separate waste water from the cabin atmosphere. If the separator is flooded and cannot be cleared, or it will not start because it is unpowered, it is considered lost.

DOCUMENTATION: Engineering judgment.

A17-352 **WCS URINE COLLECTION**

WCS URINE COLLECTION CAPABILITY IS CONSIDERED LOST IF UNABLE TO TRANSPORT URINE TO THE WASTE WATER SYSTEM THROUGH EITHER PATH IN THE WCS.

The primary function of the WCS urine collection system is to transport liquid waste water to the waste water tank. If the line is blocked, leaking, or both separators are lost or any combination of failures which prevents the WCS from transporting urine to the waste water system, the urine collection mode is considered lost.

DOCUMENTATION: Engineering judgment and schematic.

FLIGHT RULES

A17-353

WCS COMMODE

THE WCS COMMODE IS CONSIDERED LOST AND SHOULD NO LONGER BE OPERATED IF:

- A. UNABLE TO OPEN THE SLIDE VALVE.
- B. THE COMMODE IS FULL AND CANNOT BE EMPTIED.
- C. UNABLE TO ESTABLISH SUFFICIENT AIRFLOW THROUGH COMMODE OUTLET TO CONTAIN FECAL MATTER WHEN THE SLIDE VALVE IS OPEN.
- D. VACUUM VENT CANNOT BE REMOVED FROM COMMODE FOR WCS USAGE.
- E. THE FECAL STORAGE TANK IS RUPTURED.

The commode must be able to collect and retain fecal matter. Operation of the WCS with any of the above conditions (except paragraph D) results in potential fecal matter in the cabin environment, which is unacceptable for reason of crew health.

For conditions A, B, C, and E, lengthy IFM procedures may have to be executed. If the WCS cannot be repaired, the mission may be terminated early because only a finite number of bags are carried on the orbiter.

If the vacuum vent (ref. paragraph D) cannot be removed from the commode during WCS usage, the WCS is at least partially open to vacuum. Furthermore, operation of the WCS under this condition could damage the slide valve and/or its seals. Several EECOM/IFM methods exist to remove the vacuum vent from the commode (e.g., STS-33 in-flight anomaly), but the intent of this rule is to cease WCS operations while the WCS is being evaluated and repaired.

DOCUMENTATION: Engineering judgment and schematic.

FLIGHT RULES

A17-354

VACUUM VENT LOSS DEFINITION

VACUUM VENT CAPABILITY IS LOST IF THE VACUUM VENT ISOLATION VALVE FAILS CLOSED AND THE WCS WASTE COLLECTOR PRESSURE EXCEEDS 1.0 PSIA WITH THE COMMODE NOT IN USE.

The primary functions of the vacuum vent are to vent gaseous waste, particularly H₂ gas extracted from fuel cell product water (approximately 9.75 × E-5 lb/hr), overboard and to provide a means for evacuation and depressurization of the airlock for EVA. The vacuum vent isolation valve is constructed such that an orifice in the valve plate allows a flow of approximately 3 lb/hr even with the valve fully closed. Assuming the commode is not in use, an increasing WCS waste collector pressure would indicate an obstruction somewhere in the vacuum vent line, the line pressure is increasing from the buildup of hydrogen from the hydrogen separators, and cabin air from the WCS wet trash vents as the line attempts to equalize to cabin pressure. The choice of 1.0 psia as a failure definition is not precise; however, since the time required to reach 1.0 psia after the failure occurs is short (approximately 10 minutes), it is used to eliminate transducer inaccuracy as the cause and to ensure time to identify a real problem.

This mixture of hydrogen and oxygen (from the air) could produce localized pockets of potentially flammable/detonable mixture, and an alternate means to vent this mixture overboard is required. While this is no longer possible to vent gaseous waste overboard through the vacuum vent line, the capability to depressurize the airlock for EVA can still be accomplished through use of the hatch "B" equalization valves, or in the case of a Spacehab module, through the use of the hatch "C" equalization valves.

©[ED]

DOCUMENTATION: Engineering judgment and schematic.

Rule {A17-405}, VACUUM VENT SYSTEMS MANAGEMENT [CIL], references this rule.

A17-355 THROUGH A17-400 RULES ARE RESERVED

FLIGHT RULES

WCS/VACUUM VENT MANAGEMENT

A17-401 WCS USAGE CONSTRAINT

THE WCS WILL NOT BE USED IF:

A. THE CABIN IS BEING REPRESSURIZED.

Possible low O₂ concentrations resulting from high N₂ flow during cabin repressurization could cause possible acute hypoxia of the crewmember using the WCS. Due to the small area that the WCS is in and due to the location of the WCS in relation to the PCS panel, M010W, exposure to the WCS area should be minimized.

DOCUMENTATION: CSD-SH-194.

B. AN EMU IS BEING DRAINED.

The WCS fan separator maximum waste water flowrate is 0.09 lbm/sec. With a crewmember using the WCS at a flowrate of 0.088 lbm/sec, the separator will flood when the EMU waste water is also drained through the WCS.

DOCUMENTATION: SODB 4.6.2.2.1.a.1.a and 4.6.2.2.3.b.2.b.

A17-402 LEAKING WCS WATER LINES

FOR AN UNREPARABLE LEAK IN THE WCS URINE LINE FROM THE INLINE FILTER TO THE WCS/WASTE WATER INTERFACE QUICK DISCONNECT, NO LIQUIDS WILL BE TRANSPORTED THROUGH THE WCS.

This is to prevent water from flowing into the cabin. Free water in the cabin could cause crew exposure to bacteria and toxins contained in waste water or the possibility of an electrical circuit malfunction.

DOCUMENTATION: Engineering judgment and schematic.

FLIGHT RULES

A17-403 **ALTERNATE FECAL COLLECTION**

IF THE WCS COMMODE IS LOST, THE CREW WILL USE THE APOLLO FECAL BAG TO COLLECT FECAL MATTER.

Waste bags are the alternate method of collecting waste. The standard manifest provides 40 bags to accommodate at least a PLS plus 2 days (3 days).

DOCUMENTATION: Engineering judgment and Crew Compartment Configuration Drawings, drawing SED-32101800-306.

A17-404 **ALTERNATE URINE COLLECTION**

IF THE WCS URINE COLLECTION CAPABILITY IS LOST, THE CREW WILL USE THE APPROPRIATE CONTINGENCY DEVICE: THE MALE URINE COLLECTION DEVICE (UCD) OR THE FEMALE URINE ABSORPTION SYSTEM (UAS).

UCD's and UAS's are alternate measures for collecting urine. The standard manifest provides 58 UCD's (four are dedicated to the EMU's) and 36 UAS's to accommodate at least a PLS plus 2 days (3 days).

DOCUMENTATION: Engineering judgment and Crew Compartment Configuration Drawings, drawing SED-32101800-306.

FLIGHT RULES

A17-405

VACUUM VENT SYSTEMS MANAGEMENT [CIL]

- A. SHOULD THE VACUUM VENT ISOLATION VALVE FAIL CLOSED, WCS WASTE COLLECTOR PRESSURE WILL BE UTILIZED TO MONITOR PROPER VENTING OF GASEOUS WASTE OVERBOARD THROUGH THE VACUUM VENT ORIFICE.
- B. IF VACUUM VENT CAPABILITY IS LOST, THE WCS VACUUM VALVE MUST REMAIN OPEN FOR THE DURATION OF THE MISSION, INCLUDING ENTRY.
- C. IF VACUUM VENT CAPABILITY IS LOST, THE FOLLOWING STEPS WILL BE ACCOMPLISHED:
 - 1. THE "CONTINGENCY VACUUM VENT OPERATION" IFM WILL BE ACCOMPLISHED TO RESTORE VACUUM VENT CAPABILITY.
 - 2. WCS COMMODE OPS WILL BE TERMINATED UNTIL VACUUM VENT CAPABILITY IS RESTORED.
 - 3. THE IFM HOSE WILL BE DISCONNECTED AT THE CONTINGENCY WATER CROSSTIE WASTE QD DURING WASTE WATER DUMPS.
 - 4. THE "CONTINGENCY VACUUM VENT OPERATION" IFM WILL REMAIN INSTALLED THROUGH ENTRY.

Failure of the vacuum vent isolation valve in the closed position will not adversely impact nominal WCS operations; however, WCS waste collector pressure will be closely monitored to ensure proper operation of the vacuum vent system. If vacuum vent capability is considered lost (ref. Rule {A17-354}, VACUUM VENT LOSS DEFINITION), WCS commode ops will be terminated until vacuum vent capability is restored through use of the CONTINGENCY VACUUM VENT OPERATION IFM to minimize hydrogen release into the cabin and to stop the rapid (within minutes) formation of a flammable/detonable gas mixture with the WCS/vacuum vent ducting. Upon indications of vacuum vent failure, preliminary analysis calls for implementation of the IFM within 1 to 2 hours to preclude formation of localized pockets of a potentially flammable/detonable mixture. At no time should the WCS vacuum valve be closed as this would result in a potentially flammable/detonable gas mixture forming in the vacuum vent duct in a matter of minutes. Once the IFM is accomplished, it will remain in place for the duration of the mission through entry to ensure safe, overboard venting of hydrogen gas. To prevent possible waste water backup into the cabin, the IFM hose will be disconnected at the contingency water crosstie waste QD during waste water dumps.

DOCUMENTATION: Engineering judgment and schematic. Informal letter from Michael D. Pedley to John Wong; Subject: Compatibility of Nyloseal tubing with a hydrogen/air mixture, dated September 6, 1990.

A17-406 THROUGH A17-450 RULES ARE RESERVED

FLIGHT RULES

WASTE WATER LOSS DEFINITIONS

A17-451 **WASTE WATER TANK**

THE WASTE WATER TANK IS CONSIDERED LOST IF:

- A. UNABLE TO FILL THE TANK.
- B. THE TANK OR INLET MANIFOLD HAS AN IRREPARABLE LEAK.
- C. THE WASTE TANK QUANTITY IS AT 98 (93) PERCENT AND WASTE DUMP CAPABILITY IS LOST.
- D. THE WASTE TANK HAS A BELLOWS LEAK AND THE WASTE LIQUID PRESSURE IS \geq 5 PSID ABOVE THE H₂O N₂ REGULATOR INLET PRESSURE. @[ED]

The primary purpose of the waste tank is to collect and store waste water. If the line to the waste tank is blocked or has an irreparable leak, or if the waste water tank is full and cannot be dumped, the waste tank is considered lost. For an irreparable leak, the waste tank will be unable to store waste water. For a bellows leak, there is no way to determine the quantity in the waste water tank. The waste liquid pressure normally reads approximately the same as H₂O N₂ regulator inlet pressure. If the waste liquid pressure is \geq 5 psid, then the waste water tank is full and will not be allowed to store any more water, because then water will transfer into the N₂ system by passing through the hydrophobic filter.

DOCUMENTATION: Engineering judgment and SODB, 4.6.2.2.4.c.2.

FLIGHT RULES

A17-452

WASTE WATER DUMP CAPABILITY

THE WASTE WATER DUMP CAPABILITY IS CONSIDERED LOST IF:

- A. THE WASTE WATER DUMPLINE TEMPERATURE CANNOT BE MAINTAINED > 32 DEG (37 DEG) F.

This is the minimum temperature at which a successful dump may be accomplished to prevent any ice from forming on the nozzle and to prevent the water in the dumpline from freezing.

The contingency crosstie will not be used because it is downstream of the dump isolation valve. This is to prevent the stagnant water in the waste water dumpline from forming into ice, while the waste water is being dumped through the supply water nozzle.

DOCUMENTATION: SEH-TCH-85-036.

- B. THE WASTE WATER DUMPLINE IS BLOCKED AND THE CREW IS UNABLE TO USE THE CONTINGENCY CROSSTIE.

If the dumpline is blocked, the primary path to dump waste water is unusable. If the crew cannot use the contingency crosstie to dump waste water through the supply water nozzle (see Rule {A18-52}, SUPPLY/WASTE WATER CROSSCONNECT), the only other method to dump waste water has been lost.

DOCUMENTATION: Engineering judgment.

- C. AN IRREPARABLE LEAK IN THE LINE EXISTS PAST THE WASTE DUMP ISOLATION VALVE.

This is to prevent free water in the cabin if the leak is inside the crew module. If the leak is outside the 576 bulkhead, it is to prevent ice from forming under the payload bay liner causing damage to the equipment that is located under the liner.

DOCUMENTATION: Engineering judgment and schematic.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-452 WASTE WATER DUMP CAPABILITY (CONTINUED)

- D. BOTH WASTE NOZZLE TEMPERATURE TRANSDUCERS ARE FAILED, THE RMS IS UNAVAILABLE TO OBSERVE A WASTE WATER DUMP, AND THE CREW IS UNABLE TO USE THE CONTINGENCY CROSSTIE.

With no insight into the nozzle temperatures, waste water dumps will not be permitted (without the RMS observing) to prevent forming an icicle on the nozzle due to an undetectable heater failure. If available, the RMS must be used to observe all subsequent dumps. Once ice growth outward from the nozzle is visually observed, the dump shall be terminated (see Rule {A17-505C}, WASTE WATER DUMP NOZZLE TEMPERATURE CONSTRAINTS). If the crew cannot use the contingency crosstie to dump waste water through the supply water nozzle (see Rule {A18-52}, SUPPLY/WASTE WATER CROSSCONNECT), the only remaining method to dump waste water has been lost.

DOCUMENTATION: Engineering judgment.

- E. THE NOZZLE TEMPERATURE CRITERIA FOR DUMPING WASTE WATER CANNOT BE MET AND THE CREW IS UNABLE TO USE THE CONTINGENCY CROSSTIE.

If the nozzle temperature criteria cannot be met, the primary path to dump waste water is unusable (ref. Rule {A17-505}, WASTE WATER DUMP NOZZLE TEMPERATURE CONSTRAINTS). If the crew cannot use the contingency crosstie to dump waste water through the supply water nozzle (ref. Rule {A18-52}, SUPPLY/WASTE WATER CROSSCONNECT), the only other method to dump waste water has been lost.

DOCUMENTATION: Engineering judgment.

A17-453 THROUGH A17-500 RULES ARE RESERVED

FLIGHT RULES

WASTE WATER MANAGEMENT

A17-501 ALTERNATE PRESSURE VALVE MANAGEMENT

THE ALTERNATE PRESSURE VALVE WILL NORMALLY BE CLOSED THROUGHOUT THE FLIGHT.

The alternate pressure valve is a backup means of supplying pressure (cabin pressure) to the water system. Normal water system pressurization utilizes the gaseous nitrogen system. Activation of this valve only lowers available water system pressure to cabin pressure and should be used in a contingency mode only.

DOCUMENTATION: Engineering judgment, SODB 4.6.1.1.1 r, SODB figures 4.6.1-3 and 4.6.1-4.

A17-502 WASTE DUMP NOZZLE ICE FORMATION

- A. IF ICE IS DETECTED ON THE WASTE DUMP NOZZLE, ALL FURTHER DUMPS FROM EITHER NOZZLE WILL BE DISCONTINUED UNTIL SUCH TIME AS THE ABSENCE OF THE ICE CAN BE VERIFIED. ©[061396-1878C]
- B. ONCE THE ABSENCE OF ICE CAN BE VERIFIED VISUALLY OR BY THE OBSERVATION OF NOMINAL NOZZLE HEATER CYCLES, DUMPS FROM THE SUPPLY NOZZLE MAY BE PERFORMED.
- C. SUBSEQUENT WASTE DUMPS MAY BE CONSIDERED IF SUFFICIENT ULLAGE (WASTE TANK + CWCS) IS NOT AVAILABLE TO MAKE NOMINAL EOM, AND A METHOD TO VISUALLY OBSERVE THE NOZZLE IS AVAILABLE. ©[061396-1878C]

Detectable ice buildup on the waste dump nozzle has been known to compound the ice formation on the supply nozzle due to the close proximity of the nozzles to each other (approximately 6.5 to 7.0 inches). Frost has not been a problem. If the ice can be procedurally removed, supply dumping can be resumed because the mechanism aiding in the supply nozzle ice growth no longer exists. The original problem causing the waste nozzle to ice is probably still present so the risk of creating more ice is reduced by not allowing any more waste dumps. When a method is available to visually observe the nozzle for ice formation, the dump can be stopped when it is observed that the ice is starting to grow outward from the nozzle and before the ice becomes a problem. ©[061396-1878C]

DOCUMENTATION: Engineering judgment; CSD-SH-291; flight data STS-8, STS 41-B, STS 41-D and STS-65. ©[061396-1878C]

Rule {A17-505}, WASTE WATER DUMP NOZZLE TEMPERATURE CONSTRAINTS, references this rule. ©[061396-1878C]

FLIGHT RULES

A17-503

WASTE WATER STORAGE

THE FOLLOWING TECHNIQUES WILL BE USED, IN ORDER OF PRIORITY, TO MANAGE WASTE WATER.

The priorities for management of liquid waste are necessary to provide for protection of the crew's health while maintaining ability to complete certain mission objectives.

- A. PLAN TO DUMP THE WASTE WATER THROUGH THE WASTE WATER DUMP NOZZLE BEFORE THE WASTE QUANTITY REACHES 80 PERCENT. DEORBIT WAVEOFF PLANS WILL INCLUDE A WASTE DUMP PRIOR TO THE TANK REACHING 80 PERCENT. ©[042502-5329B]

Filling the waste tank up to 80 percent helps minimize the number of dumps that need to be performed during a mission. The 80 percent limit allows time for the ground and crew to react in case of problems executing the dump (ice, blockage, crew or attitude availability, etc.) and put off contingency measures such as constraining WCS ops or offloading waste water into a CWC.

- B. IF REQUIRED TO SUPPORT THE LAST POSSIBLE LANDING DAY FOR A MISSION, FILL THE WASTE TANK TO NO MORE THAN 93 (88) PERCENT AT 2 HOURS AFTER THE LAST LANDING OPPORTUNITY FOR THAT DAY.

Allowing the tank to exceed 80 percent in this case may avoid a waste dump on a waveoff day and thereby save crew time, attitude maneuvers, and propellant. Ninety-three (88) percent and the 2 hours after the last landing opportunity allow adequate ullage for postlanding prior to vehicle powerdown, as well as expansion of gas in the waste water tank when the water tanks are "unpressurized" due to vacuum vent inerting.

Paragraphs A and B are the most acceptable way to manage the waste water system because they provide for protection of the crew's health by isolating the waste water from the supply water system and from the crew compartment.

- C. UTILIZE THE CONTINGENCY WATER COLLECTION BAG (CWC).

Paragraph C also protects crew health and ground turnaround of the supply water system; however, it raises significant operational concerns, including crew time for unstowing, using and restowing equipment, temporary stowage of the CWC in the middeck, planning for CWC dump and/or stowage for landing, and possibility of odor from the CWC (unlikely due to CWC redesign). ©[042502-5329B]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-503 WASTE WATER STORAGE (CONTINUED)

- D. USE THE CONTINGENCY WATER CROSSTIE TO DUMP WASTE WATER THROUGH THE SUPPLY WATER DUMP NOZZLE.

The contingency water crosstie limits the amount of line that has to be replaced during ground turnaround (potable water is protected from contamination by the dump isolation and tank A outlet valves).

- E. TERMINATE THE FLIGHT EARLY.

- F. CONFIGURE SUPPLY WATER TANK B AS A SPARE WASTE TANK AFTER THE LAST EMU RECHARGE FOR ALL PLANNED EVA'S.

Waste water will contaminate FES feedline A and the EMU supply line. In addition, vehicle turnaround at KSC is impacted when the potable water system is contaminated by waste water.

DOCUMENTATION: Engineering judgment, schematic, and 1.3-TM-DF86050-014.

A17-504 MINIMUM WASTE TANK QUANTITY AFTER DUMPING

WASTE TANK WILL NOT BE DUMPED TO 0 PERCENT (5 PERCENT).

This is to prevent the metal bellows from being subjected to stress while hard on the stops. If the waste tank is at 0 percent, a vacuum will exist on the waste dumpline and the waste tank bellows. If there is a vacuum on the water side of the bellows, a cabin leak will occur when the WCS and the humidity separator liquid check valve cracks. If the pressure on the water side decreases sufficiently, the bellows will exceed their maximum operational pressure of 28 psid or its burst pressure of 32 psid.

DOCUMENTATION: Engineering judgment, schematic, and MC-262-0067.

FLIGHT RULES

A17-505

WASTE WATER DUMP NOZZLE TEMPERATURE CONSTRAINTS

- A. THE WASTE DUMP NOZZLE TEMPERATURE SHOULD NOT EXCEED 350 DEG F WHILE THE NOZZLE HEATERS ARE ACTIVATED.

The maximum design operating temperature of the waste water dump nozzle is 350 deg F. External tiles surrounding the nozzle are likely to debond if this temperature is exceeded.

- B. NORMALLY, WASTE WATER DUMPS WILL BE INITIATED WHEN THE NOZZLE TEMPERATURES ARE GREATER THAN 150 DEG F.

This is the minimum temperature (on STS-35) at which waste water dumps have been accomplished).

DOCUMENTATION: STS-35 flight data and STS-35 SPAN-MER CHIT 037.

- C. IF THE RMS IS USED TO OBSERVE A WASTE H₂O DUMP, THE DUMP WILL BE TERMINATED IF EITHER:

1. THE WASTE WATER DUMP NOZZLE TEMPERATURE IS < 45 DEG F. THE NOZZLE MAY BE REHEATED FOR ANOTHER DUMP ATTEMPT;

OR

2. ICE GROWTH OUTWARD FROM THE NOZZLE IS VISUALLY OBSERVED. ANOTHER DUMP WILL NOT BE ATTEMPTED UNTIL THE ICE FORMATION IS MELTED. NOZZLE GLAZING OR FROSTING IS NOT CAUSE TO TERMINATE THE DUMP.

The minimum temperature limit prevents ice from forming on the nozzle. Instrumentation error is not considered when the RMS is available to monitor for ice formation. The dump can be stopped when it is observed that the ice is starting to grow outward from the nozzle and before it becomes a problem.

DOCUMENTATION: SODB 3.4.6.2, table 3.4.6.2.1, and flight data.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-505

WASTE WATER DUMP NOZZLE TEMPERATURE CONSTRAINTS
(CONTINUED)

- D. IF THE RMS IS NOT OBSERVING THE WASTE WATER DUMP, THE DUMP WILL BE TERMINATED IF THE WASTE DUMP NOZZLE TEMPERATURE IS < 50 DEG F. THE NOZZLE MAY BE REHEATED FOR ANOTHER DUMP ATTEMPT.

This is the minimum temperature used in past missions at which successful waste water dumps have been accomplished. Another dump attempt will be done only if the slope of the dump nozzle temperature indicates a normal profile (to prevent the formation of ice on the nozzle).

DOCUMENTATION: STS-49 and STS-46 flight data.

- E. IF PLATEAUIING IS OBSERVED ANYTIME IN THE NOZZLE TEMPERATURE WARM-UP PROFILE, NO FURTHER WASTE H₂O DUMPS WILL BE PERFORMED.

The plateauiing effect, indicating that ice has formed on the nozzle, has been observed on past flights. To prevent more ice from forming on the nozzle, no dumps will be performed until Rule {A17-502}, WASTE DUMP NOZZLE ICE FORMATION, is satisfied.

DOCUMENTATION: SEH-ITA-84-134 and flight data.

Rule {A17-452}, WASTE WATER DUMP CAPABILITY, references this rule.

FLIGHT RULES

A17-506

WASTE WATER SYSTEM LEAK MANAGEMENT

FOR WASTE WATER SYSTEM LEAKS, THE FOLLOWING GUIDELINES WILL PERTAIN:

- A. IF FREE WASTE WATER IS IN THE CABIN, THE "FREE FLUID DISPOSAL" IFM PROCEDURE WILL BE PERFORMED IMMEDIATELY. IF PRACTICAL, THE WASTE WATER TANK WILL BE DUMPED TO 5 PERCENT PRIOR TO INITIALLY PERFORMING THE "FREE FLUID DISPOSAL" IFM PROCEDURE.

Immediate removal of free waste water is necessary to protect the crew from the bacteria and toxins in the waste water. Free fluid in the cabin is an unacceptable condition because of LRU exposure to the free liquid causing an electric circuit malfunction and possible subsequent LRU failures.

Dumping the waste water tank creates additional ullage so that, if the IFM procedure causes a blockage in the waste water dump line, waste water will continue to collect to maximize the on-orbit stay period. STS-32 experienced free water in the lower equipment bay due to degraded humidity separator collection. The FREE FLUID DISPOSAL IFM was employed to dump the water overboard via the waste water dump nozzle. However, while employing the IFM procedure on the third occasion during the mission on FD 10, the waste water dump line became blocked by matter collected using the free fluid nozzle (wand). The mission was then limited by the remaining ullage in the waste water tank and the CWC volume.

For the STS-36 humidity separator failure, the waste water tank was dumped prior to using the FREE FLUID DISPOSAL IFM. Even though no blockage occurred in the waste water dump line, the mission on-orbit stay was maximized by having additional ullage created by the dump.

DOCUMENTATION: Ref. STS-32 MER Anomaly #21, January 19, 1990; STS-32 CAR No. 32RF21; STS-36 MER Anomaly #11, April 3, 1990; STS-36 CAR No. 36RF13; and engineering judgment.

- B. IF THE WASTE TANK HAS AN IRREPARABLE EXTERNAL LEAK, THE TANK WILL BE VENTED TO CABIN PRESSURE AND DUMPED OVERBOARD (IF POSSIBLE). PROVISIONS WILL BE MADE FOR COLLECTION OF LIQUID WASTE USING CWC. IF POSSIBLE, NO FURTHER WASTE WATER WILL BE ALLOWED TO ACCUMULATE IN THE WASTE TANK. ©[090894-1665A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-506

WASTE WATER SYSTEM LEAK MANAGEMENT (CONTINUED)

Venting a leaking waste tank equalizes the pressure to that of the cabin, which serves to reduce the outflow of waste water into the cabin. Dumping the waste tank is necessary to further prevent waste water flow into the cabin and should be done unless otherwise prevented from doing so. Since the orbiter has only one waste tank, the CWC is used to collect liquid waste from the Humidity and WCS Fan Separators. The CWC is then dumped periodically, based on the actual flight waste production rate. Each flight typically carries two CWC's, rated at 95 lbm H₂O. For a typical 7-person crew, this is about 45 hours capability per CWC based on 0.3 lb/hr per crewmember. ©[090894-1665A]

©[041196-1874A]

- C. IF AN UNISOLABLE N₂ LEAK INVOLVING THE WASTE TANK IS PRESENT, THE N₂ SUPPLY TO THE WATER PRESSURIZATION SYSTEM WILL BE SHUT OFF. LEAK LOCATION PERMITTING, AN IFM TO ISOLATE THE WASTE TANK FROM THE REST OF THE WATER PRESSURIZATION SYSTEM WILL BE PERFORMED. THE REMAINING PARTS OF THE WATER SYSTEM WILL BE RETURNED TO NORMAL PRESSURE ONCE THAT IFM IS COMPLETE (LEAK LOCATION PERMITTING).

For an unisolable N₂ leak, the N₂ pressurant supply to the water pressurization manifold is temporarily shut off to prevent continuous N₂ flow into the cabin. Returning to normal water system pressurization is highly desirable, since the FES is sometimes adversely affected by lower system pressures (depending on orbiter power level and cooling needs).

DOCUMENTATION: STS-55 flight experience and engineering judgment.

FLIGHT RULES

A17-507

OMS & PRCS BURNS WITH FREE H₂O IN THE CABIN

CONSIDERATION WILL BE GIVEN TO DELAYING NON-CRITICAL OMS AND PRCS BURNS WHEN THE PRESENCE OF FREE H₂O IN THE CREW CABIN IS CONFIRMED. ©[051195-1755]

In microgravity, the surface tension of water tends to force free water to collect in globules. OMS and PRCS burns have the potential to disperse free H₂O throughout the Cabin/LEB, possibly being dislodged to the surfaces of electrically powered LRU's/wire bundles, thus providing the potential for an electrical short.

Several flights have had instances where large amounts of H₂O was present in the LEB. During STS-27 and STS-32, approximately 2 gallons of free H₂O was found present in the lower equipment bay. This water was found to be dispersed and present on the surfaces of several pieces of equipment in the LEB. On STS-27, some of this water seeped through two middeck panels.

The amount of H₂O present, its location and adherence to equipment or structure, and the criticality of the burn will determine if delaying of the burn will be necessary.

DOCUMENTATION: Engineering judgment. ©[051195-1755]

A17-508 THROUGH A17-550 RULES ARE RESERVED

FLIGHT RULES

GALLEY MANAGEMENT LIFE SUPPORT ©[021600-7139A]

A17-551 **IODINE REMOVAL IMPLEMENTATION**

A. HARDWARE INSTALLATION AND REMOVAL

1. ON FLIGHT DAY 1, IODINE REMOVAL HARDWARE SHALL BE INSTALLED.
2. ON ENTRY DAY, IODINE REMOVAL HARDWARE SHALL BE REMOVED AND STOWED AFTER THE CREW HAS DRAWN WATER IN PREPARATION FOR FLUID LOADING.
3. IF A 1-DAY DEORBIT WAVEOFF IS DECLARED, IODINE HARDWARE NEED NOT BE REINSTALLED AFTER DEORBIT PREP BACKOUT.

Galley Iodine Removal hardware consists of the Galley Iodine Removal Assembly (GIRA) or the Low Iodine Residual System (LIRS). The GIRA is an assembly of a microbial filter and an activated carbon/ion exchange (ACTEX) cartridge which eliminates iodine from chilled galley water and reduces the concentration to about 1.5 ppm in galley ambient/hot water. The LIRS is a single piece of hardware designed to reduce the iodine levels in both the galley chilled and hot water to about 0.25 mg/L. The hardware is installed as soon as practical to maintain the crew iodine consumption to less than 1 mg/day/crewmember. It is removed after crew fluid loading prep is complete. During the time period of a 1-day waveoff, the crew will not consume enough iodine to be a health risk. Therefore, reinstallation is not required.

Reference Rule {A13-30}, IODINE REMOVAL REQUIREMENT.

DOCUMENTATION: NSTS 07700, Vol X – Book 1, Para 3.3.1.2.4.9, defines the total iodine consumption per day/crewperson.

4. IF LIRS IS MANIFESTED AND THERE IS A FAILURE OF ANY LIRS HARDWARE THAT CANNOT BE REPAIRED, THE GIRA SHALL BE INSTALLED IN ITS PLACE. THE GIRA WILL THEN BE USED UNTIL FLUID LOADING PREP IS COMPLETE AT END OF MISSION.
5. FOR THE FAILURE OF BOTH THE LIRS AND GIRA, THE SYSTEM IN PLACE WILL BE REMOVED AND THE MISSION WILL CONTINUE TO COMPLETION.

The requirement is to minimize the amount of iodine consumed by the crew. This will be accomplished within the capacity of the hardware without compromising primary mission objectives. ©[021600-7139A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-551

IODINE REMOVAL IMPLEMENTATION (CONTINUED)

B. WATER CONSUMPTION CONSTRAINTS @[021600-7139A]

1. WHILE THE GIRA IS IN USE, CONSUMPTION OF AMBIENT OR HOT WATER DISPENSED BY THE GALLEY SHOULD BE LIMITED TO 16 OUNCES PER DAY PER CREWMEMBER. CONSUMPTION OF CHILLED WATER IS NOT CONSTRAINED.

Hot water in the amount of 16 ounces at 1.5 ppm iodine + iodide is equivalent to 0.7 mg of iodine + iodide. The galley will dispense in increments as small as 0.5 ounces. If additional hot water is desired, water from the chilled side can be heated in a drink bag or food container in the galley oven. Note that the ground has no means to monitor hot water consumption.

Reference Rule {A13-30}, IODINE REMOVAL REQUIREMENT.

2. THERE ARE NO CONSTRAINTS TO WATER CONSUMPTION WHILE THE LIRS IS IN USE.

Iodine levels are low enough in both the chilled and ambient/hot water to maintain the iodine consumption below the daily limit.

C. GALLEY SLEEP CONFIGURATION

1. IF THE GIRA IS IN USE DURING SLEEP PERIODS, THE CHILLED SUPPLY LINE WILL BE DISCONNECTED FROM THE GIRA HARDWARE AND CONNECTED TO THE SUPPLY TEE AT THE CHILLED LINE QD. IODINATED CHILLED WATER WILL BE CIRCULATED BY CYCLING THE GALLEY/RHS SWITCH. THE GIRA CONNECTION WILL BE RESTORED IN POSTSLEEP. UNIODINATED CHILLED WATER WILL BE CIRCULATED BY CYCLING THE GALLEY/RHS SWITCH.

This configuration will bypass the GIRA during chilled water recirculations and leave iodinated water in the galley overnight to inhibit microbial growth. The iodine is provided by the MCV connected on the ambient line. In the morning, uniodinated water will be restored to the chilled lines for crew consumption by returning the GIRA to its original configuration. @[021600-7139A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-551

IODINE REMOVAL IMPLEMENTATION (CONTINUED)

2. FOR DUAL SHIFT FLIGHTS UTILIZING THE GIRA, IN EACH 24-HOUR PERIOD, THE GALLEY WILL BE PLACED IN THE SLEEP CONFIGURATION FOR A MINIMUM OF 1 CONTINUOUS HOUR.

@[021600-7139A]

In order to provide microbial control in the chilled water side of the galley during dual shift flights, it is recommended that the ACTEX cartridge and microbe filter be bypassed for a minimum of 1 hour during each 24-hour period (2 hours is optimum). This is accomplished by placing the GIRA hardware in the Sleep configuration described in C.1 above. The volume of the chilled water loop is approximately 4 ounces or 120 ml. The recirculation pump operates at a rate of 1 L/min for 20-seconds every 8 minutes causing about 2.4 L iodinated water/hour to circulate through the system. The resulting iodinated water dwell time is sufficient to inhibit microbial growth.

3. IF THE LIRS IS IN USE, NO RECONFIGURATION FOR SLEEP IS REQUIRED.

There is sufficient iodine in the chilled water from the LIRS to protect the water from microbial growth during sleep periods.

- D. NOMINAL EMU DRINK BAG FILL - FOR EACH EVA, THE EMU DRINK BAGS SHALL BE FILLED FROM THE AUX PORT.

EMU drink bags will be filled from the Aux port based on crew specific preflight tests of TSH levels. The amount of iodine consumed from an EMU drink bag filled in this manner will not be detrimental to crew members with low TSH levels.

- E. ALTERNATE EMU DRINK BAG FILL:

1. FOR EACH EVA, THE EMU DRINK BAGS SHALL BE FILLED DIRECTLY DOWNSTREAM OF THE IODINE REMOVAL HARDWARE.
2. THE BAGS MUST BE USED WITHIN 24 HOURS OF FILLING.
3. AFTER EACH EVA, THE EMU DRINK BAGS WILL BE FILLED WITH WATER FROM THE GALLEY AUX PORT.
4. IODINATED WATER WILL BE DRAWN INTO THE EMU BAG DRINK VALVE. @[021600-7139A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-551

IODINE REMOVAL IMPLEMENTATION (CONTINUED)

5. THE BAG WILL SIT UNTIL THE NEXT EVA OR POST EVA ENTRY PREP OR NO LESS THAN 1 HOUR. @[021600-7139A]
6. THE AMOUNT OF WATER ADDED WILL BE AT LEAST EQUAL TO ONE HALF THE TOTAL VOLUME OF THE BAG.

If preflight tests indicate crew TSH levels are high, the EMU drink bags will be filled with low (LIRS) or uniodinated (GIRA) water for each EVA. The iodine concentration of the water used to fill the bags is not sufficient to inhibit microbial growth in the drink bag for greater than 24 hours. If the GIRA is installed, the bag must be filled from the chilled side. If the LIRS is installed, the bag can be filled from either the ambient or chilled side. After an EVA, the bags will be filled with partially iodinated water from the Galley Auxiliary port to combat any microbial growth in-between EVA's or until the bags are drained in the Post EVA Entry Prep. This sit time must be no less than 1 hour. When filled with iodinated water, water must be drawn into the EMU bag drink valve to ensure that this area is also flushed with iodinated water. Iodinated water must be added at a ratio of 1 to 2 in order to achieve a minimum iodine concentration to combat microbial growth (i.e., add a minimum 16 oz. iodinated water to a 32 oz. bag).

Reference Rule {A13-30}, IODINE REMOVAL REQUIREMENT. @[021600-7139A]

A17-552 THROUGH A17-600 RULES ARE RESERVED

FLIGHT RULES

SPACEHAB FIRE/SMOKE ©[111501-4992]

A17-601

SPACEHAB FIRE/SMOKE DETECTION LOSS

A. SPACEHAB SMOKE DETECTION SHALL BE CONSIDERED LOST FOR ANY ONE OF THE FOLLOWING REASONS:

1. ONE SMOKE DETECTOR FAILS BOTH PORTIONS OF THE CIRCUIT TEST AND THE OTHER SMOKE DETECTOR FAILS EITHER PORTION OF THE CIRCUIT TEST (LOSS OF THREE OF THE FOUR SMOKE INDICATIONS).

Each smoke detector electronics assembly provides a frequency output for continuous monitoring, rate and concentration alarm signals, reset capability to recycle the alarm signal for hazard evaluation, and a built-in self test circuit to verify the status of the smoke sensor. If either the concentration of particles (from potential fire and smoke sources) or the rate of concentration increase measured by the sensor becomes larger than defined values, a continuous alarm signal is generated. To obtain a rate alarm, the sensor output frequency must change at a rate of 4.0 Hz/sec for eight consecutive time intervals of 2.5 seconds each. The concentration alarm is obtained whenever the sensor output frequency exceeds 820 ± 36 Hz (approximately 2000 to 2500 $\mu\text{g}/\text{m}^3$) for two consecutive time intervals of 2.5 seconds each. Energizing the self-test circuit generates an internal signal, which examines the sensor electronics and produces an alarm signal to signify a properly functioning unit. This sequence verifies sensor signal circuit continuity from the sensor since a circuit failure would prevent obtaining an alarm signal. The only hardware failure that can be detected by the circuit test is an air pump failure, which would force the detector to fail both portions of the circuit test. If the smoke detector passes either portion of the circuit test, the air pump is then verified as operative, and the concentration readout sent to the GPC for FDA limit sensing (Class 0 only, does not produce alarm) is considered a valid indication. If only one indication is left in the Spacehab, the system is considered suspect to the point of being unreliable.

2. POWER TO THE DETECTORS CANNOT BE MAINTAINED.

Power is required for the smoke detectors to operate. ©[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A17-601****SPACEHAB FIRE/SMOKE DETECTION LOSS (CONTINUED)**

3. LOSS OF AIR CIRCULATION DEFINED PER THE FOLLOWING: @[111501-4992]
 - a. (SM/LDM) ONLY) LOSS OF ATMOSPHERIC REVITALIZATION SYSTEM (ARS) FAN AND CABIN FAN @[ED]
 - b. (RDM) ONLY) LOSS OF BOTH HFA FANS

Loss of air circulation prevents particulates from reaching the smoke detector in a timely manner if the combustion is not close to the smoke detector. In the SM/Logistics Double Module (LDM) configuration, either the ARS or cabin fan provides sufficient airflow for smoke detection.

For the RDM, any single fan provides airflow to the smoke sensors. Analysis to ensure adequate air circulation with the habitable volume of the Research Double Module (RDM) for crew comfort and to preclude areas of stagnation, has been performed with at least one HFA fan operating nominally. When all three fans are operating nominally, the airflow is approximately 680 cfm, which results in the module air volume being recirculated approximately every 3.5 minutes. For loss of either a single HFA fan or the ARS fan, the airflow is reduced to approximately 460 cfm, which results in the module air volume being recirculated approximately every 5 minutes such that smoke detection may only be slightly delayed. For loss of the ARS fan and a single HFA fan, the airflow is approximately 270 cfm, which results in the module air volume being recirculated approximately every 9 minutes such that delay in smoke detection is still not considered significant enough to be considered lost. The stated times are average times for each case and actual times for smoke detection is dependent on location and severity of the fire. Note that without the ARS fan operating, the mixing box cap must be removed for adequate smoke detection in the forward module subfloor volume (reference Rule {A17-757}, RDM MIXING BOX CAP). With only the ARS fan operating and neither HFA fan operating, the airflow within the aft module subfloor volume may not be sufficient to provide timely movement of smoke particles from this location to the smoke sensors. Since no analysis has been performed for this fan configuration, smoke detection is considered lost in this case. If both HFA fans are failed, opening panel(s) above the aft subfloor volume may improve air circulation in this region until an IFM can be performed to recover an HFA fan. Reference: Boeing MEMO 2C-SPACEHAB-01044 and A90-SPACEHAB-2000192. @[111501-4992] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-601 SPACEHAB FIRE/SMOKE DETECTION LOSS (CONTINUED)

- B. FOR LOSS OF ONE OF THE FOUR SMOKE INDICATIONS, NOMINAL SPACEHAB OPERATIONS MAY CONTINUE. @[111501-4992]

Three smoke indications remain that can be used to provide monitoring capability and fire confirmation, half of one smoke detector and a second/redundant smoke detector.

- C. FOR LOSS OF TWO OF THE FOUR SMOKE INDICATIONS, SPACEHAB OPERATIONS MAY CONTINUE; HOWEVER, A SMOKE SENSOR TEST IS REQUIRED EVERY 24 HOURS.

Two of four smoke indications are lost when one smoke sensor fails both portions of the circuit test or both smoke sensors fail either portion of the circuit test. A smoke sensor test is required every 24 hours to verify that the remaining two smoke detection indications are valid.

- D. FOR LOSS OF SMOKE DETECTION, SPACEHAB OPERATIONS MAY CONTINUE IF A CREWMEMBER IS AWAKE IN THE MODULE AT ALL TIMES TO MONITOR FOR SMOKE/FIRE. IF AN AWAKE CREWMEMBER WILL NOT BE IN THE MODULE, THE MODULE WILL BE DEACTIVATED (EXCEPT FOR PL AFT MN B) AND CONFIGURED FOR SAFE ENTRY AND THE HATCH CLOSED UNTIL THE CREW RETURNS.

An awake crewmember must be available for monitoring the module for smoke/fire. If an awake crewmember is not inside the module, the Spacehab must be configured for a safe entry. This configuration will force the deactivation of certain experiments.

PL AFT MN B remains powered because it is the only source of power to the Spacehab water line heaters that protect the Spacehab water line from freezing. @[111501-4992]

FLIGHT RULES

A17-602

SPACEHAB FIRE/SMOKE CONFIRMATION

- A. CONFIRMATION OF A FIRE WILL BE ANY ONE OR MORE OF THE FOLLOWING: ©[111501-4992]
1. CREW OBSERVANCE OF SMOKE OR FLAME
 2. FOR A SPACEHAB MODULE WITH A CLOSED HATCH, ANY ONE OF THE FOLLOWING:
 - a. BOTH SMOKE DETECTOR CONCENTRATION LEVELS OVER 2000 ?G/M**3
 - b. ONE CONCENTRATION LEVEL 2000 ?G/M**3 AND INCREASING (SUBSEQUENT TO A SENSOR TEST, WHEN POSSIBLE), AND THE ALTERNATE DETECTOR HAS FAILED CIRCUIT TEST
 - c. ONE CONCENTRATION LEVEL 2000 ?G/M**3 AND INCREASING, AND CONFIRMATION BY ELECTRICAL DATA OF A SUSTAINED SHORT

*A confirmation is required to accurately detect a fire condition; this confirmation can be via a separate smoke detector indicating a concentration level over 2000 ?g/m**3 or crew observations. In the event the alternate smoke detector fails both portions of the circuit test, per Rule {A17-601}, SPACEHAB FIRE/SMOKE DETECTION LOSS, the functional detector must be tested successfully every 24 hours. A sensor test is not possible during ascent/entry since the crew does not have access to the SSP. Any indications of a sustained short in the module with a concentration above 2000 ?g/m**3 will also be considered as confirmation of fire.*

- B. CONFIRMATION OF SMOKE DETECTION, AS DEFINED IN PARAGRAPH A, IS REQUIRED PRIOR TO FIRE SUPPRESSION SYSTEM (FSS) OR PORTABLE FIRE EXTINGUISHER(S) DISCHARGE.

A secondary cue is mandatory for FSS or portable extinguisher discharge. Paragraph A defines the cues required to confirm fire/smoke and ensures that action is not taken for a failed sensor.

- C. VISIBLE SMOKE AND/OR FIRE IS A CONFIRMED EMERGENCY WITH OR WITHOUT SMOKE DETECTOR WARNING.

Self-explanatory. ©[111501-4992]

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT

A. ASCENT/ENTRY @[111501-4992]

FOR A CONFIRMED SPACEHAB FIRE (SEE RULE {A17-602A}, SPACEHAB FIRE/SMOKE CONFIRMATION, FOR CONFIRMATION CUES), THE FSS WILL BE ARMED AND DISCHARGED.

The Payload Safety Review Panel approved SH HR F-1, which states that the module material selection and design practices should prevent initiation and/or propagation of a fire. Based on this, the most likely cause of smoke in the module would be from a transient electrical short.

The STS-60 Flight Techniques Panel concluded on November 23, 1993, that, for a confirmed fire during ascent, the FSS should be discharged. This panel consisted of representatives of Crew Safety, Emergency, Environmental and Consumables Management (EECOM), STS-60 CDR, Safety, Flight Surgeon, and Spacehab. Flight experiences (STS-6, STS-28, and STS-35) indicate that short-term electrical transients do not typically produce enough smoke to exceed smoke sensor noise levels, which is far below alarm thresholds. Once the fire confirmation criteria outlined in Rule {A17-602}, SPACEHAB FIRE/SMOKE CONFIRMATION, has been satisfied, it can be inferred that the cause of smoke in this case would not be self-safing and that crew action must be taken. Based on proper material selection and stowage, removal of power from the module should be adequate to safe the situation. However, if removal of main power to the module was required, it would not be advisable to subsequently repower the module (removal of power was the only corrective action taken to safe the situation). Additionally, the sustained burning described could have released highly toxic combustion products into the module atmosphere, and it should remain isolated from the orbiter. Since module ingress after an event of this magnitude is unlikely, and since removal of power removes insight into fire propagation (smoke concentration readings), it is considered prudent to maximize protection by discharging Halon from the FSS.

Documentation: SH HR F-1, STS-60 OFTP Minutes (November 23, 1993), STS-6, STS-28, STS-35 flight experience, and engineering judgment.

B. ON-ORBIT

1. FLIGHT CREW RESPONSIBILITIES

THE COMMANDER (CDR) AND PILOT (PLT) WILL EXIT THE SPACEHAB MODULE AT THE INITIAL SMOKE DETECTOR WARNING OR OBSERVANCE OF SMOKE/FLAME.

Should smoke incapacitate a portion of the crew (i.e., the Spacehab crewmember(s)), evacuating the CDR and PLT will guarantee the availability of healthy crewmembers to accomplish entry and landing.
@[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT (CONTINUED)

2. SPACELAB EMERGENCY BREATHING SYSTEM (SEBS) @[111501-4992]
@[ED]
 - a. SEBS WILL BE PARTIALLY DONNED AT THE INITIAL WARNING.
 - b. THE SEBS WILL BE DONNED AND ACTIVATED ONLY IF THE FIRE/SMOKE IS CONFIRMED AS DEFINED IN RULE {A17-602}, SPACEHAB FIRE/SMOKE CONFIRMATION.
 - c. SEBS WILL BE UTILIZED BY THE CREWMEMBER(S) UNTIL THEY EXIT FROM THE SPACEHAB MODULE AND HAVE CLOSED AND LATCHED THE SPACEHAB HATCH.

Partially donned means that the SEBS shall be unstowed and be readied for use without actually putting on the facemask. Hydrogen cyanide (HCN), hydrogen fluoride (HF), hydrogen bromide (Hbr), and carbon monoxide (CO) are four potentially toxic thermal degradation products of Halon 1301, insulation, and paint. Levels exceeding the spacecraft maximum allowable concentration criteria (SMAC) could be produced from discharging a single fire suppression system (FSS) bottle on a fire. Reference Rule {A13-152B}, CABIN ATMOSPHERE CONTAMINATION.

3. AT THE FIRST INDICATION OF FIRE/SMOKE, THE ATMOSPHERE REVITALIZATION SUBSYSTEM (ARS) FAN WILL BE DEACTIVATED AND PL ISO VLV WILL BE CLOSED, EXCEPT WHEN OPERATING IN THE LDM REDUCED POWER MODE WHERE THE ARS FAN WILL BE DEACTIVATED AND THE PL ISO VLV CLOSED UPON CONFIRMATION OF A FIRE.

Removal of power to the ARS fan and closing the PL ISO VLV is necessary to determine smoke source (Spacehab or orbiter), will reduce the chance of a fire spreading, and will reduce the circulation of fumes and smoke into the orbiter. A Spacelab analysis showed that crew movement had a negligible effect on overall cabin atmosphere with the fans off. By analogy, toxic gases, fumes, etc., in the Spacehab module will likely only propagate by diffusion. In the LDM reduced power mode, the Spacehab ARS fan will not be deactivated until a fire has been confirmed because the cabin fan is not operating to provide continued smoke detection. @[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT (CONTINUED)

4. FOR A CONFIRMED SPACEHAB FIRE, THE FOLLOWING ACTIONS WILL BE USED IN PRIORITY AS REQUIRED TO SUPPRESS THE FIRE:
 ©[111501-4992]
- a. REMOVE INDIVIDUAL LINE REPLACEABLE UNIT (LRU) POWER (IF CREW CAN DETERMINE SOURCE OF SMOKE), FOLLOWED BY CREW EVALUATION.
 - b. IF POSSIBLE, USE PORTABLE FIRE EXTINGUISHER ON INDIVIDUAL LRU, FOLLOWED BY CREW EVALUATION.
 - c. PERFORM MAIN POWER KILL BY ARMING THE FSS, FOLLOWED BY CREW EVALUATION.
 - d. SECURE MODULE FOR ENTRY AND LANDING, OPEN MANUAL CABIN DEPRESS VALVE (CDV), EGRESS MODULE, CLOSE HATCH, AND DISCHARGE THE FSS.
 - e. DEPRESS THE SPACEHAB MODULE USING THE CDV IF SIGNS OF FIRE PERSISTS AFTER FSS DISCHARGE.

The crew will attempt to remove power from the fire source (if the source can be determined). If that does not work and the crew can identify the individual LRU, the crew can use the Portable Fire Extinguisher to try to put out the fire. This is to limit the exposure to Halon 1301 to the crewmembers that are in the Spacehab module yet provide adequate fire suppression in the affected area. If the individual LRU cannot be identified or individual LRU powerdown does not stop the fire, then the crew will arm the FSS to issue a MAIN POWER KILL, which eliminates the most likely source of the ignition/fire and stops the circulation of air/oxygen to the fire. The crew will then monitor conditions to determine if the fire has been safed. If the fire has been extinguished, but the module atmosphere contaminated, cleanup procedures must be initiated and the module isolated from the orbiter, until the cleanup is complete.

If the fire is not safed, the module must be secured for entry and prepared for Halon discharge. Spacehab securing/stowing will be limited to that which is required for a safe orbiter entry and landing configuration. Required stow items will be listed on the Spacehab Fire/Smoke cue card. Isolating the module will provide protection of the crew from the fire, smoke, and impending Halon release. This isolation will also increase the effectiveness of the fire suppression system by constraining the volume. The manual cabin depress valve must be opened prior to module egress to allow for remote depressurization of the Spacehab module if signs of a fire (temperature/pressure increasing, PPO₂ decreasing) continue after FSS discharge or failure. ©[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT (CONTINUED)

5. SPACEHAB REPOWERING/REVISIT @[111501-4992]

a. AFTER FSS DISCHARGE:

- (1) SPACEHAB WILL REMAIN UNPOWERED (EXCEPT FOR THE AFT PL MN B BUS) FOR THE REMAINDER OF THE FLIGHT.

After Spacehab FSS discharge, fire suppression capability is limited to the orbiter hand-held fire extinguishers (if not previously used) or depressurization of the module, which does not require main power. The AFT PL MN B bus provides power to the H₂O loop line heaters to prevent freezing.

- (2) SPACEHAB WILL NOT BE REVISITED.

If the FSS is used, the Spacehab environment has been compromised. The unknown combustion byproducts concentration resulting from a fire requiring the FSS discharge as well as the resultant Halon concentration precludes revisiting the module for any reason.

b. AFTER PORTABLE FIRE EXTINGUISHER DISCHARGE FOR A CONFIRMED FIRE

- (1) THE MODULE MAY REMAIN POWERED, UNLESS THE PORTABLE FIRE EXTINGUISHER WAS UNSUCCESSFUL OR THERE IS AN INDICATION OF A FIRE STILL IN PROGRESS.

- (2) THE SPACEHAB MODULE WILL NOT BE REVISITED, UNLESS THE ATMOSPHERE CAN BE DEEMED SAFE PER ALL FLIGHTS RULE {A13-152}, CABIN ATMOSPHERE CONTAMINATION. @[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT (CONTINUED)

- c. FOR AN ACCIDENTAL DISCHARGE OF A SINGLE PORTABLE FIRE EXTINGUISHER ANYWHERE IN THE SPACEHAB MODULE OR FOR A SINGLE FIXED LEAKING PORTABLE FIRE EXTINGUISHER OR FSS BOTTLE WITH NO SMOKE/FIRE CONFIRMATION, THE CREW MAY BE EXPOSED TO THE HABITABLE ENVIRONMENT FOR 72-100 HOURS FOR A SPACEHAB SINGLE MODULE CONFIGURATION AND THE ENTIRE MISSION FOR DOUBLE MODULE CONFIGURATIONS. REAL-TIME DISCUSSION OF MISSION EXTENSION WILL BE DEPENDENT UPON SUCH FACTORS AS CREW SYMPTOMS AND/OR PERFORMANCE. @[111501-4992]

The above criterion was established based upon information from NASA's Halon 1301 Human Inhalation Study (reference JSC 23845, August 1989), the National Research Council (NRC), and JSC Toxicology Group. The human study involved exposing eight volunteers to Halon 1301 for a period of 24 hours at a concentration of 1 percent (10,000 ppm). The effects on both physiology and performance were studied using a computerized battery of tests on reaction time, decision-making, etc. No significant changes in any physiological parameters were noted. There were no alterations of any blood counts or chemistries, no pulmonary function changes, no cardiac dysrhythmias, and no mental status changes. There were no significant biological decrements in performance recorded from the pre-exposure baselines. Based on this study, exposure of crewmembers to Halon concentration levels above 1 percent is not recommended.

As a result of recommendations published in the "Documentation of the Spacecraft Maximal Allowable Concentration Values on Bromotrifluoromethane" (White Paper; JSC Toxicology Group), the NRC approved revised SMAC levels for Halon 1301 on November 18, 1993. These guidelines state that for 24-hour exposure, the SMAC level is 0.35 percent (3500 parts per million), and for 7 or 30-day exposure, the SMAC level is 0.18 percent (1800 ppm). The JSC Toxicology Group sponsored the mentioned study and established SMAC levels with approval from the NRC.

Discharge of a portable fire extinguisher and/or a single fixed leaking fire extinguisher into the open Spacehab module will produce an equilibration with the habitable environment. Habitable environment is defined as the orbiter crew cabin volume plus the Spacehab module volume. A Halon 1301 level of approximately 0.20 percent to 0.26 percent (2000 ppm to 2600 ppm) will be achieved in the Spacehab single module, and based on the SMAC values mentioned above, the crewmembers can be exposed to this environment for 72-100 hours. In the Spacehab double module (LDM/RDM), the Halon 1301 level will remain below the 30 day SMAC value due to the added volume. The crew can be exposed to this environment for the entire mission. @[111501-4992]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-603

SPACEHAB FIRE/SMOKE MANAGEMENT (CONTINUED)

A real-time decision to possibly land earlier than nominal EOM will be made by MCC after the crew has been exposed to Halon 1301. Although a concentration of 0.20 percent is less than the 24-hour SMAC value but slightly greater than the 7 or 30-day SMAC value for exposure to Halon 1301, the actual mission duration or extension is dependent upon such factors as crew symptoms and/or performance.
@[111501-4992]

Reference: Rule {A13-152}, CABIN ATMOSPHERE CONTAMINATION.

d. AFTER DEPRESSURIZATION:

- (1) SPACEHAB WILL REMAIN UNPOWERED FOR THE REMAINDER OF THE FLIGHT (EXCEPT FOR AFT PL MN B BUS).
- (2) SPACEHAB AND ORBITER WATER LINE HEATERS OR ORBITER ATTITUDE CONTROL FOR THERMAL MANAGEMENT TO AVOID FREEZING AND OVERPRESSURIZING THE PAYLOAD HEAT EXCHANGER WILL BE REQUIRED.
- (3) SPACEHAB WILL NOT BE REPRESSURIZED.

After depressurization, the state and operational capability of the avionics is unknown. The AFT PL MN B bus provides power to the H₂O loop line heaters to prevent freezing.

C. LOSS OF BOTH THE SPACEHAB FSS BOTTLE DISCHARGE CAPABILITIES; MONITOR AND CONTROL PANEL (MCP) AND FIRE SUPPRESSION CONTROL UNIT (FSCU); AND LOSS OF SPACEHAB DEPRESSURIZATION CAPABILITY WILL REQUIRE THE MODULE TO BE DEACTIVATED AND UNPOWERED.

Loss of both fire suppression methods and loss of depressurization capability in Spacehab would make the module zero fault tolerant to a fire. @[111501-4992]

A17-604 THROUGH A17-650 RULES ARE RESERVED

FLIGHT RULES

SPACEHAB ECS MANAGEMENT @[111501-5010A]

A17-651 SPACEHAB ENVIRONMENTAL CONTROL AND LIFE SUPPORT
(ECLS) REQUIREMENTS @[111501-4993]

A. THE ANNEX WILL USE THE FOLLOWING FORMAT TO ENSURE ORBITER COMPATIBILITY:

DURING OPERATIONS OF SPACEHAB ACTIVELY COOLED EXPERIMENTS, THE ORBITER CABIN ATMOSPHERE MUST BE MAINTAINED WITHIN THESE SPECIFIED LIMITS:

(PAYLOAD 1)	OPERATING RANGE
PPCO ₂	<u>TBD</u> < MMHG < <u>TBD</u>
TEMPERATURE	<u>TBD</u> < T < <u>TBD</u>
TOTAL PRESS, PPO ₂ , ETC	<u>TBD</u>

B. PAYLOADS WHICH REQUIRE SPECIFIC ENVIRONMENTAL CONTROLS IN EXCESS OF NORMAL SUBSYSTEM REQUIREMENTS ARE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX.

Documenting payload cooling limits in this rule in the annex ensures that the proper orbiter cooling configuration will be established for the flight. The operating range indicates absolute minimum and maximum acceptable temperatures of the payload coolant as it exits the payload heat exchanger. Analysis of heat exchanger performance will use payload heat load data as supplied in PIP annex 2 paragraph 1. The stability requirement dictates special payload limits to minimize oscillations within the operating range. The stability values reflected here are those introduced by changes in the orbiter Freon inlet temperature and do not account for perturbations due to changes in payload heat load.

Certain middeck and/or Spacehab payloads may require unique atmosphere conditions that are outside of the normal range of operations of the ARS. Documentation of the payload constraints in this rule ensures that the atmosphere is managed within the specified limits.

C. EXPERIMENTS THAT WILL NORMALLY RELEASE GASES INTO THE CABIN ARE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX. @[111501-4993]

FLIGHT RULES

A17-652

SPACEHAB SUBSYSTEM FANS/AIR LOOP @[111501-5010A]

SPACEHAB ARS, CABIN, OR HFA FAN SHALL BE CONSIDERED LOST IF ITS RESPECTIVE FAN DELTA PRESSURE IS \geq 0.2 INCHES H_2O .

The accuracy of the delta pressure sensor measurement is \pm 0.1 inches H_2O . Each fan has two redundant sensors. The RDM HFA fan pair share the same two delta pressure sensors. @[111501-5010A]

A17-653 THROUGH A17-700 RULES ARE RESERVED

FLIGHT RULES

MODULE ATMOSPHERE MANAGEMENT

A17-701 MODULE ATMOSPHERIC CONTROL ©[111501-5010A]

THE ORBITER ENVIRONMENT WILL BE MANAGED TO ALLOW THE MODULE TO OPERATE WITHIN THE FOLLOWING GUIDELINES:

- A. MODULE PRESSURE BETWEEN 10.0 AND 15.95 PSI ©[021600-7104]

Spacehab systems are certified to operate above a cabin pressure greater than or equal to 10 psia. The positive pressure relief valves are designed to maintain Spacehab pressure below its maximum design pressure (MDP) of 15.95 psia.

- B. MODULE PPO₂ PER RULE {A13-53A}, MINIMUM PPO₂ CONSTRAINTS

The orbiter ECLSS is designed to maintain these levels. The most likely cause of low PPO₂ in the Spacehab module would be inadequate air exchange with the orbiter or an orbiter malfunction.

- C. MODULE PPCO₂ PER RULE {A13-52A}, PPCO₂ CONSTRAINT

The orbiter ECLSS is designed to maintain these levels. The most likely cause of low PPCO₂ in the Spacehab module would be inadequate air exchange with the orbiter or an orbiter malfunction.

- D. MODULE TEMPERATURE BETWEEN 65 AND 80 DEG F ©[021600-7104]

The Spacehab thermal control system is designed to maintain these levels during open hatch operations.

- E. HUMIDITY

1. SM/LDM: MODULE DEWPOINT < FAN HX INLET H₂O TEMP
2. RDM: NO CONSTRAINT ON ORBITER

The Spacehab single and logistics double modules have no provision for condensate removal. Therefore, module humidity (dewpoint) must be maintained below the water loop temperature at the inlet to the air/water heat exchanger to avoid uncontained condensation. Spacehab RDM has a condensing heat exchanger; therefore, humidity control is not a concern as long as the rotary separator is functioning nominally. ©[111501-5010A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-701 MODULE ATMOSPHERIC CONTROL (CONTINUED)

F. IF ANY OF THE ABOVE CONDITIONS CANNOT BE MAINTAINED, CONSIDERATION WILL BE GIVEN TO REDUCING THE NUMBER OF CREWMEMBERS IN THE MODULE OR DEACTIVATION OF SOME EXPERIMENTS. EXCEPTIONS WILL BE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX. @[111501-5010A]

The module atmospheric composition is controlled during open hatch operations by the mixing of orbiter/module air flow. The orbiter and module systems must be operated to yield an environment as described in order to provide crew habitability and stay within certification limits. @[111501-5010A]

A17-702 PARTIAL PRESSURE OF OXYGEN (PPO₂) SENSORS @[111501-5010A]

NOMINAL SPACEHAB OPERATIONS MAY CONTINUE FOR LOSS OF BOTH SENSORS IF THE SPACEHAB ARS FAN IS OPERATIONAL. @[030994-1606A]

As long as there is air flow between the Spacehab module and the orbiter, PPO₂ parameters should be very close to orbiter readings. @[111501-5010A]

A17-703 PARTIAL PRESSURE OF CARBON DIOXIDE (PPCO₂) SENSORS @[111501-5010A]

NOMINAL SPACEHAB OPERATIONS MAY CONTINUE FOR LOSS OF BOTH SENSORS IF THE SPACEHAB ARS FAN IS OPERATIONAL. @[030994-1606A]

As long as there is air flow between the Spacehab module and the orbiter, PPCO₂ parameters should be very close to orbiter readings. @[111501-5010A]

FLIGHT RULES

A17-704

CABIN/HFA FAN @[111501-5010A]

- A. FOR LOSS OF A SINGLE PHASE, THE CABIN/HFA FAN MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER. @[021600-7105A]

Cabin fan and HFA fan can be used interchangeably throughout these rules, depending on the Spacehab module configuration. Both fans are used to circulate air within the Spacehab module. Cabin fan is applicable for Spacehab SM and LDM configurations. HFA fan is applicable for the Spacehab RDM configuration.

The cabin/HFA fan was operated during preflight testing on two phases. The cabin/HFA fan may be operated but not started on only two phases.

If the cabin/HFA fan is operating on the SH INV and phase A fails, the fan will stop working because phase A of the SH INV provides the sync pulse required for SH INV phases B and C to operate. However, the fan will continue to operate on the SH INV on two-phase power if phase A continues to operate with either phase B or phase C.

- B. FOR LOSS OF THE CABIN/HFA FAN, AN IFM WILL BE CONSIDERED TO CHANGE OUT THE FAN.

For loss of the cabin fan in the SM/LDM or a single HFA fan in the RDM, Spacehab has determined that the ARS fan in the SM/LDM or the ARS fan and a single HFA fan in the RDM can supply enough air flow to maintain smoke detection capability throughout the module. However, the temperature in the module may not be maintained. Based on temperature and other environmental parameters, it is possible that the IFM could be postponed or the mission continued using only the ARS fan in the SM/LDM or the ARS fan and a single HFA fan in the RDM. Smoke detection is considered lost in the aft subfloor volume of the RDM if both HFA fans are lost. Reference Rule {A17-601}, SPACEHAB FIRE/SMOKE DETECTION LOSS. @[111501-5010A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-704

CABIN/HFA FAN (CONTINUED)

C. RDM HFA FANS STARTUP @[111501-5010A]

1. BOTH HFA FANS WILL BE ACTIVATED PRIOR TO POWERING ON THE ARS FAN.
2. IF BOTH HFA FANS ARE TO BE OPERATED SIMULTANEOUSLY, THE AIR BYPASS VALVE (ABV) SHALL BE SET TO 80-210 COUNTS PRIOR TO POWERING THE SECOND HFA FAN.

Preflight testing by Boeing has shown that the HFA fans will operate in a degraded mode if the second HFA fan is activated while the ARS fan is operating and when the ABV is not positioned in an acceptable range. No immediate damage to the fans is associated with operation in this mode, only degraded system performance (> 30 percent reduction in HFA flow). During activation, it will be the MCC's responsibility to command the ABV to 80-210 counts because the crew does not have the capability to command the ABV. The crew can manually set the valve to the desired range, but this action would be very time consuming. Reference Rule {A17-705}, ATMOSPHERE REVITALIZATION SYSTEM (ARS) FAN.

DOCUMENTATION: Boeing RDM Certification Acceptance Review Presentation, October 4-5, 2000, ECS Special Topic. @[111501-5010A]

FLIGHT RULES

A17-705

ATMOSPHERE REVITALIZATION SYSTEM (ARS) FAN @[021600-7106B] @[111501-5101A]

- A. FOR LOSS OF A SINGLE PHASE, THE ARS FAN MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER.

The ARS fan was operated on two phases during preflight testing. The ARS fan may be operated but not started on only two phases. @[111501-5101A]

If the ARS fan is operating on the SH INV and phase A fails, the fan will stop working because phase A of the SH INV provides the sync pulse required for SH INV phases B and C to operate. However, the fan will continue to operate on the SH INV on two-phase power if phase A continues to operate with either phase B or phase C. @[021600-7106B]

- B. FOR LOSS OF THE ARS FAN, AN IFM WILL BE PERFORMED (BASED ON PPCO₂, ETC.) TO CHANGE OUT THE FAN. UNTIL THE IFM IS PERFORMED, ALLOWABLE CREW TIME IN THE MODULE IS LIMITED BY DEWPOINT, PPO₂, AND PPCO₂ RESTRICTIONS PER RULE {A17-701}, MODULE ATMOSPHERIC CONTROL. @[101096-4494]

Without the ARS fan, air exchange with the orbiter is degraded. In the Spacehab RDM, smoke detection in the forward subfloor volume is considered lost when the ARS fan is not operating with the mixing box cap installed. As long as one HFA fan is operating, smoke detection capability can be regained throughout the RDM by removing the mixing box cap. Reference Rule {A17-757}, RDM MIXING BOX CAP.

- C. (SM/LDM ONLY) THE ARS FAN SHALL NOT BE OPERATED WITH THE PL ISO VALVE CLOSED UNLESS THE ASCENT/DESCENT INLET STUB IS OPEN OR THE FLEX DUCT IS REMOVED. @[021600-7106B]

Operation of the ARS fan with the PL ISO valve closed and flex duct connected in the Spacehab single or logistics double module configurations may cause failure of the ARS fan. Reference Rule {A17-756}, SM/LDM ASCENT/DESCENT INLET STUB. @[021600-7106B]

- D. (RDM ONLY) THE ARS FAN SHALL BE DEACTIVATED PRIOR TO POWERING ON A SECOND HFA FAN.

Preflight testing by Boeing has shown that the HFA fans will operate in a degraded mode if a second HFA fan is powered up while the ARS fan is operating. Reference Rule {A17-704}, CABIN/HFA FAN. No immediate damage to the fans is associated with operation in this mode, only degraded system performance (> 30 percent reduction in HFA flow).

DOCUMENTATION: Boeing RDM Certification Acceptance Review Presentation, October 4-5, 2000, ECS Special Topic. @[111501-5101A]

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS

THE FOLLOWING FAN CONFIGURATION WILL BE USED FOR NOMINAL SPACEHAB SM/LDM OR RDM OPERATIONS FOR ASCENT, ON-ORBIT, AND ENTRY: @[111501-5000]

A. ASCENT

1. SM/LDM:

a. UNPOWERED SPACEHAB MODULE

- (1) ARS FAN - ON, CONFIGURED TO SPACEHAB INVERTER POWER, BUT NOT OPERATIONAL SINCE THE SPACEHAB INVERTER IS UNPOWERED
- (2) CABIN FAN - OFF, CONFIGURED TO SPACEHAB INVERTER POWER
- (3) AFT MODULE FAN - OFF (LDM ONLY)

When the Spacehab module is unpowered for ascent, all subsystem equipment is OFF. Although the ARS fan is configured ON, it is not operational because its power source is configured to an unpowered Spacehab inverter. This configuration simply allows the ARS fan to be activated by commanding its power source from Spacehab inverter to orbiter AC.

b. POWERED SPACEHAB MODULE

- (1) ARS FAN - ON, USING SPACEHAB INVERTER POWER
- (2) CABIN FAN - OFF, BUT CONFIGURED TO SPACEHAB INVERTER POWER
- (3) AFT MODULE FAN - OFF (LDM ONLY)

IF THE ARS FAN FAILS, IT WILL BE COMMANDED OFF AND THE CABIN FAN COMMANDED ON ASAP POST MAIN ENGINE CUTOFF (MECO). FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.

@[ED] @[ED]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

The ARS or cabin fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. The cabin fan is unpowered, but configured to inverter power to allow it to serve as a backup in case the ARS fan fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 1 (SM GPC not available), the fans will be reconfigured via ground command post MECO. The aft module fan uses Spacehab DC power and is not powered for ascent. @[111501-5000]

2. RDM: @[111501-5000]
 - a. HFA FAN 1 - ON, USING SPACEHAB INVERTER POWER
 - b. HFA FAN 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER
 - c. ARS FAN - ON, CONFIGURED TO ORBITER AC, BUT NOT OPERATIONAL SINCE ORBITER AC IS NOT AVAILABLE TO PAYLOADS FOR ASCENT

IF HFA FAN 1 FAILS, IT WILL BE COMMANDED OFF AND HFA FAN 2 COMMANDED ON ASAP POST MAIN ENGINE CUTOFF (MECO). FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED] @[ED]

The Spacehab RDM is always powered for ascent. An HFA fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. HFA fan 1 is preferred over HFA fan 2 because contingency commanding is only available to turn HFA fan 1 OFF and HFA fan 2 ON. HFA fan 2 is unpowered but configured to inverter power to allow it to serve as a backup in case HFA fan 1 fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 1 (SM GPC not available), the fans will be reconfigured via ground command post MECO. The ARS fan is not operational during ascent; however, it is configured ON, but to orbiter AC power which is not available during ascent. In this configuration, the ARS fan can be activated whenever power is applied to the payload AC 2 bus in the event of a failure that prevents Spacehab commanding.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

B. ON-ORBIT

1. SM/LDM:

- a. ARS FAN - ON, USING ORBITER AC POWER
- b. CABIN FAN - ON, USING ORBITER AC POWER
- c. AFT MODULE FAN - ON, USING SPACEHAB DC POWER (LDM ONLY)

IF ORBITER AC POWER IS UNAVAILABLE, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[111501-5000] @[ED]
@[ED]

2. RDM: @[111501-5000]

- a. ARS FAN - ON, USING ORBITER AC3 POWER
- b. HFA FAN 1 - ON, USING SPACEHAB INVERTER POWER
- c. HFA FAN 2 - ON, USING ORBITER AC2 POWER

FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]
@[ED]

All subsystem fans for Spacehab SM/LDM or RDM are nominally operating on-orbit to obtain the best air circulation throughout the module. It is highly desired to power the ARS fan from orbiter AC in order to maintain fan operation in case of an inadvertent loss of the Spacehab inverter. Powering any of the fans via the Spacehab inverter(s) or orbiter AC is acceptable and is preferred over not running the fans. In the RDM, HFA fan 1 is powered by the Spacehab inverters and HFA fan 2 is powered by orbiter AC to maintain airflow in case of a failure of either power source, as well as to off load orbiter AC 2. Operation of both HFA fans from the same power source is acceptable, but will impact troubleshooting in the case of a failed fan.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A17-706

SPACEHAB FAN CONFIGURATIONS (CONTINUED)

C. ENTRY

1. SM/LDM:

- a. ARS FAN - ON, USING SPACEHAB INVERTER POWER
- b. CABIN FAN - OFF, CONFIGURED TO ORBITER AC
- c. AFT MODULE FAN - OFF (LDM ONLY)

IF THE ARS FAN FAILS, IT WILL BE COMMANDED OFF AND THE CABIN FAN COMMANDED ON USING ORBITER AC POWER ASAP PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN RULE {A9-155}, AC INVERTER THERMAL LIFE. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. ©[ED] ©[ED]

The ARS or cabin fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. The cabin fan is unpowered but configured to orbiter AC power to allow it to serve as a backup in case the ARS fan or Spacehab inverter fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 3 (SM GPC not available), the fans will be reconfigured via ground command. The aft module fan uses Spacehab DC power and is not powered for entry. ©[111501-5000]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A17-706****SPACEHAB FAN CONFIGURATIONS (CONTINUED)**

2. RDM: @[111501-5000]
- a. HFA FAN 1 - ON, USING INVERTER POWER
 - b. HFA FAN 2 - OFF, CONFIGURED TO ORBITER AC
 - c. ARS FAN - OFF

IF HFA FAN 1 FAILS, IT WILL BE COMMANDED OFF AND HFA FAN 2 COMMANDED ON USING ORBITER AC POWER ASAP PROVIDED THE TOTAL AC LOAD (ORBITER + SPACEHAB) CAN BE MANAGED TO STAY WITHIN LIMITS SPECIFIED IN RULE {A9-155}, AC INVERTER THERMAL LIFE. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]
@[ED]

An HFA fan is required to maintain airflow for heat rejection and fire/smoke detection in the module. HFA fan 1 is preferred over HFA fan 2 because contingency commanding is only available to turn HFA fan 1 OFF and HFA fan 2 ON. HFA fan 2 is unpowered, but configured to orbiter AC to allow it to serve as a backup in case HFA fan 1 or the Spacehab inverter fails. Without switching fans, all fire/smoke detection capability is lost. Since no on-board command capability exists in OPS 3 (SM GPC not available), the fans will be reconfigured via ground command. The ARS fan is OFF during entry and is not considered a viable option to regain smoke detection should both HFA fans fail (reference Rule {A17-601}, SPACEHAB FIRE/SMOKE DETECTION LOSS). @[111501-5000]

A17-707 THROUGH A17 750 RULES ARE RESERVED

FLIGHT RULES

ATMOSPHERE INTEGRITY

A17-751 MODULE PRESSURE INTEGRITY @[111501-5010A]

FOR A NON-ISOLATABLE MODULE PRESSURE LEAK, THE MODULE WILL BE MANAGED AS FOLLOWS:

- A. IF PRIOR TO THE MISSION MDF, THE MODULE WILL BE ISOLATED FROM THE ORBITER AS REQUIRED TO PRESERVE AN MDF +2 DAYS WITHOUT VIOLATION OF ORBITER N₂ REDLINES.
- B. IF AFTER THE MISSION MDF, THE MODULE WILL BE ISOLATED FROM THE ORBITER AS REQUIRED TO PRESERVE LANDING AT THE NEXT PLS +2 DAYS WITHOUT VIOLATION OF ORBITER N₂ REDLINES.
- C. FOR CASES WHERE ORBITER REDLINES FOR THE PLANNED EOM +2-DAY DURATION CANNOT BE PROTECTED WHILE FEEDING A MODULE LEAK, THE DECISION TO SHORTEN THE MISSION OR ISOLATE THE MODULE WILL BE BASED ON MISSION PRIORITIES AND LANDING SITE AVAILABILITY.
- D. ALL POWER, EXCEPT FOR PL AFT MNB, WILL BE REMOVED FROM THE MODULE IF THE PRESSURE DROPS BELOW 10.0 PSIA.

Mission success items such as module operations cannot be allowed to impact the ability of the orbiter to reach an MDF or PLS. Adequate protection (+2 days) must always be available in the event of unforeseen circumstances such as weather or systems problems preventing deorbit. For cases where orbiter and crew safety are not in jeopardy, mission priorities (balanced with other factors) will be used to determine proper tradeoffs. Also, Spacehab equipment is not certified for operations below 10.0 psia; however, Spacehab accepts all risks associated with operating sensors below spec value. PL AFT MN B must remain powered because it is the only source of power to the SH waterline heaters that protect the waterline from freezing. @[111501-5010A]

A17-752 NEGATIVE PRESSURE RELIEF VALVE COVERS @[111501-5010A]

THE MODULE'S NEGATIVE PRESSURE RELIEF VALVE COVERS WILL BE OUT AND LOCKED OPEN DURING ASCENT. THE COVERS WILL BE CLOSED ON ORBIT AND REMAIN CLOSED DURING ENTRY.

This action prevents chatter damage to valve seats during periods of ascent vibration. @[111501-5010A]

FLIGHT RULES

A17-753 **CABIN DEPRESS VALVE (CDV)** @[111501-5010A]

- A. THE MANUAL CABIN DEPRESS VALVE LOCATED IN THE SPACEHAB MODULE WILL BE LEFT CLOSED AT ALL TIMES UNLESS OPENED BY THE CREW DURING A FIRE/SMOKE ALARM OR HAZARDOUS SPILL INITIATED MODULE EGRESS.

Leaving the CDV nominally closed eliminates a potential leak source. The CDV assembly consists of a 28-volt dc motor driven butterfly valve in series with a manually operated butterfly valve.

- B. IN THE EVENT THE FIRE SUPPRESSION SYSTEM (FSS) FAILS, THE MODULE WILL BE DEPRESSURIZED USING THE REMOTELY ACCESSED MOTORIZED CABIN DEPRESS VALVE.

Depressurization is the final method to eliminate a fire or reduce hazardous spill concentration. Reference Rule {A13-156}, SPACEHAB HAZARDOUS SUBSTANCE SPILL RESPONSE, and Rule {A17-603}, SPACEHAB FIRE/SMOKE MANAGEMENT. @[111501-5010A]

A17-754 **EXPERIMENT VENT VALVE** @[111501-4995] @[111501-5010A]

- A. IF THE EXPERIMENT VENT VALVE IS NOT IN USE, THE VALVE WILL BE CLOSED.
- B. THE EXPERIMENT VENT VALVE WILL ALWAYS BE CLOSED WHEN ALL THE CREW IS ASLEEP UNLESS REQUIRED FOR EXPERIMENT OPERATION AS DEFINED IN THE FLIGHT-SPECIFIC ANNEX. @[111501-5010A]

Closing the valve will significantly reduce the likelihood of a slow leak or of an inadvertent opening of the vent. For certain experiment complements, a vent line is attached and flown on the experiment vent valve. When this is the case, only the vent valve is closed.

FLIGHT RULES

A17-755

PPRV MANAGEMENT @[111501-5010A]

THE TWO SPACEHAB PPRV'S WILL BE CLOSED PRIOR TO ANY PLANNED INCREASE OF CABIN PRESSURE GREATER THAN 15.35 (15.00) PSIA. WHEN THE CABIN PRESSURE RETURNS TO BELOW 15.35 (15.00) PSIA OR WHEN THE SPACEHAB MODULE IS ISOLATED, THE SPACEHAB PPRV'S WILL BE REOPENED.

The Spacehab module has a maximum design pressure (MDP) of 15.95 psia, which shall not be exceeded. Based on the lower limit of the Spacehab PPRV crack pressure acceptance specification (15.35 psia), the Spacehab PPRV's will be closed prior to any planned pressure increase above the crack pressure to preserve consumables (0.35 psia is allowed for sensor and pressure control band uncertainty). Orbiter PPRV's will provide redundancy for pressure relief for the module as long as the Spacehab hatch remains open. The Spacehab PPRV's will be reopened after the pressure has decreased below the crack value or when the module is isolated in order to re-enable this design safety feature.

@[111501-5010A]

FLIGHT RULES

A17-756

SM/LDM ASCENT/DESCENT INLET STUB @[111501-5010A]

THE ASCENT/DESCENT INLET STUB WILL REMAIN CLOSED DURING OPEN HATCH OPERATIONS. IF THE SPACEHAB HATCH IS CLOSED WITHOUT DISCONNECTING THE DUCTWORK BETWEEN THE SPACEHAB TUNNEL AND THE ORBITER PL ISOLATION VALVE, THE ASCENT/DESCENT INLET STUB WILL BE OPENED BEFORE MODULE EGRESS EXCEPT IN AN EMERGENCY.

The Spacehab SM/LDM is launched with the flex duct between the Spacehab tunnel and the orbiter PL isolation valve disconnected and the ascent/descent inlet stub closed. During Spacehab activation, the crew connects this flex duct to provide air exchange from the orbiter to the Spacehab. The Ascent/Descent inlet stub remains closed so that Spacehab air is not drawn into the Ascent/Descent inlet stub to ensure good air exchange with the orbiter.

Opening the Ascent/Descent inlet stub prior to module egress or disconnecting the PL ISO Valve flex duct prior to hatch closure allows the ARS fan to operate and draw air from these openings. Nominally, the crew will disconnect the flex duct between the Spacehab tunnel and the PL isolation valve prior to closing the Spacehab hatch and leave the Ascent/Descent inlet stub closed. The option exists to leave the flex duct connected for closed hatch operations (e.g., Spacehab closeout for EVA or docking), but since the time savings is minimal, the flex duct is normally disconnected before closing the hatch. However, if the ductwork is left connected, the Ascent/Descent inlet stub will be opened to allow the ARS fan to serve as backup to the cabin fan. If the cabin fan fails, the ARS fan is required to provide air flow for smoke detectors and equipment cooling. If the module is egressed due to an emergency (e.g., cabin leak, toxic spill, fire), the ductwork and ascent/descent inlet stub will not be reconfigured prior to the emergency egress.

Reference Rule {A17-705}, ATMOSPHERE REVITALIZATION SYSTEM (ARS) FAN. @[111501-5010A]

FLIGHT RULES

A17-757 **RDM MIXING BOX CAP**

A. ASCENT/ENTRY @[111501-5000]

THE MIXING BOX CAP SHALL BE UNCAPPED/REMOVED FOR ASCENT/ENTRY.

The mixing box will be uncapped for ascent/entry to allow airflow to cool electronics and provide smoke detection in the fwd module subfloor when the ARS fan is not operating with an HFA fan operating.

B. ON-ORBIT

1. THE MIXING BOX CAP SHALL BE INSTALLED DURING SPACEHAB ACTIVATION.

The mixing box will be capped to allow proper airflow throughout the module when the ARS fan is operating.

2. THE MIXING BOX CAP SHALL BE UNCAPPED/REMOVED IF THE MODULE IS TO REMAIN POWERED WITH THE ARS FAN OFF.

Air cooling and smoke detection is highly degraded in the forward subfloor volume with the mixing box cap installed and the ARS fan not operating. If an HFA fan is operating, removing the mixing box cap will regain air cooling and smoke detection in the fwd subfloor for contingency operations.

Reference: Rule {A17-705}, ATMOSPHERE REVITALIZATION SYSTEM (ARS) FAN. @[111501-5000]

A17-758 **RDM LIOH CANISTER**

A LIOH CANISTER WILL BE INSTALLED IN THE CO₂ REMOVAL ASSEMBLY PRIOR TO ANY NOMINAL HATCH CLOSURE TO PRESERVE LIFE SCIENCE EXPERIMENTS REQUIRING CO₂ REMOVAL DURING CLOSED HATCH OPERATIONS AS DEFINED IN THE FLIGHT SPECIFIC ANNEX. @[111501-5000]

The LIOH canister is only used during Spacehab closed hatch operations to preserve life science experiments. During open hatch operations, the Spacehab RDM is dependent on the orbiter for conditioned air. @[111501-5000]

LIFE SUPPORT GO/NO-GO CRITERIA (CONTINUED)

NOTES:

- [1] ALL AIR-COOLED EQUIPMENT INCLUDING THE FAN WILL BE UNPOWERED (EXCEPT FOR THE COMMUNICATIONS EQUIPMENT, CAUTION & WARNING EQUIPMENT, AND FAN IN AV BAY 3A). ALL EQUIPMENT MAY BE REPOWERED FOR ENTRY IF SAFED WITH A HALON BOTTLE. REFERENCE RULES {A17-51A}.2 & 3, MANAGEMENT FOLLOWING LOSS OF SMOKE DETECTION. @[090894-1675]
- [2] IF TOXIC COMBUSTION PRODUCTS CANNOT BE SATISFACTORILY REMOVED FROM THE CABIN ATMOSPHERE, THE CREW WILL REMAIN ON THE QDM/LES BREATHING 100 PERCENT O₂ UNTIL ORBITER EGRESS. AN ELS OR PLS LANDING IS REQUIRED BASED UPON AVAILABLE N₂ CONSUMABLES FOR MAINTAINING THE O₂ CONCENTRATION WITHIN ACCEPTABLE LIMITS. REFERENCE RULE {A13-152C}, CABIN ATMOSPHERE CONTAMINATION AND {A17-254}, CABIN O₂ CONCENTRATION. @[070201-4726A]
- IF THE EXTENT OF THE DAMAGE TO THE EQUIPMENT AND WIRE BUNDLES IS UNKNOWN, EVEN IF THE ATMOSPHERE HAS BEEN CLEANED UP. A NEXT PLS LANDING WILL BE PERFORMED TO MINIMIZE THE RISK OF THE OCCURRENCE OF AN ADDITIONAL FIRE OR ARC TRACKING. @[090894-1675] @[070201-4726A]
- [3] UNLESS CREW PERSON REMAINS AWAKE DURING SLEEP PERIODS TO MONITOR FOR SMOKE CONDITIONS. REF. RULE {A17-2}, SMOKE DETECTION LOSS DEFINITION
- [4] LOSS OF BOTH FANS IN ANY ONE BAY IS A GO-TO-ORBIT CASE. THE AVIONICS BAY WILL BE RECONFIGURED POST-MECO (TACAN'S AND MLS ONLY) AND POST-OMS-1 (ALL AIR-COOLED EQUIPMENT).
- [5] LOSS OF THREE IMU FANS IS A GO-TO-ORBIT CASE WITH IMU CYCLING. VACUUM CLEANER FAN WILL BE INSTALLED ON ORBIT. ENTER FIRST DAY PLS. @[020196-1810A]
- [6] MDF FOR LOSS OF COOLING TO TWO GPC'S (DUE TO UNACCEPTABLE TEMPERATURE).
- [7] ENTER NEXT PLS IF A SINGLE ELECTRICAL FAILURE (AC BUS) COULD CAUSE THE LOSS OF AIR COOLING TO TWO AV BAYS.
- [8] MDF FOR LOSS OF SMOKE DETECTION (LOSS OF AIR FLOW ONLY).
- [9] PLS FOR LOSS OF COOLING TO THE C&W.
- [10] AN ALTERNATE MODE OF CO₂/HUMIDITY CONTROL WOULD BE TO PERFORM CABIN PURGES (OR PARTIAL DUMPS) VIA THE AIRLOCK DEPRESSURIZATION VALVE.
- [11] QUANTITY OF LIOH CANISTERS AND CREW SIZE WILL DETERMINE EOM.
- [12] PLS REQUIRED IF AUTO/MANUAL PPO₂ CONTROL CANNOT MAINTAIN AEROMED MINIMUM (REF. RULE {A13-53A}.1, MINIMUM PPO₂ CONSTRAINTS) AND LESS THAN 30 PERCENT O₂ AT TOUCHDOWN. ELS REQUIRED IF 40 PERCENT O₂ IS EXPECTED TO BE EXCEEDED PRIOR TO NEXT PLS TOUCHDOWN.
- [13] WITHOUT THE WCS, THE CREW REQUIRES SUFFICIENT BAGS FOR AT LEAST A PLS PLUS 2 DAYS (3 DAYS). EOM IS DEPENDENT ON DEFECATION/URINATION RATE, NUMBER/GENDER OF CREW, AND NUMBER OF ALTERNATE COLLECTION DEVICES.
- [14] CWC AND UCD ULLAGE WILL DETERMINE EOM. @[121593-1589]
- [15] ULLAGE WILL DETERMINE EOM.
- [16] FOR CONFIRMED DISCHARGE INTO AN AVIONICS BAY, AN OVERBOARD PURGE OF THE AFFECTED BAY WILL BE INITIATED AS A MEANS OF REDUCING HALON CONCENTRATIONS AND EXTENDING AVAILABLE ON-ORBIT TIME. FOR A LEAKING HANDHELD HALON BOTTLE IN THE CABIN, THE BOTTLE WILL BE DISCHARGED OVERBOARD THROUGH THE AIRLOCK DEPRESS VALVE. REFERENCE THE AEROMED FLIGHT RULE {A13-152}, CABIN ATMOSPHERE CONTAMINATION, FOR EOM DETERMINATION DUE TO HALON TOXICITY CONCERNS. REFERENCE AEROMED FLIGHT RULE {A13-54}, 100 PERCENT OXYGEN USE CONSTRAINT, FOR MAXIMUM TIME CREW CAN REMAIN ON 100 PERCENT O₂. @[090894-1675]
- [17] MDF DUE TO INABILITY TO SUPPORT LES/QDM FLOW TO ENTIRE CREW IN THE EVENT OF A CONTAMINATED CABIN (E.G., FIRE OR TOXIC SPILL). IF REAL-TIME TEST INDICATES THAT ENTIRE CREW CAN BE SUPPORTED OR AN IFM ALLEVIATES THE PROBLEM, AN MDF IS NOT REQUIRED (REF. RULE {A17-259C}, LES O₂ SUPPLY SYSTEM LOSS MANAGEMENT).
- [18] INABILITY TO SUPPORT 8 PSIA CABIN (REF. RULE {A17-203A}, PPO₂ CONTROL). @[050494-1756B]
- [19] ABORT RTLS/TAL FOR ORBITER -DP/DT > 0.15; AOA FOR ORBITER -DP/DT > 0.02.
- [20] ELS WILL PROBABLY BE REQUIRED IF THE NEXT PLS OR SLS IS GREATER THAN 8 HOURS. AS LONG AS CABIN ENVIRONMENT IS ACCEPTABLE A PLS WILL BE TARGETED. @[020196-1810A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A17-1001 LIFE SUPPORT GO/NO-GO CRITERIA (CONTINUED)****D. PCS**

The requirement for cabin pressure integrity is dependent on the leak rate. Ascent aborts are summarized in Rule {A17-201A}, CABIN PRESSURE INTEGRITY. No requirement exists for an MDF due to the philosophy that the flight will be terminated once the integrity of the cabin has been declared lost. (Ref. Rule {A17-201}, CABIN PRESSURE INTEGRITY, for rationale defining cabin pressure integrity.)

The 165-minute, 8-psia contingency return is defined by two requirements; the first being the N₂ required to perform the contingency return and the second being a functional launch/entry suit (LES) helmet for each crewmember which will supply enough oxygen to allow the crewmember to breathe normally.

The N₂ consumable is budgeted to provide enough N₂ for nominal mission requirements and remain above the N₂ redline (contingency return capability + measurement error + residuals) at EOM. If an N₂ leak develops or nominal flight activities (i.e., MMU recharges, cabin represses, etc.) cause us to break the N₂ redline prior to EOM, a next day PLS will be declared. The PLS is required due to insufficient consumables to maintain an 8-psia cabin for 165-minute contingency return in the event of a hole in the cabin equivalent to 0.45 inch.

An LEH is defined to be lost when it can no longer supply 2.5 lb/hr O₂ to the crewmember. This implies either a hardware failure or a failure in cryogenic oxygen supply which will not provide the necessary amount of O₂ to the crewmember. Since the 165-minute, 8 psia contingency return will cause cabin pressure and PPO₂ to drop below safe metabolic limits for breathing cabin atmosphere, the LES helmet will have to be used prior to touchdown to supply enough oxygen to each crewmember. Therefore, one lost helmet is loss of the contingency return requirement. (Ref. Rule {A17-202}, 8 PSIA CABIN CONTINGENCY 165-MINUTE RETURN CAPABILITY, for loss of 165-minute, 8-psia contingency return definition.)

If PPO₂ cannot be maintained within the specified control band (Ref. Rule {A17-203}, PPO₂ CONTROL) using either auto or manual control, a next day PLS will be declared to avoid operations with a 30 percent or greater O₂ concentration (Ref. Rule {A17-254A}, CABIN O₂ CONCENTRATION), or an oxygen deficient cabin which cannot support crew metabolic needs (Ref. Rule {A13-53 A}.1, MINIMUM PPO₂ CONSTRAINTS).

F. WASTE H₂O

1. The waste tank is the primary means of storing waste water. Without a place to store waste water, the crew would lose humidity control, urine collection capability, and EMU drain capability. The CWC serves as a spare waste water storage container. Waste water can be drained into it from the waste tank via the Contingency Cross-tie Waste QD. Alternatively, the CWC can function as a spare waste tank, where waste water is fed directly into it (again via the Contingency Cross-tie Waste QD). In either case, the CWC would last about 47 hours (assuming seven crew members). This would require dumping the CWC when it is full or using a second one to hold more waste water. @[121593- 1589]
2. If waste dump capability is lost, the ullage in the waste tank and the CWC will determine the end of mission. When the tank is full, the crew would lose humidity control, WCS urine collection capability, and EMU drain capability. @[121593- 1589]

FLIGHT RULES

SECTION 18 - THERMAL

SUPPLY WATER LOSS DEFINITIONS

A18-1

SUPPLY WATER TANK

THE SUPPLY WATER TANK IS CONSIDERED LOST IF:

- A. UNABLE TO EXTRACT WATER FROM OR REFILL THE TANK.
- B. THE TANK HAS AN IRREPARABLE LEAK.
- C. THE TANK HAS A BELLOWS LEAK.

The primary purpose of the supply water tanks is to store excess fuel cell water for crew consumption, EMU recharges, and for ATCS FES usage. A water tank cannot be used if unable to perform these functions. A bellows leak is loss of a tank because N₂ gas is ingested into the supply water, and it has been shown that gas adversely affects the performance of the FES by causing shutdowns.

DOCUMENTATION: Engineering judgment and flight data.

FLIGHT RULES

A18-2

SUPPLY WATER DUMPLINE

THE SUPPLY WATER DUMPLINE IS CONSIDERED LOST IF:

- A. THE DUMPLINE TEMPERATURE CANNOT BE MAINTAINED TO > 32 DEG (37 DEG) F.
- B. THE DUMPLINE IS BLOCKED.
- C. THE DUMPLINE IS RUPTURED.
- D. BOTH SUPPLY WATER NOZZLE TEMPERATURE MEASUREMENTS ARE FAILED.
- E. THE NOZZLE TEMPERATURE CRITERIA OUTLINED IN RULE {A18-56}, SUPPLY WATER DUMP NOZZLE TEMPERATURE CONSTRAINT, CANNOT BE MET. @[ED]

The primary purpose of the dumpline is to provide a transport path for the supply water to the dump nozzle. If the dumpline is blocked, ruptured, frozen, or temperatures are not within an acceptable range, the transport path cannot be utilized to effectively perform this function. For the above failures, the flash evaporator is used to dump supply water before consideration is given to using the potable contingency crosstie.

DOCUMENTATION: Engineering judgment, flight data, STS-8, STS-41B, and SEH-TCS-85-036.

FLIGHT RULES

A18-3

SUPPLY WATER DUMP CAPABILITY

THE SUPPLY WATER DUMP CAPABILITY IS CONSIDERED LOST IF:

- A. THE SUPPLY WATER DUMPLINE IS LOST AND THE CREW IS UNABLE TO USE THE CONTINGENCY CROSSTIE TO DUMP SUPPLY WATER THROUGH THE WASTE WATER NOZZLE, OR INTO A CWC AND [071494-1647A]
- B. UNABLE TO DUMP SUPPLY WATER THROUGH THE FES.

If the dumpline is lost, the primary path to dump supply water is lost. If the crew cannot use the contingency crosstie or the FES, for any reason, the alternate methods to dump supply water have also been lost.

DOCUMENTATION: Engineering judgment.

A18-4 THROUGH A18-50 RULES ARE RESERVED

FLIGHT RULES

SUPPLY WATER MANAGEMENT - THERMAL

A18-51

SUPPLY H₂O TANK A MANAGEMENT

SUPPLY H₂O DUMPS AND FES OPERATIONS WHICH REQUIRE TANK A H₂O WILL BE MINIMIZED. TANK A H₂O CAN BE UTILIZED TO ACHIEVE LANDING OPPORTUNITIES. @[111094-1689A]

Iodine has been found to be a cause of corrosion in the FES cores. This corrosion has caused several FES cores to develop Freon leaks. All four supply H₂O tanks are iodinated prelaunch but tank A remains iodinated throughout a flight. Minimizing FES and nozzle dumps which utilize tank A H₂O will minimize the overall quantity of iodinated H₂O which will pass through the FES core. If supply H₂O management cannot be accomplished with tank B only, then the crossover valve will be opened and H₂O will be managed out of tanks B and D. Supply H₂O from tank A will be used for crew consumption, contingencies, and to make entry opportunities if required.

DOCUMENTATION: STS-65 MER-SPAN CHIT 012. @[111094-1689A]

FLIGHT RULES

A18-52

SUPPLY/WASTE WATER CROSSCONNECT

THE CONTINGENCY WATER CROSSTIE CAPABILITY WILL BE USED TO:

- A. PROVIDE SUPPLY OR WASTE WATER DUMP CAPABILITY THROUGH THE ALTERNATE DUMP NOZZLE.

Provides for dumpline redundancy in the event of a dumpline failure for either system.

DOCUMENTATION: Engineering judgment.

- B. PROVIDE CONTINGENCY COOLING WATER FROM THE WASTE WATER TANK TO THE FES.

Certain launch day PLS opportunities cannot be met without increasing available supply water consumables. This is done by filling the waste tank with supply water. In the event that the PLBD's do not open, the additional supply water that was loaded in the waste tank must be used. The contingency crosstie capability allows the connection of the waste water system to the supply water system so that the supply water loaded in the waste tank is available to the FES.

DOCUMENTATION: Engineering judgment.

- C. PROVIDE CONTINGENCY WATER COLLECTION (CWC) BAG WITH FILL CAPABILITY.

A single waste tank with a maximum liquid capacity of 168 lb exists for each orbiter. Under various crew sizes and flight timelines, the amount of waste liquid generated exceeds the 168-lb storage capacity. The waste tank must be dumped under these conditions. If the waste tank cannot be dumped, additional ullage for the expected generated waste liquids must be made available. The CWC provides the additional ullage. In order for this ullage to be useful to the crew, the fill capability for the CWC must be provided via the contingency crosstie.

DOCUMENTATION: Engineering judgment.

Rule {A17-452}, WASTE WATER DUMP CAPABILITY, references this rule.

FLIGHT RULES

A18-53

SUPPLY WATER TANK A OUTLET VALVE MANAGEMENT

- A. TANK A OUTLET VALVE WILL NORMALLY REMAIN CLOSED THROUGHOUT THE FLIGHT. IT WILL BE OPENED AS REQUIRED TO ENSURE SUPPLY WATER COLLECTION CAPABILITY AND THE NECESSARY ULLAGE FOR FUEL CELL WATER COLLECTION. ©[031500-7185]

Under nominal water system management and configuration, the tank A outlet valve is closed to preserve the sterility of water used for crew consumption. In the event that immediate supply water ullage is required in the supply water system (i.e., ECLSS water line blockage), water tank A outlet valve is opened to provide the necessary ullage for fuel cell water collection. Tank A outlet valve is opened because the risk of flooding three fuel cells outweighs microbial concerns affecting potable water for the crew. IFM procedures exist to guarantee potable water for crew consumption once the requirement for supply water collection capability is satisfied.

- B. FOR ISS FLIGHTS THAT REQUIRE WATER TRANSFER, THE TANK A OUTLET VALVE MAY BE OPENED TO TIE TANKS A AND B TOGETHER IN ORDER TO MAXIMIZE WATER TRANSFER CAPABILITY. TANKS A AND B WILL BE ISOLATED FROM TANKS C AND D BY CLOSING THE SUPPLY WATER CROSSOVER VALVE.

For ISS flights where the transfer of water will take place, tanks A and B will be tied together (reference Rule {A18-57A}.2, ON-ORBIT SUPPLY WATER TANK MANAGEMENT). In addition, FES PRI B will be selected to minimize the amount of iodine that would pass through the FES. Engineering has a concern that iodine in the supply water system causes corrosion in the FES core (reference Rule {A18-51}, SUPPLY H2O TANK A MANAGEMENT).

DOCUMENTATION: Engineering judgment. ©[031500-7185]

FLIGHT RULES

A18-54

SUPPLY WATER TANK A PRESSURE CONTROL MANAGEMENT

FOR LAUNCH, THE SUPPLY WATER GN₂ TANK A SUPPLY AND SUPPLY WATER GN₂ TANK VENT VALVES WILL BE IN THE "CLOSED" AND "VENT" CONFIGURATION, RESPECTIVELY. THE VALVES WILL BE PLACED IN THE "OPEN" AND "PRESS" POSITIONS BEFORE WATER TANK A REACHES 98 (93) PERCENT AND PRIOR TO DEPLETION OF TANK B.

The orientation of the orbiter and the acceleration during launch both work against the flow of fuel cell product water into the supply water tanks. Without reducing the pressurization of water tank A to cabin pressure, the fuel cells will vent product water through the fuel cell relief line instead of transporting the water to the water tanks. The supply water GN₂ tank A supply and supply water GN₂ tank vent valves must be placed in the CLOSED and VENT position in order to depressurize water tank A.

The valves must be placed in the OPEN and PRESS position in order to pressurize water tank A. If tank A is not pressurized prior to quantity reaching 100 percent, delta pressure across the tank bellows can exceed 15 psid resulting in serious damage to the bellows. Tank A must also be pressurized prior to the depletion of tank B to prevent the FES from shutting down.

DOCUMENTATION: Engineering judgment; flight data, 1.3 - TM - DF86050 - 013; and SODB 4.6.1.1.11.

FLIGHT RULES

A18-55

SUPPLY WATER DUMP

THE METHOD OF DUMPING SUPPLY WATER WILL BE AS FOLLOWS IN ORDER OF PRIORITY:

- A. IF PAYLOAD AND CREW TIMELINE CONSTRAINTS ALLOW, UTILIZE THE SUPPLY WATER DUMPLINE.
- B. UTILIZE THE FES.
- C. UTILIZE THE POTABLE H₂O CONTINGENCY CROSSTIE AND DUMP INTO A CWC.
- D. UTILIZE THE WASTE WATER DUMPLINE VIA THE WASTE WATER CONTINGENCY CROSSTIE. @[071494-1647A]

This rule outlines the desired medical and environmental systems operation priority of dumping excess supply water. Payload constraints will be considered when applicable. Utilization of the FES to dump excess supply water will be considered to minimize crew work load and propellant usage. The dumpline will remain higher priority than the FES, to minimize nozzle pulses on the FES. This priority is consistent with ensuring crew health by maintaining supply water system sterility. Dumping supply water through the supply dumpline, FES or into a CWC guarantees water system sterility. Dumping into the two CWC's onboard will create an additional 14-18 hours of ullage (depending on KW level). Connection of the supply water system to the waste dumpline increases the risk of contamination to the supply water system. @[071494-1647A]

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A18-56

SUPPLY WATER DUMP NOZZLE TEMPERATURE CONSTRAINT

A SUPPLY WATER DUMP WILL BE TERMINATED IF BOTH OF THE SUPPLY WATER NOZZLE TEMPERATURES ARE LESS THAN 90 DEG F. NO FURTHER DUMPS WILL BE ATTEMPTED THROUGH THE SUPPLY DUMP NOZZLE. MINIMUM NOZZLE TEMPERATURE FOR SUPPLY DUMP INITIATION WILL BE 100 DEG F.

Utilizing the normal supply dump procedures, the supply water nozzle temperatures should rise and not decrease when the dump is initiated at a nozzle temperature of 100 deg F. If, instead of continuing to increase, the nozzle temperature decreases, then some problem exists with the dump nozzle which could lead to ice formation if the nozzle temperature drops below 45 deg F. The 90 deg F limit was established simply as an indication that the nozzle temperature is indeed decreasing from its original 100 deg F starting temperature and a cue that termination of the supply dump can be effected in a timely manner to prevent ice formation.

MCC GO/NO-GO requirement and visual references to frosting or glazing is not required due to the fact that ice formation, glazing, or frosting on the new supply dump nozzle does not occur until nozzle temperatures are well below 45 deg F.

The procedural act of dumping supply water calls for termination of the supply water dump if the nozzle temperatures drop below 90 deg F for no more than 4 seconds. The 90 deg F lower limit is well above the temperature at which ice, glazing, or frosting of the nozzle would occur. ©[ED]

Rule {A18-2E}, SUPPLY WATER DUMPLINE, references this rule.

TANK B INLET VALVE - CLOSED, WITH CB PULLED;
TANK B OUTLET VALVE - OPEN
- b. TANK C INLET, OUTLET VALVE (TWO) - OPEN;
TANK D INLET, OUTLET VALVE (TWO) - OPEN
- c. XOVR VALVE - CLOSED, WITH CB PULLED ©[031500-7185]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-57

ON-ORBIT SUPPLY WATER TANK MANAGEMENT (CONTINUED)

3. EVA EMU WATER RECHARGE: @[031500-7185]
 - a. NOMINAL CONFIGURATION – SUPPLY WATER TANK C INLET AND OUTLET VALVES MAY BE CLOSED TO PROTECT EVA EMU WATER RECHARGES.
 - b. WATER TRANSFER CONFIGURATION – EMU WATER RECHARGES WILL BE PERFORMED USING SUPPLY WATER TANK B. THIS CONFIGURATION POSES NO THREAT OF H₂ CONTAMINATION; THEREFORE, NO RECONFIGURATION SHOULD BE REQUIRED.

Nominal management is accomplished through water tanks B, C, and D with the crossover valve open. Tanks B, C, and D are usually tied together to provide maximum flexibility for filling and dumping. Tanks B, C, and D feed water to FES PRI A. Tank C can be isolated depending on mission requirements. Tank C is normally isolated at EOM deorbit prep to protect for waveoff opportunities.

Water Transfer management is accomplished through water tanks C and D with the crossover valve closed. Supply tanks A and B are tied and allowed to be filled to 100 percent to provide additional ullage capacity for water transfer. In this configuration, the tank B inlet valve and crossover valve circuit breakers are opened. These breakers are opened to prevent an inadvertent switch throw from contaminating tanks A and B, possibly eliminating capability to transfer water for the rest of the flight. In addition, FES PRI B will be selected, fed by tanks C and D, to minimize the amount of iodine that would pass through the FES. Engineering has a concern that iodine in the supply water system causes corrosion in the FES core (reference Rule {A18-51}, SUPPLY H₂O TANK A MANAGEMENT).

In a Nominal configuration, tank C may be isolated for EVA to protect against ingestion of hydrogen-laden fuel cell water into the EMU. In sufficient quantities, H₂ has the potential for creating a flammable condition within the EMU. On STS-82, H₂ was introduced into the supply water system through the alternate path with tanks B, C, and D tied together. Unlike the primary path, which has an H₂ Separator, the alternate path does not have H₂ separation capability. Tank C was isolated until all planned EVA's and EMU water recharges were accomplished. After the last EVA, tank C was reopened and managed with tanks B and D until EOM.

DOCUMENTATION: Engineering judgment, flight data, H84-22-HS Hamilton Standard, and 1.2-TM-DF86050-02.8. @[031500-7185]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-57

ON-ORBIT SUPPLY WATER TANK MANAGEMENT (CONTINUED)

- B. TO REFILL SUPPLY WATER TANKS C AND/OR D, FLOW THROUGH THE B/C CHECK VALVE WILL BE MINIMIZED. @[031500-7185]

In a Nominal configuration, refilling of tanks B, C, and D will be handled by opening the crossover valve. Closing the tank B inlet and the crossover valve would result in a configuration that is one failure away (i.e., B/C check valve failed closed) from forcing the fuel cell water to relieve overboard. By opening the crossover valve instead, the fuel cell water will retain its path redundancy.

In a Water Transfer configuration, water produced by the fuel cells will enter tanks C and D through the B/C check valve once tanks A and B are full. Water planning will be utilized to minimize the amount of water that must flow through the B/C check valve. Water management must consider water transfer from tanks A and B, FES use from tanks C and D, and the supply water redlines. Tanks C and D must be refilled through the B/C check valve to maintain total water above the redlines and allow continued water transfer. When necessary, the tank A inlet valve may be closed to control the timeframe that the B/C check valve is required (e.g., to avoid reliance on the B/C check valve during crew sleep). After all water transfer has taken place, the supply water tanks will be reconfigured to a nominal on-orbit configuration (reference paragraph A).

- C. FOR REFILL, TANKS C AND D WILL NOT BE ALLOWED TO EXCEED 98 (93) PERCENT.

Tanks are fill-restricted to 98 (93) percent to prevent hardfilling the tanks which could result in venting FC water overboard. Tank A (or A and B) is not constrained because the FC water alternate path is a backup to the A/B check valve and will prevent FC water from relieving overboard. @[031500-7185]

FLIGHT RULES

A18-58

SUPPLY WATER SYSTEM LEAK MANAGEMENT

FOR SUPPLY WATER SYSTEM LEAKS, THE FOLLOWING GUIDELINES WILL PERTAIN:

- A. IF FREE SUPPLY WATER IS IN THE CABIN, THE "FREE FLUID DISPOSAL" IFM PROCEDURE WILL BE PERFORMED IMMEDIATELY. IF PRACTICAL, THE WASTE WATER TANK WILL BE DUMPED TO 5 PERCENT PRIOR TO INITIALLY PERFORMING THE "FREE FLUID DISPOSAL" IFM PROCEDURE.

Free fluid in the cabin is an unacceptable condition because of LRU exposure to the free liquid causing an electric circuit malfunction and possible subsequent LRU failures.

Dumping the waste water tank creates additional ullage so that, if the IFM procedure causes a blockage in the waste water dump line, waste water will continue to collect to maximize the on-orbit stay period. STS-32 experienced free water in the lower equipment bay due to degraded humidity separator collection. The FREE FLUID DISPOSAL IFM was employed to dump the water overboard via the waste water dump nozzle. However, while employing the IFM procedure on the third occasion during the mission on FD 10, the waste water dump line became blocked by matter collected using the free fluid nozzle (wand). The mission was then limited by the remaining ullage in the waste water tank and the CWC volume.

For the STS-36 humidity separator failure, the waste water tank was dumped prior to using the FREE FLUID DISPOSAL IFM. Even though no blockage occurred in the waste water dump line, the mission on-orbit stay was maximized by having additional ullage created by the dump.

DOCUMENTATION: Ref. STS-32 MER Anomaly #21, January 19, 1990; STS-32 CAR No. 32RF21; STS-36 MER Anomaly #11, April 3, 1990; STS-36 CAR No. 36RF13; and Engineering judgment.

- B. ANY SUPPLY WATER TANK WITH AN IRREPARABLE OR NONISOLATABLE LEAK WILL BE VENTED, DUMPED, ISOLATED, AND NOT USED FOR THE REMAINDER OF THE MISSION. THE TANK WILL REMAIN DEPRESSURIZED UNTIL DUMPED.

A leaking supply water tank cannot be pressurized without forcing water out of the tank. If the tank is dumped and isolated from further fuel cell water collection, then the remaining water tanks can be repressurized and normal operations can continue until end of mission. A tank that is depressurized is not likely to leak in a zero gravity field as no pressure differential exists to force the water out of the tank.

DOCUMENTATION: Engineering judgment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-58

SUPPLY WATER SYSTEM LEAK MANAGEMENT (CONTINUED)

- C. FOR A SUPPLY WATER TANK OUTLET MANIFOLD LEAK, TWO TANKS NOT SUPPLYING THE LEAK WILL BE SELECTED ALONG WITH THE PROPER FLASH EVAPORATOR SUBSYSTEM (IF REQUIRED). THE LEAKING MANIFOLD WILL BE ISOLATED FOR THE REMAINDER OF THE MISSION.

Any water system manifold leak has the potential of reducing the ability of two water tanks to supply water under demand conditions. By isolating the leaking manifold, the amount of free water introduced into the cabin is minimized while maintaining water system support integrity.

DOCUMENTATION: Engineering judgment.

- D. FOR A SUPPLY WATER TANK INLET MANIFOLD LEAK, THE WATER TANKS WILL REMAIN DEPRESSURIZED.

When water tanks are depressurized for an inlet manifold leak, the available water supply to the leak has been reduced such that the rate at which water is expelled into the cabin cannot exceed FC generation rate.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A18-59

SUPPLY WATER REDLINE

- A. THE MINIMUM SUPPLY WATER QUANTITY ACCEPTABLE TO ALLOW FOR ANYTIME ENTRY REQUIREMENTS IS 175 LBM.

Analysis results conclude that 175 lbm of water is sufficient to supply orbiter cooling requirements for an anytime 165-minute emergency deorbit.

DOCUMENTATION: Anytime Contingency Deorbit Water Redline, STSOC Transmittal Form No. FDD-SA-88-220-082, 5/25/88.

- B. FOR A NORMAL ORBITER CONFIGURATION, SUPPLY WATER SHOULD BE MANAGED SO THAT 281 LBM IS AVAILABLE 4 HOURS PRIOR TO EVERY PLS TIG TIME (THIS SHOULD BE MAINTAINED UNTIL THE PLS TIG IS PASSED) .
- C. RETURN PAYLOAD COOLING WATER REQUIREMENTS ARE SPECIFIED IN THE APPROPRIATE FLIGHT-SPECIFIC ANNEX.

Normal orbiter configuration assumes no active payload cooling (both FCL flow proportioning valves in ICH position) and normal orbiter power levels. For active payload cooling cases, additional water is required, depending on flight-specific cooling requirements. This redline is derived as a minimum water quantity required to support a nominal deorbit timeline. Contingency return cases require less water (175 lbm) due to a shorter deorbit time. Failures requiring EVA (PLBD fail to close) would require a 1-day waveoff to accumulate extra water required to support the new deorbit and EVA timeline. The study used to define this redline uses the following major assumptions:

- a. RAD coldsoak (RADS HI, Topping FES-ON) starts at TIG minus 3:56.*
- b. RAD bypass at TIG minus 2:50.*
- c. PLBD's closed at TIG minus 2:35.*
- d. FES deactivated at TD minus 12 minutes.*
- e. Entry power level of 19 kw.*

Measurement error, crew consumption and 10 percent dispersion are included in the analysis.

DOCUMENTATION: Anytime Contingency Deorbit Water Redline, STSOC Transmittal Form No. FDD-SA-88-220-082, 5/25/88.

FLIGHT RULES

A18-60

EXTERNAL AIRLOCK WATER LINES

THE EXTERNAL AIRLOCK WATER LINES ARE CONSIDERED LOST IF: [061297-4904]

- A. THE EXTERNAL AIRLOCK WATER LINE TEMPERATURES IN EITHER ZONE 1 OR ZONE 2 CANNOT BE MAINTAINED TO > 32 DEG (40 DEG) F.

The external airlock water lines consist of six different water lines broken up into two zones, routed between the Xo=576 bulkhead and the external airlock. They are:

One EMU/ISS transfer supply water line

One EMU waste water return line

Two EMU liquid cooling garment supply lines (one for each EMU)

Two EMU liquid cooling garment return lines (one for each EMU)

Each line is wrapped with triply redundant heater strings in each of the two zones. Redundant temperature transducers are available for each zone (two each for zones 1 and 2) and they are located to be representative of the temperature in all six of the lines when water is not flowing. A third transducer (V64T0185A) is available on zone 2 but, because of its location and subsequent sluggish response, it is not used for fault detection. It is mainly used to detect a short between heater segments.

Due to the location of each of the sensors, they do not indicate the exact temperature of the coldest segment of the six water lines. Per analysis, the following indicated temperatures reflect when the coldest segment of the lines has reached 32 deg. These values do not include the measurement error of the transducer:

H₂O SPLY T ZN1 (V64T0181A) - 34 deg F

LCG2 SPLY T ZN1 (V64T0182A) - 47 deg F

QD PNL T ZN2 (V64T0183A) - 42 deg F

H₂O SPLY T ZN2 (V64T0184A) - 36 deg F

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-60

EXTERNAL AIRLOCK WATER LINES (CONTINUED)

- B. THE EXTERNAL AIRLOCK STRUCTURAL TEMPERATURES CANNOT BE MAINTAINED TO > 32 DEG (40 DEG) F.

Preliminary analysis indicates that with the airlock depressed and the hatch and thermal cover open, the internal water line temperatures decrease faster than the indicated structural temperatures (reference Rule {A15-201}, EXTERNAL AIRLOCK HATCH THERMAL COVER). During EVA and while the ductwork is disconnected, the only active thermal control for the interior of the airlock is provided by the structural heaters. Based upon attitude, there is a concern for water line freezing if an active heater zone fails.

DOCUMENTATION: Engineering judgment and Rockwell I.L. 270-200-95-152, Rev 1. @[061297-4904]

FLIGHT RULES

A18-61

EXTERNAL AIRLOCK LCG FLUID LINE LOSS DEFINITION

THE LCG FLUID LINES SHALL BE CONSIDERED LOST IF: @[061297-4904]

- A. WITH THE SCU DISCONNECTED FROM THE EMU, THE LCG PRESSURE CANNOT BE MAINTAINED ? 28.1 (26.4) PSIG.
- B. WITH THE SCU CONNECTED TO THE EMU AND THE EMU UNPOWERED, THE LCG PRESSURE CANNOT BE MAINTAINED ? 18 (16.6) PSIG.

The pressure in either of the LCG lines (MSID V64P0170A or V64P0171A) shall be maintained below the SCU certified maximum operating pressure of 28.1 psig, in order to protect the SCU from exposure to proof pressure cycles (SCU proof pressure is 42.2 psig, burst pressure is 56.2 psig). The SCU can be connected to the EMU to relieve the pressure in the LCG lines.

A steady pressure increase in either of the LCG lines with the SCU connected, EMU fan/pump and O₂ actuator off, indicates the EMU water tanks no longer contain any nominal ullage and are no longer acting as an accumulator for the LCG lines. In the EMU, the LCG loop is connected to the water tanks through the bypass of the EMU coolant isolation valve. At 19.0 ±1.0 psig, the EMU feedwater relief valve will open and vent water from the EMU water tanks into the airlock.

DOCUMENTATION: Hamilton Standard EMUM-1337, S/AD SV767730/2 (Service & Cooling Umbilical Drawing), and engineering judgment. @[061297-4904]

FLIGHT RULES

A18-62

EXTERNAL AIRLOCK WATER LINE OVERPRESSURE/TEMPERATURE MANAGEMENT

UNEXPECTED PRESSURE AND/OR TEMPERATURE INCREASES IN THE EXTERNAL AIRLOCK LIQUID COOLING GARMENT (LCG) FLUID LINES WILL BE MANAGED AS FOLLOWS IN ORDER OF PRIORITY: ©[061297-4904]

- A. DEACTIVATION OF WATER LINE HEATERS
- B. CHANGE ORBITER ATTITUDE, IF OPERATIONAL AND PAYLOAD CONSTRAINTS ALLOW
- C. CIRCULATE THE WATER IN THE LCG LINES VIA THE EMU FAN/PUMP (REF RULE {A15-202}, EXTERNAL AIRLOCK LCG PRESSURE AND TEMPERATURE MANAGEMENT USING THE EMU).

There is no accumulator located on the LCG fluid lines, and they are configured in a closed loop system. The only room for thermal expansion in these fluid lines is via the flexible portion of the SCU lines, when disconnected from the EMU, or the available ullage in the EMU water tanks when the SCU is connected to the EMU. It is possible, in "hot" thermal attitudes, that the available expansion in the LCG lines may not be sufficient to prevent a hydraulic lockup condition, without taking action to lower the pressure/temperature of the fluid lines.

DOCUMENTATION: Engineering judgment. ©[061297-4904]

FLIGHT RULES

ARS H2O LOOP LOSS DEFINITIONS

A18-101

ARS WATER LOOP

AN ARS WATER LOOP IS CONSIDERED LOST IF:

- A. ACCUMULATOR QUANTITY EQUALS 0 (? 5) PERCENT.

When the accumulator is empty, voids are created in the water loop causing pump cavitation.

DOCUMENTATION: Engineering judgment.

- B. INTERCHANGER FLOWRATE CANNOT BE MAINTAINED ? 600 (649) LB/HR IN THE "MIN BYP" POSITION.

At flowrate < 600 lb/hr, avionics bay 2 coldplates cannot be maintained below their 130 deg F upper limit in a normal entry (five GPC's).

DOCUMENTATION: SEH-ECS-86-106.

- C. ACTIVE LOOP PUMP OUTLET TEMPERATURE CANNOT BE MAINTAINED TO < 85 DEG (82.75 DEG) F AT A 14.7 PSIA CABIN PRESSURE.

The maximum air supply temperature to the avionics bays is 95 deg F at 14.7 psia cabin pressure by design specification. The air temperature leaving the avionics heat exchanger is about 10 deg F hotter than the water coolant loop pump outlet temperature. Avionics equipment may overheat if pump outlet temperature cannot be maintained to less than 85 deg F.

DOCUMENTATION: MF0004-009, REV A; Flight data (E.G. SEH-ITA-82-333).

- D. THERE IS CONFIRMED INTERLOOP LEAKAGE (WATER-TO-WATER OR FREON-TO-WATER).

For a water-to-water loop leak, the loops are now operating as one loop. (Ref. Rule {A18-151D}, ARS WATER LOOP.) The next failure, an external leak, could result in loss of both loops. For a Freon-to-water loop leak, high pressures and material incompatibilities between Freon 21 and water loop components increase the probability of an external leak in the water loop and exposing the crew to the toxic Freon 21. To reduce such probability, the affected water loop is not to be operated unless required. (Ref. Rule {A18-101E}, ARS WATER LOOP.)

DOCUMENTATION: Engineering judgment; JSC-08934, vol. 3, 4.6.1.2.1.2.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-101 ARS WATER LOOP (CONTINUED)

E. THERE IS CONFIRMED ACCUMULATOR BELLOWS FAILURE CAUSING GN₂
 AND WATER COOLANT TO MIX.

For an accumulator bellows failure causing GN₂ to mix with water coolant, nitrogen bubbles will pass through the pump if the affected loop is activated. The pump would operate erratically as would be demonstrated by the pump delta P and interchanger flowrate. Since a reliable continuous pump operation cannot be expected, the loop should be considered lost.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

ARS H2O LOOP LOSS MANAGEMENT

A18-151

ARS WATER LOOP

A. NORMAL CONFIGURATION FOR ASCENT/ENTRY:

BYPASS VALVE CONTROL IN THE "MAN" MODE AND THE INTERCHANGER FLOW PRESET TO 950 ± 50 LB/HR ON BOTH LOOPS.

1. LOOP 1 -PUMP B WITH CONTROL "OFF".
2. LOOP 2 -PUMP CONTROL "ON".

The heat load mismatch between Freon and water loops at the interchanger causes the bypass valve controller to operate improperly at high heat loads when in the AUTO mode. Reference the Environmental Systems Console Handbook for a complete description of this mismatch. The optimum water loop flowrate for both the cabin temperatures and the avionics temperatures is determined by analysis to be 950 lb/hr for when the Freon loop FPM's are in either ICH or P/L positions. For these reasons, it is desirable to operate at this constant 950 lb/hr flowrate with the bypass valve in the MAN mode, during Ascent/Entry.

Water loop 2 is used as the active loop because of the "undetected failure" concern. Water loop 2 has one pump and water loop 1 has two pumps. If water loop 1 were to be the prime active loop, the pump in water loop 2 could fail and remain undetected until loop 1 failed and loop 2 was needed.

Water loop 1 is preset to a 950 lb/hr flowrate so that, when needed, it can be brought on line with optimum performance.

DOCUMENTATION: 1.2-TM-B1109-27; SEH-ITA-82-029.

B. CONFIGURATION FOR ON ORBIT:

1. AUTO MODE

BYPASS VALVE CONTROL IN THE AUTO MODE: LOOP 2 - PUMP CONTROL "ON", AND LOOP 1 - PUMP B WITH "GPC" CONTROL AND BYPASS VALVE IN MAN MODE.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-151 ARS WATER LOOP (CONTINUED)

2. MANUAL MODE

BYPASS VALVE CONTROL IN THE MAN MODE AND THE INTERCHANGER FLOW PRESET TO 950 ± 50 LB/HR ON BOTH LOOPS: LOOP 1 - PUMP B WITH "GPC" CONTROL, AND LOOP 2 - PUMP CONTROL "ON."

Flight data has indicated that the heat load mismatch at the Freon/H₂O interchanger is not as severe as previously predicted by analysis. Water loop control temperature (PUMP OUT TEMP) is not significantly affected by the FREON/H₂O ICH heat load mismatch. During STS-44, H₂O LOOP 2 performed nominally in the AUTO mode. Postflight crew comments about cabin temperature indicate AUTO mode is also beneficial to the persistent cabin temperature problem. Reference OFTP 8-14-91, 12-13-91.

H₂O loop 1, pump B, is in the GPC position for periodic cycling to satisfy thermal conditioning requirements. Pump A is normally operated on the ground. ©[041196-1882]

DOCUMENTATION: SEH-ITA-83-151

C. BOTH WATER LOOPS WILL BE TURNED ON IF THE EVAPORATOR OUTLET TEMPERATURES IN BOTH FREON LOOPS ARE <32 DEG (34.6 DEG) F. (REF. {A18-251E}, FREON COOLANT LOOPS (FCL).)

Turning both water loops on allows more heat to be transferred to the water loops at their coldplates and heat exchangers, which at the same time reduces the interchanger heat transfer effectiveness from water-to-Freon loops. Analysis has shown that with both water loops operating and both Freon FPM's at the ICH positions, freezing of water is prevented until the Freon inlet temperature to the interchanger drops below 6 deg F.

DOCUMENTATION: LEMSCO 19630.

D. FOR A WATER-TO-WATER LOOP LEAK, BOTH WATER LOOPS WILL BE ACTIVATED.

Depending on the loading of the water loops, it is possible to empty the accumulator of the operating loop into the nonoperating loop in the case of an interloop leak. Operating both loops eliminates this problem.

DOCUMENTATION: Engineering judgment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-151 ARS WATER LOOP (CONTINUED)

E. FOR A FREON-TO-WATER LOOP LEAK, THE AFFECTED WATER LOOP WILL NOT BE OPERATED UNLESS REQUIRED.

For a Freon-to-water loop leak, pressures in the water loop can get up to 135 psig (proof pressure) and higher if the affected water loop is operated. In addition, several components in the water loop are incompatible with Freon 21 and may fail to seal or function. Operating the affected water loop will circulate Freon 21 in the loop and accelerate seal degradation. The high pressures and material incompatibilities together increase the probability of an external leak in the water loop and exposing the crew to the toxic Freon 21. ©[082593-1527]

F. FOR A WATER LOOP LEAK, THE AFFECTED LOOP WILL BE DEACTIVATED.

When there is a coolant leak into the cabin from the water loop, it becomes zero-fault tolerant to crew safety because the next failure, a Freon-to-water leak at the interchanger, will introduce toxic Freon 21 into the crew habitable area. Deactivating the leaking loop may slow the leak rate (depending on the location of the leak on the loop) and minimize the risk of transferring Freon into the cabin should an interchanger leak occur. This would allow this loop to be used in the contingency event the other water loop should fail.

DOCUMENTATION: Engineering judgment; JSC-08934, volume 3, section 4.6.1.2.1.2.

Rule {A18-101D}, ARS WATER LOOP, references this rule.

ACTIVE THERMAL CONTROL SYSTEM (ATCS) LOSS DEFINITIONS

A18-201 FREON COOLANT LOOPS (FCL)

AN FCL IS CONSIDERED LOST IF:

A. CALCULATED FREON FLOWS, WHICH ASSUME THE RADIATORS ARE BYPASSED AND THE FLOW PROPORTIONING MODULE (FPM) IN "ICH," CANNOT BE MAINTAINED GREATER THAN:

1. INTERCHANGER FLOW EQUALS 1800 (1925) LB/HR.

The minimum interchanger flowrate required to support a one Freon loop entry (with three GPC's) is 1800 lb/hr. This flowrate is required to ensure that the fuel cell coolant return temperature is maintained below its 140 deg F limit until just before touchdown. (The exceedance is of short enough duration that no fuel cell damage will occur.)

DOCUMENTATION: G189A analysis dated 8/4/89.

A Freon loop with a flow proportioning valve failed in the PL position is considered lost because, with loss of the other loop, it will not provide enough cooling to the interchanger (av bays and cabin) during a one Freon loop entry. Assuming one FCL powerdown and an additional two GPC's powered down (one GPC/avionics bay powered up), avionics bays 1, 2, and 3 violate mixed air outlet temperature limits. The PL position provides only 51 percent (1500 lb/hr/lp) of the total Freon flow to the interchanger, while the ICH position provides 81 percent (2400 lb/hr/lp). Freon loop total flow is not greatly affected by the FPM position and thus, FC cooling is not a concern for this failure. ©[041097-3104B]

DOCUMENTATION: SE-TSAT-95-010. Reference SODB Volume III, par. 4.5.4.1.2, memo ED5-90-48, and IBM report 90-544-004 for GPC cooling requirements. ©[041097-3104B]

2. AFT COLDPLATE FLOW EQUALS 211 (236) LB/HR.

The minimum aft coldplate flow required for a one Freon loop entry is 211 lb/hr. This flowrate is required to maintain the aft avionics bay 4 coldplate temperature below the 112 deg F limit and the aft avionics RGA outlet temperature below the 120 deg F limit. This assumes that the aft coldplate equipment is powered up for a nominal deorbit prep and entry (no powerdown), and no waveoffs are performed.

225 (250) lb/hr aft coldplate flow is required to support a nominal entry, with two weather waveoff revs (3- hour extended deorbit prep) with no powerdown or cycling of the aft coldplate equipment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-201 FREON COOLANT LOOPS (FCL) (CONTINUED)

If PLS is declared for low aft coldplate Freon flow, then all landing sites should be made available to maximize a single opportunity if a good FCL should fail. If the good FCL should fail and deorbit cannot be accomplished, backout, powerdown, and another single deorbit attempt the next day will not violate orbiter cooling requirements (as long as flow is greater than 211 lbs/hr total).

DOCUMENTATION: SE-TSAT-93-068, SEH-ITA-84-249T, and Engineering judgment. ©[012694-1542A]

B. PUMP INLET PRESSURE < 33.5 (48.5) PSIA

Pump cavitation will occur for a pressure at the pump inlet below Freon vaporization point. Since there is not a measurement of pump inlet temperature, the maximum pump inlet temperature vaporization pressure is used. The FCL's were designed for a 90 deg F inlet to the midbody coldplates for one FCL operation (90 deg F pump outlet temperature). Therefore, based on design, the maximum pump inlet temperature without exceeding the midbody coldplate outlet temperature is 88 deg F. This corresponds to a vaporization pressure of 32 psia for Freon.

However, the location of the pressure transducer is at the upstream of the pump inlet filter, and the pressure loss through the filter must be accounted for to make sure the pump inlet pressure is above vaporization point. The maximum pressure drop of the filter is 1.5 psid; therefore, the pressure shall be no less than 33.5 psid to ensure proper pump performance. The pump cavitation will cause erratic discharge pressure and pumping flowrate.

DOCUMENTATION: SODB figure 4.6.3-8; SODB TBD.

C. THERE IS A CONFIRMED INTERLOOP LEAKAGE (FREON-TO-FREON).

The FCL, as related to fluid volume, would now be acting as one FCL. One additional failure (external fluid leak) would result in loss of both FCL's. For GO/NO-GO purposes, one FCL would be considered lost in the event of interloop leakage.

DOCUMENTATION: N/A, engineering judgment.

D. ACCUMULATOR QUANTITY EQUALS 0 (3) PERCENT.

When there is no Freon left in the accumulator, voids are created in the FCL, causing pump cavitation.

DOCUMENTATION: N/A, engineering judgment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-201 **FREON COOLANT LOOPS (FCL) (CONTINUED)**

- E. FOR THE PURPOSES OF MAKING ASCENT ABORT CALLS, A FREON LEAK IS CONFIRMED BY AN OTHERWISE UNEXPLAINED 1.6 PERCENT DECREASE IN ACCUMULATOR QUANTITY AND A CORRESPONDING 2 PSI DROP IN PUMP IN PRESSURE FROM LIFT-OFF VALUES.

An earliest possible abort is required for loss of two Freon loops. A 1.6 percent quantity drop and 2 psi drop in PUMP IN PRESSURE is the minimum amount needed to confirm a loop leaking during ascent. Quantity and pressure always increase slightly during ascent due to the heat loads; therefore, any drop in quantity and pressure is always indicative of a leak. If, for any reason, the ascent heat loads should decrease (i.e., H2O loop failure), this could cause a drop in pressure and quantity, and the loop would not be called lost on this criteria. Once a loop is leaking, the FCL loss is imminent and is considered failed for abort calls. Pressing to orbit with leaking loops is not desirable, since the loss of two Freon loops during entry could result in loss of crew/vehicle.

DOCUMENTATION: Flight history and engineering judgment.

FLIGHT RULES

A18-202

TOPPING EVAPORATOR

THE TOPPING EVAPORATOR IS CONSIDERED LOST IF:

- A. BOTH PRIMARY CONTROLLERS AND THE SECONDARY CONTROLLER CANNOT MAINTAIN PROPER CONTROL, AS DEFINED IN THE CONTROLLER LOSS DEFINITION.

The topping evaporator cannot function without a controller. Reference controller loss definitions, Rules {A18-204}, FES PRIMARY A (B) CONTROLLER, and {A18-205}, FES SECONDARY CONTROLLER.

DOCUMENTATION: Hamilton Std, SEM 62408.

- B. FORWARD OR AFT TOPPING DUCTS CANNOT BE MAINTAINED ? 100 DEG (120 DEG) F.

This temperature ensures that, as the topping evaporator boils water, the H₂O vapor does not condense and freeze in the ducts. If freezing occurs, the back pressure in the Flash Evaporator System (FES) core increases, which raises the boiling point. This may result in an overtemp shutdown.

DOCUMENTATION: Hamilton Std, SEM 62449.

- C. BOTH A AND B FEEDLINES ARE LOST.

If both feedlines are lost, H₂O cannot be supplied to the topping evaporator. Reference Rule {A18-206}, FES H₂O FEEDLINE, loss definition.

DOCUMENTATION: N/A, system schematic analysis.

FLIGHT RULES

A18-203

HIGH-LOAD EVAPORATOR

THE HIGH-LOAD EVAPORATOR IS CONSIDERED LOST IF:

- A. BOTH PRIMARY CONTROLLERS AND THE SECONDARY CONTROLLER CANNOT MAINTAIN PROPER CONTROL, AS DEFINED IN THE CONTROLLER LOSS DEFINITION.

The high-load evaporator cannot function without a controller. Ref. Rules {A18-204}, FES PRIMARY A (B) CONTROLLER; and {A18-205}, FES SECONDARY CONTROLLER.

DOCUMENTATION: Hamilton Std, SEM 62408.

- B. INBOARD OR OUTBOARD HIGH-LOAD DUCT SECTIONS CANNOT BE MAINTAINED ? 150 DEG (170 DEG) F. @[ED]

This temperature ensures that, as the high-load evaporator boils water, the H₂O vapor does not condense and freeze in the duct. If freezing occurs, the back pressure in the FES core increases, which raises the boiling point. This may result in an overtemp shutdown.

- C. BOTH A AND B FEEDLINES ARE LOST.

If both feedlines are lost, H₂O cannot be supplied to the high-load evaporator. Reference Rule {A18-206}, FES H₂O FEEDLINE, loss definition.

DOCUMENTATION: N/A, system schematic analysis.

FLIGHT RULES

A18-204

FES PRIMARY A (B) CONTROLLER

THE FES PRIMARY A (B) CONTROLLER IS CONSIDERED LOST IF:

- A. UNABLE TO MAINTAIN EVAPORATOR OUTLET TEMPERATURE BETWEEN 36 DEG F AND 42 DEG F WHEN THE EVAPORATOR IS ENABLED.
©[ED]

If the controller is controlling at temperatures outside this range, three failures have occurred in the PRI A controller (one control sensor and two shutdown sensors) and two failures have occurred in the PRI B controller (one control sensor and one shutdown sensor). Based on the number of failures, the controllers are not considered reliable and, therefore, must be considered failed. The primary controller controls between 38 deg and 40 deg F and is enabled at an inlet temperature of 41 deg F. The 36 deg F lower limit is based on the fact that the undertemperature shutdown logic on each controller will shut down the controller if the evaporator-outlet temperature remains below 37 ± 0.25 deg F for 20 seconds. The 42 deg F upper limit is based on the fact that the overtemperature shutdown logic will shut down the controller if the evaporator-outlet temperature does not decrease to less than 41.5 ± 0.25 deg F when the FES is enabled.

DOCUMENTATION: Hamilton Std, SEM 62408.

- B. AUTO SHUTDOWN CIRCUITRY WILL NOT ALLOW FES TO REMAIN ONLINE.

Auto shutdown logic will shut down the FES if temperatures and temperature decrease rates are not satisfied.

DOCUMENTATION: Hamilton Std, SEM 62408.

- C. A(B) FEEDLINE IS LOST.

If the A(B) feedline is lost, the primary A(B) controller will not operate (no H₂O).

Reference Rule {A18-206}, FES H₂O FEEDLINE, loss definition.

DOCUMENTATION: N/A, system schematic analysis.

Rules {A18-202A}, TOPPING EVAPORATOR; and {A18-203A}, HIGH-LOAD EVAPORATOR, reference this rule.

FLIGHT RULES

A18-205

FES SECONDARY CONTROLLER

THE FES SECONDARY CONTROLLER IS CONSIDERED LOST IF IT IS UNABLE TO MAINTAIN EVAPORATOR OUTLET TEMPERATURE BETWEEN > 60 DEG F AND < 65 DEG F.

The control band for the secondary controller is 62 deg \pm 2 deg F. If the secondary controller is controlling below 60 deg F, a failure in the controller has occurred and it cannot be considered reliable.

The FES secondary controller does not have shutdown logic. In the event the orbiter heat load exceeds the FES capability, the evaporator outlet temperature will be maintained greater than its normal control band without shutdown.

The SODB requires the maximum temperature of air entering the avionics boxes to be less than 95 deg F and less than 130 deg F at the outlet of the boxes. At a 65 deg F evaporator outlet temperature with flow proportioning valves of both Freon loops configured to the ICH position and H₂O loop flowrate adjusted to full interchanger flow, analyses indicate that these limits will not be violated for a normal on-orbit ARS heat load (seven crewmembers, one GPC per avionics bay, etc.) in a 14.7 psia cabin environment. Powering up an additional GPC in the avionics bay will raise the measured outlet air temperature by approximately 10 deg to 15 deg F. This will cause frequent temperature excursions over the 130 deg F limit at the box outlet, leaving little or no margin for the operation of additional equipment in the same avionics bay. Since adequate thermal control cannot be maintained for a fully powered ARS when evaporator outlet temperatures are greater than 65 deg F, the FES is considered lost.

Rules {A18-202A}, TOPPING EVAPORATOR; and {A18-203A}, HIGH-LOAD EVAPORATOR, reference this rule.

DOCUMENTATION: Hamilton Std, SEM 62408; 283-440-84-005; STS85-0246; JSC 08934, 4.6.1.

FLIGHT RULES

A18-206

FES H2O FEEDLINE

THE FES H₂O FEEDLINE IS CONSIDERED LOST IF:

- A. TEMPERATURES IN ANY SECTION ARE <32 DEG (40 DEG) F.

At 32 deg F, the H₂O in the lines will freeze.

DOCUMENTATION: N/A, engineering judgment.

- B. FEEDLINE ACCUMULATOR N₂ CHARGE IS LOST ("NOK" INDICATION PRESENT).

The N₂ charge is required to prevent water hammer effect which could cause erratic FES operations.

DOCUMENTATION: N/A, engineering judgment.

- C. THERE IS A CONFIRMED LEAK IN THE FEEDLINE SUCH THAT H₂O USAGE RATE WILL NOT SUPPORT NOMINAL ENTRY.

If the leak is large enough that H₂O requirements for entry cannot be met, the feedline cannot be used.

DOCUMENTATION: N/A, engineering judgment.

- D. SUPPLY ISOLATION VALVE IS FAILED CLOSED (B FEEDLINE ONLY).

If the valve is failed closed, the feedline cannot supply H₂O to the FES.

DOCUMENTATION: N/A, System schematic analysis.

Rules {A18-202C}, TOPPING EVAPORATOR; {A18-203C}, HIGH-LOAD EVAPORATOR; and {A18-204C}, FES PRIMARY A (B) CONTROLLER, reference this rule.

FLIGHT RULES

A18-207

AMMONIA BOILER SUBSYSTEM (ABS)

THE ABS SUBSYSTEM IS CONSIDERED LOST IF:

- A. UNABLE TO MAINTAIN EVAPORATOR OUTLET TEMPERATURE AT ? 31 DEG F AND ? 65 DEG F.

The control point for the ammonia boiler is 34 deg ± 3 deg F. Less than 31 deg F is unacceptable due to the potential for freezing the orbiter water loops or a payload water loop, if installed. If the EVAP OUT TEMP reaches 32 deg F, a C&W will be annunciated and the EVAP OUT TEMP LOW procedure will be worked. This will provide freeze protection for temperatures down to 6 deg F.

If the NH₃ boiler is controlling above 65 deg F, adequate thermal control of the vehicle cannot be maintained.

DOCUMENTATION: Lockheed analysis, LEMSCO 19630; 283-440-84-005; STS85-0245; JSC 08934, 4.6.1.

- B. NH₃ QUANTITY EQUALS 0 (3) LB AS DETERMINED BY P-V-T RELATIONSHIPS (GROUND ONLY).

When there is no NH₃ left, the ABS cannot cool. The NH₃ system does not have a quantity reading and, therefore, quantity must be determined by tank pressure and tank temperature. Temperature does not remain constant on orbit, and, therefore, P-V-T curves must be used to determine quantity.

DOCUMENTATION: N/A, engineering judgment.

FLIGHT RULES

A18-208 RADIATOR FLOW CONTROL ASSEMBLY (RFCA)

THE RFCA IS CONSIDERED LOST IF:

- A. FAILED IN RADIATOR BYPASS POSITION.

The radiator, as a heat rejection source, is unusable. Therefore, the RFCA is considered lost.

DOCUMENTATION: N/A, engineering judgment.

- B. UNABLE TO MAINTAIN CONTROLLER OUTLET TEMPERATURE > 32 DEG (35 DEG) F.

The potential exists for freezing the FES water spray valves, the ARS water coolant loops, and the payload water loop (if installed) if the RFCA cannot maintain > 32 deg F control.

DOCUMENTATION: N/A, engineering judgment.

- C. CANNOT MAINTAIN EVAPORATOR OUTLET TEMPERATURE < 65 DEG F WITH THE FES DISABLED.

The SODB requires the maximum temperature of air entering the avionics boxes to be less than 95 deg F and less than 130 deg F at the outlet of the boxes. At a 65 deg F evaporator outlet temperature with flow proportioning valves of both Freon loops configured to the ICH position and H₂O loop flowrate adjusted to full interchanger flow, analyses indicate that these limits will not be violated for a normal on-orbit ARS heat load (seven crewmembers, one GPC per avionics bay, etc.) in a 14.7 psia cabin environment. Powering up an additional GPC in the avionics bay will raise the measured outlet air temperature by approximately 10 deg to 15 deg F. This will cause frequent temperature excursions over the 130 deg F limit at the box outlet, leaving little or no margin for the operation of additional equipment in the same avionics bay. Since adequate thermal control cannot be maintained for a fully powered ARS when evaporator outlet temperatures are greater than 65 deg F, the RFCA is considered lost.

DOCUMENTATION: 283-440-84-005; STS85-0245; JSC-08934, 4.6.1.

Rule {A18-255B}, RADIATOR FLOW CONTROL ASSEMBLY (RFCA), references this rule.

A18-209 THROUGH A18-250 RULES ARE RESERVED

FLIGHT RULES

ATCS MANAGEMENT

A18-251 **FREON COOLANT LOOPS (FCL)**

- A. BOTH FCL'S, WITH ONE PUMP OPERATING IN EACH FCL, ARE REQUIRED FOR NORMAL OPERATIONS.

To operate with only one FCL on orbit could require a minor powerdown (to 15 kW) and would require the use of the FES or flying in a cold attitude. If -ZLV (the most common attitude) is flown, a negative net H₂O storage rate would exist. To eliminate these types of constraints and issues, both FCL's are operated.

DOCUMENTATION: SEH-ITA-80-054T.

- B. THE FOLLOWING TEMPERATURES SHALL NOT BE EXCEEDED:
1. FOR ASCENT/ENTRY (RADIATORS BYPASSED): 140 DEG (132 DEG) F AT RADIATOR INLET.
 2. ON-ORBIT (RADIATORS IN FLOW):
 - a. 65 DEG (60 DEG) F AT EVAPORATOR OUTLET FOR NO FES OPERATIONS (BOTH LOOPS IN ICH POSITION).
 - b. 68 DEG (63 DEG) F AT RADIATOR OUTLET FOR FES OPERATIONS.

In all cases (pre-liftoff, while on orbit, and pre-deorbit) orbiter power levels are planned to ensure that these limits are not exceeded.

The maximum capability of the FES (full up mode) is 148,000 Btu/hr (test data). This is equivalent to a 140 deg F radiator inlet temperature.

The SODB requires the maximum temperature of air entering the avionics boxes to be less than 95 deg F and less than 130 deg F at the outlet of the boxes. At a 65 deg F evaporator outlet temperature with flow proportioning valves of both Freon loops configured to the ICH position and H₂O loop flowrate adjusted to full interchanger flow, analyses indicate that these limits will not be violated for a normal on-orbit ARS heat load (seven crewmembers, one GPC per avionics bay, etc.) in a 14.7 psia cabin environment. Powering up an additional GPC in the avionics bay will raise the measured outlet air temperature by approximately 10 deg to 15 deg F. This will cause frequent temperature excursions over the 130 deg F limit at the box outlet, leaving little or no margin for the operation of additional equipment in the same avionics bay.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-251 **FREON COOLANT LOOPS (FCL) (CONTINUED)**

The maximum capability for the topping evaporator is 39,000 Btu/hr (SODB, based on test data). This is equivalent to a 68 deg F radiator outlet temperature.

DOCUMENTATION: SEH-ITA-81-107; 283-440-84-005; STS85-0245; JSC 08934, 4.6.1.

C. IF IT IS REQUIRED TO DEACTIVATE AN OPERATING FCL OR BYPASS A RADIATOR:

1. THE ASSOCIATED RADIATOR WILL BE STOWED.

Stowing the radiators prevents Freon freezing (except in total deep space attitudes).

*DOCUMENTATION: SODB **TBD** (request submitted).*

2. ATTITUDES THAT EXCLUDE EARTH OR SUN VIEWING (DEEP SPACE) WILL BE LIMITED TO NO MORE THAN 1 HOUR.

For an initial Freon temperature of -40 deg F, it will take approximately 1.5 hours for Freon to freeze. Since there is no insight into the actual temperature of the Freon in the radiators, a conservative limit of 1 hour was chosen.

*DOCUMENTATION: SODB **TBD** (request submitted).*

3. ORBITER ATTITUDES WILL BE MANAGED TO MAINTAIN THE ACCUMULATOR QUANTITY ? 5 PERCENT INDICATED.

For a good FCL (not leaking), the minimum acceptable accumulator quantity is 5 percent indicated. Taking instrumentation accuracy into account, the actual quantity could be 2 percent. At 2 percent quantity, the loop can still be activated if needed in an emergency. At 0 percent quantity, thermal conditioning would be required prior to activating the FCL.

DOCUMENTATION: N/A, engineering judgment.

4. CLOSING THE AFFECTED RADIATOR'S PLBD WILL BE CONSIDERED IF ATTITUDE CONSTRAINTS CANNOT BE MET.

Closing the PLBD increases the temperature of the FCL.

DOCUMENTATION: Flight data.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-251 FREON COOLANT LOOPS (FCL) (CONTINUED)

- D. THE FLOW PROPORTIONING VALVE (FPV) IN BOTH FCL'S WILL NORMALLY BE PLACED IN THE "ICH" POSITION FOR ALL PHASES OF FLIGHT. EITHER OR BOTH FPV'S MAY BE PLACED IN "P/L" IF A PAYLOAD REQUIREMENT EXISTS.

Placing the FPV's in the ICH position maximizes the Freon flowrate to the H₂O Freon interchanger: approximately 4800 lb/hr in the ICH position vs. approximately 3000 lb/hr in the P/L HX position. This maximizes cooling to the cabin and avionics bays via the water loop. However, placing both loops in the P/L position does not increase the temperatures a significant amount (5 deg to 7 deg F).

DOCUMENTATION: Flight data.

- E. THE FPV IN BOTH FCL'S WILL BE PLACED TO THE "ICH" POSITION IF BOTH THE EVAPORATOR OUTLET TEMPERATURES ARE < 32 DEG (34.4 DEG) F. IF THE PAYLOAD LOOP DOES NOT CONTAIN WATER, A REAL-TIME CALL WILL BE MADE TO PLACE BOTH FPV'S TO THE "P/L" POSITION.

This will prevent or delay the freezing of the payload and orbiter water loops. Provided that both orbiter water loops and a 500 lb/hr flowrate payload water loop (if installed) are flowing, the ICH position provides orbiter water loop freeze protection for Freon temperatures as low as 6 deg F, and payload water loop protection for Freon temperatures as low as -30 deg F (extrapolated). If left in the P/L position, the payload water loop would freeze at Freon temps of 32 deg F and the orbiter water loops at -30 deg F (extrapolated) Freon temperatures. For payload flowrates <150 lb/hr, the payload water loop will freeze eventually, but is delayed if the FPV is placed in the ICH position.

DOCUMENTATION: Lockheed analysis, LEMSCO 19630.

- F. IF AN FCL IS DEACTIVATED, THE ASSOCIATED PRESSURE CONTROL O₂ SYSTEM (PCS) SUPPLY VALVE WILL BE CLOSED.

If the FCL is deactivated, Freon in the stagnant loop will freeze if O₂ is flowing (cryogenic O₂ temperature is -254 deg F). Since the O₂ is no longer being warmed by the Freon, the O₂ restrictor seal will leak when exposed to the cryogenic temperatures. Normal flow of O₂ is 0.5 lb/hr for crew metabolic usage. For 0.1 lb/hr O₂ flow, the stagnant FCL will freeze in 10 minutes. For a 10 lb/hr flowrate the FCL will freeze in 100 seconds. Lab test results indicate that the O₂ restrictor seal will leak when exposed to -100 deg to -240 deg F temperatures. The leak will stop when the temperature gets above -47 deg F.

DOCUMENTATION: SEH-ITA-80-236T; LTR 4309-3101.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-251 FREON COOLANT LOOPS (FCL) (CONTINUED)

- G. FOR A FREON-TO-WATER LOOP LEAK, THE RADIATORS WILL NOT BE COLDSOAKED FOR ENTRY AND ATTITUDES THAT EXCLUDE EARTH OR SUN VIEWING (DEEP SPACE) WILL BE AVOIDED.

For a Freon-to-water loop leak, it is possible to get water into the Freon. Coldsinking the Freon increases the chances of freezing this water, which may affect the performance of the Freon loop. This risk outweighs the gain of a coldsoak. It is not likely that water will be introduced into the Freon loop until the pressures in the two loops equalize; therefore if coldsoak starts before the leak occurs, it should be stopped anytime before the affected water loop's accumulator quantity reaches 100 (97) percent. The radiator controllers should be returned to the norm set point, and to avoid decreasing the Freon temperature in the radiators, deep space attitudes should be avoided.

DOCUMENTATION: N/A, engineering judgment.

- H. IF AN FCL'S RFCA IS FAILED IN BYPASS (MINIMUM RADIATOR FLOW), THE AFFECTED FCL WILL BE DEACTIVATED, AND A POWERDOWN TO AT LEAST 15 KW WILL BE PERFORMED. THE FCL WILL BE REACTIVATED FOR DEORBIT PREPARATION.

An RFCA, failed in bypass or minimum radiator flow, will result in negative H₂O production if the FES is activated, or temperature violations if the FES is deactivated. Deactivating the FCL will alleviate these problems and only requires a powerdown to 15 kW. (Also reference paragraphs C and F.)

DOCUMENTATION: SEH-ITA-80-054T; SEH-ECS-86-102T.

- I. FOR AN EXTERNAL FREON LEAK (INCLUDING FREON TO HYDRAULIC), WHICH WILL NOT SUPPORT NEXT PLS, THE AFFECTED LOOP WILL BE DEACTIVATED IN AN ATTEMPT TO SLOW THE LEAK RATE FOR USE DURING ENTRY.

Deactivating the pump decreases pressure around the loop, slowing most leaks. This is done to save the loop for deorbit/entry. Reactivating the affected Freon loop for entry would allow a full powerup and opening of the associated O₂ supply valve required to provide an adequate O₂ source for greater than four crewmembers on LES.

DOCUMENTATION: Engineering judgment.

Rule {A18-151C}, ARS WATER LOOP, references this rule.

FLIGHT RULES

A18-252

FLASH EVAPORATOR SYSTEM (FES)

- A. NO MORE THAN ONE FES CONTROLLER SHALL BE ACTIVATED AT ANY TIME.

If two controllers are activated, both may pulse water when required thereby providing an increased rate of cooling. This will most likely result in an FES undertemperature shutdown or a freezeup of the FES core.

DOCUMENTATION: Flight data STS-51-B.

- B. FOR INITIAL TROUBLESHOOTING OF ON-ORBIT FES SHUTDOWNS, ONLY ONE RESTART ON EACH PRIMARY CONTROLLER WILL BE ATTEMPTED. DURING ASCENT OR ENTRY, THE SECONDARY CONTROLLER WILL BE ACTIVATED IF RESTARTS ON THE PRIMARY CONTROLLERS WERE UNSUCCESSFUL.

Repeated FES restarts after an unexplainable FES shutdown may add ice in the core if icing was the initial cause of the shutdown. Minimizing the number of restarts to one per controller minimizes de-icing time on orbit. During high heat load periods such as ascent or entry, every effort should be made to avoid vehicle overtemperature. Therefore, it is worth the risk to make another attempt using the secondary controller. The alternative is to open the PLBD post-OMS-1 or to establish radiator flow during entry.

DOCUMENTATION: Flight data; engineering judgment.

- C. THE HIGH-LOAD EVAPORATOR CONTROL SWITCH WILL BE PLACED IN THE "OFF" POSITION DURING ORBITAL OPERATIONS WHEN RADIATOR COOLING IS VERIFIED (CONTROLLER OUTLET TEMPERATURE < 68 DEG (62.8 DEG) F).

The high-load evaporator is unstable at low heat loads and will cause an FES shutdown under these conditions. This has been seen on several flights. The topping evaporator can maintain < 40 deg F evaporator outlet temperature for a maximum FES inlet temperature of 68 deg F (39,000 Btu/hr). Also, in disabling the high-load evaporator, the orbiter can maintain attitude control with the vernier RCS jets instead of the primary jets (minimizes propellant usage). Jet duty cycle is also a concern if VRCS is used for attitude control while in high load operations.

DOCUMENTATION: Flight data.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-252 FLASH EVAPORATOR SYSTEM (FES) (CONTINUED)

- D. THE TOPPING EVAPORATOR WILL BE USED WITH A PRIMARY CONTROLLER TO SUPPLEMENT RADIATOR COOLING AND MAY BE USED FOR DUMPING EXCESS FC WATER ON ORBIT.

The topping evaporator will maintain a stable evaporator outlet temperature when the radiators cannot control to < 41 deg F. The topping evaporator is used particularly when the orbiter is in a "warm" radiator attitude and the payload requires low temperatures or steady temperatures. Rule {A18-55}, SUPPLY WATER DUMP, covers dumping of FC water. The secondary controller which controls the evaporator outlet temperature of 62 deg F cannot normally be used since the radiator outlet temperatures are normally less than 62 deg F. The FES is normally on for either a payload need or for 10.2 psi cabin operations, both of which require considerably less than a 62 deg F Freon temperature.

DOCUMENTATION: N/A, engineering judgment.

- E. FES DUCT TEMPERATURES MUST BE GREATER THAN THE MINIMUM VALUES LISTED BELOW PRIOR TO FES STARTUP, EXCEPT FOR TIME-CRITICAL DEORBITS:

	<u>DUCT (DEG F)</u>
1. HIGH-LOAD - INBOARD, OUTBOARD	150 (170)
2. TOPPING - FORWARD, AFT	100 (120)

These temperatures ensure that, as the FES boils water, the duct is sufficiently warm so that the water vapor does not condense and begin to freeze in any portion of the FES outlet ducting.

DOCUMENTATION: Hamilton Standard SEM #62449.

- F. FES ICING @[082593-1528]

 - 1. THE FES SHOULD NOT BE OPERATED WITH THE SUPPLY WATER TANKS VENTED UNLESS ABSOLUTELY NECESSARY TO STAY WITHIN ORBITER OR PAYLOAD CONSTRAINTS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-252

FLASH EVAPORATOR SYSTEM (FES) (CONTINUED)

2. A FES CORE FLUSH CAN BE ATTEMPTED AFTER SUSPECTED ICING. THE PREFERRED METHOD IS TO BYPASS THE RADIATORS USING THE FLOW CONTROL VALVES AND THEN USE THE SECONDARY FES CONTROLLER TO FLUSH ICE FROM THE CORE.

Vendor test results show that even at a pressure of 20 psia, ice can build up in the topping core. This was especially evident at heat loads between 23 and 32 kBtu/hr; however, even at lower heat loads, icing is possible. When the tanks are vented to cabin pressure (15.0 psia or less), there is increased risk of building ice in the topping core. During STS-55, the FES operated with the radiator set point in HI, water dump mode (24.3 kBtu/hr), successfully for 10.1 hours while the tanks were vented to 14.7 psia. It continued to operate normally in and out of standby with the radiator set point in NORM and heat loads between 0 and 17.5 Btu/hr. When a second dump was attempted, the FES overtemp shut down after 2.3 hours due to icing. Even after repressurizing the water tanks, the FES could not be restarted. It was suspected that the ice build up was gradual, interfering with the FES's capability to function and finally resulting in the shutdown.

The ice was later removed using a topping core flush procedure proven during SESL testing which had the Freon loop radiators bypassed, inducing a high heat load, and cycling the secondary FES controller. If the FES is used with the tanks vented for any reason and icing causes a FES shutdown, this flush procedure could be used at the earliest available time to flush the core and resume normal FES operations as required. If possible, the radiator set point should be left in HI to help thaw the core; however, this is not required prior to performing the flush procedure. User of the flow control valves is preferred to minimize the risk encountered during radiator bypass.

DOCUMENTATION: STS-55 mission data; Hamilton Standard SESL Test Data documented in Internal Correspondence Letter: SPACE SHUTTLE ORBITER Flash Evaporator Program, Justification for Increased Feedwater Pressure and Addition of an Accumulator to the Vehicle Feedwater System, February 15, 1978 (analysis 78-37, File 2.16.2).

- G. IF ICING IS SUSPECTED IN AN EVAPORATOR CORE DURING ASCENT, THE SECONDARY CONTROLLER WILL BE SELECTED ON BOTH CORES (AND ALTERNATE FEEDLINE, IF REQUIRED, ON THE SECONDARY HI LOAD) PRIOR TO RADIATOR ACTIVATION IN AN ATTEMPT TO FLUSH THE CORES AND PROVIDE DIAGNOSTIC INFORMATION.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-252

FLASH EVAPORATOR SYSTEM (FES) (CONTINUED)

During STS-26, FES shutdowns occurred during 38 to 55 minutes MET. Both primary controllers were selected and repeatedly shut down. The secondary topper was selected and appeared to operate nominally. A postlanding inspection indicated corrosion in the topping core surface which degraded the evaporation process and gave ice a foothold. Use of the secondary controller cleared the ice out of the topping core (secondary topper uses both A and B H₂O spray nozzles alternately, has no shutdown feature, and operates at a higher control temperature), but the high load core, which was considered suspect, was not tested until the radiator bypass FES checkout toward the end of the flight. An earlier indication of system status is preferred.

After radiator activation, the secondary controller will not operate, since radiator output temperature will be below the secondary control temperature. Flushing the core with secondary controller would require bypassing the radiators on orbit.

DOCUMENTATION: STS-26 Flight Data, engineering judgment.

- H. THE FES FEEDLINE A(B) HEATERS WILL BE DEACTIVATED IF THE HIGH-LOAD LINE TEMPERATURE EXCEEDS 250 DEG F (OSH) FOR 1 HOUR AND THE ACCUMULATOR LINE TEMPERATURE FOR FEEDLINE A(B) IS NOT CYCLING. THE ALTERNATE HEATERS MAY BE SELECTED. IF THE ACCUMULATOR LINE TEMPERATURE INDICATES THAT THE THERMOSTAT IS DITHERING, HEATER OPERATION CAN CONTINUE SO LONG AS THE ACCUMULATOR LINE TEMPERATURE IS WITHIN THE NORMAL CONTROL BAND. ©[092195-1790A]

FES feedline A and B high-load line temperatures (V63T1895A and V63T1896A) have exceeded the upper limit of 250 deg F during several missions with no adverse effects. If the 250 deg F limit is exceeded for extended periods (? 1hour), however, the water in the feedline may boil to such an extent that damage could result. This could cause a vapor barrier in the line and possible heater burnout or FES shutdown when the high-load evaporator is used for entry. Heater failure will occur at a line temperature of 400 deg F. This will be reached approximately 1 hour after exceeding 250 deg F with a failed-on heater. The accumulator line heater and the high-load line heater are controlled by the same thermostat. The accumulator line temperatures A (V63T1892A) and B (V63T1894A) indicate that the associated thermostat is operating properly. If the accumulator line temperature indicates that the thermostat is dithering, operation of the heaters can continue. Flight experience from STS-68 with a dithering thermostat showed no overheating damage after 8 hours of operation. The dithering thermostat is acceptable, provided that the thermostat is not constantly on at a temperature near the upper limit of the normal control band. ©[092195-1790A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-252

FLASH EVAPORATOR SYSTEM (FES) (CONTINUED)

DOCUMENTATION: Flight data and MER-SPAN Mission Action Requests 26 for STS 41-D and 13 for STS 61-A. document the acceptability of exceeding the 250 deg F limit for 1 hour. STS-68 PR #PV6-275540 (IFA #5, EICN ECL-5-08-0398) indicates that no damage or evidence of overheating were found during postflight inspection and replacement of dithering thermostat. ©[092195-1790A]

- I. IF A 1-DAY WAVE-OFF IS DECLARED AFTER RADIATOR BYPASS, THE TOPPING EVAPORATOR WILL BE DEACTIVATED, AS REQUIRED, DURING THE EXTENSION DAY. DISABLING THE FES WILL TAKE PRECEDENCE OVER ANY FES REQUIREMENT FOR PAYLOAD OPERATIONS BEING CONSIDERED FOR THE EXTENSION DAY. CONSIDERATION WILL BE GIVEN TO ENABLING THE FES WHEN/IF SUPPLY H₂O QUANTITIES ARE SUFFICIENT TO SUPPORT FUTURE DEORBIT OPPORTUNITIES.

After the radiators have been bypassed, the FES is the sole means of vehicle cooling. During this time, the net H₂O rate is approximately -55 lb/hr. If a wave-off is called after the radiator panels have been bypassed, supply H₂O quantities may not support multiple deorbit opportunities at a later time. Disabling the FES and allowing the radiators to maintain vehicle cooling during extension days will allow supply H₂O quantities to increase so that future deorbit opportunities may be supported. Maximizing deorbit opportunities is a high priority than conducting unplanned payload operations on extension day.

DOCUMENTATION: Engineering judgment.

FLIGHT RULES

A18-253

AMMONIA BOILER SUBSYSTEM (ABS)

- A. IF RADIATORS HAVE BEEN COLDSOAKED, BOTH NH₃ CONTROLLERS WILL REMAIN OFF, EXCEPT WHEN REQUIRED FOR ENTRY COOLING BELOW 120K FEET. WHEN RADIATOR HEAT SINK CAPACITY IS DEPLETED, ONE NH₃ CONTROLLER WILL BE ACTIVATED. THE ALTERNATE CONTROLLER WILL BE ACTIVATED WHEN THE FIRST SYSTEM IS DEPLETED.

If the radiators are coldsoaked in deorbit preparation, the radiators can provide adequate cooling from FES deactivation to touchdown. Also, since NH₃ is a consumable which can be depleted, leaving the NH₃ system off until the radiator heat sink capacity is depleted will maximize orbiter cooling capability postlanding (length of time) until GSE cooling carts can be connected to the orbiter.

- B. THE ABS MAY BE ACTIVATED POST-EI IF ADDITIONAL COOLING IS REQUIRED.

For the ABS to operate, enough gravitational force is required in the relative direction of the tank outlet to keep the NH₃ at the outlet and not allow the helium pressurant to escape first (NH₃ tanks do not have a bladder system). The vehicle orientation combined with the gravitational force is correct for ABS activation for altitudes of 400k feet (EI) or less. Therefore, if cooling is required (no radiator coldsoak, no FES, etc.), the ABS is operable post-EI and may be used.

DOCUMENTATION: SODB 3.4.6.3-2B.

- C. FOR A LOST/DEGRADED FCL:

1. IF AN FCL IS TOTALLY LOST (E.G., NO FLOW), ITS ASSOCIATED ABS CONTROLLER WILL BE DEACTIVATED AND NOT REACTIVATED. IN THE EVENT NO OTHER COOLING IS AVAILABLE DURING ENTRY, THE ABS WILL BE REACTIVATED AND MANUAL CYCLING MAY BE REQUIRED TO PREVENT WATER LOOP FREEZING.

NH₃ system A controller uses three temperature sensors on the FCL 1 outlet line while NH₃ system B controller uses three sensors on the FCL 2 outlet. If FCL 1(2) is lost and NH₃ A(B) controller is selected, the temperature at the control sensors of the lost loop will not provide proper control of the cooling. This will result in the ABS flowing NH₃ at whatever rate the inoperative sensors demand, which may result in too much cooling, thus undertemping the active loop, or too little cooling, causing an overtemperature condition. Some manual cycling of the NH₃ controller while observing the evaporator outlet temperature may be possible, but should be used only if no other cooling options exist.

DOCUMENTATION: N/A, system schematic analysis.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-253 AMMONIA BOILER SUBSYSTEM (ABS) (CONTINUED)

2. FOR A DEGRADED FCL IF THE DIFFERENCE IN TOTAL FLOW BETWEEN THE TWO FCL'S IS > 450 LB/HR, THE DEGRADED FCL'S NH₃ SYSTEM WILL BE SELECTED IF COOLING IS REQUIRED.

For a difference in total flow between the two FCL's of greater than 450 lb/hr, activating the good loop NH₃ system will result in NH₃ system outlet temperatures < 32 degrees F. This can cause freezing of low flowrate payload water loops and rupture of the payload heat exchanger.

DOCUMENTATION: SEH-ECS-85-052T.

- D. NH₃ CONTROLLERS WILL BE ALTERNATED FLIGHT TO FLIGHT FOR POSTLANDING COOLING, WHEN PRACTICAL, SO THAT EACH OF THE FOUR IS USED AT LEAST ONCE EVERY FOUR FLIGHTS (TO SATISFY STEP). ABS SECONDARY MODE OPERATION WILL BE SELECTED ONLY WHEN DATA TO THE GROUND AND VOICE COMMUNICATION ARE AVAILABLE.

NH₃ controller alternation is implemented to accomplish periodic checkout of the secondary controllers, which is a program requirement but results in an unacceptable impact to vehicle turnaround if done postflight (KSC checkout). Secondary mode operation on the ABS is attended by slightly higher risk due to the design of the undertemperature protection, such that an ABS failure causing undertemperature results in an automatic switchover from the primary to the secondary, but not from secondary to primary. For this reason, the secondary controller should be selected only when data and communication are available so that ground controllers have visibility into and can react quickly to any ABS problem that might develop.

DOCUMENTATION: MD3/84-20; DF/83-178.

A18-254 ABS AMMONIA REDLINE

ABS AMMONIA - THERE IS NO REQUIREMENT FOR NH₃ AFTER ORBIT INSERTION.

There is no requirement for NH₃ after nominal orbit insertion. The FES and radiators are used for orbit and entry cooling. The NH₃ boiler is not required until post-rollout and an emergency powerdown can be performed if NH₃ is not available. The ammonia boiler is required for launch aborts since the radiators cannot be coldsoaked in these cases. Therefore, after nominal ascent and insertion have been completed, there is no requirement for the NH₃ boiler.

DOCUMENTATION: Flight data.

FLIGHT RULES

A18-255

RADIATOR FLOW CONTROL ASSEMBLY (RFCA)

A. ASCENT OPERATIONS:

1. THE RADIATORS WILL BE BYPASSED FOR ASCENT, EXCEPT IN CASE OF LOSS OF FES OPERATION.

The radiators are used as a backup heat sink in case of loss of topping, high-load, or total FES during ascent. If the radiators are not bypassed for launch, this heat sink would not be available. There are also some ground problems with launching in radiator flow. Should radiator flow be initiated with the GSE cooling system still connected (anytime the vehicle is on the pad, pre-lift-off, or during a launch hold), the GSE cannot react quickly enough to the decreased heat load. This could result in very low orbiter Freon temperatures. For these reasons radiator flow prior to lift-off is not attempted.

DOCUMENTATION: SEH-ITA-83-OI7T.

2. IF THE TOTAL FES FAILS, RADIATOR FLOW WILL BE INITIATED.

During ascent, the FES is the only means of cooling the vehicle. If the total FES is lost, radiator flow is initiated for cooling. This takes advantage of any coldsoak that exists in the radiators. If only one evaporator is lost, the secondary controller can be used with the good evaporator core. Flight data from STS-26 showed that the secondary topper can handle nominal ascent loads and control to 62 deg F.

DOCUMENTATION: SEH-ITA-81-107, SEH-ITA-80-047T, and STS-26 flight data.

3. IF THE RADIATOR BYPASS VALVE FAILS IN BYPASS (NOT IN TRANSIT) DURING RADIATOR FLOW INITIATION, THE ALTERNATE CONTROLLER WILL BE SELECTED. IF THE ALTERNATE CONTROLLER IS INOPERATIVE OR THE VALVE WAS FAILED IN TRANSIT, ATTEMPTS WILL BE MADE TO MANUALLY POSITION IT TO FULL RADIATOR FLOW. IF THE VALVE REMAINS IN AN INTERMEDIATE POSITION OR WAS MANUALLY POSITIONED TO FULL RADIATOR FLOW, THE CONTROLLER AC CB'S WILL BE OPENED AND CONSIDERATION GIVEN TO ATTITUDE CONSTRAINTS FOR UNDER TEMPERATURE PROTECTION MEASURES ON ORBIT.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A18-255 RADIATOR FLOW CONTROL ASSEMBLY (RFCA) (CONTINUED)**

If the bypass valve fails in-transit during flow initiation, the alternate controller will not be selected since the possibility exists that the valve could be driven back to bypass (initialization sequence) and stick there. If it is already stuck in bypass, changing controllers does not increase the risk. For either case, attempts should be made to drive the valve manually to radiator flow so that proper cooling from both FCL's is available. Opening the controller ac circuit breaker ensures that the valve will not be inadvertently driven to bypass where it might stick (possibly permanently) causing early mission termination.

B. ON-ORBIT OPERATIONS:

1. NORMALLY, THE RADIATORS WILL BE LEFT IN THE STOWED POSITION BUT MAY BE DEPLOYED IF ANY OF THE FOLLOWING CONDITIONS EXIST:
 - a. IF THE AVERAGE NET WATER STORAGE RATE IS ≥ 0 AND/OR THE SUPPLY WATER QUANTITY REDLINE WILL BE VIOLATED BASED ON EXPECTED WATER STORAGE RATES.
 - b. IF MINIMIZING FES OPERATION, FROM A PAYLOAD STANDPOINT, IS DESIRED.
 - c. IF AN EVAPORATOR OUTLET TEMPERATURE WILL RESULT IN VIOLATION OF AN ORBITER OR PAYLOAD LIMIT WHEN THE FES CANNOT BE OPERATED.

The radiators normally remain stowed. If deployed, and a failure occurs such that the radiators cannot be stowed, an EVA would be required to cut the radiator deploy/stow linkage to allow the EVA crewmember to manually stow the radiator. The PLBD will not close if the radiator is deployed. Deploying the radiators, in most attitudes, increases cooling capacity by utilizing additional surface area. Therefore, if present cooling capabilities are not adequate or if FES usage is great enough to jeopardize mission success/completion, any available cooling capacity should be used. See also the rationale for Rule {A18-208C}, RADIATOR FLOW CONTROL ASSEMBLY (RFCA).

DOCUMENTATION: N/A, engineering judgment.

2. THE RADIATOR PANEL OUT TEMPERATURES SHOULD NOT BE ALLOWED TO DECREASE BELOW -90 DEG F (-85 DEG F) TO PROTECT AGAINST WATER CONTENT COMING OUT OF SOLUTION AND FREEZING. IF THIS VIOLATION OCCURS, ACTION WILL BE TAKEN TO INCREASE THE TEMPERATURES IN THE RADIATORS.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-255

RADIATOR FLOW CONTROL ASSEMBLY (RFCA) (CONTINUED)

The SODB (volume 1, table 3.4.6.3-1) lists the minimum operating temperature for the RFCA at -85 deg F. This limit protects up to 20 ppm of water content in Freon and allows for cold spots in the radiators. The maximum allowable H₂O content in the Freon loops is 15 ppm. Data indicates that, at approximately -93 deg F, 15 ppm moisture precipitates as ice crystals. If this temperature is exceeded, ice crystals can form and damage the temperature sensor and cause flow loss by collecting on RFCA filters. The -90 deg F limit was added to protect against the maximum allowable limit of H₂O in Freon 21 (15 ppm) and to give the operations team some margin in mission planning. The -90 deg F temperature has only been exceeded once in flight (STS-35). It is believed that, since the -90 deg F protects the allowable content of H₂O from freezing and would rarely be reached, the -90 deg F limit would protect the RFCA and not impact the mission timeline. Since the radiator panel out temperatures are the inlet temperatures to the RFCA, this limit must be protected. Actions may include stowing radiators, positioning radiators to normal, and an attitude change. The -85 deg F is the limit without transducer error included. Due to the large range of the RAD PNL out temperature transducer (-250 deg to 400 deg F) a 5 percent error would make the lower limit (-53 deg F) unreasonable. Flight experience has shown that the transducer has performed better than the 5 percent error allowed.

DOCUMENTATION: JSC-08934, 3.4.6.3-1, RI IL No. 287-203-90-090.

C. ENTRY OPERATIONS:

1. IF VEHICLE STATUS PERMITS, THE RADIATORS WILL NORMALLY BE COLD SOAKED 1 HOUR PRIOR TO PLBD CLOSURE BY PLACING THE RADIATOR CONTROLLER IN THE HIGH TEMPERATURE CONTROL MODE, AND THEN BY BYPASSING THE RADIATORS AT PLBD CLOSURE.

This coldsoak provides heat sink capacity which may be used in a nominal entry to delay ABS activation until post-rollout, or which may be used in the event of a FES failure to provide some cooling prior to the availability of the ABS at entry interface. The radiator controller is placed in the high temperature control mode instead of bypassing the radiators in order to conserve both supply water and propellant. Greater than 1 hour is acceptable in the normal cold soak attitude and configuration.

DOCUMENTATION: SEH-ITA-85-001T.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-255 RADIATOR FLOW CONTROL ASSEMBLY (RFCA) (CONTINUED)

2. IF, DUE TO AUTO CONTROLLER PROBLEMS, THE BYPASS VALVE HAS BEEN MANUALLY POSITIONED IN "RAD FLOW" PRIOR TO DEORBIT, OR IF THE BYPASS VALVE IS STUCK IN TRANSIT, ATTEMPTS WILL NOT BE MADE TO POSITION IT TO "BYPASS" AT PLBD CLOSURE.

If positioned to "bypass," the valve could permanently stick and radiator flow could not be initiated. For loss of FES or partial loss of FES, radiator flow is required.

DOCUMENTATION: N/A, engineering judgment.

3. RADIATOR FLOW WILL NORMALLY BE INITIATED AT V = 12K FPS (APPROXIMATELY 175K FEET) AND NO LATER THAN 130K FEET. RADIATOR FLOW MAY BE INITIATED EARLIER IF REQUIRED.
@[ED]

Once radiator flow is initialized, 90 seconds must pass before the valves go to the flow position. If radiator flow is initiated at 175k feet, flow will begin around 154k feet. This is prior to FES shutdown (approximately 100k to 110k feet) and eliminates thermal transients. If initiated at 130k feet, radiator flow will begin around 110k feet, or right at FES shutdown. Radiator flow can be initiated earlier in contingency situations.

DOCUMENTATION: Flight data.

4. IF EITHER RFCA AUTOMATICALLY BYPASSES WHEN RADIATOR FLOW IS INITIATED, THAT CONTROLLER WILL BE CYCLED ONCE.

This situation occurred on past flights where certain conditions (a warm slug of fluid immediately followed by a cold slug of fluid) caused the controller logic to bypass the radiators. Procedures were changed to alleviate this condition; however, should it exist, cycling the controller one time remedies this situation.

DOCUMENTATION: Flight experience.

FLIGHT RULES

A18-256

RADIATOR ISOLATION VALVE MANAGEMENT

A. ASCENT/ENTRY OPERATIONS: @[090999-6815A]

THE RADIATOR ISOLATION VALVES ARE CONFIGURED TO THE RAD FLOW POSITION AND OFF.

The radiators are used as a backup heat sink in case of loss of topping, high-load, or total FES during ascent. To minimize operational impacts, the isolation valves are configured for radiator flow.

The cb's that provide power to the bypass valves and control electronics will be configured closed to provide the capability to manually bypass the radiators to isolate an additional portion of the affected loop, should the need arise.

DOCUMENTATION: Engineering judgment.

B. ON-ORBIT OPERATIONS

1. NORMALLY, AUTOMATIC RADIATOR ISOLATION CAPABILITY WILL BE CONFIGURED FOR "AUTO" OPERATIONS DURING ON-ORBIT OPERATIONS.
2. IF A RADIATOR IS ISOLATED BY THE AUTO SOFTWARE, AND GROUND DATA INDICATES NO FCL LEAK, THE AFFECTED LOOP'S ISOLATION VALVE WILL BE RECONFIGURED MANUALLY TO RADIATOR FLOW.
3. IF A LEAK IS DETECTED ON AN FCL, BEFORE AUTO ISOLATION IS INITIATED, THE AFFECTED LOOP'S RADIATOR WILL BE MANUALLY ISOLATED IN ORDER TO ISOLATE AND STOP THE LEAK.
4. IF A FCL'S RADIATOR ISOLATION VALVE IS FAILED IN BYPASS OR A LEAK HAS BEEN ISOLATED, THE AFFECTED FCL WILL BE DEACTIVATED, AND A POWERDOWN TO AT LEAST 15 KW WILL BE PERFORMED. THE FCL WILL BE REACTIVATED FOR DEORBIT PREPARATION.
5. IF RADIATOR ISOLATION CAPABILITY IS LOST ON EITHER OR BOTH LOOPS, THERE ARE NO MISSION DURATION CONSTRAINTS. NO ADDITIONAL ATTITUDE CONSTRAINTS FOR ORBITAL DEBRIS WILL BE LEVIED. @[090999-6815A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-256

RADIATOR ISOLATION VALVE MANAGEMENT (CONTINUED)

Analysis indicates that depletion of a Freon loop, due to debris puncture of a radiator tube, allows for reaction times of only seconds, even for small diameters (i.e., a 0.10 in diameter puncture will deplete the loop within 75 to 80 seconds). Due to this concern, hardware and software has been incorporated that will allow the automatic or manual isolation of a leaking radiator, based upon accumulator quantity. This "AUTO" capability will normally be activated during on-orbit operations, to ensure adequate protection of the Freon loops, for the duration of the mission. ©[090999-6815A]

Because the software is dependent upon a single accumulator quantity transducer for each loop, the capability exists to either manually position the isolation valve to the radiator flow position or the radiator isolated position. Should automatic isolation be initiated by the software, data evaluation by the MCC is required to confirm or deny a real leak (the MCC has additional insight not available to the crew, radiator leg pressures and isolation valve positions, that allow for confirmation of leaks). If no leak is detected, the valve may be moved back to radiator flow using the manual capability to prevent another inadvertent auto isolation.

The software in the GPC is intended to isolate the radiator upon detection of large leaks, based solely upon the accumulator quantity (V63Q1130A/1330A < 12 percent). In the event that a small leak is detected, prior to detection by the software, the affected loop's radiator can be manually isolated in order to troubleshoot and possibly isolate the leak. If leak isolation is unsuccessful, radiator flow may be regained for nominal loop operations until depletion of the loop.

A radiator isolation valve failed in bypass, or is positioned in bypass due to a leak, will result in a negative H₂O storage rate if the FES is activated, or temperature violations if the FES is deactivated. Deactivating the FCL will alleviate these problems and only requires a powerdown to 15 kW. (Ref Rule {A18-251C} and F, FREON COOLANT LOOPS (FCL)).

Radiator isolation capability does not affect the odds of debris penetration. It is assumed that attitude planning already considers debris impact odds while satisfying payload and other mission objectives.

DOCUMENTATION: MCR 92184B, "Freon Radiator Iso Valve Automation"; AEFTP #145, December 19, 1997; Radiator Shielding & Isolation CDR, 10/7/97; SEH-ECS-86-102T; and engineering judgment. ©[090999-6815A]

FLIGHT RULES

A18-257

POSTLANDING NH₃ TERMINATION

DURING THE POSTLANDING TIMEFRAME, THE NH₃ SYSTEM WILL BE DEACTIVATED AS SOON AS POSSIBLE FOLLOWING THE OBSERVANCE OF NH₃ SYSTEM BLOW DOWN. ©[052401-4674]

The intent of this rule is to avoid drawing ambient air into the NH₃ system. The NH₃ system is pressurized with helium gas. Once the NH₃ is depleted, the tank pressure will drop as helium quickly exits the system. The system also cools as this occurs. If the system is allowed to drop to ambient pressure and the system experiences any residual cooling, the pressure inside the tank could then drop below ambient pressure and draw air into the depleted NH₃ tank. The blow down from NH₃ depletion to ambient pressure takes approximately 3 minutes.

This is especially undesirable at KSC where the salt content in the air will cause system corrosion.

DOCUMENTATION: Flight data, Engineering judgment ©[052401-4674]

A18-258 THROUGH A18-300 RULES ARE RESERVED

FLIGHT RULES

EECOM HEATER MANAGEMENT

A18-301 TCS HEATER CONFIGURATION

A. THE FOLLOWING HEATERS WILL BE ENABLED FOR LIFT-OFF:

1. FES TOP NOZZLE (LEFT AND RIGHT) [ED]
2. FUEL CELL RELIEF LINE
3. FES TOPPING AND HIGH-LOAD DUCT
4. FUEL CELL WATER LINE

NOTE: IN ALL CASES, UNLESS THERMAL CONDITIONS REQUIRE OTHERWISE, ONLY A SINGLE HEATER SYSTEM WILL NORMALLY BE ENABLED.

FES heaters are activated prior to lift-off and remain on through lift-off to ensure that duct temperatures are high enough to prevent freezing of the water vapor in the ducts upon FES activation. Nozzle heaters are not required for nominal situations, but are desired in case of high FES carryover.

For the fuel cell relief line heater and water line heater, see Rule {A9-53}, FC H₂O SYSTEM HEATERS.

DOCUMENTATION: HAMILTON STD. SEM 62449.

B. THE FES FEEDLINE HEATERS WILL BE ENABLED POST-OMS-1:

The feedline heaters are enabled at this time to prevent freezing of the water in these lines. With PLBD's open it is estimated that in a cold attitude these lines will freeze in approximately 45 minutes and in a warm attitude in approximately 1.5 hours.

DOCUMENTATION: ES2-81-256M.

C. THE FOLLOWING HEATERS WILL BE ENABLED AFTER SEAT EGRESS:

1. VACUUM VENT NOZZLE
2. SUPPLY/WASTE/VACUUM VENT LINE

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-301

TCS HEATER CONFIGURATION (CONTINUED)

3. EXTERNAL AIRLOCK STRUCTURAL AND WATER LINE ©[061297-4904]

Prelaunch PLB thermal conditioning maintains proper temperatures; therefore, the associated heaters are not required. As a general guideline, power not required for ascent is inhibited from use. The heaters should be enabled as soon as practical once on orbit so possible freezing water will not become a concern when the PLBD's are opened and so the WCS can be used normally, if required.

DOCUMENTATION: Rockwell I.L. 270-200-95-152, Rev 1, and engineering judgment. ©[061297-4904]

D. THE FOLLOWING HEATERS WILL BE ENABLED WHEN REQUIRED:

1. SUPPLY DUMP NOZZLE
2. WASTE DUMP NOZZLE
3. FUEL CELL PURGE
4. HIGH-LOAD DUCT

The high-load evaporator and high-load duct heaters are disabled on orbit. Prior to re-enabling the high-load evaporator, the duct heaters must be reactivated to prevent freezing of the water vapor in the ducts upon high-load activation.

FC purging and water dumping are normally performed only during the presleep and post sleep periods, and thus, not continuously required. Using the heaters during the overboard venting prevents the possibility of water freezing and rendering the nozzles worthless for future mandatory dumps and purges.

DOCUMENTATION: HAMILTON STD. SEM 62449 and engineering judgment.

FLIGHT RULES

A18-302 **TCS HEATER REDUNDANCY**

ALL REDUNDANT HEATERS WILL NORMALLY HAVE ONLY ONE CIRCUIT ENABLED AT A TIME.

The heaters are designed so that only one circuit is necessary.

DOCUMENTATION: Engineering judgment and flight data.

A18-303 **REDUNDANT TCS HEATER VERIFICATION**

AT APPROXIMATELY THE MIDPOINT IN THE FLIGHT, ALL REDUNDANT HEATERS WILL BE RECONFIGURED TO THE ALTERNATE CIRCUITS TO VERIFY SYSTEM HEALTH AND MAXIMIZE TOTAL SYSTEM OPERATING LIFETIME.

The heaters will be switched to verify that the redundant heater works. This is necessary because KSC has difficulty verifying the operation of most heaters, since ambient temperatures at the Cape will prevent automatic heater operation. The heaters are designed such that both heater circuits are encased in a common insulator. For this reason, if the "a" circuit is used exclusively and fails, then both circuits, including the circuit that has never been used, would have to be replaced. By alternating their use, total system lifetime is maximized.

DOCUMENTATION: N/A; system schematic analysis.

FLIGHT RULES

A18-304

TCS HEATER OPERATIONS FOR LOSS OF INSTRUMENTATION

IF INSTRUMENTATION IS LOST ON REDUNDANT HEATER SYSTEMS OF THE FOLLOWING COMPONENTS, BOTH SYSTEMS WILL BE OPERATED SIMULTANEOUSLY FOR THE REMAINDER OF THE FLIGHT:

- A. HIGH-LOAD FES DUCT/NOZZLE (WHILE OPERATING)
- B. TOPPING FES DUCT (FORWARD OR AFT)
- C. SUPPLY AND WASTE WATER DUMP LINES
- D. EXTERNAL AIRLOCK STRUCTURAL AND WATER LINES ©[061297-4904]

This is done to protect against an undetected heater failure which could cause freezing of water vapor in the duct upon FES activation and loss of FES, freezing of water in the dump lines resulting in the loss of mandatory dump capability, or freezing of water in the external airlock water lines.

The water line heaters protect against freezing of water in the externally routed airlock water lines resulting in a loss of EMU servicing and ISS water transfer. They are triply redundant; therefore, only two of the three strings are required in this scenario. Each of the two zones for the water lines have two transducers for monitoring heater performance.

The external airlock structural heaters protect against the freezing of the internally routed airlock water lines during periods when the airlock is at vacuum resulting in a loss of EMU servicing and ISS water transfer and against condensation build-up in the external airlock avionics bay where the docking avionics are installed. Each of the three structural heater zones have only one temperature transducer for the monitoring of heater performance.

DOCUMENTATION: Hamilton Standard SEM 62449; Rockwell I.L. 270-200-95-152, Rev 1, and 270-200-97-007; and engineering judgment. ©[061297-4904]

FLIGHT RULES

A18-305 LOSS OF HEATER SM CAPABILITY

IF SM CAPABILITY IS LOST, BOTH SYSTEMS OF THE TOPPING FES DUCT HEATER SYSTEMS WILL BE ENABLED FOR THE REMAINDER OF THE FLIGHT.

If SM capability is lost, so is onboard alert capability for these temperatures. If a heater failed, the crew would not be alerted, causing possible loss of a critical function. Both heaters are enabled so that an undetected failure of one will not present a problem. A failed-on heater here cannot produce a high enough temperature to present a problem.

DOCUMENTATION: JSC-18549.

A18-306 EXTERNAL AIRLOCK HEATER LOSS MANAGEMENT

FOR LOSS OF EITHER THE EXTERNAL AIRLOCK WATER LINE HEATERS OR STRUCTURAL HEATERS, ATTITUDE MANAGEMENT WILL BE USED TO PRECLUDE FREEZING OF THE EXTERNAL AIRLOCK INTERNAL AND EXTERNAL WATER LINES. ©[061297-4904]

Loss of the external airlock water lines will result in the loss of EMU servicing and ISS water transfer capabilities.

DOCUMENTATION: Engineering judgment and Rockwell I.L. 270-200-95-152, Rev 1, and 270-200-97-007. ©[061297-4904]

TPS BONDLINE TEMPERATURES MANAGEMENT

A18-401 **THERMAL PROTECTION SYSTEM (TPS) BONDLINE TEMPERATURES**

- A. ORBITER ATTITUDE WILL BE MANAGED TO MAINTAIN BONDLINE TEMPERATURES AT GREATER THAN -170 DEG (-137.5 DEG) F AND LESS THAN THE MAXIMUM ENTRY INTERFACE TEMPERATURES, DEFINED IN PARAGRAPH B.

The minimum temperature of -170 deg F corresponds to the temperature at which glassy transition occurs on the RTV (becomes brittle). Maximum allowable entry and postlanding bondline temperatures are dependent on the type of structure underlying the TPS, and on structural thermal stress limits, as follows:

a. *Underlying Material Limits:*

- (1) ALUMINUM 350 deg F. (400 deg F or greater) is a lifetime constraint.
- (2) GRAPHITE EPOXY SKIN
 - (a) OMS POD 250 deg F (presumes water ingestion into the laminated skin)
 - (b) PLBD 350 deg F

DOCUMENTATION: SODB, Table 3.4.1.3; Shuttle Vehicle Systems Temperature Limits and STS Operational Flight Rules Review Meeting; RI IL SAS-TA-P/C/TCS-87-031; and RI IL SETO-TCS-87-066-RI, On-Orbit Thermal Constraints Summary, Revision 1.

b. *Structural Stress Limits:*

Midbody structural stress is generated by temperature gradients present in the vehicle. Bondline temperatures are used to determine the magnitude of the gradients and therefore the amount of structural stress. Limits have been established for the bondline temperatures, and exceeding these limit could result in less than 1.4 factor of safety for design entry loads. ©[030994-1598A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-401

**THERMAL PROTECTION SYSTEM (TPS) BONDLINE
TEMPERATURES (CONTINUED)**

Predicted values for bondline temperatures are calculated by the Simplified Thermal Evaluation Program (STEP) analyses based on actual and predicted vehicle attitudes during the mission. Accuracy of STEP has been determined by comparing calculated temperatures to past flight data. Resulting delta-temperature biases needed to correct each bondline MSID have been tabulated. To complete a STEP analysis, the appropriate biases are added to STEP outputs to obtain the corrected prediction values. These predictions are compared to flight-specific limits similar to those shown in the table of paragraph B to verify that bondline temperatures will be acceptable at EI. The correction biases are, strictly, only applicable to attitudes, durations, sequences, and beta-angle. which duplicate flight data used to generate the biases (ref. Annex Flight Rule, THERMAL PROTECTION SYSTEM (TPS) BONDLINE TEMPERATURES, and Rule {A18-451C}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL]. ©[ED]

DOCUMENTATION: STEP Accuracy Definition Document, RI IL SE-TCS-93-042, May 14, 1993, and NASA JSC Memo ES2-93-096.

Rules {A2-110}, STRUCTURES THERMAL CONDITIONING; {A2-129}, ORBITER ON-ORBIT HIGH DATA RATE REQUIREMENTS; and {A18-451B}, ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL], reference this rule.

- B. MAXIMUM ALLOWABLE BONDLINE ENTRY INTERFACE (EI) TEMPERATURES ARE BASED ON STRUCTURAL CONSTRAINTS AND FLIGHT-SPECIFIC PARAMETERS FOR ENTRY AND VEHICLE LOADING. THE MAXIMUM GENERICALLY-ACCEPTABLE BONDLINE TEMPERATURE MEASUREMENTS ARE SHOWN BELOW. SPECIFIC MAXIMUM VALUES (RELAXED FROM THE GENERIC LIMITS) FOR EACH FLIGHT WILL BE PROVIDED IN THE FLIGHT-SPECIFIC FLIGHT RULES ANNEX. EACH FLIGHT-SPECIFIC BONDLINE LIMIT WILL REPRESENT THE WORST-CASE LIMIT FROM ANALYSIS OF ALL POSSIBLE DEORBIT OPPORTUNITIES FOR THAT FLIGHT. ©[030994-1598A]

ORBITER THERMAL CONSTRAINTS AND ATTITUDE MANAGEMENT [CIL] (CONTINUED)

NOTES:

- [1] DEVIATIONS FROM THE SPECIFIED ATTITUDES MAY NEED TO BE FURTHER ANALYZED.
- [2] THE ATTITUDE HOLD CONSTRAINED DURATION IS FROM PTC EQUILIBRIUM TEMPERATURES TO THE LIMIT TEMPERATURE.
- [3] ALL CONCERNS ARE SAFETY ISSUES UNLESS OTHERWISE NOTED.
- [4] UNLESS OTHERWISE NOTED, FLYING THE RECOVERY ATTITUDE ALLOWS REPETITION OF THE CONSTRAINED ATTITUDE FOR THE CONSTRAINED DURATION. ALL RECOVERY IS TO PTC EQUILIBRIUM TEMPERATURE UNLESS OTHERWISE NOTED.
- [5] SYSTEMS PERFORMANCE IS AFFECTED.
- [6] RESERVED @[030994-1598A]
- [7] RECOVERY IS TO THE MINIMUM OPERATIONAL LIMIT TEMPERATURE FROM THE MINIMUM NON-OPERATIONAL LIMIT TEMPERATURE OR ATTITUDE THERMAL EQUILIBRIUM TEMPERATURE (WHICHEVER IS WARMER).
- [8] THIS ATTITUDE RESULTS IN ONLY A MINIMAL RATE OF INCREASE ($< 2^{\circ}$ F/DAY) OF ARCS BULK PROPELLANT TEMPERATURE. THE CONSTRAINED DURATION CANNOT BE REPEATED.
- [9] RESERVED @[030994-1598A]
- [10] TCS DESIGN DATA BOOK SECTION L REFERENCE.
- [11] ATTITUDE CONSTRAINTS ARE NOT NORMALLY REQUIRED IF ARCS PROP "B" HEATERS ARE OPERATIONAL. THE ARCS CONCERN IS VALID IF ONLY THE "A" HEATERS ARE AVAILABLE.
- [12] ARCS PROP + 70° F FOR ENTRY FOR ZOT PREVENTION. ON-ORBIT (TANK CERTIFICATION) LIMIT = + 50° F.

There are six areas of concern where orbiter structure and/or systems thermal constraints can be exceeded if an unfavorable orbiter vehicle attitude is maintained for an excessive period of time. The maximum/minimum temperature, the time in the constraining attitude, and the attitude/time used to recover from a violation of the constraints are all dependent on the structure or orbiter system involved, the vehicle (OV102, 103, 104) used, Sun beta angle, and the three basic attitude control modes used; i.e., LVLH, ORB RATE (single axis), and inertial (three axis) hold. The six areas of concern, their limits (temperature or time), and the impact (lifetime (L), system performance (P), and safety of flight (S)) of violating the limits are identified below: @[030994-1598A]

**ORBITER THERMAL CONSTRAINTS AND ATTITUDE
MANAGEMENT [CIL] (CONTINUED)**

B. ORBITER SYSTEMS CONSTRAINTS VERSUS BETA ANGLE - CONCLUDED

Matrix Limitations:

This table is intended as a first iteration for attitude planning. The orbiter attitudes listed represent "pure" orientations. Flight-specific STEP analysis will confirm the acceptability of the integrated attitude timeline. The table limits, which represent the constrained attitude durations in hours, were derived from analyses initialized to PTC equilibrium temperatures. These durations define the time it takes to go from PTC equilibrium temperature to the system limit. The concern column lists the vehicle structural/system limit that constrains the attitude duration. In most cases, flying the recovery attitude provides the capability to repeat the constrained attitude for the constrained duration. Exceptions to this recovery attitude definition exist for hydraulic systems, the TPS bondline, and the ARCS propellant temperature limits. For hydraulics, the recovery attitude allows the system temperature to recover to its temperature limit (presumes that the limit can be exceeded). For the TPS bondlines, preentry thermal conditioning (in addition to the normal end of mission timeline) may be required. In the case of the ARCS propellant minimum temperatures, the recovery attitude will "maintain" the bulk propellant temperature above its limit. In all three cases, the recovery to the limiting temperatures must be accomplished prior to entry. ©[030994-1598A]

**ORBITER THERMAL CONSTRAINTS AND ATTITUDE
MANAGEMENT [CIL] (CONTINUED)**

- C. ORBITER SYSTEMS CONSTRAINTS THAT ARE APPLIED BY THE USE OF THE SIMPLIFIED THERMAL EVALUATION PROGRAM (STEP) ARE LISTED IN THE FOLLOWING TABLES. THESE CONSTRAINTS INCORPORATE STEP ACCURACY EVALUATION DATA AND REPRESENT THE WAY IN WHICH VEHICLE CONSTRAINTS ARE ANALYZED BY APPLICATION OF A BIAS AS GIVEN IN TABLE {A18-451-I} OR AS REFERENCED. THE LISTED BIASES ARE CONSERVATIVE ONLY FOR ATTITUDES AND TPS CONFIGURATIONS THAT HAVE BEEN PREVIOUSLY FLOWN. IT IS UNDERSTOOD THAT IF ACTUAL ATTITUDES, DURATIONS, SEQUENCES, AND BETA-ANGLES ARE BEING FLOWN FOR THE FIRST TIME, A LARGER ERROR CAN RESULT WHICH SHOULD CAUSE LIMIT VIOLATIONS AND REQUIRE REAL-TIME CORRECTIVE ACTION.

FOR THE OMS OXIDIZER HIGH-POINT BLEED QUICK DISCONNECT (QD), IF THE ENVIRONMENT CONSTRAINT CANNOT BE MET DIRECTLY, THE HEATER DUTY CYCLE WILL BE VERIFIED TO BE ACCEPTABLE USING FIGURE {A18-451-II}.

DETERMINATION OF WHETHER AN RCS THRUSTER CONSTRAINT MAY EXIST WILL BE DONE USING FIGURE {A18-451-III} AND {A18-451-IV}. IF A LIMIT VIOLATION IS POSSIBLE, PREFLIGHT COORDINATION WITH ENGINEERING DIRECTORATE WILL DETERMINE ACCEPTABLE ATTITUDES.

THE DRAG CHUTE WILL BE ANALYZED BY ASSUMING THAT IT IS THE SAME TEMP AS THE ENVIRONMENT OF HYDRAULIC SYSTEM 2 RSB RETURN TEMP (V58T0298) AND RSB SEAL DRAIN LINE TEMP AT LOWER AFT OF VERTICAL STABILIZER (V58T1600).

EDO CRYO PALLET CONSTRAINT ASSESSMENT WILL BE COORDINATED WITH ENGINEERING DIRECTORATE PREFLIGHT. @[030994-1598A]

ORBITER THERMAL CONSTRAINTS AND ATTITUDE
MANAGEMENT [CIL] (CONTINUED)

STEP accuracy biases were generated by evaluation of attitudes normally flown. Application to other attitudes may result in predicted temperatures that differ from actual values by additional bias uncertainty.

Documentation: STEP Accuracy Definition Document, RI IL SE-TCS-93-042, May 14, 1993; and OV-103 Orbiter On-Orbit Thermal Constraints, RI IL SE-TCS-94-004, January 17, 1994.

A18-452 THROUGH A18-500 RULES ARE RESERVED

FLIGHT RULES

COOLING EQUIPMENT CONSTRAINTS

A18-501

MAXIMUM OFF TIME FOR COOLING EQUIPMENT

ORBIT @[051194-1610A]

THE FOLLOWING IS A LISTING OF THE MAXIMUM TIME THAT COOLING EQUIPMENT CAN BE OFF BEFORE POWERDOWN ACTION IS REQUIRED:

- A. CABIN FANS: @[032802-5276C]
 - 1. 20 MIN (FOR OLD DDU)
 - 2. 30 MIN (FOR MDU)
- B. AVIONICS FAN - 26 MIN
- C. IMU FANS - 45 MIN
- D. H₂O LOOPS - 10 MIN
- E. BOTH FREON LOOPS - 10 MIN

Cooling equipment off time is constrained by the requirements of the LRU's that they cool. If cooling equipment remains off for a time exceeding the LRU specific cooling limits, then a powerdown may be required due to a potential overtemp condition.

- a. *The CABIN fans can only be off for 20 minutes due to the cooling constraints of the Display Driver Units (old DDU's) if any old DDU is flown. If only passively cooled Device Driver Units (new DDU's) are flown in place of all of the Display Driver Units, the CABIN fans can only be off for 30 minutes due to the cooling constraints of the Multifunction Display Units. @[032802-5276C]*
- b. *The AVIONICS bay fans can only be off for 26 minutes due to the cooling constraints of the GPC's.*
- c. *The IMU fans can only be off for 45 minutes due to the cooling constraints of the IMU's.*
- d. *The H₂O loops can only be off for 10 minutes due to the cooling constraints of the S-band power amplifier.*
- e. *Both FREON loops can only be off for 10 minutes due to the cooling constraints of the S-band power amplifier. Note that the catastrophic failure may occur as early as 50 minutes due to loss of cooling to the fuel cells.*

Documentation: SODB Vol. III, Table 4.5.0-1, Dual Freon Loop Failure Entry Analysis, Rockwell International, IL #388-301-79-018, 7/21/81. @[051194-1610A]

FLIGHT RULES

A18-502 THROUGH A18-550 RULES ARE RESERVED

FLIGHT RULES

WATER LOOP

A18-551 SPACEHAB SUBSYSTEM WATER LOOP @[111501-5011A]

LOST IF:

- A. PUMP ACCUMULATOR QUANTITY IS \leq 0 (3.4) PERCENT AND SYMPTOMS OF PUMP CAVITATION ARE PRESENT.

Spacehab has identified this percentage as an indication of accumulator failure; 3.4 percent is the range of uncertainty of the quantity sensor.

- B. FLOW CANNOT BE MAINTAINED GREATER THAN:

1. ASCENT/ENTRY: 130 POUNDS PER HOUR (LB/HR)

Analysis indicates this minimum flow is required to reject powered Spacehab ascent/entry heat loads.

2. ON-ORBIT: 140 LB/HR

For a Spacehab continuous heat load of 2 kW, this is the minimum flow which will avoid violating the maximum coolant return temperature of 104 degrees F.

- C. THERE ARE SYMPTOMS OF PUMP CAVITATION AND THE PUMP INLET PRESSURE IS LESS THAN 20 PSIA.

Pump will operate erratically and may cavitate at pressures less than specified value.

- D. FLOW TO THE PAYLOAD HEAT EXCHANGER (PLHX) CANNOT BE MAINTAINED GREATER THAN 50 (55) LB/HR. @[021600-7111A]

The water line heaters are activated to preclude water freezing in case the flow through the PLHX decreases below 50 lb/hr. The manual bypass IFM may result in flow rate to the PLHX less than 50 (55) lb/hr. The PLHX flow in the RDM configuration is measured via a flow sensor with an uncertainty of 5 lb/hr at 50 lb/hr. The PLHX flow in the Single Module/Logistics Double Module (SM/LDM) configurations is not measured directly and verification will be done analytically. In the event of water line heater failure, attitude adjustment would be necessary to prevent water freezing.

Reference: Rule {A18-555}, WATER LINE HEATER MANAGEMENT, and ICD 21095, Interface Review Notice 37. @[121593-1594] @[111501-5011A]

FLIGHT RULES

A18-552 **SPACEHAB SUBSYSTEM WATER LOOP MANAGEMENT** @[111501-5011A]

- A. THE SPACEHAB SUBSYSTEM WATER LOOP SHOULD BE OPERATING AT ALL TIMES WHEN THE MODULE IS POWERED; ONLY ONE PUMP WILL BE RUNNING AT ANY TIME.

Pump 2 can operate on orbiter or inverter power. Pump 1 can only operate on inverter power.

- B. FOR A DECLARED FAILURE OF THE SPACEHAB SUBSYSTEM WATER LOOP AS DEFINED IN RULE {A18-551}, SPACEHAB SUBSYSTEM WATER LOOP:
1. LIMITED SPACEHAB EXPERIMENT OPERATIONS MAY CONTINUE.
 2. WATER LINE HEATERS WILL BE ACTIVATED.
 3. IF THE WATER LINE HEATERS ARE LOST OR INEFFECTIVE, CONTROL THE ORBITER ATTITUDE TO PRECLUDE WATER LINE FREEZING OR PAYLOAD HEAT EXCHANGER OVER PRESSURIZATION. (REFERENCE RULE {A18-555}, WATER LINE HEATER MANAGEMENT, FOR ACCEPTABLE ATTITUDES.)

Although heat rejection via water cooling has been lost, limited heat can be rejected via air exchange with the orbiter. This would require some subsystem and experiment equipment to be powered off. This configuration is also more beneficial than total module deactivation since module temperatures are more easily controlled. The water line heaters must be activated so that the lines between the module and the orbiter's payload heat exchanger interface do not freeze. Attitude changes are the least desirable option to control water line temperatures.

- C. THE SUBSYSTEM WATER LOOP OR WATER LINE HEATERS MUST BE ACTIVE PRIOR TO PAYLOAD BAY DOOR OPENING AND MUST REMAIN ACTIVE UNTIL POST LANDING.

No analysis has been done to determine if the subsystem water loop will freeze if the water loop or water line heater is not active when the payload bay doors are closed during entry. @[111501-5011A]

FLIGHT RULES

A18-553

SPACEHAB SUBSYSTEM PUMP OPERATIONS @[111501-5012]

- A. FOR LOSS OF A SINGLE PHASE, THE SUBSYSTEM WATER PUMP MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER.

The Subsystem Water Pump was operated on two phases during preflight testing. The Subsystem Water Pump may be operated but not started on only two phases.

If the Subsystem Water Pump is operating on the Spacehab INV and phase A fails, the pump will stop working because phase A of the Spacehab INV provides the sync pulse required for Spacehab INV phases B and C to operate. However, the Subsystem Water Pump will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C.

- B. THE FOLLOWING SUBSYSTEM WATER PUMP CONFIGURATION WILL BE USED FOR NOMINAL SPACEHAB SM/LDM OR RDM OPERATIONS FOR ASCENT/ENTRY AND ON-ORBIT:

1. ASCENT/ENTRY

a. POWERED SPACEHAB MODULE

- (1) SUBSYSTEM WATER PUMP 1 - ON, USING SPACEHAB INVERTER POWER
- (2) SUBSYSTEM WATER PUMP 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

FOR FAILURE OF WATER PUMP 1, WATER PUMP 2 WILL BE COMMANDED ON ASAP POST-MECO OR DURING ENTRY. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

Subsystem water pump 2 is configured to inverter power to allow it to serve as a backup in case pump 1 fails. Without switching pumps, module heat rejection is lost. Subsystem water pump 1 can only be powered from the Spacehab inverter. Pump 2 can be powered from Spacehab inverter or orbiter AC power. Since no on-board command capability exists in OPS 1 (Single Module General Purpose Computer (SM GPC) not available), the pumps will be reconfigured via ground command post MECO or during entry. @[111501-5012]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-553

SPACEHAB SUBSYSTEM PUMP OPERATIONS (CONTINUED)

- b. UNPOWERED SPACEHAB MODULE (SM/LDM ASCENT ONLY)
@[111501-5012]

SUBSYSTEM WATER PUMP 2 IS CONFIGURED ON AND TO ORBITER POWER, BUT THE PUMP WILL NOT BE OPERATING SINCE ORBITER AC POWER IS NOT AVAILABLE TO PAYLOADS DURING ASCENT.

When the Spacehab module is unpowered for ascent, this configuration allows the Spacehab Subsystem Pump to be activated whenever power is applied to the payload AC bus in the event of a failure that prevents Spacehab commanding. Spacehab is always powered for entry.

2. ON-ORBIT

- a. SUBSYSTEM WATER PUMP 2 - ON, USING ORBITER AC
- b. SUBSYSTEM WATER PUMP 1 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

PUMP 1 WILL BE COMMANDED ON FOR FAILURE OF PUMP 2. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

A subsystem water pump is required to provide heat rejection for the module. Operation of either pump on Spacehab inverter power is acceptable, but orbiter AC power is preferred to maintain pump operation in case of a Spacehab Main Power Kill. Subsystem pump 2 is preferred because pump 1 cannot be configured to orbiter AC power. @[111501-5012]

FLIGHT RULES

A18-554 **WATER LINE HEATERS** @[111501-5011A]

WATER LINE HEATERS WILL BE CONSIDERED LOST IF ANY ONE OF THE FOLLOWING IS TRUE:

- A. SPACEHAB WATER LINE STATUS IS 0 INSTEAD OF 1 WHEN ACTIVATED.
- B. IF ORBITER WATER LINE HEATERS INSTALLED, HEATER AMPS < 1.0 WHEN ACTIVATED.

Spacehab water line heaters and orbiter water line heaters are required to protect the Spacehab water lines from freezing. When the Spacehab module is directly against the 576 bulkhead, the orbiter set of heaters will not be installed. In this case, the water line heaters will be considered lost per paragraph A. If installed, orbiter water line heater amps ? 1.0 would indicate that the heaters are operating. @[111501-5011A]

FLIGHT RULES

A18-555

WATER LINE HEATER MANAGEMENT

A. THE WATER LINE HEATERS WILL BE ACTIVATED FOR ANY OF THE FOLLOWING CONDITIONS (WHEN THE PLBD'S ARE OPEN) : @[111501-5011A]

1. LOSS OR DEACTIVATION OF SPACEHAB WATER LOOP

Loss of water loop results in loss of flow through the PLHX.

2. PRIOR TO PERFORMING AN IFM TO ADJUST THE WFCV MANUAL BYPASS VALVES

Crew adjustment of the bypass valves may result in water flow rates to the PLHX below 50 lb/hr, leaving the water lines susceptible to freezing. Reference: ICD 21095, Interface Review Notice 37.

3. WHEN MAIN DC AND AC POWER HAVE BEEN REMOVED FROM THE SPACEHAB

If PLBD's remain open after emergency deactivation, water line heaters must be active since the pumps are no longer operational. Note that emergency power from PL AFT MN B must be supplied to the Spacehab for the water line heaters to receive power. @[111501-5011A]

4. LOSS OF THE DMU DATA STREAM TO THE PDI WHILE CONTINUING SPACEHAB OPERATIONS @[111501-5011A]

Heaters are turned on since the status of the water pumps is no longer available.

5. WHEN CONTINUING SPACEHAB OPERATIONS WITH A DEGRADED WATER LOOP, CONSIDERATION WILL BE GIVEN TO DEACTIVATING THE HEATERS IF IT CAN BE SHOWN THAT FLOW TO THE PLHX IS ? 50 LB/HR.

A degraded water loop could result in reduced flow to the PLHX, while providing sufficient heat rejection to continue the mission. After the heaters are activated, if power savings are required, the heaters may be deactivated if the flow through the PLHX is high enough that there is not a potential for freezing the water loop.

Reference: Rule {A18-551}, SPACEHAB SUBSYSTEM WATER LOOP.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-555 WATER LINE HEATER MANAGEMENT (CONTINUED)

B. THERMAL CONDITIONING BY ADJUSTING THE ORBITER ATTITUDE WILL BE USED TO PREVENT WATER LINE FREEZING IF THE WATER LINE HEATERS CANNOT BE VERIFIED ACTIVE AND THE WATER LOOP IS OFF.

In the event of a water line heater failure, no other means exists to prevent the water lines from freezing.

C. IF THE SPACEHAB WATER LINE HEATERS ARE LOST, PER RULE {A18-554}, WATER LINE HEATERS, AND WATER LOOP FLOW TO THE PLHX IS LESS THAN 50 LB/HR, A TOP SUN ATTITUDE IS REQUIRED.

ALTERNATIVE ATTITUDES OTHER THAN THE TOP SUN CAN BE ACCOMMODATED ONLY PER THE FOLLOWING TABLE. OTHER ALTERNATIVE ATTITUDES WILL ONLY BE PERFORMED AFTER THERMAL ANALYSIS CAN BE ACCOMPLISHED.

NUMBER OF ORBITS IN ALTERNATIVE ATTITUDE ALLOWED AFTER:			?? ANGLE (DEG)	ALTERNATIVE ATTITUDE FROM -ZSI
4 ORBITS OF -ZSI	8 ORBITS OF -ZSI	12 ORBITS OF -ZSI		
5	8	NOT ANALYZED	-60<?<+60	ANY -ZLV
1	1	1	-60<?<+60	WORST CASE ?
2	4	6	-60<?<+60	?XLV ?ZVV
1	1	2	+?	-XLV +YVV OR +XLV -YVV
1	1	2	-?	-XLV -YVV OR +XLV +YVV

? - EXCLUDING TOP EARTH OR SUN VIEWING @[111501-5011A]

Freezing of the water lines may result in orbiter Freon loop payload heat exchanger damage which puts both Freon loops at risk of leaking. Analysis results indicate that the onset of freezing of the water lines may occur as early as 10 minutes after this failure in an attitude which excludes Earth or Sun viewing; 12 minutes for typical ?XLV rendezvous attitudes; and 30 minutes for a -ZLV attitude. To protect against the worst case, a maneuver to a top Sun attitude should be initiated immediately. @[111501-5011A]

A nominal rendezvous lasting no more than 9 hours can be flown only if preceded by 12 or more orbits of top Sun (analyzed for Beta angles between -60 deg and +60 deg). This applies only if the rendezvous attitude is predominantly ?XLV ?ZVV.

Top Sun/alternative attitude times in table cannot be ratioed to longer durations. For example, the 4/5 -ZSI/-ZLV ratio cannot be flown as an 8/10 attitude sequence.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-555

WATER LINE HEATER MANAGEMENT (CONTINUED)

For Beta angles > 60 deg, the -ZSI attitudes can be biased in pitch or roll only as required to avoid upfiring RCS jet or orbiter maneuvering engine (OME) line thermal violations. However, in the event of conflicting constraints, the water loop must be considered a high priority to be protected from freezing.

Documentation: Rockwell International Internal Letter #SE-PSE-94-087, November 17, 1994, Flight Rule Revision to Payload Active Cooling Kit (PACK) Thermal Constraints.

Rule {A18-552}, SPACEHAB SUBSYSTEM WATER LOOP MANAGEMENT, references this rule.

D. EXCEPTIONS TO THIS RULE WILL BE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-5011A]

FLIGHT RULES

A18-556

RDM CENTRALIZED EXPERIMENT WATER LOOP (CEWL)

A. LOST IF: @[111501-5013]

1. PUMP ACCUMULATOR QUANTITY IS ? 0 (3.4) PERCENT AND SYMPTOMS OF PUMP CAVITATION ARE PRESENT.

Spacehab has identified this percentage as an indication of accumulator failure; 3.4 percent is the range of uncertainty of the quantity sensor.

2. THERE ARE SYMPTOMS OF PUMP CAVITATION AND THE PUMP INLET PRESSURE IS LESS THAN 20 PSIA.

Pump will operate erratically and may cavitate at pressures less than specified value.

B. FOR LOSS OF THE CEWL, POWER WILL BE REMOVED FROM EXPERIMENT COMPONENTS BEING COOLED BY THE CEWL IF REQUIRED TO MAINTAIN THERMAL LIMITS.

C. THE CEWL INLET QD'S SHALL BE CAPPED FOR ASCENT/ENTRY AND UNCAPPED PRIOR TO ACTIVATING THE CEWL PUMP.

The CEWL inlet QD's, when uncapped, provide pressure relief capability for the CEWL when active. This pressure relief capability is a safety requirement to prevent temperature induced over pressurization of the CEWL in case of loss of flow. Ascent/Entry loads may cause water to leak into the Spacehab subfloor from the CEWL inlet QD's if not capped.

Reference: Hazard Report RDM HR-5. @[111501-5013]

FLIGHT RULES

A18-557

RDM CEWL PUMP OPERATIONS

- A. FOR LOSS OF A SINGLE PHASE, THE CEWL PUMP MAY CONTINUE TO BE OPERATED ON TWO-PHASE POWER. @[111501-5013]

The CEWL pump was operated on two phases during preflight testing. The CEWL pump may be operated but not started on only two phases.

If the CEWL pump is operating on the Spacehab Aft INV and phase A fails, the CEWL pump will stop working because phase A of the Spacehab INV provides the sync pulse required for Spacehab INV phases B and C to operate. However, the CEWL pump will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C.

- B. THE ON-ORBIT CEWL PUMP CONFIGURATION FOR NOMINAL OPERATIONS IS AS FOLLOWS:

1. CEWL PUMP 1 - ON, USING ORBITER AC POWER
2. CEWL PUMP 2 - OFF, CONFIGURED TO SPACEHAB AFT INVERTER POWER

FOR FAILURE OF CEWL PUMP 1, CEWL PUMP 2 WILL BE AUTOMATICALLY COMMANDED ON. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.
@[ED]

CEWL pump 1 is considered the prime pump since an automatic switchover capability exists in the Aft Power Distribution Unit (APDU) logic to power on CEWL pump 2 in case of a pump 1 failure. This capability does not exist from pump 2 to pump 1. Pump 2 is configured to an alternate power source to allow it to be powered in case the power source to pump 1 fails. Orbiter AC is considered the preferred source for the prime pump. Operation of either CEWL pump by Spacehab Aft Inverter or orbiter AC is acceptable. Whenever CEWL cooled experiments are operating, a CEWL pump is required to provide heat rejection. @[11105-5013]

A18-558 THROUGH A18-600 RULES ARE RESERVED

FLIGHT RULES

SPACEHAB ENVIRONMENTAL CONTROL SYSTEM (ECS) MANAGEMENT

A18-601 ORBITER/SPACEHAB/EXPERIMENT THERMAL PRIORITIES
@[111501-4993]

IF CONFLICTS OCCUR, ORBITER THERMAL LIMITS WILL NORMALLY BE PROTECTED AT THE EXPENSE OF SPACEHAB THERMAL LIMITS. SPACEHAB HAS PRIORITY OVER EXPERIMENTS. @[111501-4976A]

The orbiter thermal limits must always take precedence over Spacehab to ensure the capabilities of the orbiter. @[111501-4976A]

A18-602 ORBITER FREON FLOW PROPORTIONING VALVE (FPV) USAGE
@[111501-5011A]

THE TWO ORBITER FREON FPV'S WILL NOMINALLY BE USED ACCORDING TO THE FOLLOWING PLAN: @[111501-4976A]

- A. PRELAUNCH (POWERED ASCENT): ONE FPV IN THE INTERCHANGER (ICH) POSITION AND ONE FPV IN THE PAYLOAD HEAT EXCHANGER (PLHX) POSITION AS REQUIRED BY THE PAYLOAD UNTIL FLIGHT-SPECIFIC LAUNCH MINUS TIME SPECIFIED IN THE FLIGHT SPECIFIC ANNEX. THEN BOTH FPV'S ARE PLACED IN ICH FOR ASCENT.

Both FPV's must be in ICH for ascent. However, cold soaking the Spacehab module prelaunch via one FPV in PLHX keeps the predicted module temperatures acceptable until post insertion. Moving the FPV back to the ICH position still guarantees a nominal crew cabin temperature at ingress and during ascent.

- B. ON-ORBIT 14.7 PSI OPS: AFTER SUCCESSFULLY REACHING ORBIT, ONE FPV WILL BE PLACED IN "PLHX" POSITION UNTIL DEORBIT PREP. THE SECOND FPV WILL ONLY BE TAKEN TO "PLHX" IF REQUIRED TO SATISFY PAYLOAD THERMAL REQUIREMENTS AS DEFINED IN THE FLIGHT SPECIFIC ANNEX. AT DEORBIT PREP, BOTH FPV'S WILL BE RETURNED TO "ICH" FOR ENTRY AND LANDING. FOR EXTENSION DAYS, AN FPV IN "PLHX" IS NOT REQUIRED AS LONG AS SPACEHAB REMAINS IN THE ENTRY CONFIGURATION OR WITHIN THERMAL REQUIREMENTS.

If the cabin is at 14.7 psi, marginal cooling exists for orbiter systems if both FPV's are given to the payload. To provide sufficient cooling to the orbiter, only one FPV should be in the PLHX position unless both are required to avoid violating payload thermal limits. In the entry configuration, Spacehab thermal loads are lower such that an FPV in PLHX is not required. However, if Spacehab is reconfigured, (i.e., hatch opened), an FPV in the PLHX position may be required. @[111501-4976A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-602 **ORBITER FREON FLOW PROPORTIONING VALVE (FPV) USAGE**
(CONTINUED)

- C. ON-ORBIT 10.2 PSI ORBITER OPS: REFERENCE ALL FLIGHTS RULE {A17-308A}, ATCS (10.2 PSIA CABIN) CONFIGURATION. @[111501-4976A]
- D. POSTLANDING: BOTH FPV'S WILL BE IN THE "ICH" POSITION UNTIL REQUESTED FOR PAYLOAD COOLING NO EARLIER THAN CREW EGRESS. THEN ONE FPV IS PLACED INTO THE "PLHX" POSITION FOR THE DURATION OF EARLY EXPERIMENT RETRIEVAL OPERATIONS.

Moving one FPV to PLHX allows Spacehab to maintain module temperature during early experiment sample retrieval operations. Waiting until crew egress to move one FPV to PLHX maximizes orbiter cabin cooling for crew comfort until ground ventilation can be connected.

- E. EXCEPTIONS TO THIS RULE ARE DOCUMENTED IN THE FLIGHT SPECIFIC ANNEX. @[111501-4976A]

FLIGHT RULES

A18-603

SM/LDM WATER FLOW CONTROL ELECTRONICS UNIT (WFCEU)

@[111501-5011A]

- A. THE PRIORITIES, FROM HIGHEST TO LOWEST, FOR THE WFCEU CONFIGURATION ARE AS FOLLOWS: @[111501-4995]
1. MODE 2 (AUTOMATIC CONTROL OF FAN/HX INLET TEMPERATURE)
 2. MODE 1 (AUTOMATIC CONTROL OF CABIN TEMPERATURE)
 3. MODE 3 (CONTROL OF VALVE POSITION BY CABIN TEMPERATURE SET POINT KNOB)
 4. MANUAL ADJUSTMENT OF TWO WATER BYPASS VALVES (WITH WATER LINE HEATERS ON)

The WFCEU software has multiple modes to allow for multiple sensor failures. Mode 2 requires an operational fan/HX inlet temperature sensor and controls the module temperature more accurately than the other modes. Therefore, mode 2 is the preferred mode of operation. The MCC will inform the crew if an alternate operational mode is necessary and which specific commands are required. Mode 1 provides for automatic cabin temperature control by allowing the WFCEU to operate even if one of the water temperature sensors fails. Mode 3 does not require any operational temperature sensors, only the cabin temperature set point. If none of the three modes operate satisfactorily, an IFM will be necessary to reconfigure the water loop. Direction on WFCV bypass valve adjustment will be provided by the POCC. Crew adjustment of water metering valves could cause a flow rate to the PLHX less than 50 lbm/hour.

Reference: ICD 21095, Interface Review Notice 37.

- B. DURING MODE 1 OPS, IF ANY ONE OF SEVEN SENSOR INPUTS TO THE WFCEU FAIL OR GIVE ERRONEOUS DATA, A COMMAND WILL BE ISSUED FROM THE ORBITER DISPLAY SYSTEM WHICH ALLOWS THE WFCEU TO OVERRIDE THAT INPUT.

The seven inputs to the WFCEU are: dew point temperature, cabin temperature, cabin temperature setpoint, water pump inlet temperature, fan/HX inlet temperature, WFCV cold inlet temperature, and WFCV position. Any of the seven can be compensated for by the WFCEU upon commanding from the Orbiter Display System. The MCC will inform the crew which flag command should be issued.

@[111501-4995]

FLIGHT RULES

A18-604

RDM ENVIRONMENTAL CONTROL UNIT (ECU) OPERATIONS

- A. AUTOMATIC CONTROL OF THE AIR BYPASS VALVE (ABV) BY THE ECU IS THE NORMAL OPERATING MODE. @[111501-5013]
- B. FOR ERRATIC OR UNSATISFACTORY ENVIRONMENTAL CONTROL OF THE SPACEHAB MODULE, THE ECU SOFTWARE CONTROL PARAMETERS MAY BE UPDATED/MODIFIED VIA UPLINK COMMANDING.
- C. IF THE SOFTWARE UPDATES DO NOT IMPROVE ECU OPERATION, THE ABV POSITION MAY BE SET VIA GROUND COMMANDING.
- D. FOR COMPLETE LOSS OF THE ECU AND ECU COMMANDING, THE CREW CAN MANUALLY ADJUST THE ABV POSITION VIA IFM.

The above methods of ECU operation are listed in order of preference. The order was based on maintaining optimal operation of the RDM thermal control system while minimizing impact on crew operations. @[111501-5013]

FLIGHT RULES

A18-605

RDM ROTARY SEPARATOR (RS) OPERATIONS

- A. THE RS SENSORS SHALL BE POWERED PRIOR TO RS ACTIVATION.
@[111501-5013]

The RS sensors can be powered by orbiter AC or Spacehab inverter power. The sensors must be active before RS activation to prevent RS automatic switchover.

- B. THE RS MAY BE OPERATED, BUT NOT STARTED USING ONLY TWO-PHASE POWER.

The RS was operated on two phases during preflight testing. The RS may be operated but not started on only two phases.

If the RS is operating on the Spacehab Aft INV and phase A fails, the RS will stop working because phase A of the Spacehab INV provides the sync pulse required for phases B and C to operate. However, the RS will continue to operate on the Spacehab INV on two-phase power if phase A continues to operate with either phase B or phase C. @[111501-5013]

- C. THE RS CONFIGURATION FOR ASCENT/ENTRY WILL BE AS FOLLOWS:
@[111501-5013]

1. RS 1 - ON, USING SPACEHAB INVERTER POWER
2. RS 2 - OFF, CONFIGURED TO SPACEHAB INVERTER POWER

RS 1 WILL BE AUTOMATICALLY COMMANDED OFF AND RS 2 COMMANDED ON, IF RS 1 FAILS. FOR FAILURE OF THE SPACEHAB INVERTER, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT. @[ED]

RS 1 is the prime RS since an automatic switchover capability exists in the APDU logic to power on RS 2 in case of an RS 1 failure. RS 2 is configured to inverter power to allow it to serve as a backup in case of an RS 1 failure. This automatic switchover capability does not exist to turn on RS 1 if RS 2 fails. Therefore, as long as RS 1 is operational, it will always be prime. RS 2 operating would indicate failure of RS 1. An operational RS is required to maintain moisture removal capability in the Spacehab module. Unlike fans and pumps, the backup RS is not configured to orbiter AC because it is not critical for entry and the RS switches automatically without opportunity for flight controller intervention. @[111501-5013]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-605

RDM ROTARY SEPARATOR (RS) OPERATIONS (CONTINUED)

D. THE RS CONFIGURATION FOR ON-ORBIT OPERATIONS WILL BE AS FOLLOWS:

1. RS 1 - ON, USING SPACEHAB INVERTER POWER
2. RS 2 - OFF, CONFIGURED TO ORBITER AC POWER

RS 1 WILL BE AUTOMATICALLY COMMANDED OFF AND RS 2 COMMANDED ON, IF RS 1 FAILS. FOR FAILURE OF THE SPACEHAB INVERTER OR ORBITER AC, REFERENCE RULE {A9-354}, SPACEHAB AC MANAGEMENT.
©[ED]

RS 1 is the prime RS since an automatic switchover capability exists in the APDU logic to power on RS 2 in case of an RS 1 failure. This automatic switchover capability does not exist to turn on RS 1 if RS 2 fails. Therefore, as long as RS 1 is operational, it will always be prime. RS 2 operating would indicate a failure in RS 1. It is preferred for RS 1 to remain on Spacehab aft inverter power from the ascent configuration. RS 2 is commanded to orbiter AC to allow RS 2 to be powered by an alternate source in case of a Spacehab aft inverter failure. Operation of either RS from Spacehab inverter power or orbiter AC power is acceptable. An operational RS is required to maintain moisture removal capability in the Spacehab module. The Spacehab inverters are the preferred source of power for the prime RS in order to off load orbiter AC power. ©[111501-5013]

FLIGHT RULES

A18-606

RDM CONDENSATE STORAGE TANK (CST)/CONTINGENCY WATER CONTAINER (CWC) MANAGEMENT

- A. SPACEHAB WILL UTILIZE ORBITER DUMP CAPABILITY TO DUMP CWC'S OVERBOARD. @[111501-5013]

Spacehab does not have overboard condensate dump capability and must rely on the orbiter for this function. During nominal operations, it takes approximately 20 hours for the CST to be filled (based on 3.25 crew members in the Spacehab module). The CWC will be emptied after six condensate transfers from the CST to CWC to comply with the operational constraint of only filling the CWC to 90 lbs (approximately 75 percent of capacity).

- B. FILLED SPACEHAB CWC'S WILL BE STOWED IN THE SPACEHAB IF ORBITER CERTIFIED STOWAGE LOCATIONS ARE NOT AVAILABLE IN THE EVENT OF AN ORBITER FAILURE/EMERGENCY WHERE THE SPACEHAB CWC CANNOT BE EMPTIED.

Spacehab has one certified stowage location in the module in which to stow a partially filled CWC and will consider using orbiter stowage first, if it is available. Otherwise, Spacehab will stow full bags in the stowage staging area or aft of the intermediate adapter on the floor. Rupture of a bag does not pose a risk to crew safety, but to damaging Spacehab hardware.

Reference: Rule {A10-385}, FILLED CWC STOWAGE MANAGEMENT.

- C. CWC'S MAY REMAIN CONNECTED AND NOT DUMPED FOR AN EMERGENCY DEACTIVATION.

If time permits, the CWC will be disconnected and stowed. The bag remaining connected does not pose a risk to crew safety, but to damaging Spacehab hardware.

- D. IF THE CWC IS CONNECTED WITH THE CWC VALVE OPEN, THE CWC WILL BE DISCONNECTED AND DUMPED OR STOWED BEFORE THE CST PRESSURE EXCEEDS 10 PSIG.

The CST pressure should be zero if the CWC valve between the CST and the CWC is open. A pressure greater than zero indicates that the CWC is being pressurized. Since it is desired not to pressurize the CWC, the frequency of CWC changeouts will be managed to prevent pressurization of the bag. However, in the event that some pressurization of the CWC occurs, the maximum rated pressure of 10 psig shall not be exceeded. @[111501-5013]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-606 **RDM CONDENSATE STORAGE TANK (CST)/CONTINGENCY
WATER CONTAINER (CWC) MANAGEMENT (CONTINUED)**

- E. THE CONDENSATE TANK CONTENTS MUST BE TRANSFERRED TO THE CWC OR THE RS TURNED OFF BEFORE THE CST PRESSURE EXCEEDS 15 PSIG. ©[111501-5013]

The contents of the CST must be transferred or the rotary separator deactivated prior to the CST becoming full to prevent deadheading the Water Separator Assembly (WSA). Deadheading the WSA will cause water to be carried over into the exit air stream and potential rotary separator motor damage. The CST pressure is 17.5 psig when the CST diaphragm is fully extended.

- F. THE CST IS NOT REQUIRED TO BE EMPTIED FOR EXTENSION DAYS. CONSTRAINTS ON THE FINAL CST TRANSFER AND DUMP WILL BE DOCUMENTED IN THE FLIGHT-SPECIFIC ANNEX.

If the Spacehab Module remains closed for an extension day, the condensate generation is negligible and the CST is capable of accommodating all condensate generated, provided the CST was emptied based on the constraints in the Flight-Specific Annex. If the Spacehab hatch is opened and there is little to no crew activity in the module for extension days; condensate generation will be minimal and the CST should be capable of accommodating all condensate generated. ©[111501-5013]

- [11] FOR A LEAKING FREON LOOP WHICH WILL SUPPORT NEXT PLS BUT NOT THE FOLLOWING PLS, A PLS WILL BE DECLARED IN ORDER TO ACHIEVE A NOMINAL D/O PREP AND ENTRY. A LOSS OF ONE FREON LOOP ENTRY REQUIRES A POWERDOWN TO 14 KW. @[061396-3104A]

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)A. SUPPLY H₂O

1. *Supply Water - two supply water tanks are required to maintain redundancy for FC water removal capability. If only one supply water tank was maintained, one additional failure (the remaining tank) could result in loss of all three FC's.*
2. *Dump Capability - Loss of dump capability requires FC relief system activation when all water tanks are full. The FC relief system is zero fault tolerant under these conditions and failure of this relief system would cause losses of vehicle and crew.*

B. ARS H₂O1. H₂O LOOPS

Loss of one water loop has no impact to the orbiter cooling since only one loop is normally activated. However, the failure places the orbiter in a zero-fault tolerant level. The next failure, loss of the other loop, would leave the orbiter with no control for humidity and no cooling available to the avionics inside the crew module. Effective P_{PCO₂} concentration control would also be lost due to restricted operations of cabin fans to avoid overheating ac inverters which are actively cooled by water loops. For loss of one water loop during ascent, nominal ascent should therefore be continued and first day PLS be executed.

An AOA, rather than an earlier ascent abort mode, is preferred for loss of both water loops during ascent because the avionics, with proper management, will not overtemp in an AOA timeframe (approximately 110 minutes). Avionics, due to the hot thermal environment encountered in the ascent phase, cannot be managed properly for the extended time required for a first day PLS to ensure a safe entry.

Thermal analysis indicates that, if two water loops are lost, cabin conditions will become intolerable within 2 hours of the failure. Cabin temperatures approach 90 deg F and relative humidity reaches 100 percent. Avionics temperatures exceed their loss of cooling operate periods and must be powered down. The cabin conditions can be relieved by performing cabin depress/repress (DEP/REP) cycles. The 4-hour time to landing is based on a crew of seven with an N₂ quantity of 262 lb. Crew exposure to the extreme cabin conditions is the primary driver for terminating the flight. The DEP/REP cycles provide relief from the high heat and humidity by dumping the excessive heat and humidity overboard and replacing the air with cool, dry N₂ and O₂.

DOCUMENTATION: Lockheed Technical Memorandum, G189A ECLSS ANALYSIS OF THE LOSS OF TWO WATER LOOPS AFO (TIG > 2.5), to be published. Document no. LESC-24843; engineering judgment; 1.1-ECLSS-09.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001 THERMAL GO/NO-GO CRITERIA (CONTINUED)

2. *H₂O LOOP LEAK*

When there is a coolant leak into the cabin from the water loop, it becomes zero-fault tolerant to crew safety because the next failure, a Freon-to-water leak at the interchanger, will introduce toxic Freon 21 into the crew habitable area. However, based upon the confidence in the interchanger hardware integrity (stainless steel construction; no leak experience) and the desire to provide on-orbit time for crew adaption (SAS concerns), an MDF will be performed.

DOCUMENTATION: Engineering judgment; JSC-08934, volume 3, section 4.6.1.2.1.2.

C. *ATCS*

1. *FCL:*

Loss of one Freon loop requires a PLS because the next failure (loss of other Freon loop) could result in loss of crew/vehicle.

Nominal ascent is continued so that more time is available to reconfigure for a one Freon loop entry and also because loss of one Freon loop is not an emergency. If both loops are lost, an emergency entry (ascent abort) is required because all cooling to the vehicle is lost.

If both Freon loops are lost, an emergency entry is required because the FC stack temperatures will reach the specification operational limit of 250 deg F within approximately 50 minutes. In addition, the electrolyte will reach the 25 percent operational limit in approximately 75 minutes. At this point, continued operation of the FC's is questionable. This assumes a simultaneous purge of all three FC's and 12.54 kWh (4.18 kWh/FCP).

DOCUMENTATION: Dual Freon Loop Failure Entry Analysis, Rockwell International, IL #388-301-79-018, 7/21/81.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES**A18-1001 THERMAL GO/NO-GO CRITERIA (CONTINUED)****2. FCL PUMPS:**

Loss of FCL 1 pump B and FCL 2 pump A requires a PLS because both remaining pumps are powered by AC1. Loss of AC1 would cause the loss of both FCLS and could result in loss of crew/vehicle.

If both Freon loops are lost, an emergency entry is required because the FC stack temperatures will reach the specification operational limit of 250 deg F within approximately 50 minutes. In addition, the electrolyte will reach the 25 percent operational limit in approximately 75 minutes. At this point, continued operation of the FC's is questionable. This assumes a simultaneous purge of all three FC's and 12.54 kWh (4.18 kWh/FCP).

DOCUMENTATION: Dual Freon Loop Failure Entry Analysis, Rockwell International, IL #388-301-79-018, 7/21/81.

3. FES**Total FES**

Loss of total FES requires a next PLS because the next failure (loss of one Freon loop) could result in loss of the crew/vehicle.

If the failure occurs on ascent, entry is not accomplished at the first day PLS because:

The thermal condition of the vehicle would be extremely hot. Whether or not an entry could be accomplished without a massive powerdown has not been established. It is desirable to remain on orbit until the next day PLS in order to "coldsoak" the vehicle. No analysis for an orbit 3/5 loss of FES case has been run. An AOA case was run with the following assumptions and results:

- a. PLBD open at 15 minutes.*
- b. PLBD closed at EI-7 minutes (total time PLBD open ? 50 minutes).*
- c. Touchdown occurred ? 38 minutes after doors closed.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001 THERMAL GO/NO-GO CRITERIA (CONTINUED)

- d. Av bays 1 and 2 were 11 deg F above the air inlet for 27 minutes.
- e. Av bays 1 and 2 were 6 deg F above the air outlet for 13 minutes.
- f. Only two crewmembers were used.

If the FES fails prior to TIG -45 minutes, there is sufficient time for reopening the PLBD, coldsoaking the radiators, performing the required powerdown, and reclosing the PLBD prior to TIG. No thermal violations are expected during entry. ©[020196-1810A]

If the FES fails between 45 and 15 minutes before TIG and a one rev late deorbit is available, a one rev wave off will be performed to allow time to reopen the doors, coldsoak the radiator, and perform the powerdown. No thermal violations are expected during entry if a one rev wave off is performed.

If the FES fails with the radiator coldsoaked between 45 and 15 minutes before TIG and a one rev deorbit is not available, the coldsoak will be utilized to continue with the planned TIG. Assuming the failure occurs at TIG -45 minutes, cabin temperature is expected to exceed 92 degrees F. Avionics bay supply air temperatures are expected to peak at 105 degrees (96 degrees being a violation) prior to NH3 activation. These thermal violations are limited to approximately 10 minutes, peaking at EI and returning with limits shortly after NH3 activation at EI, and will not affect crew performance. A one day wave off is not preferred since the next worst failure, loss of one Freon Loop, could cause the loss of the crew and vehicle.

If the FES fails without a radiator coldsoak between 45 and 15 minutes before TIG and a one rev deorbit is not available, a day wave off is required. There is insufficient time to reopen the PLBD and coldsoak the radiators prior to TIG. And there is not adequate thermal capacitance in the radiators to support the orbiter for up to 1.25 hours without active cooling.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)

If the FES fails after TIG -15 minutes, powerdown will be performed and planned TIG will be executed. Without a coldsoak, avionics bay supply air temperatures are expected to peak at 105 degrees (96 degrees being a violation) prior to NH3 activation. These thermal violations are limited to approximately 20 minutes, peaking at EI and returning with limits shortly after NH3 activation at EI, and will not affect crew performance. A one day wave off is not preferred since the next worst failure, loss of one Freon Loop, could cause the loss of the crew and vehicle. However, with a coldsoak, no thermal violations are expected.

®[020196-1810A]

DOCUMENTATION: SEH-ITA-85-001T; SEH-ITA-80-206T.

4. **FES CONTRS****Partial loss of FES/controllers**

Loss of high-load evaporator is a PLS (including first day PLS) because the next failure (loss of one Freon loop) could result in loss of crew or vehicle. The capability of the topping evaporator on Freon loop one (worst case) is ? 24,600 Btu/hr or 5.5 kW. The 24,600 Btu/hr is based on test data on one topping evaporator core. No specification data exists for the topping evaporator on one Freon loop. Freon loop 1 is worst case because loop 2 runs closer to the topping evaporator core and has better heat transfer than loop 1.

Loss of topping evaporator or the loss of both primary controllers requires an MDF because the next failure (loss of one Freon loop) would cause an extensive powerdown to be completed before entry; however, it is believed an entry can be performed at this power level. The capability of the high-load evaporator/secondary controller on Freon loop 2 (worst case) is ? 44,200 Btu/hr or 10 kW. The 44,200 Btu/hr is based on test data on one high-load evaporator core. No specification data exists for the high-load evaporator on one Freon loop. Freon loop 2 is worst case because Freon loop 1 runs closer to the high-load evaporator core and has better heat transfer than loop 2.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)

For loss of either the topping or high-load evaporator, due to a suspected freeze-up, consideration will be given to staying on orbit in order to attempt to thaw out the affected evaporator. It must be noted, however, that the symptoms of freeze-up are ambiguous with the instrumentation available. Further, simply flushing out the ice does not necessarily address the root cause of the problem as our flight history (below) has demonstrated. Flushing the core with the secondary controller on orbit will require elevated Freon temperatures to the FES. This can be accomplished by bypassing the radiators or by closing the doors.

Flight and Ground History. During Space Environment Simulation Laboratory (SESL) testing of the FES pre-STIS-1, there were several episodes of core freezing, all of which were successfully flushed within very short periods (hours). SESL testing was done under one g conditions, however, and the effects of that are not well known. During STS 41-G, when the topping evaporator froze, the ice was successfully removed from the core after 28 hours with the radiators in the high set point. During STS-26, FES shutdowns occurred between 38 and 55 minutes MET. Corrosion in the topping core surface degraded the evaporation process and gave the ice a foothold. Use of the secondary controller cleared the ice out of the topping core (secondary topper uses both A and B H₂O nozzles alternately, has no shutdown feature, and operates at a higher control temperature). On orbit, the radiator controllers were operated in the high set point to thaw out any ice that remained in the high load or topping cores.

There is a high probability that the FES core can be thawed and/or flushed while the next worst failure, loss of a Freon loop, is severe but it is a low probability. It has been decided that the risk of staying on orbit to thaw the FES is warranted.

DOCUMENTATION: SEH-ITA-081-107; SEH-ITA-83-011T; STS 41-G and STS-26 flight data; and engineering judgment.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)5. FES FEEDLINES

Loss of two feedlines is equivalent to the loss of total FES that requires a next PLS. This is because the next failure (loss of one Freon loop) could result in loss of crew or vehicle.

With the loss of one feedline, full operational capability is maintained. Although this results in a single fault tolerant situation, an MDF is not called because the Freon loops and flash evaporator system are single-fault tolerant systems from launch.

DOCUMENTATION: SEH-ITA-83-011T; SEH-ITA-81-107.

6. ABS

There is no requirement for the NH₃ after nominal orbit insertion. The FES and radiators are used for orbit and entry cooling. The NH₃ boiler is not required until post-rollout and an emergency powerdown can be performed if NH₃ is not available. The ammonia boiler is required for launch aborts since the radiators cannot be coldsoaked in these cases. Therefore, after nominal ascent and insertion have been completed, there is no requirement for the NH₃ boiler.

DOCUMENTATION: Flight data.

7. RFCA/RADIATOR ISOLATION VALVE @[050400-7192]

An RFCA failed in min rad flow, a leak isolated to the radiators, or an isolation valve failed in the isolate position (loss of radiator) is a PLS with the following considerations:

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)

Continuing to run the loop with the failed radiator will result in high FES rates and depletion of supply H₂O. Upon the first radiator failure, the following actions are required to safe the vehicle (ref Rule {A18-251}, FREON COOLANT LOOPS (FCL)): ©[050400-7192]

- a. *Deactivate affected Freon loop and flash evaporator and power down to 14 kW. ©[050400-7192]*
- b. *Maneuver to a cold radiator attitude (e.g., GG, nose Sun).*
 - *Debris Avoidance or Docked attitudes may not be possible.*
 - *Closing the affected PLBD may be required to keep the Freon in the failed loop from freezing.*
- c. *Move the Flow Prop Valve on the good loop to the ICH position.*
- d. *Payloads that require active cooling will be terminated.*
- e. *If at 10.2 psi and cabin temps are violated, a 14.7 repress will be required.*

These actions place the orbiter in a safe configuration and allow for the filling of the supply H₂O tanks. Full Supply H₂O tanks protect the vehicle in the event of the next worst failure (loss of the good Freon loop). The next worst failure would require the following:

- a. *Power down to 7 kW immediately after the flowing loop fails.*
- b. *Power up the loop with the failed radiator with a FES controller active.*
 - *Secondary Topper or full up primary controller may be required.*
- c. *Power up to 11 kW for entry at TIG-2 hours.*
- d. *If supply water quantities will not support the next PLS, an ELS will be declared. Depletion of supply H₂O would result in loss of cooling. Loss of cooling could result in loss of crew and vehicle.*

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)

Loss of both RFCA's is a PLS because the next failure (loss of FES) could result in loss of crew/vehicle.

Note that the first day PLS is passed up in order to allow the crew to recover from space adaptation sickness (SAS). This does incur some risk in that there is a window of time in which supply H2O quantities will not support the next worst failure (loss of the good loop). The probability of this occurring is low, however, so SAS takes priority.

DOCUMENTATION: AEFTP #162, October 29, 1999. ©[050400-7192]

If an RFCA is failed in the "full open" position, several measures can be taken to ensure the evaporator outlet temperature remains above 32 deg F. This is required to prevent freezing of the H2O loops at the interchanger. These measures include:

- a. Bypassing the good loop's radiator.*
- b. Going to high control set point (57 deg F) on the good loop.*
- c. Attitude constraints (-ZLV).*
- d. Closing the PLBD of the failed loop.*
- e. Raise ATCS heat load.*
- f. Disable flow control valve on good loop in a hotter position.*

When deciding which measure to use, it should be taken into account that, if the good loop should suddenly fail, the evaporator outlet temperature on the failed loop should be warm enough so as not to freeze the water loops.

Since several measures can be taken to ensure the evaporator outlet temperature remains above 32 deg F, it is not necessary to shorten the mission for this failure.

THIS RULE CONTINUED ON NEXT PAGE

FLIGHT RULES

A18-1001

THERMAL GO/NO-GO CRITERIA (CONTINUED)

If both Freon loop RFCA's are failed in the full open position, the following steps can be taken to ensure the evaporator outlet temperature remains above 32 deg F:

- a. *Attitude constraints (-ZLV; bay to Earth).*
- b. *Closing the PLBD of either loop.*
- c. *Raise ATCS heat load.*

If one loop suddenly stops running, the evaporator outlet temperature will be above 32 deg F.

Since these measures can be taken to ensure the evaporator outlet temperature remains above 32 deg F, it is not necessary to shorten the mission for these failures.

It should be noted that, if a loop with an RFCA failed full open cannot be bypassed, either manually or automatically, it should not be deactivated if at all possible. A stagnant loop will coldsoak to temperatures below zero degrees. If the loop is deactivated, depending on the length of time deactivated, attitude, and temperature of the loop when deactivated, the loop may not be usable without freezing the interchanger.

DOCUMENTATION: SEH-ITA-81-416T

8. **HEAT EXCHANGER LEAK**

An MDF is required for a heat exchanger leak between dissimilar fluids (other than Freon and cabin water) because the possibility exists that a generic problem, such as corrosion, exists in the heat exchanger. This type of problem could eventually result in a total loss of the heat exchanger and the vehicle. It is considered that the risk of losing the heat exchanger does not warrant a PLS, but does warrant an MDF.

If the leak is between Freon and a cabin water loop, PLS is required because the next failure (external leak in the water loop) could result in the crew being exposed to Freon 21, which is very toxic. In addition, the water loop is considered lost because several components in the water loop are incompatible with Freon 21 and may fail to seal or function. These material incompatibilities, in addition to high pressures in the water loop (caused by the Freon loop leaking into the water loop), increase the chances of the water loop developing an external leak into the cabin and exposing the crew to Freon 21. In November of 1985, the following statement was published in the SODB, volume III concerning a Freon to water loop leak: "In the case of leakage occurring during a mission, it is mandatory to abort the mission at the earliest practical time in order to minimize the possibility for a second failure which could result in Freon leak into the cabin air."

FLIGHT RULES

APPENDIX B

CHANGE CONTROL

1.0 INTRODUCTION

1.1 PURPOSE

The purpose of this appendix is to delineate change control procedures for Volumes A, B, C, D, and flight-specific/increment-specific Flight Rules Annexes. This will ensure the proper coordination of changes and provide a record of the proposed changes including the rule rationale and the reason for making the change. The web-based database, Workflow, is now being used to generate CR's for Volumes A, B, C, D, and Flight Rules Annexes and is the preferred method for initiating CR's. Refer to paragraph 2.1.1 for Workflow enrollment instructions. The change request (CR) form on page B-10 is designed to assist this change control process only when it is not possible to use Workflow. Workflow is available at URL: <http://mod.jsc.nasa.gov/da8>. Under the **Workflow Link** title, click on the **Flight Rule CR System** link.

1.2 GENERAL

All Flights critical items list (CIL)-related rules and generic rules with a recurring potential for mission-specific options or exceptions will be flagged so that they are readily identifiable in the All Flights generic documents. Hazard control (HC)-related rules are monitored by NA/Safety Division, and impact to an HC rule requiring PRCB/JPRCB/SSPCB is reported to the FRCB/JFRCB. When a change to a CIL-related specific flight rule, or an HC-related rule, is approved and CIL retention rationale is affected by the change, the change will not be incorporated until a corresponding change to the retention rationale is approved by the Shuttle or Station Programs. The same general philosophy applies to the changes that modify existing payload or orbiter hazard controls. These flight rule changes will not be incorporated until the appropriate safety organization approves a corresponding change to the related hazard control documentation. A [CIL] tag, in brackets, will be added to the title for CIL-related rules. Some Volume A rules not identified as CIL are identified as hazard control and an [HC] tag, in brackets, will be added to the title of those rules. Volume B rules primarily have been identified for hazard control and will be tagged [HC] in the title. Examples of All Flights rules that have the recurring potential for flight-specific options or exceptions are some of the remote manipulator system rules. For those type flight rules, the options or exceptions can be exercised as part of the flight-specific Flight Rules Annex development process. Flight-specific exceptions to any other All Flights generic rules must be approved by the appropriate Flight Rules Control Board (FRCB) or Joint Flight Rules Control Board (JFRCB).

It is suggested that those organizations with flight rules which affect CIL retention rationale or hazard controls implement an independent internal CR handling procedure that identifies CIL or HC flight rules and protects against inappropriate changes to these types of rules.

The FRCB/JFRCB is responsible for review and approval of CR's written against the Volume A, B, C, and D generic rules documents. The FRCB/JFRCB is chaired by the Director, Mission Operations or his designee.

FLIGHT RULES

1.3 EFFECTIVITY

January 21, 2002.

2.0 CHANGE PROCEDURES

2.1 SUBMISSION OF CHANGES

The flight rules change control process starts when someone in the technical community identifies a valid need to delete or modify an existing flight rule or to add a new rule. The web-based database, Workflow, is now being used to generate CR's for Volumes A, B, C, D, and Flight Rules Annexes. Refer to the paragraphs below for Workflow user and enrollment instructions. That individual fills out the Workflow CR form. (If access to the Workflow form is not available to the user, a paper form is provided on page B-10.) In developing the Workflow change file, the CR author should cut and paste appropriate pages from the Flight Rules document and SAVE AS a user file in the user's directory. Changes may be made to the appropriate rules of the author's file. When working this file, please accept any revisions on the copied page then turn the REVISION MODE **ON** so the change inputs are highlighted. Extracted rule pages or blank pages free of the graphics frame are encouraged.

All of the current Flight Rules documents are available on the internet. The URL is:

<http://mod.jsc.nasa.gov/da8>. No ID or password will be required to access any of the rules provided the user is accessing from a trusted site (all NASA centers, contractors, and International Partners). If unable to access, users need to send an e-mail note to DA8/M. L. Griffith (mary.l.griffith1@jsc.nasa.gov) with their full name, company, IP address, and a justification statement for access.

The completed CR is then submitted to a division FRCB/JFRCB representative for approval. That representative should ensure that all CR's are coordinated within the originating division before submitting them to the DA8/Flight Director Office, Lyndon B. Johnson Space Center, Houston, Texas 77058. Each division should establish its own process to handle this internal coordination. DF/System Division is an exception to this protocol. CR's from DF are not processed through the DF FRCB representative, but submitted to the Flight Director Office by DF Branch Offices. When internal coordination has been completed, the division FRCB/JFRCB representative signs the form and forwards it to the Flight Director Office. For Workflow CR's, facsimile signature is recognized by the DA8/Flight Director Office when the CR is routed electronically from the appropriate Group Lead, Branch Manager, or the Division FRCB/JFRCB representative within MOD to DA8/J. M. Bryant (to the appropriate DA8/Book Manager for Annexes) for generic rule CR's and cc to DA8/W. P. Dill for Space Shuttle Operational Flight Rules, Volume A; DA8/J. M. Bryant for ISS Generic Operational Flight Rules, Volume B; and DA8/W. P. Dill for Joint Shuttle/ISS Generic Operational Flight Rules, Volume C, or Soyuz/Progress/ISS Joint Flight Rules, Volume D. **Examples of the electronic addresses are: SMPT: william.p.dill1@jsc.nasa.gov or smpt: wdill@ems.jsc.nasa.gov.** Organizations outside MOD may submit CR's through the appropriate MOD division to facilitate presubmittal review and coordination or may submit completed CR's directly to the Flight Director Office. Workflow CR's submitted from outside MOD require a tailored setup for the author as the CR will not be processed without one additional review/approval inside the author's Branch, Group, etc. When practicable, coordination should include the Flight Director. Workflow CR's are encouraged from outside MOD.

FLIGHT RULES

2.1.1 Enrollment

“Workflow” is a web-based database which uses e-mail to route and announce CR’s for review or approval. The approval process is discussed in paragraph 2.2. Workflow requires the user to be enrolled in the database.

Anyone with a need who resides in the JSC Domain or certain trusted domains may be enrolled in Workflow by providing their full name, 4-digit mail code, domain user ID, telephone number, and e-mail address. The request and information should be provided to Division database editors, trusted domain database editors, or to the Book Manager listed on the Preface page of the flight rules documents.

Enrollment for users outside the JSC Domain/trusted domains is available if the user has a need to change or review flight rules. At URL: <http://mod.jsc.nasa.gov/da8>, under the title **Workflow Link**, click the **Process for obtaining access to Workflow** link. Fill out the form and follow the submitting instructions. The DA8/Flight Director Office will sponsor each request. The requester will be informed when the application is approved and enrollment completed.

The Workflow URL is: <https://jsc-mod-wrkflow.jsc.nasa.gov>. Refer to the Help and Frequently Asked Questions and the Complete Users Guide links for further information. There is also a Workflow Trainer CBT which is at URL: <http://mod.jsc.nasa.gov/da8>.

2.1.2 Format

Individuals desiring to submit a flight rule change will complete the Workflow CR form. For new flight rule submittals, the rule and its associated rationale should be phrased as it is intended to appear in the flight rules document. Supporting data for the rationale may be attached. For changes to existing rules, the proposed changes must be made obvious when making the Workflow file attachment by accepting any revisions on the Flight Rule page to be modified, then turn the revision mode **ON** so that changes may be clearly identified.

2.1.3 CR Input Nonconformance

If an error is discovered while reviewing an incorporated Flight Rule CR, please notify the Book Manager of the nonconformance using the EZ CR form provided on the next page of this appendix. (Be aware that this is not the Flight Rule CR form and should only be used to report nonconformances.) Verification of the nonconformance initiates a metric input, correction, possible corrective action, nonconformance disposition/approval, and closure. Closure of “Control of Nonconforming Product” nonconformance EZ CR’s are approved by the Flight Director Office USA supervisor or his designee. Closure of “Corrective and Preventive Action” nonconformance EZ CR’s are approved by the Chief of the Flight Director Office or his designee.

FLIGHT RULES

INSTRUCTIONS

1. DATE - Enter FLIGHT RULES EZ CR initiation date.
2. INITIATED BY: ORG/NAME/PHONE - Enter the originator's organization, name, and phone number (including area code if other than JSC).
3. RULE NUMBER - Enter the nonconformance rule number.
4. CONTROL NUMBER - Leave blank; will be assigned and entered by the document manager.
5. FLIGHT EFFECTIVITY - Enter whether Generic or Flight Specific Number.
6. OTHER AFFECTED RULES - Enter other rules affected.
7. DOCUMENT DATE w/Date/ REV Date - Enter the "affective document" document date and the PCN/Rev (if applicable) that contains the rule to be modified.
8. Enter All Flights Volume A, B, or C, or check the appropriate box for the annex
9. RULE ELEMENT - Enter the rule element number.
10. RULE SECTION - Enter the rule section number
11. SHORT DESCRIPTIVE TITLE OF CHANGE - Enter a short descriptive title of the change.
12. RULE, RATIONALE - Check appropriate box for whether the nonconformance is in rule and/or rationale.
13. NONCONFORMANCE DESCRIPTION - Enter a description of the nonconformance.
14. SPECIAL INSTRUCTIONS (IF REQUIRED) - Enter any special instruction here.
15. NONCONFORMANCE - Leave blank; will be assigned and entered by the document manager.

FLIGHT RULES

2.2 CR APPROVAL

2.2.1 Coordination

Pre-coordination between the author and affected disciplines is assumed. In Workflow, when the Flight Director Office receives a generic flight rule CR for disposition, it will automatically be assigned a control number, and it will be assigned to a coordinating flight director. The coordinating flight director works with the initiator on any desired changes to the wording for the rule or rationale. The coordinating flight director conducts the Flight Director Office review and assists in the identification of any additional data or coordination that may be required. When this initial coordination has been completed and external coordination is required, a mandatory review sheet is readied by the coordinating flight director and distributed for formal review and comment with an appropriate suspense date provided. When required, all FRCB/JFRCB members plus others identified by the coordinating flight director will receive review copies via Workflow. To allow adequate review time, the suspense date is established to support the next scheduled FRCB/JFRCB (or specific launch date). CR's are required to be delivered to the Flight Director Office for review no later than 3 weeks prior to the FRCB/JFRCB. CR's submitted after the 3-week deadline may be scheduled on the FRCB/JFRCB agendas at the discretion of the Board Chair.

This review includes an assessment of impact to retention rationale for CIL-related rules and a review of related orbiter or payload hazard reports. For all proposed changes to CIL/HC-related flight rules, the rationale must be approved by the respective Program before the CR may be placed on the Board agenda.

FLIGHT RULES

2.2.2 Approved/Disapproved/Deferred CR's

2.2.2.1 Generic CR's

For minor changes to generic rules/rationale, format only changes to flight rules, and when no mandatory review assignments have been made by the reviewing Flight Director, the FRCB/JFRCB Chairman may approve the CR without formal presentation to the board, provided no changes were recommended by the board members. These are the CR's identified on the FRCB/JFRCB agenda with an asterisk. Occasionally, the FRCB/JFRCB Chairman will approve and sign a CR out of board to expedite a CR through the process, and usually that CR will be presented at the next FRCB/JFRCB. All other CR's will be considered by the FRCB/JFRCB with a formal presentation. The FRCB/JFRCB considers each CR based on the impact on operations, the impact on documented hazard controls or CIL retention rationale, and the technical justification. Each CR will then be approved, disapproved, or deferred. Approved changes will be incorporated into the next page change notice (PCN) or revision to the generic document. Disapproved CR changes will be returned to the initiator along with the reason for disapproval. Disapprovals may be appealed to the Level II Program Office, if desired. The last possible FRCB/JFRCB action is deferral. CR's will be deferred for only two reasons: all mandatory concurrences have not been received, or additional data or analysis is needed. CR deferrals will be rescheduled for a subsequent FRCB/JFRCB meeting.

FRCB/JFRCB minutes document the status of each CR dispositioned (approved, deferred, approved with modification, actions given, and status of past actions). Workflow databased CR's may be processed by the Book Manager acting for the FRCB/JFRCB Chair in accordance with the FRCB/JFRCB CR status documented in the minutes.

2.2.2.2 Annex CR's

The Lead Flight Director has approval authority of CR's for Flight Specific Increment Annexes or for Flight Specific Annexes.

3.0 DOCUMENT REVISIONS/DEVELOPMENT

3.1 DEVELOPMENT

The Flight Director Office will compile for the generic documents the effective changes and corrections of minor typographical errors into complete Revisions or PCN's to the basic document.

The Flight Director Office prepares annexes on a per flight basis according to schedule template at approximately launch minus 7 months in most cases.

Editorial changes may be used to correct typographical errors if there are no other changes on the page concerned.

FLIGHT RULES

3.2 DOCUMENT APPROVAL

3.2.1 Generic Rules Documents

Revisions/PCN's to the Volume A document will be approved by the Chief, Flight Director Office; Director, Mission Operations; and Manager, Space Shuttle Program. Pen and Ink (P&I) changes will be approved by the Chief, Flight Director Office under DA8 memorandum with concurrence by the Director, Mission Operations. Real-time CR's are approved by the Flight Director and the Mission Operations Director and are statused to the Mission Management Team.

Revisions/PCN's to the Volume B and D documents will be approved by the Chief, Flight Director Office; Director, Mission Operations; and Manager, Space Station Program. P&I changes will be approved by the Chief, Flight Director Office under DA8 memorandum with concurrence by the Director, Mission Operations. Real-time CR's are approved by the Flight Director and the Mission Operations Director and are statused to the Mission Management Team.

Revisions/PCN's to the Volume C document will be approved by the Chief, Flight Director Office; Director, Mission Operations; Manager, Space Shuttle Program; and Manager, Space Station Program. P&I changes will be approved by the Chief, Flight Director Office under DA8 memorandum with concurrence by the Director, Mission Operations. Real-time CR's are approved by the Flight Director and the Mission Operations Director and are statused to the Mission Management Team.

Documents are updated with approved CR's and statused at program review boards. If all signatures are not obtained in time to meet publication schedules, signatures pages will be posted by eratta when they are received.

3.2.2 Annex Documents

A "Headsup" review copy of the "Final" document is provided for program review 5 working days prior to "Final" presentation to the affected Program Requirements Control Board (PRCB) or SSCB or Joint Board. After the 5-day review, the Flight Director is scheduled on the appropriate board agenda via a Control Board CR to brief any flight specific issues potentially affecting Program policies. Also, any additional significant changes received during the 5-day review period will be briefed.

Pre-Final documents are approved by the Lead Flight Director or his designee.

The Annex Final and Revisions/PCN's to the Final document will be approved by the Chief, Flight Director Office; Director, Mission Operations; and Manager, Space Shuttle Program. Pen and Ink (P&I) changes will be approved by the Lead Flight Director under DA8 memorandum with concurrence by the Chief, Flight Director Office and Director, Mission Operations. Real-time CR's are approved by the Flight Director and the Mission Operations Director and are statused to the Mission Management Team.

The Increment Annex Final and Revisions/PCN's to the Final will be approved by the Chief, Flight Director Office; Director, Mission Operations; Manager, Space Shuttle Program; and Manager, Space Station Program. Pen and Ink changes will be approved by the Lead Flight Director under DA8 memorandum with concurrence from the Chief, Flight Director Office and the Director, Mission Operations. Real-time CR's are approved by the Flight Director and the Mission Operations Director and are statused to the Mission Management Team.

FLIGHT RULES

3.3 PUBLICATION

3.3.1 Schedule

3.3.1.1 Generic Rules

All Flights documents (Volumes A, B, C, and D) originating as initial documents would approximately follow the schedule described for annexes except the FRCB/JFRCB would exercise individual rules approval prior to obtaining respective PRCB/JPRCB/SSPCB approvals. After initial release of Volumes A, B, C, etc., in "Final" form, subsequent revisions will be in the form of PCN's or Pen and Inks (P&I's), depending on CR traffic and mission requirements.

3.3.1.2 Annex/Increment Rules

Initial publication of annexes will be in "Basic" form and provided for the Flight Operations Review (FOR) data pack distribution at approximately launch minus 4 months for Space Shuttle only missions and L-5 months for Joint Shuttle/ISS missions (schedule provided by Payload FOR memorandum.) Post-FOR, the flight rules will be published in "Basic, Revision" form and distributed in time to support the flight simulation schedule. The "Final" approval process takes place at approximately liftoff minus 1 month. The logistics required for the formal approval process precludes initiating a PCN within 2 weeks of launch. Within 2 weeks of the launch, the Pen and Ink (P&I) process is invoked with P&I changes processed "on console" at launch minus 1 day, and produced on an "as required" basis. After liftoff, changes will be processed real time per JSC-26843, Flight Control Operations Handbook (FCOH) Shuttle Operations, SOP 1.2.1, Real-Time Flight Rules Changes, or JSC-29279, FCOH Station Operations, SOP 2.6, Real-Time Flight Rules Changes.

3.3.2 Distribution

Hard copy publications will be printed and distributed through normal administrative channels. Use of electronic copies off the website is encouraged. All of the current Flight Rules documents are available on the internet at URL: <http://mod.jsc.nasa.gov/da8>.

FLIGHT RULES

INSTRUCTIONS

1. DATE - Enter CR initiation date.
2. INITIATED BY: ORG/NAME/PHONE - Enter the originator's organization, name, and phone number (including area code if other than JSC).
3. CONTROL NUMBER - Leave blank; will be assigned and entered by the document manager.
4. RULE NUMBER - Enter the existing rule number to be modified. If this is a new rule, enter the section number and the document manager will assign a rule number.
5. FLIGHT EFFECTIVITY & Term and Terminate after: - Enter the first flight for which the rule is required. If generic, enter "ALL". For Annex or Increment Annex STS-XX or INC X/STS-XX, if there is a mission that requires termination thereafter, make that entry here using similar annotation STS-XX, etc.
6. OTHER AFFECTED RULES - Enter other rules which either reference this rule or which this rule references.
7. DOCUMENT DATE w/Date/ REV Date - Enter the "affective document" document date and the PCN/Rev (if applicable) that contains the rule to be modified.
8. ALL FLIGHTS VOL, ANNEX - Enter All Flights Volume A, B, or C, or check the appropriate box for the annex document for which the CR is intended.
9. RULE ELEMENT - Enter the rule element number.
10. RULE SECTION - Enter the rule section number.
11. SHORT DESCRIPTIVE TITLE OF CHANGE - Enter a short descriptive title of the change.
12. RULE, RATIONALE - Check appropriate box for rule and/or rationale.
13. RULE CHANGE- ATTACHED - Enter the rule and rationale exactly as it will appear in the document to be changed. It is preferred that the page(s) being changed be copied and pasted below the page break of the CR form ("Instructions" page to be deleted). The rule/rationale should be modified with revision mode ON. For a new rule, enter rule below the page break using format shown below:
14. TITLE - In capital letters and underlined.
 RULE - In capital letters exactly as it will appear in the document.
 RATIONALE - Enter the word "Rationale" followed by the rule rationale in lower case letters.
15. SPECIAL INSTRUCTIONS (IF REQUIRED) - Enter any special instruction here.
16. REASON FOR CHANGE - Enter the technical or philosophical reason for changing the existing rule or why a new rule is required.
17. PRE-COORD: (ORG/NAME) - Enter any pre-coordination information obtained here.
18. APPROVED: SUBMITTING ORGANIZATION FRCB/JFRCB MEMBER/DATE - This block is to be signed/dated by the Flight Rules Control Board (FRCB) or Joint FRCB member of the organization submitting the rule. Concurrences, if required, may be initialed in this block. Changes originating from organizations which have no FRCB/JFRCB membership may submit their proposed changes directly to the Flight Director Office, DA8, Lyndon B. Johnson Space Center, Houston, Texas 77058.
19. CIL HAZARD CONSTRAINTS TO OPERATIONS: YES NO - Optional, the originator may attempt to answer this question; however, the responsibility lies with DF to determine if the CR affects JSC 23227, "CIL/Hazard Constraints to Operations." This is the MOD ops retention rationale document.
20. DOES THIS CHANGE MODIFY EXISTING CIL RETENTION RATIONALE: YES NO - Optional, the originator may attempt to answer this question; however, the responsibility lies with DF to make this assertion.
21. DOES THIS CHANGE AFFECT CREW PROCEDURES? YES NO - The originator should attempt to answer this question and make reference to changes in the crew procedures document in item 11.
22. DOES THIS CHANGE MODIFY RATIONALE FOR A CONTROLLED HAZARD? YES NO - Optional, the originator may attempt to answer this question; however, the responsibility lies with the Systems or Operations Divisions to make this assessment.
23. APPROVED: FRCB/JFRCB CHAIRMAN - This block is to be signed by the FRCB/JFRCB Chairman, Operations Director, or his alternate signifying approval by the FRCB/JFRCB.
24. APPROVED: LEAD FLIGHT DIRECTOR - This block is to be used only for Lead Flight Director concurrence for changes to the flight-specific annexes.
25. CHANGE IS RESULT OF - Check appropriate box.
26. EVALUATION SUMMARY - Leave blank; used by DA8 to identify/request mandatory CR review.
27. RECEIVED/INCORPORATED/CR STATUS: - Leave blank; this block is used for internal document control by the document manager.

FLIGHT RULES

APPENDIX C

INDEX OF WAIVERS

1.0 **INTRODUCTION**

1.1 **PURPOSE**

APPENDIX C CONTAINS THE LIST OF WAIVERS TO THE NSTS 12820, SPACE SHUTTLE OPERATIONAL FLIGHT RULES ALL FLIGHTS DOCUMENT, VOLUME A.

1.2 **SCOPE**

EACH WAIVER IS APPROVED BY THE SPACE SHUTTLE PROGRAM REQUIREMENTS CONTROL BOARD FOR THE FLIGHT EFFECTIVITY AS SPECIFIED. WAIVERS THAT HAVE BEEN APPROVED FOR MULTIPLE FLIGHTS ARE CURRENT AND IN EFFECT UNLESS THEY ARE IDENTIFIED AS HAVING BEEN RESCINDED BY THE PROGRAM OFFICE BOARD.

THE FLIGHT OPERATIONS TEAM IS RESPONSIBLE FOR IMPLEMENTATION OF THE WAIVERS TO THE OPERATIONS FLIGHT RULES THAT HAVE BEEN APPROVED BY THE SPACE SHUTTLE REQUIREMENTS CONTROL BOARD AS SPECIFIED BY THE PRCB DIRECTIVE SIGNED BY THE CHAIR.

FLIGHT RULES

LIST OF WAIVERS

NUMBER	TITLE	FLIGHT EFFECTIVITY	PRCB DIRECTIVE
1	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-52	STS-52	S063689Q
2	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-66	STS-66	S063689BQ
3	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-71	STS-71	S063689CH
4	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-75	STS-75	S063689CT
5	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-76	STS-76	S063689CU
6	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-94	STS-94	S063689DW
7	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-95	STS-95	S063689EL
8	WAIVER TO SPACE SHUTTLE OPERATIONAL FLIGHT RULES, ALL FLIGHTS DOCUMENT FOR STS-108	STS-108	S063689FB

FLIGHT RULES

APPENDIX D

HAZARD REPORT/CIL CROSS-REFERENCE

1.0 INTRODUCTION @[012402-5144]

1.1 PURPOSE

THIS APPENDIX PROVIDES A CROSS-REFERENCE BETWEEN THE FLIGHT RULES, HAZARD REPORTS (HR'S), AND CRITICAL ITEMS LIST (CIL). THIS MATRIX FULFILLS THE REQUIREMENT DOCUMENTED IN NSTS 22206, REQUIREMENTS FOR PREPARATION AND APPROVAL OF FAILURE MODES AND EFFECTS ANALYSIS (FMEA) AND CRITICAL ITEMS LIST (CIL), FOR MISSION OPERATIONS DIRECTORATE (MOD) TO CONTROL AND MAINTAIN A DATABASE WHICH CORRELATES CIL'S WITH APPLICABLE FLIGHT RULES/CREW PROCEDURES.

1.2 GENERAL

FLIGHT RULE TITLES ARE CURRENTLY FLAGGED WITH "[HC]" AND "[CIL]" IN ORDER TO IDENTIFY THEIR RELATIONSHIP TO THE SPACE SHUTTLE PROGRAM HAZARD REPORTS (HR) AND CRITICAL ITEMS LIST (CIL). THIS APPENDIX PROVIDES THE CROSS REFERENCE FROM FLIGHT RULES TO THE ASSOCIATED HR'S AND CIL'S. NOTE: THERE IS A DIRECT ONE-TO-ONE CORRELATION BETWEEN THE FLIGHT RULE AND THE HR CAUSE. THERE IS ALSO A DIRECT CORRELATION BETWEEN THE HR CAUSE AND THE CIL'S. HOWEVER, THE CORRELATION BETWEEN THE FLIGHT RULES AND CIL'S IS NOT DIRECT. CIL EXAMINATION IS THEREFORE REQUIRED TO DETERMINE ITS APPLICABILITY TO THE FLIGHT RULE UNDER CONSIDERATION (I.E., A CIL APPLICABLE ONLY TO ASCENT/ENTRY WOULD NOT APPLY TO AN ON-ORBIT FLIGHT RULE).

2.0 UPDATE PROCEDURE

2.1 RESPONSIBLE PARTY

THIS APPENDIX WILL BE UPDATED WITH THE CHANGE REQUEST PROCEDURE THROUGH THE FLIGHT RULES CONTROL BOARD (FRCB) AS CORRECTIONS AND MODIFICATIONS ARE REQUIRED.

2.2 CURRENCY REQUIREMENT

HAZARD REPORTS AND CIL'S HAVE CURRENCY REQUIREMENTS. THIS APPENDIX IS NOT THE CONTROLLING DOCUMENT FOR HR OR CIL CURRENCY; THE USER MUST REFER TO THE APPROPRIATE PROGRAM DOCUMENTATION FOR CURRENCY OF THESE CROSS-REFERENCE ITEMS. @[012402-5144]

FLIGHT RULES

3.0 USER INFORMATION @[012402-5144]

3.1 COLUMN IDENTIFICATION

OLD FLIGHT RULE # - OLD FLIGHT RULE NUMBER

NEW FLIGHT RULE # - NEW FLIGHT RULE NUMBER

HR & CAUSE # - HAZARD REPORT NUMBER AND CAUSE NUMBER

EXAMPLE: "ORBI-086B A" STANDS FOR ORBITER HAZARD REPORT 086, REVISION B, CAUSE A. THERE IS A DIRECT CORRELATION BETWEEN THE HAZARD CAUSE AND THE FLIGHT RULE IDENTIFIED TO MITIGATE THE HAZARDOUS SITUATION.

CIL # - CRITICAL ITEMS LIST NUMBER

THIS NUMBER IS CORRELATED TO THE FLIGHT RULE BY WAY OF THE HAZARD REPORT CAUSE. THE CIL FAILURE MODE IS USUALLY (BUT NOT ALWAYS) RELATED TO THE FLIGHT RULE.

3.2 LINK EXECUTION

IF THIS DOCUMENT IS ACCESSED ON THE FLIGHT DIRECTOR OFFICE WEB SITE, ALL ASSOCIATED LINKS TO FLIGHT RULES CAN BE TRAVERSED. HOWEVER, THE LINKS TO HAZARD REPORTS OR CRITICAL ITEMS MAY NOT BE TRAVERSABLE. THOSE DOCUMENTS ARE NOT LOCATED ON THE SAME SERVER WITH THIS DOCUMENT AND ARE SUBJECT TO SECURITY RESTRICTION ON THE USA WEB SERVER.

4.0 FLIGHT RULE/HAZARD REPORT/CIL CROSS REFERENCE TABLE @[012402-5144]

NOTE: LINK TO TABLE REMOVED UNTIL ACCURACY OF DATA CAN BE VERIFIED. IF ACCESS IS REQUIRED, PLEASE [CONTACT MARY LOU GRIFFITH](#).
